ELEMENTS OF ALGEBRAIC GEOMETRY

A. Grothendieck and J. Dieudonné

Complete Linked English Reader

EGA 0/I, II, III-1, III-2, and IV-1 through IV-4, assembled in canonical order as one complete cumulative reader.

Independently maintained English edition, source-rechecked against the French NUMDAM authority. Corrected readings, decisions, and exact inverses are documented in the provenance package.

Edition principles

- All eight fascicles complete and canonically ordered
- Independent French and English editions
- Editable sources and SHA-256 controls published separately

I	II	III-1	III-2	IV-1	IV-2	IV-3	IV-4

Reader body	1,409 pages - complete EGA 0-IV-4

§1. Rings of fractions

1.0. Rings and Algebras $\mathbf{0_I}$ | 11

(1.0.1). All the rings considered in this treatise will have a *unit element*; all the modules over such a ring will be assumed to be *unitary*; the ring homomorphisms will always be assumed to *send the unit element to the unit element*; unless otherwise stated, a subring of a ring A will be assumed to *contain the unit element of* A. We will focus in particular on *commutative* rings, and when we speak of a ring without specifying any details, it will be implied that it is commutative. If A is a not-necessarily-commutative ring, by A-module we will we mean a *left* module unless stated otherwise.

(1.0.2). Let A and B be not-necessarily-commutative rings and $\phi : A \to B$ a homomorphism. Any left (resp. right) B-module M can be provided with a left (resp. right) A-module structure by $a \cdot m = \phi(a) \cdot m$ (resp. $m \cdot a = m \cdot \phi(a)$); when it will be necessary to distinguish M as an A-module or a B-module, we will denote by $M_{[\phi]}$ the left (resp. right) A-module defined as such. If L is an A-module, then a homomorphism $u : L \to M_{[\phi]}$ is a homomorphism of abelian groups such that $u(a \cdot x) = \phi(a) \cdot u(x)$ for $a \in A$, $x \in L$; we will also say that it is a *ϕ-homomorphism $L \to M$*, and that the pair (ϕ, u) (or, by abuse of language, u) is a *di-homomorphism* from (A, L) to (B, M). The pairs (A, L) consisting of a ring A and an A-module L thus form a *category* whose morphisms are di-homomorphisms.

(1.0.3). Under the hypotheses of (1.0.2), if $\mathfrak{J}$ is a left (resp. right) ideal of A, we denote by $B\mathfrak{J}$ (resp. $\mathfrak{J}B$) the left (resp. right) ideal $B\phi(\mathfrak{J})$ (resp. $\phi(\mathfrak{J})B$) of B generated by $\phi(\mathfrak{J})$; it is also the image of the canonical homomorphism $B \otimes_A \mathfrak{J} \to B$ (resp. $\mathfrak{J} \otimes_A B \to B$) of left (resp. right) B-modules.

(1.0.4). If A is a (commutative) ring, and B a not-necessarily-commutative ring, then the data of a structure of an *A-algebra* on B is equivalent to the data of a ring homomorphism $\phi : A \to B$ such that $\phi(A)$ is contained in the center of B. For all ideals $\mathfrak{J}$ of A, $\mathfrak{J}B = B\mathfrak{J}$ is then a two-sided ideal of B, and for every B-module M, $\mathfrak{J}M$ is then a B-module equal to $(B\mathfrak{J})M$.

(1.0.5). We will not dwell much on the notions of *modules of finite type* and (commutative) *algebras of finite type*; to say that an A-module M is of finite type means that there exists an exact sequence $\mathbf{0_I}$ | 12
$A^p \to M \to 0$. We say that an A-module M admits a *finite presentation* if it is isomorphic to the cokernel of a homomorphism $A^p \to A^q$, or, in other words, if there exists an exact sequence $A^p \to A^q \to M \to 0$. We note that for a *Noetherian* ring A, every A-module of finite type admits a finite presentation.

Let us recall that an A-algebra B is said to be *integral* over A if every element in B is a root in B of a monic polynomial with coefficients in A; equivalently, if every element of B is contained in a subalgebra of B which is an *A-module of finite type*. When this is so, and if B is commutative, the subalgebra of B generated by a finite subset of B is an A-module of finite type; for a commutative algebra B to be integral and of finite type over A, it is necessary and sufficient that B be an A-module of finite type; we also say that B is an *integral A-algebra of finite type* (or simply *finite*, if there is no chance of confusion). It should be noted that in these definitions, it is not assumed that the homomorphism $A \to B$ defining the A-algebra structure is injective.

(1.0.6). An *integral* ring (or an *integral domain*) is a ring in which the product of a finite family of elements $\neq 0$ is $\neq 0$; equivalently, in such a ring, we have $0 \neq 1$, and the product of two elements $\neq 0$ is $\neq 0$. A *prime* ideal of a ring A is an ideal $\mathfrak{p}$ such that $A/\mathfrak{p}$ is integral; this implies that $\mathfrak{p} \neq A$. For a ring A to have at least one prime ideal, it is necessary and sufficient that $A \neq \{0\}$.

(1.0.7). A *local* ring is a ring A in which there exists a unique maximal ideal, which is thus the complement of the invertible elements, and contains all the ideals $\neq A$. If A and B are local rings, and $\mathfrak{m}$ and $\mathfrak{n}$ their respective maximal ideals, then we say that a homomorphism $\phi : A \to B$ is *local* if $\phi(\mathfrak{m}) \subset \mathfrak{n}$ (or, equivalently, if $\phi^{-1}(\mathfrak{n}) = \mathfrak{m}$). By passing to quotients, such a homomorphism then defines a monomorphism from the residue field $A/\mathfrak{m}$ to the residue field $B/\mathfrak{n}$. The composition of any two local homomorphisms is a local homomorphism.

1.1. Radical of an ideal. Nilradical and radical of a ring

(1.1.1). Let $\mathfrak{a}$ be an ideal of a ring A; the *radical* of $\mathfrak{a}$, denoted by $\mathfrak{r}(\mathfrak{a})$, is the set of $x \in A$ such that $x^n \in \mathfrak{a}$ for an integer $n > 0$; it is an ideal containing $\mathfrak{a}$. We have $\mathfrak{r}(\mathfrak{r}(\mathfrak{a})) = \mathfrak{r}(\mathfrak{a})$; the relation $\mathfrak{a} \subset \mathfrak{b}$ implies $\mathfrak{r}(\mathfrak{a}) \subset \mathfrak{r}(\mathfrak{b})$; the radical of a finite intersection of ideals is the intersection of their radicals. If ϕ is a homomorphism from another ring A' to A, then we have $\mathfrak{r}(\phi^{-1}(\mathfrak{a})) = \phi^{-1}(\mathfrak{r}(\mathfrak{a}))$ for any ideal $\mathfrak{a} \subset A$. For an ideal to be the radical of an ideal, it is necessary and sufficient that it be an intersection of prime ideals. The radical of an ideal $\mathfrak{a}$ is the intersection of the *minimal* prime ideals which contain $\mathfrak{a}$; if A is Noetherian, there are finitely many of these minimal prime ideals.

The radical of the ideal (0) is also called the *nilradical* of A; it is the set $\mathfrak{N}$ of the nilpotent elements of A. We say that the ring A is *reduced* if $\mathfrak{N} = (0)$; for every ring A, the quotient $A/\mathfrak{N}$ of A by its nilradical is a reduced ring.

(1.1.2). Recall that the *radical* $\mathfrak{r}(A)$ of a (not-necessarily-commutative) ring A is the intersection of the maximal left ideals of A (and also the intersection of maximal right ideals). The radical of $A/\mathfrak{r}(A)$ is (0).

1.2. Modules and rings of fractions $\mathbf{0_I}$ | 13

(1.2.1). We say that a subset S of a ring A is *multiplicative* if $1 \in S$ and the product of two elements of S is in S. The examples which will be the most important in what follows are: 1st, the set S_f of powers f^n ($n \geqslant 0$) of an element $f \in A$; and 2nd, the complement $A - \mathfrak{p}$ of a *prime* ideal $\mathfrak{p}$ of A.

(1.2.2). Let S be a multiplicative subset of a ring A, and M an A-module; on the set $M \times S$, the relation between pairs (m_1, s_1) and (m_2, s_2):

$$\text{“there exists an } s \in S \text{ such that } s(s_1 m_2 - s_2 m_1) = 0\text{”}$$

is an equivalence relation. We denote by $S^{-1}M$ the quotient set of $M \times S$ by this relation, and by m/s the canonical image of the pair (m, s) in $S^{-1}M$; we call $i_M^S : m \mapsto m/1$ (also denoted i^S) the *canonical* map from M to $S^{-1}M$. This map is, in general, neither injective nor surjective; its kernel is the set of $m \in M$ such that there exists an $s \in S$ for which $sm = 0$.

On $S^{-1}M$ we define an additive group law by setting

$$(m_1/s_1) + (m_2/s_2) = (s_2 m_1 + s_1 m_2)/(s_1 s_2)$$

(one can check that it is independent of the choice of representative of the elements of $S^{-1}M$, which are equivalence classes). On $S^{-1}A$ we further define a multiplicative law by setting $(a_1/s_1)(a_2/s_2) = (a_1 a_2)/(s_1 s_2)$, and finally an exterior law on $S^{-1}M$, acted on by the set of elements of $S^{-1}A$, by setting $(a/s)(m/s') = (am)/(ss')$. It can then be shown that $S^{-1}A$ is endowed with a ring structure (called *the ring of fractions of A with denominators in* S) and $S^{-1}M$ with the structure of an $S^{-1}A$-module (called *the module of fractions of M with denominators in* S); for all $s \in S$, $s/1$ is invertible in $S^{-1}A$, its inverse being $1/s$. The canonical map i_A^S (resp. i_M^S) is a ring homomorphism (resp. a homomorphism of A-modules, $S^{-1}M$ being considered as an A-module by means of the homomorphism $i_A^S : A \to S^{-1}A$).

(1.2.3). If $S_f = \{f^n\}_{n \geqslant 0}$ for a $f \in A$, we write A_f and M_f instead of $S_f^{-1}A$ and $S_f^{-1}M$; when A_f is considered as algebra over A, we can write $A_f = A[1/f]$. A_f is isomorphic to the quotient algebra $A[T]/(fT - 1)A[T]$. When $f = 1$, A_f and M_f are canonically identified with A and M; if f is nilpotent, then A_f and M_f are 0.

When $S = A - \mathfrak{p}$, with $\mathfrak{p}$ a prime ideal of A, we write $A_\mathfrak{p}$ and $M_\mathfrak{p}$ instead of $S^{-1}A$ and $S^{-1}M$; $A_\mathfrak{p}$ is a *local ring* whose maximal ideal $\mathfrak{q}$ is generated by $i_A^S(\mathfrak{p})$, and we have $(i_A^S)^{-1}(\mathfrak{q}) = \mathfrak{p}$; by passing to quotients, i_A^S gives a monomorphism from the integral ring $A/\mathfrak{p}$ to the field $A_\mathfrak{p}/\mathfrak{q}$, which can be identified with the field of fractions of $A/\mathfrak{p}$.

(1.2.4). The ring of fractions $S^{-1}A$ and the canonical homomorphism i_A^S are a solution to a *universal mapping problem*: any homomorphism u from A to a ring B such that $u(S)$ is composed of *invertible* elements in B factors uniquely as

$$u : A \xrightarrow{i_A^S} S^{-1}A \xrightarrow{u^*} B$$

where u^* is a ring homomorphism. Under the same hypotheses, let M be an A-module, N a B-module, and $v : M \to N$ a homomorphism of A-modules (for the B-module structure on N defined by $u : A \to B$); then v factors uniquely as $\mathbf{0_I}$ | 14

$$v : M \xrightarrow{i^S_M} S^{-1}M \xrightarrow{v^*} N$$

where v^* is a homomorphism of $S^{-1}A$-modules (for the $S^{-1}A$-module structure on N defined by u^*).

(1.2.5). We define a canonical isomorphism $S^{-1}A \otimes_A M \simeq S^{-1}M$ of $S^{-1}A$-modules, sending the element $(a/s) \otimes m$ to the element $(am)/s$, with the inverse isomorphism sending m/s to $(1/s) \otimes m$.

(1.2.6). For every ideal $\mathfrak{a}'$ of $S^{-1}A$, $\mathfrak{a} = (i^S_A)^{-1}(\mathfrak{a}')$ is an ideal of A, and $\mathfrak{a}'$ is the ideal of $S^{-1}A$ generated by $i^S_A(\mathfrak{a})$, which can be identified with $S^{-1}\mathfrak{a}$ (1.3.2). The map $\mathfrak{p}' \mapsto (i^S_A)^{-1}(\mathfrak{p}')$ is an isomorphism, for the structure given by ordering, from the set of *prime* ideals of $S^{-1}A$ to the set of prime ideals $\mathfrak{p}$ of A such that $\mathfrak{p} \cap S = \varnothing$. In addition, the local rings $A_\mathfrak{p}$ and $(S^{-1}A)_{S^{-1}\mathfrak{p}}$ are canonically isomorphic (1.5.1).

(1.2.7). When A is an *integral* ring, for which K denotes its field of fractions, the canonical map $i^S_A : A \to S^{-1}A$ is injective for any multiplicative subset S not containing 0, and $S^{-1}A$ is then canonically identified with a subring of K containing A. In particular, for every prime ideal $\mathfrak{p}$ of A, $A_\mathfrak{p}$ is a local ring containing A, with maximal ideal $\mathfrak{p}A_\mathfrak{p}$, and we have $\mathfrak{p}A_\mathfrak{p} \cap A = \mathfrak{p}$.

(1.2.8). If A is a *reduced* ring (1.1.1), so is $S^{-1}A$: indeed, if $(x/s)^n = 0$ for $x \in A$, $s \in S$, then this means that there exists an $s' \in S$ such that $s'x^n = 0$, hence $(s'x)^n = 0$, which, by hypothesis, implies $s'x = 0$, so $x/s = 0$.

1.3. Functorial properties

(1.3.1). Let M and N be A-modules, and u an A-homomorphism $M \to N$. If S is a multiplicative subset of A, we define a $S^{-1}A$-homomorphism $S^{-1}M \to S^{-1}N$, denoted by $S^{-1}u$, by setting $S^{-1}u(m/s) = u(m)/s$; if $S^{-1}M$ and $S^{-1}N$ are canonically identified with $S^{-1}A \otimes_A M$ and $S^{-1}A \otimes_A N$ (1.2.5), then $S^{-1}u$ is considered as $1 \otimes u$. If P is a third A-module, and v an A-homomorphism $N \to P$, we have $S^{-1}(v \circ u) = (S^{-1}v) \circ (S^{-1}u)$; in other words, $S^{-1}M$ is a *covariant functor in* M, from the category of A-modules to that of $S^{-1}A$-modules (A and S being fixed).

(1.3.2). The functor $S^{-1}M$ is *exact*; in other words, if the sequence

$$M \xrightarrow{u} N \xrightarrow{v} P$$

is exact, then so is the sequence

$$S^{-1}M \xrightarrow{S^{-1}u} S^{-1}N \xrightarrow{S^{-1}v} S^{-1}P.$$

In particular, if $u : M \to N$ is injective (resp. surjective), the same is true for $S^{-1}u$; if N and P are submodules of M, $S^{-1}N$ and $S^{-1}P$ are canonically identified with submodules of $S^{-1}M$, and we have $\mathbf{0_I}$ | 15

$$S^{-1}(N+P) = S^{-1}N + S^{-1}P \text{ and } S^{-1}(N \cap P) = (S^{-1}N) \cap (S^{-1}P).$$

(1.3.3). Let $(M_\alpha, \phi_{\beta\alpha})$ be an inductive system of A-modules; then $(S^{-1}M_\alpha, S^{-1}\phi_{\beta\alpha})$ is an inductive system of $S^{-1}A$-modules. Expressing the $S^{-1}M_\alpha$ and $S^{-1}\phi_{\beta\alpha}$ as tensor products ((1.2.5) and (1.3.1)), it follows from the permutability of the tensor product and inductive limit operations that we have a canonical isomorphism

$$S^{-1}\varinjlim M_\alpha \simeq \varinjlim S^{-1}M_\alpha$$

which is we can further express by saying that the functor $S^{-1}M$ (in M) *commutes with inductive limits*.

(1.3.4). Let M and N be A-modules; there is a canonical *functorial* (in M and N) isomorphism

$$(S^{-1}M) \otimes_{S^{-1}A} (S^{-1}N) \simeq S^{-1}(M \otimes_A N)$$

which sends $(m/s) \otimes (n/t)$ to $(m \otimes n)/st$.

(1.3.5). We also have a *functorial* (in M and N) homomorphism

$$S^{-1}\operatorname{Hom}_A(M,N) \longrightarrow \operatorname{Hom}_{S^{-1}A}(S^{-1}M, S^{-1}N)$$

which sends u/s to the homomorphism $m/t \mapsto u(m)/st$. When M has a finite presentation, the above homomorphism is an *isomorphism*: it is immediate when M is of the form A^r, and we pass to the general case by starting with the exact sequence $A^p \to A^q \to M \to 0$ and using the exactness of the functor $S^{-1}M$ and the left-exactness of the functor $\operatorname{Hom}_A(M,N)$ in M. Note that this is always the case when A is *Noetherian* and the A-module M is *of finite type*.

1.4. Change of multiplicative subset

(1.4.1). Let S and T be multiplicative subsets of a ring A such that $S \subset T$; there exists a canonical homomorphism $\rho_A^{T,S}$ (or simply $\rho^{T,S}$) from $S^{-1}A$ to $T^{-1}A$, sending the element denoted a/s of $S^{-1}A$ to the element denoted a/s in $T^{-1}A$; we have $i_A^T = \rho_A^{T,S} \circ i_A^S$. For every A-module M, there exists, in the same way, an $S^{-1}A$-linear map from $S^{-1}M$ to $T^{-1}M$ (the latter considered as an $S^{-1}A$-module by the homomorphism $\rho_A^{T,S}$), which sends the element m/s of $S^{-1}M$ to the element m/s of $T^{-1}M$; we denote this map by $\rho_M^{T,S}$, or simply $\rho^{T,S}$, and we still have $i_M^T = \rho_M^{T,S} \circ i_M^S$; by the canonical identification (1.2.5), $\rho_M^{T,S}$ is identified with $\rho_A^{T,S} \otimes 1$. The homomorphism $\rho_M^{T,S}$ is a *functorial morphism* (or natural transformation) from the functor $S^{-1}M$ to the functor $T^{-1}M$, in other words, the diagram

$$\begin{tikzcd} S^{-1}M \arrow[r, "S^{-1}u"] \arrow[d, "\rho_M^{T,S}"'] & S^{-1}N \arrow[d, "\rho_N^{T,S}"] \\ T^{-1}M \arrow[r, "T^{-1}u"] & T^{-1}N \end{tikzcd}$$

is commutative, for every homomorphism $u : M \to N$; $T^{-1}u$ is entirely determined by $S^{-1}u$, since, for $m \in M$ and $t \in T$, we have $\mathbf{0_I} \mid 16$

$$(T^{-1}u)(m/t) = (t/1)^{-1}\rho^{T,S}((S^{-1}u)(m/1)).$$

(1.4.2). With the same notation, for A-modules M and N, the diagrams (cf. (1.3.4) and (1.3.5))

$$\begin{tikzcd} (S^{-1}M) \otimes_{S^{-1}A} (S^{-1}N) \arrow[r, "\sim"] \arrow[d] & S^{-1}(M \otimes_A N) \arrow[d] \\ (T^{-1}M) \otimes_{T^{-1}A} (T^{-1}N) \arrow[r, "\sim"] & T^{-1}(M \otimes_A N) \end{tikzcd}$$

$$\begin{tikzcd} S^{-1}\operatorname{Hom}_A(M,N) \arrow[r] \arrow[d] & \operatorname{Hom}_{S^{-1}A}(S^{-1}M, S^{-1}N) \arrow[d] \\ T^{-1}\operatorname{Hom}_A(M,N) \arrow[r] & \operatorname{Hom}_{T^{-1}A}(T^{-1}M, T^{-1}N) \end{tikzcd}$$

are commutative.

(1.4.3). There is an important case, in which the homomorphism $\rho^{T,S}$ is *bijective*, when we then know that every element of T is a divisor of an element of S; we then identify the modules $S^{-1}M$ and $T^{-1}M$ via $\rho^{T,S}$. We say that S is *saturated* if every divisor in A of an element of S is in S; by replacing S with the set T of all the divisors of the elements of S (a set which is multiplicative and saturated), we see that we can always, if we wish, consider only modules of fractions $S^{-1}M$, where S is saturated.

(1.4.4). If S, T, and U are three multiplicative subsets of A such that $S \subset T \subset U$, then we have

$$\rho^{U,S} = \rho^{U,T} \circ \rho^{T,S}.$$

(1.4.5). Consider an *increasing filtered family* (S_α) of multiplicative subsets of A (we write $\alpha \leqslant \beta$ for $S_\alpha \subset S_\beta$), and let S be the multiplicative subset $\bigcup_\alpha S_\alpha$; let us put $\rho_{\beta\alpha} = \rho_A^{S_\beta,S_\alpha}$ for $\alpha \leqslant \beta$; according to (1.4.4), the homomorphisms $\rho_{\beta\alpha}$ define a ring A' as the *inductive limit* of the inductive system of rings

$(S_\alpha^{-1}A, \rho_{\beta\alpha})$. Let ρ_α be the canonical map $S_\alpha^{-1}A \to A'$, and let $\phi_\alpha = \rho_A^{S,S_\alpha}$; as $\phi_\alpha = \phi_\beta \circ \rho_{\beta\alpha}$ for $\alpha \leqslant \beta$ according to (1.4.4), we can uniquely define a homomorphism $\phi : A' \to S^{-1}A$ such that the diagram

$$\begin{tikzcd}
& S_\alpha^{-1}A \arrow[d, "\rho_{\beta\alpha}"] \arrow[ddl, "\rho_\alpha"'] \arrow[ddr, "\phi_\alpha"] & \\
& S_\beta^{-1}A \arrow[dl, "\rho_\beta"] \arrow[dr, "\phi_\beta"'] & \\
A' \arrow[rr, "\phi"'] & & S^{-1}A
\end{tikzcd} \qquad (\alpha \leqslant \beta)$$

is commutative. In fact, ϕ is an *isomorphism*; it is indeed immediate by construction that ϕ is surjective. On the other hand, if $\rho_\alpha(a/s_\alpha) \in A'$ is such that $\phi(\rho_\alpha(a/s_\alpha)) = 0$, then this means that $a/s_\alpha = 0$ in $S^{-1}A$, that is to say that there exists an $s \in S$ such that $sa = 0$; but there is a $\beta \geqslant \alpha$ such that $s \in S_\beta$, and consequently, as $\rho_\alpha(a/s_\alpha) = \rho_\beta(sa/ss_\alpha) = 0$, we find that ϕ is injective. The case for an A-module M is treated likewise, and we have thus defined canonical isomorphisms

$$\varinjlim S_\alpha^{-1}A \simeq (\varinjlim S_\alpha)^{-1}A, \ \varinjlim S_\alpha^{-1}M \simeq (\varinjlim S_\alpha)^{-1}M,$$

the second being *functorial* in M.

$\mathbf{0_I}$ | 17

(1.4.6). Let S_1 and S_2 be multiplicative subsets of A; then S_1S_2 is also a multiplicative subset of A. Let us denote by S_2' the canonical image of S_2 in the ring $S_1^{-1}A$, which is a multiplicative subset of this ring. For every A-module M there is then a functorial isomorphism

$$S_2'^{-1}(S_1^{-1}M) \simeq (S_1S_2)^{-1}M$$

which sends $(m/s_1)/(s_2/1)$ to the element $m/(s_1s_2)$.

1.5. Change of ring

(1.5.1). Let A and A' be rings, ϕ a homomorphism $A' \to A$, and S (resp. S') a multiplicative subset of A (resp. A'), such that $\phi(S') \subset S$; the composition homomorphism $A' \xrightarrow{\phi} A \to S^{-1}A$ factors as

$$A' \longrightarrow S'^{-1}A' \xrightarrow{\phi^{S'}} S^{-1}A,$$

by (1.2.4); where $\phi^{S'}(a'/s') = \phi(a')/\phi(s')$. If $A = \phi(A')$ and $S = \phi(S')$, then $\phi^{S'}$ is *surjective*. If $A' = A$ and ϕ is the identity, then $\phi^{S'}$ is exactly the homomorphism $\rho_A^{S,S'}$ defined in (1.4.1).

(1.5.2). Under the hypotheses of (1.5.1), let M be an A-module. There exists a canonical functorial morphism

$$\sigma : S'^{-1}(M_{[\phi]}) \longrightarrow (S^{-1}M)_{[\phi^{S'}]}$$

of $S'^{-1}A'$-modules, sending each element m/s' of $S'^{-1}(M_{[\phi]})$ to the element $m/\phi(s')$ of $(S^{-1}M)_{[\phi^{S'}]}$; indeed, we immediately see that this definition does not depend on the representative m/s' of the element in question. When $S = \phi(S')$, the homomorphism σ is *bijective*. When $A' = A$ and ϕ is the identity, σ is none other than the homomorphism $\rho_M^{S,S'}$ defined in (1.4.1).

When, in particular, we take $M = A$ the homomorphism ϕ defines an A'-algebra structure on A; $S'^{-1}(A_{[\phi]})$ is then endowed with a ring structure, with which it can be identified with $(\phi(S'))^{-1}A$, and the homomorphism $\sigma : S'^{-1}(A_{[\phi]}) \to S^{-1}A$ is a homomorphism of $S'^{-1}A'$-algebras.

(1.5.3). Let M and N be A-modules; by composing the homomorphisms defined in (1.3.4) and (1.5.2), we obtain a homomorphism

$$(S^{-1}M \otimes_{S^{-1}A} S^{-1}N)_{[\phi^{S'}]} \longleftarrow S'^{-1}((M \otimes N)_{[\phi]})$$

which is an isomorphism when $\phi(S') = S$. Similarly, by composing the homomorphisms in (1.3.5) and (1.5.2), we obtain a homomorphism

$$S'^{-1}((\mathrm{Hom}_A(M,N))_{[\phi]}) \longrightarrow (\mathrm{Hom}_{S^{-1}A}(S^{-1}M, S^{-1}N))_{[\phi^{S'}]}$$

which is an isomorphism when $\phi(S') = S$ and M admits a finite presentation.

(1.5.4). Let us now consider an A'-module N', and form the tensor product $N' \otimes_{A'} A_{[\phi]}$, which can be considered as an A-module by setting $a \cdot (n' \otimes b) = n' \otimes (ab)$. There is a functorial isomorphism of $S^{-1}A$-modules

$$\tau : (S'^{-1}N') \otimes_{S'^{-1}A'} (S^{-1}A)_{[\phi^{S'}]} \simeq S^{-1}(N' \otimes_{A'} A_{[\phi]})$$

which sends the element $(n'/s') \otimes (a/s)$ to the element $(n' \otimes a)/(\phi(s')s)$; indeed, we can show that when we replace n'/s' (resp. a/s) by another expression of the same element, $(n' \otimes a)/(\phi(s')s)$ does not change; on the other hand, we can define a homomorphism inverse to τ by sending $(n' \otimes a)/s$ to the element $(n'/1) \otimes (a/s)$: we use the fact that $S^{-1}(N' \otimes_{A'} A_{[\phi]})$ is canonically isomorphic to $(N' \otimes_{A'} A_{[\phi]}) \otimes_A S^{-1}A$ (1.2.5), so also to $N' \otimes_{A'} (S^{-1}A)_{[\psi]}$, where we denote by ψ the composite homomorphism $a' \mapsto \phi(a')/1$ from A' to $S^{-1}A$. $\mathbf{0_I}$ | 18

(1.5.5). If M' and N' are A'-modules, then by composing the isomorphisms (1.3.4) and (1.5.4), we obtain an isomorphism

$$S'^{-1}M' \otimes_{S'^{-1}A'} S'^{-1}N' \otimes_{S'^{-1}A'} S^{-1}A \simeq S^{-1}(M' \otimes_{A'} N' \otimes_{A'} A).$$

Likewise, if M' admits a finite presentation, we have by (1.3.5) and (1.5.4) an isomorphism

$$\mathrm{Hom}_{S'^{-1}A'}(S'^{-1}M', S'^{-1}N') \otimes_{S'^{-1}A'} S^{-1}A \simeq S^{-1}(\mathrm{Hom}_{A'}(M',N') \otimes_{A'} A).$$

(1.5.6). Under the hypotheses of (1.5.1), let T (resp. T') be another multiplicative subset of A (resp. A') such that $S \subset T$ (resp. $S' \subset T'$) and $\phi(T') \subset T$. Then the diagram

$$\begin{tikzcd} S'^{-1}A' \arrow[r, "\phi^{S'}"] \arrow[d, "\rho^{T',S'}"'] & S^{-1}A \arrow[d, "\rho^{T,S}"] \\ T'^{-1}A' \arrow[r, "\phi^{T'}"'] & T^{-1}A \end{tikzcd}$$

is commutative. If M is an A-module, then the diagram

$$\begin{tikzcd} S'^{-1}(M_{[\phi]}) \arrow[r, "\sigma"] \arrow[d, "\rho^{T',S'}"'] & (S^{-1}M)_{[\phi^{S'}]} \arrow[d, "\rho^{T,S}"] \\ T'^{-1}(M_{[\phi]}) \arrow[r, "\sigma"'] & (T^{-1}M)_{[\phi^{T'}]} \end{tikzcd}$$

is commutative. Finally, if N' is an A'-module, then the diagram

$$\begin{tikzcd} (S'^{-1}N') \otimes_{S'^{-1}A'} (S^{-1}A)_{[\phi^{S'}]} \arrow[r, "\tau", "\sim"'] \arrow[d] & S^{-1}(N' \otimes_{A'} A_{[\phi]}) \arrow[d, "\rho^{T,S}"] \\ (T'^{-1}N') \otimes_{T'^{-1}A'} (T^{-1}A)_{[\phi^{T'}]} \arrow[r, "\sim", "\tau"'] & T^{-1}(N' \otimes_{A'} A_{[\phi]}) \end{tikzcd}$$

is commutative, the left vertical arrow obtained by applying $\rho_{N'}^{T',S'}$ to $S'^{-1}N'$ and $\rho_A^{T,S}$ to $S^{-1}A$.

$\mathbf{0_I}$ | 19

(1.5.7). Let A'' be a third ring, $\phi' : A'' \to A'$ a ring homomorphism, and S'' a multiplicative subset of A'' such that $\phi'(S'') \subset S'$. Let $\phi'' = \phi \circ \phi'$; then we have

$$\phi''^{S''} = \phi^{S'} \circ \phi'^{S''}.$$

Let M be an A-module; evidently we have $M_{[\phi'']} = (M_{[\phi]})_{[\phi']}$; if σ' and σ'' are the homomorphisms defined by ϕ' and ϕ'' in the same way as how σ is defined in (1.5.2) by ϕ, then we have the transitivity formula

$$\sigma'' = \sigma \circ \sigma'.$$

Finally, let N'' be an A''-module; the A-module $N'' \otimes_{A''} A_{[\phi'']}$ is canonically identified with $(N'' \otimes_{A''} A'_{[\phi']}) \otimes_{A'} A_{[\phi]}$, and likewise the $S^{-1}A$-module $(S''^{-1}N'') \otimes_{S''^{-1}A''} (S^{-1}A)_{[\phi''^{S''}]}$ is canonically identified with $((S''^{-1}N'') \otimes_{S''^{-1}A''} (S'^{-1}A')_{[\phi'^{S''}]}) \otimes_{S'^{-1}A'} (S^{-1}A)_{[\phi^{S'}]}$. With these identifications, if τ' and τ'' are the isomorphisms defined by ϕ' and ϕ'' in the same way as how τ is defined in (1.5.4) by ϕ, then we have the transitivity formula

$$\tau'' = \tau \circ (\tau' \otimes 1).$$

(1.5.8). Let A be a subring of a ring B; for every *minimal* prime ideal $\mathfrak{p}$ of A, there exists a minimal prime ideal $\mathfrak{q}$ of B such that $\mathfrak{p} = A \cap \mathfrak{q}$. Indeed, $A_{\mathfrak{p}}$ is a subring of $B_{\mathfrak{p}}$ (1.3.2) and has *a single prime ideal* $\mathfrak{p}'$ (1.2.6); since $B_{\mathfrak{p}}$ is not 0, it has at least one prime ideal $\mathfrak{q}'$ and we necessarily have $\mathfrak{q}' \cap A_{\mathfrak{p}} = \mathfrak{p}'$; the prime ideal $\mathfrak{q}_1$ of B, the inverse image of $\mathfrak{q}'$, is thus such that $\mathfrak{q}_1 \cap A = \mathfrak{p}$, and *a fortiori* we have $\mathfrak{q} \cap A = \mathfrak{p}$ for every minimal prime ideal $\mathfrak{q}$ of B contained in $\mathfrak{q}_1$.

1.6. Identification of the module M_f as an inductive limit

(1.6.1). Let M be an A-module and f an element of A. Consider a sequence (M_n) of A-modules, all identical to M, and for each pair of integers $m \leqslant n$, let ϕ_{nm} be the homomorphism $z \mapsto f^{n-m}z$ from M_m to M_n; it is immediate that $((M_n), (\phi_{nm}))$ is an *inductive system* of A-modules; let $N = \varinjlim M_n$ be the inductive limit of this system. We define a canonical *functorial* A-isomorphism from N to M_f. For this, let us note that, for all n, $\theta_n : z \mapsto z/f^n$ is an A-homomorphism from $M = M_n$ to M_f, and it follows from the definitions that we have $\theta_n \circ \phi_{nm} = \theta_m$ for $m \leqslant n$. As a result, there exists an A-homomorphism $\theta : N \to M_f$ such that, if ϕ_n denotes the canonical homomorphism $M_n \to N$, then we have $\theta_n = \theta \circ \phi_n$ for all n. Since, by hypothesis, every element of M_f is of the form z/f^n for at least one n, it is clear that θ is surjective. On the other hand, if $\theta(\phi_n(z)) = 0$, or, in other words, if $z/f^n = 0$, then there exists an integer $k > 0$ such that $f^k z = 0$, so $\phi_{n+k,n}(z) = 0$, which gives $\phi_n(z) = 0$. We can therefore identify M_f with $\varinjlim M_n$ via θ.

(1.6.2). Now write $M_{f,n}$, ϕ^f_{nm}, and ϕ^f_n instead of M_n, ϕ_{nm}, and ϕ_n. Let g be another element of A. Since f^n divides $f^n g^n$, we have a functorial homomorphism

$$\rho_{fg,f} : M_f \longrightarrow M_{fg} \quad ((1.4.1) \text{ and } (1.4.3));$$

if we identify M_f and M_{fg} with $\varinjlim M_{f,n}$ and $\varinjlim M_{fg,n}$ respectively, then $\rho_{fg,f}$ identifies with the *inductive limit* of the maps $\rho^n_{fg,f} : M_{f,n} \to M_{fg,n}$, defined by $\rho^n_{fg,f}(z) = g^n z$. Indeed, this follows immediately from the commutativity of the diagram **0**$_{\mathbf{I}}$ | 20

$$\begin{tikzcd} M_{f,n} \arrow[r, "\rho^n_{fg,f}"] \arrow[d, "\phi^f_n"'] & M_{fg,n} \arrow[d, "\phi^{fg}_n"] \\ M_f \arrow[r, "\rho_{fg,f}"] & M_{fg}. \end{tikzcd}$$

1.7. Support of a module

(1.7.1). Given an A-module M, we define the *support* of M, denoted by $\operatorname{Supp}(M)$, to be the set of prime ideals $\mathfrak{p}$ of A such that $M_{\mathfrak{p}} \neq 0$. For it to be the case that $M = 0$, it is necessary and sufficient that $\operatorname{Supp}(M) = \varnothing$, because if $M_{\mathfrak{p}} = 0$ for all $\mathfrak{p}$, then the annihilator of an element $x \in M$ cannot be contained in any prime ideal of A, and so is the whole of A.

(1.7.2). If $0 \to N \to M \to P \to 0$ is an exact sequence of A-modules, then we have

$$\operatorname{Supp}(M) = \operatorname{Supp}(N) \cup \operatorname{Supp}(P)$$

because, for every prime ideal $\mathfrak{p}$ of A, the sequence $0 \to N_{\mathfrak{p}} \to M_{\mathfrak{p}} \to P_{\mathfrak{p}} \to 0$ is exact (1.3.2) and in order that $M_{\mathfrak{p}} = 0$, it is necessary and sufficient that $N_{\mathfrak{p}} = P_{\mathfrak{p}} = 0$.

(1.7.3). If M is the sum of a family (M_λ) of submodules, then $M_{\mathfrak{p}}$ is the sum of the $(M_\lambda)_{\mathfrak{p}}$ for every prime ideal $\mathfrak{p}$ of A ((1.3.3) and (1.3.2)), so $\operatorname{Supp}(M) = \bigcup_\lambda \operatorname{Supp}(M_\lambda)$.

(1.7.4). If M is an A-module *of finite type*, then $\operatorname{Supp}(M)$ is the set of prime ideals *containing the annihilator of* M. Indeed, if M is cyclic and generated by x, then to say that $M_{\mathfrak{p}} = 0$ is to say that that there exists an $s \notin \mathfrak{p}$ such that $s \cdot x = 0$, and thus that $\mathfrak{p}$ does not contain the annihilator of x. Now if M admits a finite system $(x_i)_{1 \leqslant i \leqslant n}$ of generators, and if $\mathfrak{a}_i$ is the annihilator of x_i, then it follows from (1.7.3) that $\operatorname{Supp}(M)$ is the set of the $\mathfrak{p}$ containing one of the $\mathfrak{a}_i$, or equivalently, the set of the $\mathfrak{p}$ containing $\mathfrak{a} = \bigcap_i \mathfrak{a}_i$, which is the annihilator of M.

(1.7.5). If M and N are two A-modules *of finite type*, then we have

$$\operatorname{Supp}(M \otimes_A N) = \operatorname{Supp}(M) \cap \operatorname{Supp}(N).$$

It is a question of seeing that, if $\mathfrak{p}$ is a prime ideal of A, then the condition $M_{\mathfrak{p}} \otimes_{A_{\mathfrak{p}}} N_{\mathfrak{p}} \neq 0$ is equivalent to "$M_{\mathfrak{p}} \neq 0$ and $N_{\mathfrak{p}} \neq 0$" (taking (1.3.4) into account). In other words, it is a question of seeing that, if P and Q are modules of finite type over a *local* ring $B \neq 0$, then $P \otimes_B Q \neq 0$. Let $\mathfrak{m}$ be the maximal ideal of B. By Nakayama's Lemma, the vector spaces $P/\mathfrak{m}P$ and $Q/\mathfrak{m}Q$ are not 0, and so it is the same for the tensor product $(P/\mathfrak{m}P) \otimes_{B/\mathfrak{m}} (Q/\mathfrak{m}Q) = (P \otimes_B Q) \otimes_B (B/\mathfrak{m})$, whence the conclusion.

In particular, if M is an A-module of finite type, and $\mathfrak{a}$ an ideal of A, then $\operatorname{Supp}(M/\mathfrak{a}M)$ is the set of prime ideals containing both $\mathfrak{a}$ and the annihilator $\mathfrak{n}$ of M (1.7.4), that is, the set of prime ideals containing $\mathfrak{a} + \mathfrak{n}$.

§2. Irreducible spaces. Noetherian spaces

2.1. Irreducible spaces $\mathbf{0_I}$ | 21

(2.1.1). We say that a topological space X is *irreducible* if it is nonempty and if it is not a union of two distinct closed subspaces of X. It is equivalent to say that $X \neq \varnothing$ and the intersection of two nonempty open sets (and consequently of a finite number of open sets) of X is nonempty, or that every nonempty open set is everywhere dense, or that any closed set is *rare*[1], or, lastly, that all open sets of X are *connected*.

(2.1.2). For a subspace Y of a topological space X to be irreducible, it is necessary and sufficient that its closure $\overline{Y}$ be irreducible. In particular, any subspace which is the closure $\overline{\{x\}}$ of a singleton is irreducible; we will express the relation $y \in \overline{\{x\}}$ (equivalent to $\overline{\{y\}} \subset \overline{\{x\}}$) by saying that y is a *specialization of* x or that x is a *generalization of* y. When there exists, in an irreducible space X, a point x such that $X = \overline{\{x\}}$, we will say that x is a *generic point of* X. Any nonempty open subset of X then contains x, and any subspace containing x has x as a generic point.

(2.1.3). Recall that a *Kolmogoroff space* is a topological space X satisfying the axiom of separation:

(T_0) If $x \neq y$ are any two points of X, there is an open set containing one of the points x and y, but not the other.

[1][Trans] also known as *nowhere dense*.

If an irreducible Kolmogoroff space admits a generic point, it admits *exactly* one, since a nonempty open set contains any generic point.

Recall that a topological space X is said to be *quasi-compact* if, from any collection of open sets of X, one can extract a finite cover of X (or, equivalently, if any decreasing filtered family of nonempty closed sets has a nonempty intersection). If X is a quasi-compact space, then any nonempty closed subset A of X contains a *minimal* nonempty closed set M, because the set of nonempty closed subsets of A is inductive under the relation $\supset$; if, in addition, X is a Kolmogoroff space, M is necessarily a single point (or, as we say by abuse of language, is a *closed point*).

(2.1.4). In an irreducible space X, every nonempty open subspace U is irreducible, and if X admits a generic point x, x is also a generic point of U.

To prove this, let (U_α) be a cover (whose set of indices is nonempty) of a topological space X, consisting of nonempty open sets; if X is irreducible, it is necessary and sufficient that U_α is irreducible for all α, and that $U_\alpha \cap U_\beta \neq \varnothing$ for any α, β. The condition is clearly necessary; to see that it is sufficient, it suffices to prove that if V is a nonempty open subset of X, then $V \cap U_\alpha$ is nonempty for all α, since then $V \cap U_\alpha$ is dense in U_α for all α, and consequently V is dense in X. Now there is at least one index γ such that $V \cap U_\gamma \neq \varnothing$, so $V \cap U_\gamma$ is dense in U_γ, and as for all α, $U_\alpha \cap V_\alpha \neq \varnothing$, we also have $V \cap U_\alpha \cap U_\gamma \neq \varnothing$.

$\mathbf{0_I}$ | 22

(2.1.5). Let X be an irreducible space, and f a continuous map from X into a topological space Y. Then $f(X)$ is irreducible, and if x is a generic point of X, then $f(x)$ is a generic point of $f(X)$ and hence also of $\overline{f(X)}$. In particular, if, in addition, Y is irreducible and with a single generic point y, then for $f(X)$ to be everywhere dense, it is necessary and sufficient that $f(x) = y$.

(2.1.6). Any irreducible subspace of a topological space X is contained in a maximal irreducible subspace, which is necessarily closed. Maximal irreducible subspaces of X are called the *irreducible components* of X. If Z_1 and Z_2 are two irreducible components distinct from the space X, then $Z_1 \cap Z_2$ is a closed *rare* set in each of the subspaces Z_1, Z_2; in particular, if an irreducible component of X admits a generic point (2.1.2), such a point cannot belong to any other irreducible component. If X has only a *finite* number of irreducible components Z_i ($1 \leqslant i \leqslant n$), and if, for each i, we put $U_i = \bigcup_{j \neq i} Z_j$, then the U_i are open, irreducible, disjoint, and their union is dense in X. Let U be an **Err$_{\mathrm{II}}$** open subset of a topological space X. If Z is an irreducible subset of X that intersects U, then $Z \cap U$ is open and dense in Z, thus irreducible; conversely, for any irreducible closed subset Y of U, the closure $\overline{Y}$ of Y in X is irreducible and $\overline{Y} \cap U = Y$. We conclude that there is a *bijective correspondence* between the irreducible components of U and the irreducible components of X which intersect U.

(2.1.7). If a topological space X is a union of a *finite* number of irreducible closed subspaces Y_i, then the irreducible components of X are the maximal elements of the set of the Y_i, because if Z is an irreducible closed subset of X, then Z is the union of the $Z \cap Y_i$, from which one sees that Z must be contained in one of the Y_i. Let Y be a subspace of a topological space X, and suppose that Y has only a finite number of irreducible components Y_i, ($1 \leqslant i \leqslant n$); then the closures $\overline{Y_i}$ in X are the irreducible components of Y.

(2.1.8). Let Y be an irreducible space admitting a single generic point y. Let X be a topological space, and f a continuous map from X to Y. Then, for any irreducible component Z of X intersecting $f^{-1}(y)$, $f(Z)$ is dense in Y. The converse is not necessarily true; however, if Z has a generic point z, and if $f(Z)$ is dense in Y, then we must have $f(z) = y$ (2.1.5); in addition, $Z \cap f^{-1}(y)$ is then the closure of $\{z\}$ in $f^{-1}(y)$ and is therefore irreducible, and as an irreducible subset of $f^{-1}(y)$ containing z is necessarily contained in Z (2.1.6), z is a generic point of $Z \cap f^{-1}(y)$. As any irreducible component of $f^{-1}(y)$ is contained in an irreducible component of X, we see that, if any irreducible component Z of X intersecting $f^{-1}(y)$ admits a generic point, then there is a *bijective correspondence* between all these components and all the irreducible components $Z \cap f^{-1}(y)$ of $f^{-1}(y)$, the generic points of Z being identical to those of $Z \cap f^{-1}(y)$.

2.2. Noetherian spaces **$\mathbf{0_I}$ | 23**

(2.2.1). We say that a topological space X is *Noetherian* if the set of open subsets of X satisfies the *maximal* condition, or, equivalently, if the set of closed subsets of X satisfies the *minimal* condition. We say that X is *locally Noetherian* if each $x \in X$ admits a neighbourhood which is a Noetherian subspace.

(2.2.2). Let E be an ordered set satisfying the *minimal* condition, and let $\mathbf{P}$ be a property of the elements of E subject to the following condition: if $a \in E$ is such that for any $x < a$, $\mathbf{P}(x)$ is true, then $\mathbf{P}(a)$ is true. Under these conditions, $\mathbf{P}(x)$ *is true for all* $x \in E$ ("principle of Noetherian induction"). Indeed, let F be the set of $x \in E$ for which $\mathbf{P}(x)$ is false; if F were not empty, it would have a minimal element a, and as then $\mathbf{P}(x)$ is true for all $x < a$, $\mathbf{P}(a)$ would be true, which is a contradiction.

We will apply this principle in particular when E is a *set of closed subsets of a Noetherian space*.

(2.2.3). Any subspace of a Noetherian space is Noetherian. Conversely, any topological space that is a finite union of Noetherian subspaces is Noetherian.

(2.2.4). Any Noetherian space is quasi-compact; conversely, any topological space in which all open sets are quasi-compact is Noetherian.

(2.2.5). A Noetherian space has only a *finite* number of irreducible components, as we see by Noetherian induction.

§3. SUPPLEMENT ON SHEAVES

3.1. Sheaves with values in a category

(3.1.1). Let $\mathtt{C}$ be a category, $(A_\alpha)_{\alpha\in I}$, $(A_{\alpha\beta})_{(\alpha,\beta)\in I\times I}$ two families of objects of $\mathtt{C}$ such that $A_{\beta\alpha} = A_{\alpha\beta}$, and $(\rho_{\alpha\beta})_{(\alpha,\beta)\in I\times I}$ a family of morphisms $\rho_{\alpha\beta} : A_\alpha \to A_{\alpha\beta}$. We say that a pair consisting of an object A of $\mathtt{C}$ and a family of morphisms $\rho_\alpha : A \to A_\alpha$ is a *solution to the universal problem* defined by the data of the families (A_α), $(A_{\alpha\beta})$, and $(\rho_{\alpha\beta})$ if, for every object B of $\mathtt{C}$, the map which sends $f \in \operatorname{Hom}(B, A)$ to the family $(\rho_\alpha \circ f) \in \Pi_\alpha \operatorname{Hom}(B, A_\alpha)$ is a *bijection* of $\operatorname{Hom}(B, A)$ to the set of all (f_α) such that $\rho_{\alpha\beta} \circ f_\alpha = \rho_{\beta\alpha} \circ f_\beta$ for any pair of indices (α, β). If such a solution exists, it is unique up to an isomorphism.

(3.1.2). We will not recall the definition of a *presheaf* $U \mapsto \mathscr{F}(U)$ on a topological space X with values in a category $\mathtt{C}$ (G, I, 1.9); we say that such a presheaf is a *sheaf with values in* $\mathtt{C}$ if it satisfies the following axiom:

(F) *For any covering* (U_α) *of an open set* U *of* X *by open sets* U_α *contained in* U, *if we denote by* ρ_α (resp. $\rho_{\alpha\beta}$) *the restriction morphism*
$$\mathscr{F}(U) \longrightarrow \mathscr{F}(U_\alpha) \quad (\text{resp. } \mathscr{F}(U_\alpha) \longrightarrow \mathscr{F}(U_\alpha \cap U_\beta)),$$
the pair formed by $\mathscr{F}(U)$ *and the family* (ρ_α) *are a solution to the universal problem for* $(\mathscr{F}(U_\alpha))$, **$\mathbf{0_I}$ | 24** $(\mathscr{F}(U_\alpha \cap U_\beta))$, *and* $(\rho_{\alpha\beta})$ *in* (3.1.1)[2].

Equivalently, we can say that, for each object T of $\mathtt{C}$, that the family $U \mapsto \operatorname{Hom}(T, \mathscr{F}(U))$ is a *sheaf of sets*.

(3.1.3). Assume that $\mathtt{C}$ is the category defined by a "type of structure with morphisms" Σ, the objects of $\mathtt{C}$ being the sets with structures of type Σ and morphisms those of Σ. Suppose that the category $\mathtt{C}$ also satisfies the following condition:

(E) If $(A, (\rho_\alpha))$ is a solution of a universal mapping problem *in the category* $\mathtt{C}$ for families (A_α), $(A_{\alpha\beta})$, $(\rho_{\alpha\beta})$, then it is also a solution of the universal mapping problem for the same families *in the category of sets* (that is, when we consider A, A_α, and $A_{\alpha\beta}$ as sets, ρ_α and $\rho_{\alpha\beta}$ as functions)[3].

---

[2] This is a special case of the more general notion of a (non-filtered) *projective limit* (*see* (T, I, 1.8) and the book in preparation announced in the introduction).

[3] It can be proved that it also means that the canonical functor $\mathtt{C} \to \mathtt{Set}$ *commutes with projective limits* (not necessarily filtered).

Under these conditions, the condition (F) gives that, when considered as a presheaf *of sets*, $U \mapsto \mathscr{F}(U)$ is a *sheaf*. In addition, for a map $u : T \to \mathscr{F}(U)$ to be a morphism of $\mathtt{C}$, it is necessary and sufficient, according to (F), that each map $\rho_\alpha \circ u$ is a morphism $T \to \mathscr{F}(U_\alpha)$, which means that the structure of type Σ on $\mathscr{F}(U)$ is the *initial structure* for the morphisms ρ_α. Conversely, suppose a presheaf $U \mapsto \mathscr{F}(U)$ on X, with values in $\mathtt{C}$, is a *sheaf of sets* and satisfies the previous condition; it is then clear that it satisfies (F), so it is a *sheaf with values in* $\mathtt{C}$.

(3.1.4). When Σ is a type of a group or ring structure, the fact that the presheaf $U \mapsto \mathscr{F}(U)$ with values in $\mathtt{C}$ is a sheaf of *sets* implies *ipso facto* that it is a sheaf with values in $\mathtt{C}$ (in other words, a sheaf of groups or rings within the meaning of (G))[4]. But it is not the same when, for example, $\mathtt{C}$ is the category of *topological rings* (with morphisms as continuous homomorphisms): a sheaf with values in $\mathtt{C}$ is a sheaf of rings $U \mapsto \mathscr{F}(U)$ such that for any open U and any covering of U by open sets $U_\alpha \subset U$, the topology of the ring $\mathscr{F}(U)$ is to be *the least fine* making the homomorphisms $\mathscr{F}(U) \to \mathscr{F}(U_\alpha)$ continuous. We will say in this case that $U \mapsto \mathscr{F}(U)$, considered as a sheaf of rings (without a topology), is *underlying* the sheaf of topological rings $U \mapsto \mathscr{F}(U)$. Morphisms $u_V : \mathscr{F}(V) \to \mathscr{G}(V)$ (V an arbitrary open subset of X) of sheaves of topological rings are therefore homomorphisms of the underlying sheaves of rings, such that u_V is *continuous* for all open $V \subset X$; to distinguish them from any homomorphisms of the sheaves of the underlying rings, we will call them continuous homomorphisms of sheaves of topological rings. We have similar definitions and conventions for sheaves of topological spaces or topological groups.

$\mathbf{0_I}$ | 25

(3.1.5). It is clear that for any category $\mathtt{C}$, if there is a presheaf (respectively a sheaf) $\mathscr{F}$ on X with values in $\mathtt{C}$ and U is an open set of X, the $\mathscr{F}(V)$ for open $V \subset U$ constitute a presheaf (or a sheaf) with values in $\mathtt{C}$, which we call the presheaf (or sheaf) *induced* by $\mathscr{F}$ on U and denote it by $\mathscr{F}|U$.

For any morphism $u : \mathscr{F} \to \mathscr{G}$ of presheaves on X with values in $\mathtt{C}$, we denote by $u|U$ the morphism $\mathscr{F}|U \to \mathscr{G}|U$ consisting of the u_V for $V \subset U$.

(3.1.6). Suppose now that the category $\mathtt{C}$ admits *inductive limits* (T, 1.8); then, for any presheaf (and in particular any sheaf) $\mathscr{F}$ on X with values in $\mathtt{C}$ and each $x \in X$, we can define the *stalk* $\mathscr{F}_x$ as the object of $\mathtt{C}$ defined by the inductive limit of the $\mathscr{F}(U)$ with respect to the filtered set (for $\supset$) of the open neighbourhoods U of x in X, and the morphisms $\rho_U^V : \mathscr{F}(V) \to \mathscr{F}(U)$. If $u : \mathscr{F} \to \mathscr{G}$ is a morphism of presheaves with values in $\mathtt{C}$, we define for each $x \in X$ the morphism $u_x : \mathscr{F}_x \to \mathscr{G}_x$ as the inductive limit of $u_U : \mathscr{F}(U) \to \mathscr{G}(U)$ with respect to all open neighbourhoods of x; we thus define $\mathscr{F}_x$ as a covariant functor in $\mathscr{F}$, with values in $\mathtt{C}$, for all $x \in X$.

When $\mathtt{C}$ is further defined by a kind of structure with morphisms Σ, we call *sections over* U *of a sheaf* $\mathscr{F}$ with values in $\mathtt{C}$ the elements of $\mathscr{F}(U)$, and we write $\Gamma(U, \mathscr{F})$ instead of $\mathscr{F}(U)$; for $s \in \Gamma(U, \mathscr{F})$, V an open set contained in U, we write $s|V$ instead of $\rho_V^U(s)$; for all $x \in U$, the canonical image of s in $\mathscr{F}_x$ is the *germ* of s at the point x, denoted by s_x (*we will never replace the notation $s(x)$ in this sense*, this notation being reserved for another notion relating to sheaves which will be considered in this treatise (5.5.1)).

If then $u : \mathscr{F} \to \mathscr{G}$ is a morphism of sheaves with values in $\mathtt{C}$, we will write $u(s)$ instead of $u_V(s)$ for all $s \in \Gamma(V, \mathscr{F})$. $\mathbf{Err_{II}}$

If $\mathscr{F}$ is a sheaf of commutative groups, or rings, or modules, we say that the set of $x \in X$ such that $\mathscr{F}_x \neq \{0\}$ is the *support* of $\mathscr{F}$, denoted $\operatorname{Supp}(\mathscr{F})$; this set is not necessarily closed in X.

When $\mathtt{C}$ is defined by a type of structure with morphisms, *we systematically refrain from using the point of view of "étalé spaces"* in terms of relating to sheaves with values in $\mathtt{C}$; in other words, we will never consider a sheaf as a topological space (nor even as the whole union of its stalks), and we will not consider also a morphism $u : \mathscr{F} \to \mathscr{G}$ of such sheaves on X as a continuous map of topological spaces.

[4]This is because in the category $\mathtt{C}$, any morphism that is a *bijection* (as a map of sets) is an *isomorphism*. This is no longer true when $\mathtt{C}$ is the category of topological spaces, for example.

3.2. Presheaves on an open basis

(3.2.1). We will restrict to the following categories $\mathtt{C}$ admitting *projective limits* (generalized, that is, corresponding to not necessarily filtered preordered sets, cf. (T, 1.8)). Let X be a topological space, $\mathfrak{B}$ an open basis for the topology of X. We will call a *presheaf on* $\mathfrak{B}$, *with values in* $\mathtt{C}$, a family of objects $\mathscr{F}(U) \in \mathtt{C}$, corresponding to each $U \in \mathfrak{B}$, and a family of morphisms $\rho_U^V : \mathscr{F}(V) \to \mathscr{F}(U)$ defined for any pair (U, V) of elements of $\mathfrak{B}$ such that $U \subset V$, with the conditions $\rho_U^U =$ identity and $\rho_U^W = \rho_U^V \circ \rho_V^W$ if U, V, W in $\mathfrak{B}$ are such that $U \subset V \subset W$. We can associate a *presheaf with values in* $\mathtt{C}$: $U \mapsto \mathscr{F}(U)$ in the ordinary sense, taking for all open U, $\mathscr{F}'(U) = \varprojlim \mathscr{F}(V)$, where V runs through the ordered set (for $\subset$, *not filtered* in general) of $V \in \mathfrak{B}$ sets such that $V \subset U$, since the (V) form a projective system for the ρ_V^W ($V \subset W \subset U$, $V \in \mathfrak{B}$, $W \in \mathfrak{B}$). Indeed, if U, U' are two open sets of X such that $U \subset U'$, we define $\rho'^{U'}_U$ as the projective limit (for $V \subset U$) of the canonical morphisms $\mathscr{F}'(U') \to \mathscr{F}(V)$, in other words the unique morphism $\mathscr{F}'(U') \to \mathscr{F}'(U)$, which, when composed with the canonical morphisms $\mathscr{F}'(U) \to \mathscr{F}(V)$, gives the canonical morphisms $\mathscr{F}'(U') \to \mathscr{F}(V)$; the verification of the transitivity of $\rho'^{U'}_U$ is then immediate. Moreover, if $U \in \mathfrak{B}$, the canonical morphism $\mathscr{F}'(U) \to \mathscr{F}(U)$ is an isomorphism, allowing us to identify these two objects[5]. $\mathbf{0_I}$ | 26

(3.2.2). For the presheaf $\mathscr{F}'$ thus defined to be a *sheaf*, it is necessary and sufficient that the presheaf $\mathscr{F}$ on $\mathfrak{B}$ satisfies the condition:

(F_0) *For any covering* (U_α) *of* $U \in \mathfrak{B}$ *by sets* $U_\alpha \in \mathfrak{B}$ *contained in* U, *and for any object* $T \in \mathtt{C}$, *the map which sends* $f \in \operatorname{Hom}(T, \mathscr{F}(U))$ *to the family* $(\rho_{U_\alpha}^U \circ f) \in \prod_\alpha \operatorname{Hom}(T, \mathscr{F}(U_\alpha))$ *is a bijection from* $\operatorname{Hom}(T, \mathscr{F}(U))$ *to the set of all* (f_α) *such that* $\rho_V^{U_\alpha} \circ f_\alpha = \rho_V^{U_\beta} \circ f_\beta$ *for any pair of indices* (α, β) *and any* $V \in \mathfrak{B}$ *such that* $V \subset U_\alpha \cap U_\beta$[6].

The condition is obviously necessary. To show that it is sufficient, consider first a second basis $\mathfrak{B}'$ of the topology of X, *contained in* $\mathfrak{B}$, and show that if $\mathscr{F}''$ denotes the presheaf induced by the subfamily $(\mathscr{F}(V))_{V \in \mathfrak{B}'}$, $\mathscr{F}''$ is *canonically isomorphic* to $\mathscr{F}'$. Indeed, first the projective limit (for $V \in \mathfrak{B}'$, $V \subset U$) of the canonical morphisms $\mathscr{F}'(U) \to \mathscr{F}(V)$ is a morphism $\mathscr{F}'(U) \to \mathscr{F}''(U)$ for all open U. If $U \in \mathfrak{B}$, this morphism is an isomorphism, because by hypothesis the canonical morphisms $\mathscr{F}''(U) \to \mathscr{F}(V)$ for $V \in \mathfrak{B}'$, $V \subset U$, factorize as $\mathscr{F}''(U) \to \mathscr{F}(U) \to \mathscr{F}(V)$, and it is immediate to see that the composition of morphisms $\mathscr{F}(U) \to \mathscr{F}''(U)$ and $\mathscr{F}''(U) \to \mathscr{F}(U)$ thus defined are the identities. This being so, for all open U, the morphisms $\mathscr{F}''(U) \to \mathscr{F}''(W) = \mathscr{F}(W)$ for $W \in \mathfrak{B}$ and $W \subset U$ satisfy the conditions characterizing the projective limit of $\mathscr{F}(W)$ ($W \in \mathfrak{B}$, $W \subset U$), which proves our assertion given the uniqueness of a projective limit up to isomorphism.

This being so, let U be any open set of X, (U_α) a covering of U by the open sets contained in U, and $\mathfrak{B}'$ the subfamily of $\mathfrak{B}$ formed by the sets of $\mathfrak{B}$ contained in at least one U_α; it is clear that $\mathfrak{B}'$ is still a basis of the topology of U, so $\mathscr{F}'(U)$ (resp. $\mathscr{F}''(U_\alpha)$) is the projective limit of $\mathscr{F}(V)$ for $V \in \mathfrak{B}'$ and $V \subset U$ (resp., $V \subset U_\alpha$), the axiom (F) is then immediately verified by virtue of the definition of the projective limit. $\mathbf{0_I}$ | 27

When (F_0) is satisfied, we will say by abuse of language that the presheaf $\mathscr{F}$ on the basis $\mathfrak{B}$ is a sheaf.

(3.2.3). Let $\mathscr{F}, \mathscr{G}$ be two presheaves on a basis $\mathfrak{B}$, with values in $\mathtt{C}$; we define a *morphism* $u : \mathscr{F} \to \mathscr{G}$ as a family $(u_V)_{V \in \mathfrak{B}}$ of morphisms $u_V : \mathscr{F}(V) \to \mathscr{G}(V)$ satisfying the usual compatibility conditions with the restriction morphisms ρ_V^W. With the notation of (3.2.1), we have a morphism $u' : \mathscr{F}' \to \mathscr{G}'$ of (ordinary) presheaves by taking for u'_U the projective limit of the u_V for $V \in \mathfrak{B}$ and $V \subset U$; the

[5]If X is a *Noetherian* space, we can still define $\mathscr{F}'(U)$ and show that it is a presheaf (in the ordinary sense) when one supposes only that $\mathtt{C}$ admits projective limits for *finite* projective systems. Indeed, if U is any open set of X, there is a *finite* covering (V_i) of U consisting of sets of $\mathfrak{B}$; for every couple (i, j) of indices, let (V_{ijk}) be a finite covering of $V_i \cap V_j$ formed by sets of $\mathfrak{B}$. Let I be the set of i and triples (i, j, k), ordered only by the relations $i > (i, j, k)$, $j > (i, j, k)$; we then take $\mathscr{F}'(U)$ to be the projective limit of the system of $\mathscr{F}(V_i)$ and $\mathscr{F}(V_{ijk})$; it is easy to verify that this does not depend on the coverings (V_i) and (V_{ijk}) and that $U \mapsto \mathscr{F}'(U)$ is a presheaf.

[6]It also means that the pair formed by $\mathscr{F}(U)$ and the $\rho_\alpha = \rho_{U_\alpha}^U$ is a *solution to the universal problem* defined in (3.1.1) by the data of $A_\alpha = \mathscr{F}(U_\alpha)$, $A_{\alpha\beta} = \Pi\mathscr{F}(V)$ (for $V \in \mathfrak{B}$ such that $V \subset U_\alpha \cap U_\beta$) and $\rho_{\alpha\beta} = (\rho''_V) : \mathscr{F}(U_\alpha) \to \Pi\mathscr{F}(V)$ defined by the condition that for $V \in \mathfrak{B}$, $V' \in \mathfrak{B}$, $W \in \mathfrak{B}$, $V \cup V' \subset U_\alpha \cap U_\beta$, $W \subset V \cap V'$, $\rho_W^V \circ \rho''_V = \rho_W^{V'} \circ \rho''_{V'}$.

verification of the compatibility conditions with the ${\rho'}_U^{U'}$ follows from the functorial properties of the projective limit.

(3.2.4). If the category $\mathtt{C}$ admits inductive limits, and if $\mathscr{F}$ is a presheaf on the basis $\mathfrak{B}$, with values in $\mathtt{C}$, for each $x \in X$ the neighbourhoods of x belonging to $\mathfrak{B}$ form a cofinal set (for $\supset$) in the set of neighbourhoods of x, therefore, if $\mathscr{F}'$ is the (ordinary) presheaf corresponding to $\mathscr{F}$, the stalk $\mathscr{F}'_x$ is equal to $\varinjlim_{\mathfrak{B}} \mathscr{F}(V)$ over the set of $V \in \mathfrak{B}$ containing x. If $u : \mathscr{F} \to \mathscr{G}$ is morphism of presheaves on $\mathfrak{B}$ with values in $\mathtt{C}$, $u' : \mathscr{F}' \to \mathscr{G}'$ the corresponding morphism of ordinary presheaves, u'_x is likewise the inductive limit of the morphisms $u_V : \mathscr{F}(V) \to \mathscr{G}(V)$ for $V \in \mathfrak{B}$, $x \in V$.

(3.2.5). We return to the general conditions of (3.2.1). If $\mathscr{F}$ is an ordinary *sheaf* with values in $\mathtt{C}$, $\mathscr{F}_1$ the sheaf *on* $\mathfrak{B}$ obtained by the restriction of $\mathscr{F}$ to $\mathfrak{B}$, then the ordinary sheaf $\mathscr{F}'_1$ obtained from $\mathscr{F}_1$ by the procedure of (3.2.1) is canonically isomorphic to $\mathscr{F}$, by virtue of the condition (F) and the uniqueness properties of the projective limit. We identify the ordinary sheaf $\mathscr{F}$ with $\mathscr{F}'_1$.

If $\mathscr{G}$ is a second (ordinary) sheaf on X with values in $\mathtt{C}$, and $u : \mathscr{F} \to \mathscr{G}$ a morphism, the preceding remark shows that the data of the $u_V : \mathscr{F}(V) \to \mathscr{G}(V)$ *for only the* $V \in \mathfrak{B}$ completely determines u; conversely, it is sufficient, the u_V being given for $V \in \mathfrak{B}$, to verify the commutative diagram with the restriction morphisms ρ_V^W for $V \in \mathfrak{B}$, $W \in \mathfrak{B}$, and $V \subset W$, for there to exist a unique morphism u' from $\mathscr{F}$ to $\mathscr{G}$ such that $u'_V = u_V$ for each $V \in \mathfrak{B}$ (3.2.3).

(3.2.6). Suppose that $\mathtt{C}$ admits projective limits. Then the category of *sheaves on X with values in* $\mathtt{C}$ admits *projective limits*; if $(\mathscr{F}_\lambda)$ is a projective system of sheaves on X with values in $\mathtt{C}$, the $\mathscr{F}(U) = \varprojlim_\lambda \mathscr{F}_\lambda(U)$ indeed define a presheaf with values in $\mathtt{C}$, and the verification of the axiom (F) follows from the transitivity of projective limits; the fact that $\mathscr{F}$ is then the projective limit of the $\mathscr{F}_\lambda$ is immediate.

When $\mathtt{C}$ is the category of sets, for each projective system $(\mathscr{H}_\lambda)$ such that $\mathscr{H}_\lambda$ is a *subsheaf* of $\mathscr{F}_\lambda$ **$\mathbf{0_I}$ | 28** for each λ, $\varprojlim_\lambda \mathscr{H}_\lambda$ canonically identifies with a *subsheaf* of $\varprojlim_\lambda \mathscr{F}_\lambda$. If $\mathtt{C}$ is the category of abelian groups, the covariant functor $\varprojlim_\lambda \mathscr{F}_\lambda$ is *additive* and *left exact*.

3.3. Gluing sheaves

(3.3.1). Suppose still that the category $\mathtt{C}$ admits (generalized) projective limits. Let X be a topological space, $\mathfrak{U} = (U_\lambda)_{\lambda \in L}$ an open cover of X, and for each $\lambda \in L$, let $\mathscr{F}_\lambda$ be a sheaf on U_λ, with values in $\mathtt{C}$; for each pair of indices (λ, μ), suppose that we are given an *isomorphism* $\theta_{\lambda\mu} : \mathscr{F}_\mu|(U_\lambda \cap U_\mu) \simeq \mathscr{F}|(U_\lambda \cap U_\mu)$; in addition, suppose that for each triple (λ, μ, ν), if we denote by $\theta'_{\lambda\mu}, \theta'_{\mu\nu}, \theta'_{\lambda\nu}$ the restrictions of $\theta_{\lambda\mu}, \theta_{\mu\nu}, \theta_{\lambda\nu}$ to $U_\lambda \cap U_\mu \cap U_\nu$, then we have $\theta'_{\lambda\nu} = \theta'_{\lambda\mu} \circ \theta'_{\mu\nu}$ (*gluing condition* for the $\theta_{\lambda\mu}$). Then there exists a sheaf $\mathscr{F}$ on X, with values in $\mathtt{C}$, and for each λ an isomorphism $\eta_\lambda : \mathscr{F}|U_\lambda \simeq \mathscr{F}_\lambda$ such that, for each pair (λ, μ), if we denote by η'_λ and η'_μ the restrictions of η_λ and η_μ to $U_\lambda \cap U_\mu$, then we have $\theta_{\lambda\mu} = \eta'_\lambda \circ {\eta'}_\mu^{-1}$; in addition, $\mathscr{F}$ and the η_λ are determined up to unique isomorphism by these conditions. The uniqueness indeed follows immediately from (3.2.5). To establish the existence of $\mathscr{F}$, denote by $\mathfrak{B}$ the open basis consisting of the open sets contained in at least one U_λ, and for each $U \in \mathfrak{B}$, choose (by the Hilbert function τ) one of the $\mathscr{F}_\lambda(U)$ for one of the λ such that $U \subset U_\lambda$; if we denote this object by $\mathscr{F}(U)$, the ρ_U^V for $U \subset V$, $U \in \mathfrak{B}$, $V \in \mathfrak{B}$ are defined in an evident way (by means of the $\theta_{\lambda\mu}$), and the transitivity conditions is a consequence of the gluing condition; in addition, the verification of (F_0) is immediate, so the presheaf on $\mathfrak{B}$ thus clearly defines a sheaf, and we deduce by the general procedure (3.2.1) an (ordinary) sheaf still denoted $\mathscr{F}$ and which answers the question. We say that $\mathscr{F}$ is obtained by *gluing the $\mathscr{F}_\lambda$ by means of the* $\theta_{\lambda\mu}$ and we usually identify the $\mathscr{F}_\lambda$ and $\mathscr{F}|U_\lambda$ by means of the η_λ.

It is clear that each sheaf $\mathscr{F}$ on X with values in $\mathtt{C}$ can be considered as being obtained by the gluing of the sheaves $\mathscr{F}_\lambda = \mathscr{F}|U_\lambda$ (where (U_λ) is an arbitrary open cover of X), by means of the isomorphisms $\theta_{\lambda\mu}$ reduced to the identity.

(3.3.2). With the same notation, let $\mathscr{G}_\lambda$ be a second sheaf on U_λ (for each $\lambda \in L$) with values in $\mathtt{C}$, and for each pair (λ, μ) let us be given an isomorphism $\omega_{\lambda\mu} : \mathscr{G}_\mu|(U_\lambda \cap U_\mu) \simeq \mathscr{G}_\lambda|(U_\lambda \cap U_\mu)$, these isomorphisms satisfying the gluing condition. Finally, suppose that we are given for each λ a morphism $u_\lambda : \mathscr{F}_\lambda \to \mathscr{G}_\lambda$, and that the diagrams

(3.3.2.1)
$$\begin{tikzcd}
\mathscr{F}_\mu|(U_\lambda \cap U_\mu) \arrow[r, "u_\mu"] \arrow[d] & \mathscr{G}_\mu|(U_\lambda \cap U_\mu) \arrow[d] \\
\mathscr{F}_\lambda|(U_\lambda \cap U_\mu) \arrow[r, "u_\lambda"'] & \mathscr{G}_\lambda|(U_\lambda \cap U_\mu)
\end{tikzcd}$$

are commutative. Then, if $\mathscr{G}$ is obtained by gluing the $\mathscr{G}_\lambda$ by means of the $\omega_{\lambda\mu}$, there exists a unique morphism $u : \mathscr{F} \to \mathscr{G}$ such that the diagrams $\mathbf{0_I}$ | 29

$$\begin{tikzcd}
\mathscr{F}|U_\lambda \arrow[r, "u|U_\lambda"] \arrow[d] & \mathscr{G}|U_\lambda \arrow[d] \\
\mathscr{F}_\lambda \arrow[r, "u_\lambda"'] & \mathscr{G}_\lambda
\end{tikzcd}$$

are commutative; this follows immediately from (3.2.3). The correspondence between the family (u_λ) and u is in a functorial bijection with the subset of $\Pi_\lambda \operatorname{Hom}(\mathscr{F}_\lambda, \mathscr{G}_\lambda)$ satisfying the conditions (3.3.2.1) on $\operatorname{Hom}(\mathscr{F}, \mathscr{G})$.

(3.3.3). With the notation of (3.3.1), let V be an open set of X; it is immediate that the restrictions to $V \cap U_\lambda \cap U_\mu$ of the $\theta_{\lambda\mu}$ satisfy the gluing condition for the induced sheaves $\mathscr{F}_\lambda|(V \cap U_\lambda)$ and that the sheaves on V obtained by gluing the latter identifies canonically with $\mathscr{F}|V$.

3.4. Direct images of presheaves

(3.4.1). Let X, Y be two topological spaces, $\psi : X \to Y$ a continuous map. Let $\mathscr{F}$ be a presheaf on X with values in a category $\mathtt{C}$; for each open $U \subset Y$, let $\mathscr{G}(U) = \mathscr{F}(\psi^{-1}(U))$, and if U, V are two open subsets of Y such that $U \subset V$, let ρ_U^V be the morphism $\mathscr{F}(\psi^{-1}(V)) \to \mathscr{F}(\psi^{-1}(U))$; it is immediate that the $\mathscr{G}(U)$ and the ρ_U^V define a *presheaf* on Y with values in $\mathtt{C}$, that we call the *direct image of $\mathscr{F}$ by ψ* and we denote it by $\psi_*(\mathscr{F})$. If $\mathscr{F}$ is a sheaf, we immediately verify the axiom (F) for the presheaf $\mathscr{G}$, so $\psi_*(\mathscr{F})$ is a sheaf.

(3.4.2). Let $\mathscr{F}_1$, $\mathscr{F}_2$ be two presheaves of X with values in $\mathtt{C}$, and let $u : \mathscr{F}_1 \to \mathscr{F}_2$ be a morphism. When U varies over the set of open subsets of Y, the family of morphisms $u_{\psi^{-1}(U)} : \mathscr{F}_1(\psi^{-1}(U)) \to \mathscr{F}_2(\psi^{-1}(U))$ satisfies the compatibility conditions with the restriction morphisms, and as a result defines a morphism $\psi_*(u) : \psi_*(\mathscr{F}_1) \to \psi_*(\mathscr{F}_2)$. If $v : \mathscr{F}_2 \to \mathscr{F}_3$ is a morphism from $\mathscr{F}_2$ to a third presheaf on X with values in $\mathtt{C}$, we have $\psi_*(v \circ u) = \psi_*(v) \circ \psi_*(u)$; in other words, $\psi_*(\mathscr{F})$ is a *covariant functor* in $\mathscr{F}$, from the category of presheaves (resp. sheaves) on X with values in $\mathtt{C}$, to that of presheaves (resp. sheaves) on Y with values in $\mathtt{C}$.

(3.4.3). Let Z be a third topological space, $\psi' : Y \to Z$ a continuous map, and let $\psi'' = \psi' \circ \psi$. It is clear that we have $\psi''_*(\mathscr{F}) = \psi'_*(\psi_*(\mathscr{F}))$ for each presheaf $\mathscr{F}$ on X with values in $\mathtt{C}$; in addition, for each morphism $u : \mathscr{F} \to \mathscr{G}$ of such presheaves, we have $\psi''_*(u) = \psi'_*(\psi_*(u))$. In other words, ψ''_* is the *composition* of the functors ψ'_* and ψ_*, and this can be written as

$$(\psi' \circ \psi)_* = \psi'_* \circ \psi_*.$$

In addition, for each open set U of Y, the image under the restriction $\psi|\psi^{-1}(U)$ of the induced presheaf $\mathscr{F}|\psi^{-1}(U)$ is none other than the induced presheaf $\psi_*(\mathscr{F})|U$.

(3.4.4). Suppose that the category $\mathtt{C}$ admits inductive limits, and let $\mathscr{F}$ be a presheaf on X with values in $\mathtt{C}$; for all $x \in X$, the morphisms $\Gamma(\psi^{-1}(U), \mathscr{F}) \to \mathscr{F}_x$ (U an open neighbourhood of $\psi(x)$ in Y) form an inductive limit, which gives by passing to the limit a morphism $\psi_x : (\psi_*(\mathscr{F}))_{\psi(x)} \to \mathscr{F}_x$ of $\mathbf{0_I}$ | 30
the stalks; in general, these morphisms are *neither injective nor surjective*. It is functorial; indeed, if

$u : \mathscr{F}_1 \to \mathscr{F}_2$ is a morphism of presheaves on X with values in $\mathtt{C}$, the diagram

$$\begin{tikzcd} (\psi_*(\mathscr{F}_1))_{\psi(x)} \arrow[r, "\psi_x"] \arrow[d, "(\psi_*(u))_{\psi(x)}"'] & (\mathscr{F}_1)_x \arrow[d, "u_x"] \\ (\psi_*(\mathscr{F}_2))_{\psi(x)} \arrow[r, "\psi_x"'] & (\mathscr{F}_2)_x \end{tikzcd}$$

is commutative. If Z is a third topological space, $\psi' : Y \to Z$ a continuous map, and $\psi'' = \psi' \circ \psi$, then we have $\psi''_x = \psi_x \circ \psi'_{\psi(x)}$ for $x \in X$.

(3.4.5). Under the hypotheses of (3.4.4), suppose in addition that ψ is a *homeomorphism* from X to the subspace $\psi(X)$ of Y. Then, for each $x \in X$, ψ_x is an *isomorphism*. This applies in particular to the canonical injection j of a subset X of Y into Y.

(3.4.6). Suppose that $\mathtt{C}$ be the category of groups, or of rings, etc. If $\mathscr{F}$ is a sheaf on X with values in $\mathtt{C}$, of support S, and if $y \notin \overline{\psi(S)}$, then it follows from the definition of $\psi_*(\mathscr{F})$ that $(\psi_*(\mathscr{F}))_y = \{0\}$, or in other words, that the support of $\psi_*(\mathscr{F})$ is contained in $\overline{\psi(S)}$; but it is not necessarily contained in $\psi(S)$. Under the same hypotheses, if j is the canonical injection of a subset X of Y into Y, the sheaf $j_*(\mathscr{F})$ induces $\mathscr{F}$ on X; if moreover X is *closed* in Y, $j_*(\mathscr{F})$ is the sheaf on Y which induces $\mathscr{F}$ on X and 0 on $Y - X$ (G, II, 2.9.2), but it is in general distinct from the latter when we suppose that X is locally closed but not closed.

3.5. Inverse images of presheaves

(3.5.1). Under the hypotheses of (3.4.1), if $\mathscr{F}$ (resp. $\mathscr{G}$) is a presheaf on X (resp. Y) with values in $\mathtt{C}$, then each morphism $u : \mathscr{G} \to \psi_*(\mathscr{F})$ of presheaves on Y is called a *ϕ-morphism* from $\mathscr{G}$ to $\mathscr{F}$, and we denote it also by $\mathscr{G} \to \mathscr{F}$. We denote also by $\mathrm{Hom}_\phi(\mathscr{G}, \mathscr{F})$ the set of $\mathrm{Hom}_Y(\mathscr{G}, \psi_*(\mathscr{F}))$ the ψ-morphisms from $\mathscr{G}$ to $\mathscr{F}$. For each pair (U, V), where U is an open set of X, V an open set of Y such that $\psi(U) \subset V$, we have a morphism $u_{U,V} : \mathscr{G}(V) \to \mathscr{F}(U)$ by composing the restriction morphism $\mathscr{F}(\psi^{-1}(V)) \to \mathscr{F}(U)$ and the morphism $u_V : \mathscr{G}(V) \to \psi_*(\mathscr{F})(V) = \mathscr{F}(\psi^{-1}(V))$; it is immediate that these morphisms render commutative the diagrams

(3.5.1.1)
$$\begin{tikzcd} \mathscr{G}(V) \arrow[r, "u_{U,V}"] \arrow[d] & \mathscr{F}(U) \arrow[d] \\ \mathscr{G}(V') \arrow[r, "u_{U',V'}"'] & \mathscr{F}(U') \end{tikzcd}$$

for $U' \subset U$, $V' \subset V$, $\psi(U') \subset V'$. Conversely, the data of a family $(u_{U,V})$ of morphisms rendering commutative the diagrams (3.5.1.1) define a ψ-morphism u, since it suffices to take $u_V = u_{\psi^{-1}(V),V}$.

If the category $\mathtt{C}$ admits (generalized) projective limits, and if $\mathfrak{B}$, $\mathfrak{B}'$ are bases for the topologies $\mathbf{0_I}$ | 31
of X and Y respectively, to define a ψ-morphism u of *sheaves*, we can restrict to giving the $u_{U,V}$ for $U \in \mathfrak{B}$, $V \in \mathfrak{B}'$, and $\psi(U) \subset V$, satisfying the compatibility conditions of (3.5.1.1) for U, U' in $\mathfrak{B}$ and V, V' in $\mathfrak{B}'$; it indeed suffices to define u_W, for each open $W \subset Y$, as the projective limit of the $u_{U,V}$ for $V \in \mathfrak{B}'$ and $V \subset W$, $U \in \mathfrak{B}$ and $\psi(U) \subset V$.

When the category $\mathtt{C}$ admits inductive limits, we have, for each $x \in X$, a morphism $\mathscr{G}(V) \to \mathscr{F}(\psi^{-1}(V)) \to \mathscr{F}_x$, for each open neighbourhood V of $\psi(x)$ in Y, and these morphisms form an inductive system which gives by passing to the limit a morphism $\mathscr{G}_{\psi(x)} \to \mathscr{F}_x$.

(3.5.2). Under the hypotheses of (3.4.3), let $\mathscr{F}$, $\mathscr{G}$, $\mathscr{H}$ be presheaves with values in $\mathtt{C}$ on X, Y, Z respectively, and let $u : \mathscr{G} \to \psi_*(\mathscr{F})$, $v : \mathscr{H} \to \psi'_*(\mathscr{G})$ be a ψ-morphism and a ψ'-morphism respectively. We obtain a ψ''-morphism $w : \mathscr{H} \xrightarrow{v} \psi'_*(\mathscr{G}) \xrightarrow{\psi'_*(u)} \psi'_*(\psi_*(\mathscr{F})) = \psi''_*(\mathscr{F})$, that we call, by definition, the *composition* of u and v. We can therefore consider the pairs $(X, \mathscr{F})$ consisting of a topological space X and a presheaf $\mathscr{F}$ on X (with values in $\mathtt{C}$) as forming a *category*, the morphisms being the pairs $(\psi, \theta) : (X, \mathscr{F}) \to (Y, \mathscr{G})$ consisting of a continuous map $\psi : X \to Y$ and of a ψ-morphism $\theta : \mathscr{G} \to \mathscr{F}$.

(3.5.3). Let $\psi : X \to Y$ be a continuous map, $\mathscr{G}$ a *presheaf* on Y with values in $\mathtt{C}$. We call the *inverse image of $\mathscr{G}$ under ψ* the pair $(\mathscr{G}', \rho)$, where $\mathscr{G}'$ is a *sheaf* on X with values in $\mathtt{C}$, and $\rho : \mathscr{G} \to \mathscr{G}'$ a ψ-morphism (in other words a homomorphism $\mathscr{G} \to \psi_*(\mathscr{G}')$) such that, for each *sheaf* $\mathscr{F}$ on X with values in $\mathtt{C}$, the map

$$\mathrm{Hom}_X(\mathscr{G}', \mathscr{F}) \longrightarrow \mathrm{Hom}_\psi(\mathscr{G}, \mathscr{F}) \longrightarrow \mathrm{Hom}_Y(\mathscr{G}, \psi_*(\mathscr{F})) \tag{3.5.3.1}$$

sending v to $\psi_*(v) \circ \rho$, is a *bijection*; this map, being functorial in $\mathscr{F}$, then defines an isomorphism of functors in $\mathscr{F}$. The pair $(\mathscr{G}', \rho)$ is the solution of a universal problem, and we say it is *determined up to unique isomorphism* when it exists. We then write $\mathscr{G}' = \psi^*(\mathscr{G})$, $\rho = \rho_\mathscr{G}$, and by abuse of language, we say that $\psi^*(\mathscr{G})$ is *the inverse image sheaf* of $\mathscr{G}$ under ψ, and we agree that $\psi^*(\mathscr{G})$ is considered as equipped with a *canonical ψ-morphism* $\rho_\mathscr{G} : \mathscr{G} \to \psi^*(\mathscr{G})$, that is to say the *canonical homomorphism* of presheaves on Y:

$$\rho_\mathscr{G} : \mathscr{G} \longrightarrow \psi_*(\psi^*(\mathscr{G})). \tag{3.5.3.2}$$

For each homomorphism $v : \psi^*(\mathscr{G}) \to \mathscr{F}$ (where $\mathscr{F}$ is a sheaf on X with values in $\mathtt{C}$), we put $v^\flat = \psi_*(v) \circ \rho_\mathscr{G} : \mathscr{G} \to \psi_*(\mathscr{F})$. By definition, *each* morphism of presheaves $u : \mathscr{G} \to \psi_*(\mathscr{F})$ is of the form $v^\flat$ for a unique v, which we will denote $u^\sharp$. In other words, each morphism $u : \mathscr{G} \to \psi_*(\mathscr{F})$ of presheaves factorizes in a unique way as

$$u : \mathscr{G} \xrightarrow{\rho_\mathscr{G}} \psi_*(\psi^*(\mathscr{G})) \xrightarrow{\psi_*(u^\sharp)} \psi_*(\mathscr{F}). \tag{3.5.3.3}$$

$\mathbf{0_I}$ | 32

(3.5.4). Suppose now that the category $\mathtt{C}$ be such[7] that *each* presheaf $\mathscr{F}$ on Y with values in $\mathtt{C}$ admits an inverse image under ψ, and we denote it by $\psi^*(\mathscr{G})$.

We will see that we can define $\psi^*(\mathscr{G})$ as a *covariant functor* in $\mathscr{G}$, from the category of presheaves on Y with values in $\mathtt{C}$, to that of sheaves on X with values in $\mathtt{C}$, in such a way that the isomorphism $v \mapsto v^\flat$ is an *isomorphism of bifunctors*

$$\mathrm{Hom}_X(\psi^*(\mathscr{G}), \mathscr{F}) \simeq \mathrm{Hom}_Y(\mathscr{G}, \psi_*(\mathscr{F})) \tag{3.5.4.1}$$

in $\mathscr{G}$ and $\mathscr{F}$.

Indeed, for each morphism $w : \mathscr{G}_1 \to \mathscr{G}_2$ of presheaves on Y with values in $\mathtt{C}$, consider the composite morphism $\mathscr{G}_1 \xrightarrow{w} \mathscr{G}_2 \xrightarrow{\rho_{\mathscr{G}_2}} \psi_*(\psi^*(\mathscr{G}_2))$; to it corresponds a morphism $(\rho_{\mathscr{G}_2} \circ w)^\sharp : \psi^*(\mathscr{G}_1) \to \psi^*(\mathscr{G}_2)$, that we denote by $\psi^*(w)$. We therefore have, according to (3.5.3.3),

$$\psi_*(\psi^*(w)) \circ \rho_{\mathscr{G}_1} = \rho_{\mathscr{G}_2} \circ w. \tag{3.5.4.2}$$

For each morphism $u : \mathscr{G}_2 \to \psi_*(\mathscr{F})$, where $\mathscr{F}$ is a sheaf on X with values in $\mathtt{C}$, we have, according to (3.5.3.3), (3.5.4.2), and the definition of $u^\flat$, that

$$(u^\sharp \circ \psi^*(w))^\flat = \psi_*(u^\sharp) \circ \psi_*(\psi^*(w)) \circ \rho_{\mathscr{G}_1} = \psi_*(u^\sharp) \circ \rho_{\mathscr{G}_2} \circ w = u \circ w$$

where again

$$(u \circ w)^\sharp = u^\sharp \circ \psi^*(w). \tag{3.5.4.3}$$

If we take in particular for u a morphism $\mathscr{G}_2 \xrightarrow{w'} \mathscr{G}_3 \xrightarrow{\rho_{\mathscr{G}_3}} \psi_*(\psi^*(\mathscr{G}_3))$, it becomes $\psi^*(w' \circ w) = (\rho_{\mathscr{G}_3} \circ w' \circ w)^\sharp = (\rho_{\mathscr{G}_3} \circ w')^\sharp \circ \psi^*(w) = \psi^*(w') \circ \psi^*(w)$, hence our assertion.

Finally, for each sheaf $\mathscr{F}$ on X with values in $\mathtt{C}$, let $i_\mathscr{F}$ be the identity morphism of $\psi_*(\mathscr{F})$ and denote by

$$\sigma_\mathscr{F} : \psi^*(\psi_*(\mathscr{F})) \longrightarrow \mathscr{F}$$

the morphism $(i_\mathscr{F})^\sharp$; the formula (3.5.4.3) gives in particular the factorization

$$u^\sharp : \psi^*(\mathscr{G}) \xrightarrow{\psi^*(u)} \psi^*(\psi_*(\mathscr{F})) \xrightarrow{\sigma_\mathscr{F}} \mathscr{F} \tag{3.5.4.4}$$

for each morphism $u : \mathscr{G} \to \psi_*(\mathscr{F})$. We say that the morphism $\sigma_\mathscr{F}$ is *canonical*.

[7] In the book mentioned in the introduction, we will give very general conditions on the category $\mathtt{C}$ ensuring the existence of inverse images of presheaves with values in $\mathtt{C}$.

(3.5.5). Let $\psi' : Y \to Z$ be a continuous map, and suppose that each presheaf $\mathscr{H}$ on Z with values in $\mathtt{C}$ admits an inverse image $\psi'^*(\mathscr{H})$ under ψ'. Then (with the hypotheses of (3.5.4)) each presheaf $\mathscr{H}$ on Z with values in $\mathtt{C}$ admits an inverse image under $\psi'' = \psi' \circ \psi$ and we have a canonical functorial isomorphism

$$\psi''^*(\mathscr{H}) \simeq \psi^*(\psi'^*(\mathscr{H})). \tag{3.5.5.1}$$

This indeed follows immediately from the definitions, taking into account that $\psi''_* = \psi'_* \circ \psi_*$. In addition, if $u : \mathscr{G} \to \psi_*(\mathscr{F})$ is a ψ-morphism, $v : \mathscr{H} \to \psi'_*(\mathscr{G})$ a ψ'-morphism, and $w = \psi'_*(u) \circ v$ their composition (3.5.2), then we have immediately that $w^\sharp$ is the composite morphism $\mathbf{0_I}$ | 33

$$w^\sharp : \psi^*(\psi'^*(\mathscr{H})) \xrightarrow{\psi^*(v^\sharp)} \psi^*(\mathscr{G}) \xrightarrow{u^\sharp} \mathscr{F}.$$

(3.5.6). We take in particular for ψ the identity map $1_X : X \to X$. Then if the inverse image under ψ of a presheaf $\mathscr{F}$ on X with values in $\mathtt{C}$ exists, we say that this inverse image is the *sheaf associated to the presheaf* $\mathscr{F}$. Each morphism $u : \mathscr{F} \to \mathscr{F}'$ from $\mathscr{F}$ to a *sheaf* $\mathscr{F}'$ with values in $\mathtt{C}$ factorizes in a unique way as $\mathscr{F} \xrightarrow{\rho_{\mathscr{F}}} 1_X^*(\mathscr{F}) \xrightarrow{u^\sharp} \mathscr{F}'$.

3.6. Simple and locally simple sheaves

(3.6.1). We say that a *presheaf* $\mathscr{F}$ on X, with values in $\mathtt{C}$, is *constant* if the canonical morphisms $\mathscr{F}(X) \to \mathscr{F}(U)$ are *isomorphisms* for each nonempty open $U \subset X$; we note that $\mathscr{F}$ is not necessarily a sheaf. We say that a *sheaf* is *simple* if it is the associated sheaf (3.5.6) of a constant presheaf. We say that a sheaf $\mathscr{F}$ is *locally simple* if each $x \in X$ admits an open neighbourhood U such that $\mathscr{F}|U$ is simple.

(3.6.2). Suppose that X is *irreducible* (2.1.1); then the following properties are equivalent:

(a) *$\mathscr{F}$ is a constant presheaf on X;*
(b) *$\mathscr{F}$ is a simple sheaf on X;*
(c) *$\mathscr{F}$ is a locally simple sheaf on X.*

Indeed, let $\mathscr{F}$ be a constant presheaf on X; if U, V are two nonempty open sets in X, then $U \cap V$ is nonempty, so $\mathscr{F}(X) \to \mathscr{F}(U) \to \mathscr{F}(U \cap V)$ and $\mathscr{F}(X) \to \mathscr{F}(U)$ being isomorphisms, the same is true for $\mathscr{F}(U) \to \mathscr{F}(U \cap V)$, and similarly, $\mathscr{F}(V) \to \mathscr{F}(U \cap V)$ is an isomorphism. We therefore conclude immediately that the axiom (F) of (3.1.2) is clearly satisfied, $\mathscr{F}$ is isomorphic to its associated sheaf, and as a result (a) implies (b).

Now let (U_α) be an open cover of X by nonempty open sets and let $\mathscr{F}$ be a sheaf on X such that $\mathscr{F}|U_\alpha$ is simple for each α; as U_α is irreducible, $\mathscr{F}|U_\alpha$ is a constant presheaf according to the above. As $U_\alpha \cap U_\beta$ is not empty, $\mathscr{F}(U_\alpha) \to \mathscr{F}(U_\alpha \cap U_\beta)$ and $\mathscr{F}(U_\beta) \to \mathscr{F}(U_\alpha \cap U_\beta)$ are isomorphisms, hence we have a canonical isomorphism $\theta_{\alpha\beta} : \mathscr{F}(U_\alpha) \to \mathscr{F}(U_\beta)$ for each pair of indices. But then if we apply the condition (F) for $U = X$, we see that for each index α_0, $\mathscr{F}(U_{\alpha_0})$ and the $\theta_{\alpha_0\alpha}$ are solutions to the universal problem, which (according to the uniqueness) implies that $\mathscr{F}(X) \to \mathscr{F}(U_{\alpha_0})$ is an isomorphism, and hence proves that (c) implies (a).

3.7. Inverse images of presheaves of groups or rings $\mathbf{0_I}$ | 34

(3.7.1). We will show that when we take $\mathtt{C}$ to be the category of sets, the inverse image under ψ for each presheaf $\mathscr{G}$ with values in $\mathtt{C}$ *always exists* (the notation and hypotheses on X, Y, ψ being that of (3.5.3)). Indeed, for each open $U \subset X$, define $\mathscr{G}'(U)$ as follows: an element s' of $\mathscr{G}'(U)$ is a family $(s'_x)_{x \in U}$, where $s'_x \in \mathscr{G}_{\psi(x)}$ for each $x \in U$, and where, for each $x \in U$, the following condition is satisfied: there exists an open neighbourhood V of $\psi(x)$ in Y, a neighbourhood $W \subset \psi^{-1}(V) \cap U$ of x, and an element $s \in \mathscr{G}(V)$ such that $s'_z = s_{\psi(x)}$ for all $z \in W$. We verify immediately that $U \mapsto \mathscr{G}'(U)$ clearly satisfies the axioms of a *sheaf*.

Now let $\mathscr{F}$ be a sheaf of sets on X, and let $u : \mathscr{G} \to \psi_*(\mathscr{F})$, $v : \mathscr{G}' \to \mathscr{F}$ be morphisms. We define $u^\sharp$ and $v^\flat$ in the following manner: if s' is a section of $\mathscr{G}'$ over a neighbourhood U of $x \in X$ and if V is an open neighbourhood of $\psi(x)$ and $s \in \mathscr{G}(V)$ such that we have $s'_z = s_{\psi(x)}$ for z in a neighbourhood of x contained in $\psi^{-1}(V) \cap U$, we take $u^\sharp_x(s'_x) = u_{\psi(x)}(s_{\psi(x)})$. Similarly, if $s \in \mathscr{G}(V)$ (V open in Y), $v^\flat(s)$ is the section of $\mathscr{F}$ over $\psi^{-1}(V)$, the image under v of the section s' of $\mathscr{G}'$ such that $s'_x = s_{\psi(x)}$

for all $x \in \psi^{-1}(V)$. In addition, the canonical homomorphism (3.5.3) $\rho : \mathscr{G} \to \psi_*(\psi^*(\mathscr{G}))$ is defined in the following manner: for each open $V \subset Y$ and each section $s \in \Gamma(V, \mathscr{G})$, $\rho(s)$ is the section $(s_{\psi(x)})_{x \in \psi^{-1}(V)}$ of $\psi^*(\mathscr{G})$ over $\psi^{-1}(V)$. The verification of the relations $(u^\sharp)^\flat = u$, $(v^\flat)^\sharp = v$, and $v^\flat = \psi_*(v) \circ \rho$ is immediate, and proves our assertion.

We check that, if $w : \mathscr{G}_1 \to \mathscr{G}_2$ is a homomorphism of sheaves of sets on Y, $\psi^*(w)$ is expressed in the following manner: if $s' = (s'_x)_{x \in U}$ is a section of $\psi^*(\mathscr{G}_1)$ over an open set U of X, then $(\psi^*(w))(s')$ is the family $(w_{\psi(x)}(s'_x))_{x \in U}$. Finally, it is immediate that for each open set V of Y, the inverse image of $\mathscr{G}|V$ under the restriction of ψ to $\psi^{-1}(V)$ is identical to the induced sheaf $\psi^*(\mathscr{G})|\psi^{-1}(V)$.

When ψ is the identity 1_X, we recover the definition of a sheaf of sets associated to a presheaf (G, II, 1.2). The above considerations apply without change when $\mathtt{C}$ is the category of groups or of rings (not necessarily commutative).

When X is any subset of a topological space Y, and j the canonical injection $X \to Y$, for each sheaf $\mathscr{G}$ on Y with values in a category $\mathtt{C}$, we call the *induced* sheaf of X by $\mathscr{G}$ the inverse image $j^*(\mathscr{G})$ (whenever it exists); for the sheaves of sets (or of groups, or of rings) we recover the usual definition (G, II, 1.5).

(3.7.2). Keeping the notation and hypotheses of (3.5.3), suppose that $\mathscr{G}$ is a *sheaf* of groups (resp. of rings) on Y. The definition of sections of $\psi^*(\mathscr{G})$ (3.7.1) shows (taking into account (3.4.4)) that the homomorphism of stalks $\psi_x \circ \rho_{\psi(x)} : \mathscr{G}_{\psi(x)} \to (\psi^*(\mathscr{G}))_x$ is a *functorial isomorphism in* $\mathscr{G}$, that identifies the two stalks; with this identification, $u_x^\sharp$ is identical to the homomorphism defined in (3.5.1), and in particular, we have $\operatorname{Supp}(\psi^*(\mathscr{G})) = \psi^{-1}(\operatorname{Supp}(\mathscr{G}))$.

An immediate consequence of this result is that *the functor* $\psi^*(\mathscr{G})$ *is exact in* $\mathscr{G}$ on the abelian category of sheaves of abelian groups.

3.8. Sheaves on pseudo-discrete spaces $\mathbf{0_I}$ | 35

(3.8.1). Let X be a topological space whose topology admits a basis $\mathfrak{B}$ consisting of open *quasi-compact* subsets. Let $\mathscr{F}$ be a *sheaf of sets* on X; if we equip each of the $\mathscr{F}(U)$ with the *discrete* topology, $U \mapsto \mathscr{F}(U)$ is a *presheaf of topological spaces*. We will see that there exists a *sheaf of topological spaces* $\mathscr{F}'$ *associated to* $\mathscr{F}$ (3.5.6) such that $\Gamma(U, \mathscr{F}')$ is the discrete space $\mathscr{F}(U)$ for each open *quasi-compact* subsets U. It will suffice to show that the presheaf $U \mapsto \mathscr{F}(U)$ of discrete topological spaces *on* $\mathfrak{B}$ satisfy the condition (F_0) of (3.2.2), and more generally that if U is an open quasi-compact subset and if (U_α) is a cover of U by sets of $\mathfrak{B}$, then the least fine topology $\mathscr{T}$ on $\Gamma(U, \mathscr{F})$ making the maps $\Gamma(U, \mathscr{F}) \to \Gamma(U_\alpha, \mathscr{F})$ continuous is the *discrete* topology. There exists a finite number of indices α_i such that $U = \bigcup_i U_{\alpha_i}$. Let $s \in \Gamma(U, \mathscr{F})$ and let s_i be its image in $\Gamma(U_{\alpha_i}, \mathscr{F})$; the intersection of the inverse images of the sets $\{s_i\}$ is by definition a neighbourhood of s for $\mathscr{T}$; but since $\mathscr{F}$ is a sheaf of sets and the U_{α_i} cover U, this intersection is reduced to s, hence our assertion.

We note that if U is an open non-quasi-compact subset of X, the topological space $\Gamma(U, \mathscr{F}')$ still has $\Gamma(U, \mathscr{F})$ as the underlying set, but the topology is not discrete in general: it is the least fine making the maps $\Gamma(U, \mathscr{F}) \to \Gamma(V, \mathscr{F})$ continuous, for $V \in \mathfrak{B}$ and $V \subset U$ (the $\Gamma(V, \mathscr{F})$ being discrete).

The above considerations apply without modification to sheaves of groups or of rings (not necessarily commutative), and associate to them sheaves of *topological groups* or *topological rings*, respectively. To summarize, we say that the sheaf $\mathscr{F}'$ is the *pseudo-discrete* sheaf of *spaces* (resp. *groups*, *rings*) associated to a sheaf of sets (resp. groups, rings) $\mathscr{F}$.

(3.8.2). Let $\mathscr{F}, \mathscr{G}$ be two sheaves of sets (resp. groups, rings) on X, $u : \mathscr{F} \to \mathscr{G}$ a homomorphism. Then u is thus a *continuous* homomorphism $\mathscr{F}' \to \mathscr{G}'$, if we denote by $\mathscr{F}'$ and $\mathscr{G}'$ the pseudo-discrete sheaves associated to $\mathscr{F}$ and $\mathscr{G}$; this follows indeed from (3.2.5).

(3.8.3). Let $\mathscr{F}$ be a sheaf of sets, $\mathscr{H}$ a subsheaf of $\mathscr{F}$, $\mathscr{F}'$ and $\mathscr{H}'$ the pseudo-discrete sheaves associated to $\mathscr{F}$ and $\mathscr{H}$ respectively. Then, for each open $U \subset X$, $\Gamma(U, \mathscr{H}')$ is *closed* in $\Gamma(U, \mathscr{F}')$: indeed, it is the intersection of the inverse images of the $\Gamma(V, \mathscr{H})$ (for $V \in \mathfrak{B}$, $V \subset U$) under the continuous maps $\Gamma(U, \mathscr{F}) \to \Gamma(V, \mathscr{F})$, and $\Gamma(V, \mathscr{H})$ is closed in the discrete space $\Gamma(V, \mathscr{F})$.

§4. Ringed spaces

4.1. Ringed spaces, sheaves of $\mathscr{A}$-modules, $\mathscr{A}$-algebras

(4.1.1). A *ringed space* (resp. topologically ringed space) is a pair $(X, \mathscr{A})$ consisting of a topological space X and a sheaf of (not necessarily commutative) rings (resp. of a sheaf of topological rings) $\mathscr{A}$ on X; we say that X is the *underlying* topological space of the ringed space $(X, \mathscr{A})$, and $\mathscr{A}$ the *structure sheaf*. The latter is denoted $\mathscr{O}_X$, and its stalk at a point $x \in X$ is denoted $\mathscr{O}_{X,x}$ or simply $\mathscr{O}_x$ when there is no chance of confusion.

We denote by 1 or e the *unit section* of $\mathscr{O}_X$ over X (the unit element of $\Gamma(X, \mathscr{O}_X)$).

As in this treatise we will have to consider in particular sheaves of *commutative* rings, it will be understood, when we speak of a ringed space $(X, \mathscr{A})$ without specification, that $\mathscr{A}$ is a sheaf of commutative rings.

The ringed spaces with not-necessarily-commutative structure sheaves (resp. the topologically ringed spaces) form a *category*, where we define a *morphism* $(X, \mathscr{A}) \to (Y, \mathscr{B})$ as a couple $(\psi, \theta) = \Psi$ consisting of a continuous map $\psi : X \to Y$ and a ψ*-morphism* $\theta : \mathscr{B} \to \mathscr{A}$ (3.5.1) of sheaves of **Err$_{\text{II}}$** rings (resp. of sheaves of topological rings); the *composition* of a second morphism $\Psi' = (\psi', \theta') : (Y, \mathscr{B}) \to (Z, \mathscr{C})$ and of Ψ, denoted $\Psi'' = \Psi' \circ \Psi$, is the morphism (ψ'', θ'') where $\psi'' = \psi' \circ \psi$, and θ'' is the composition of θ and θ' (equal to $\psi'_*(\theta) \circ \theta'$, cf. (3.5.2)). For ringed spaces, remember that we then have $\theta''^\sharp = \theta^\sharp \circ \psi^*(\theta'^\sharp)$ (3.5.5); therefore if $\theta'^\sharp$ and $\theta^\sharp$ are *injective* (resp. *surjective*), then the same is true of $\theta''^\sharp$, taking into account that $\psi_x \circ \rho_{\psi(x)}$ is an isomorphism for all $x \in X$ (3.7.2). We verify immediately, thanks to the above, that when ψ is an *injective* continuous map and when $\theta^\sharp$ is a *surjective* homomophism of sheaves of rings, the morphism (ψ, θ) is a *monomorphism* (T, 1.1) in the category of ringed spaces.

By abuse of language, we will often replace ψ by Ψ in notation, for example in writing $\Psi^{-1}(U)$ in place of $\psi^{-1}(U)$ for a subset U of Y, when the is no risk of confusion.

(4.1.2). For each subset M of X, the pair $(M, \mathscr{A}|M)$ is evidently a ringed space, said to be *induced* on M by the ringed space $(X, \mathscr{A})$ (and is still called the *restriction* of $(X, \mathscr{A})$ to M). If j is the canonical injection $M \to X$ and ω is the identity map of $\mathscr{A}|M$, $(j, \omega^\flat)$ is a monomorphism $(M, \mathscr{A}|M) \to (X, \mathscr{A})$ of ringed spaces, called the *canonical injection*. The composition of a morphism $\Psi : (X, \mathscr{A}) \to (Y, \mathscr{B})$ and this injection is called the *restriction* of Ψ to M.

(4.1.3). We will not revisit the definitions of $\mathscr{A}$*-modules* or *algebraic sheaves* on a ringed space $(X, \mathscr{A})$ (G, II, 2.2); when $\mathscr{A}$ is a sheaf of not necessarily commutative rings, by $\mathscr{A}$-module we will always mean "left $\mathscr{A}$-module" unless expressly stated otherwise. The $\mathscr{A}$-submodules of $\mathscr{A}$ will be called *sheaves of ideals* (left, right, or two-sided) in $\mathscr{A}$ or $\mathscr{A}$*-ideals*.

When $\mathscr{A}$ is a sheaf of commutative rings, and in the definition of $\mathscr{A}$-modules, we replace everywhere the *module* structure by that of an *algebra*, we obtain the definition of an $\mathscr{A}$*-algebra* on X. It is the same to say that an $\mathscr{A}$-algebra (not necessarily commutative) is a $\mathscr{A}$-module $\mathscr{C}$, given with a homomorphism of $\mathscr{A}$-modules $\phi : \mathscr{C} \otimes_{\mathscr{A}} \mathscr{C} \to \mathscr{C}$ and a section e over X, such that: 1st the diagram

$$\begin{tikzcd}
\mathscr{C} \otimes_{\mathscr{A}} \mathscr{C} \otimes_{\mathscr{A}} \mathscr{C} \arrow[r, "\phi\otimes 1"] \arrow[d, "1\otimes\phi"'] & \mathscr{C} \otimes_{\mathscr{A}} \mathscr{C} \arrow[d, "\phi"] \\
\mathscr{C} \otimes_{\mathscr{A}} \mathscr{C} \arrow[r, "\phi"'] & \mathscr{C}
\end{tikzcd}$$

is commutative; 2nd for each open $U \subset X$ and each section $s \in \Gamma(U, \mathscr{C})$, we have $\phi((e|U) \otimes s) = \phi(s \otimes (e|U)) = s$. We say that $\mathscr{C}$ is a commutative $\mathscr{A}$-algebra if the diagram

$$\begin{tikzcd}
\mathscr{C} \otimes_{\mathscr{A}} \mathscr{C} \arrow[rr, "\sigma"] \arrow[dr, "\phi"'] & & \mathscr{C} \otimes_{\mathscr{A}} \mathscr{C} \arrow[dl, "\phi"] \\
& \mathscr{C} &
\end{tikzcd}$$

is commutative, σ denoting the canonical symmetry (twist) map of the tensor product $\mathscr{C} \otimes_{\mathscr{A}} \mathscr{C}$.

The homomorphisms of $\mathscr{A}$-algebras are also defined as the homomorphisms of $\mathscr{A}$-modules in (G, II, 2.2), but naturally no longer form an abelian group.

If $\mathscr{M}$ is an $\mathscr{A}$-submodule of an $\mathscr{A}$-algebra $\mathscr{C}$, the $\mathscr{A}$*-subalgebra of* $\mathscr{C}$ *generated by* $\mathscr{M}$ is the sum of the images of the homomorphisms $\bigotimes^n \mathscr{M} \to \mathscr{C}$ (for each $n \geqslant 0$). This is also the sheaf associated to the presheaf $U \mapsto \mathscr{B}(U)$ of algebras, $\mathscr{B}(U)$ being the subalgebra of $\Gamma(U, \mathscr{C})$ generated by the submodule $\Gamma(U, \mathscr{M})$.

(4.1.4). We say that a sheaf of rings $\mathscr{A}$ on a topological space X is *reduced at a point x in X* if the stalk $\mathscr{A}_x$ is a *reduced* ring (1.1.1); we say that $\mathscr{A}$ is *reduced* if it is reduced at all points of X. Recall that a ring A is called *regular* if each of the local rings $A_\mathfrak{p}$ (where $\mathfrak{p}$ varies over the set of prime ideals of A) is a regular local ring; we will say that a sheaf of rings $\mathscr{A}$ on X is *regular at a point x* (resp. *regular*) if the stalk $\mathscr{A}_x$ is a regular ring (resp. if $\mathscr{A}$ is regular at each point). Finally, we will say that a sheaf of rings $\mathscr{A}$ on X is *normal at a point x* (resp. *normal*) if the stalk $\mathscr{A}_x$ is an *integral and integrally closed* ring (resp. if $\mathscr{A}$ is normal at each point). We will say that a ringed space $(X, \mathscr{A})$ has any of these preceeding properties if the sheaf of rings $\mathscr{A}$ has that property.

A *graded* sheaf of rings $\mathscr{A}$ is by definition a sheaf of rings that is the direct sum (G, II, 2,7) of a family $(\mathscr{A}_n)_{n\in\mathbf{Z}}$ of sheaves of abelian groups with the conditions $\mathscr{A}_m\mathscr{A}_n \subset \mathscr{A}_{m+n}$; a *graded $\mathscr{A}$-module* is an $\mathscr{A}$-module $\mathscr{F}$ that is the direct sum of a family $(\mathscr{F}_n)_{n\in\mathbf{Z}}$ of sheaves of abelian groups, satisfying the conditions $\mathscr{A}_m\mathscr{F}_n \subset \mathscr{F}_{m+n}$. It is equivalent to say that $(\mathscr{A}_m)_x(\mathscr{A}_n)_x \subset (\mathscr{A}_{m+n})_x$ (resp. $(\mathscr{A}_m)_x(\mathscr{F}_n)_x \subset (\mathscr{F}_{m+n})_x$) for each point x.

(4.1.5). Given a ringed space $(X, \mathscr{A})$ (not necessarily commutative), we will not recall here the definitions of the bifunctors $\mathscr{F} \otimes_\mathscr{A} \mathscr{G}$, $\mathscr{H}om_\mathscr{A}(\mathscr{F}, \mathscr{F})$, and $\operatorname{Hom}_\mathscr{A}(\mathscr{F}, \mathscr{G})$ (G, II, 2.8 and 2.2) in the categories of left or right (depending on the case) $\mathscr{A}$-modules, with values in the category of sheaves of abelian groups (or more generally of $\mathscr{C}$-modules, if $\mathscr{C}$ is the center of $\mathscr{A}$). The stalk $(\mathscr{F} \otimes_\mathscr{A} \mathscr{G})_x$ for each point $x \in X$ canonically identifies with $\mathscr{F}_x \otimes_{\mathscr{A}_x} \mathscr{G}_x$ and we define a canonical and functorial homomorphism $(\mathscr{H}om_\mathscr{A}(\mathscr{F}, \mathscr{G}))_x \to \operatorname{Hom}_{\mathscr{A}_x}(\mathscr{F}_x, \mathscr{G}_x)$ which is in general neither injective nor surjective. The bifunctors considered above are additive and in particular, commute with finite direct limits; $\mathscr{F} \otimes_\mathscr{A} \mathscr{G}$ is right exact in $\mathscr{F}$ and in $\mathscr{G}$, commutes with inductive limits, and $\mathscr{A} \otimes_\mathscr{A} \mathscr{G}$ (resp. $\mathscr{F} \otimes_\mathscr{A} \mathscr{A}$) canonically identifies with $\mathscr{G}$ (resp. $\mathscr{F}$). The functors $\mathscr{H}om_\mathscr{A}(\mathscr{F}, \mathscr{G})$ and $\operatorname{Hom}_\mathscr{A}(\mathscr{F}, \mathscr{G})$ are *left exact* in $\mathscr{F}$ and $\mathscr{G}$; more precisely, if we have an exact sequence of the form $0 \to \mathscr{G}' \to \mathscr{G} \to \mathscr{G}''$, the sequence

$$0 \longrightarrow \mathscr{H}om_\mathscr{A}(\mathscr{F}, \mathscr{G}') \longrightarrow \mathscr{H}om_\mathscr{A}(\mathscr{F}, \mathscr{G}) \longrightarrow \mathscr{H}om_\mathscr{A}(\mathscr{F}, \mathscr{G}'')$$

is exact, and if we have an exact sequence of the form $\mathscr{F}' \to \mathscr{F} \to \mathscr{F}'' \to 0$, the sequence

$$0 \longrightarrow \mathscr{H}om_\mathscr{A}(\mathscr{F}'', \mathscr{G}) \longrightarrow \mathscr{H}om_\mathscr{A}(\mathscr{F}, \mathscr{G}) \longrightarrow \mathscr{H}om_\mathscr{A}(\mathscr{F}', \mathscr{G})$$

is exact, with the analogous properties for the functor Hom. In addiiton, $\mathscr{H}om_\mathscr{A}(\mathscr{A}, \mathscr{G})$ canonically identifies with $\mathscr{G}$; finally, for each open $U \subset X$, we have

$$\Gamma(U, \mathscr{H}om_\mathscr{A}(\mathscr{F}, \mathscr{G}) = \operatorname{Hom}_{\mathscr{A}|U}(\mathscr{F}|U, \mathscr{G}|U).$$

For each left (resp. right) $\mathscr{A}$-module, we define the *dual* of $\mathscr{F}$ and denote it by $\mathscr{F}^\vee$ the right (resp. left) $\mathscr{A}$-module $\mathscr{H}om_\mathscr{A}(\mathscr{F}, \mathscr{A})$.

Finally, if $\mathscr{A}$ is a sheaf of commutative rings, $\mathscr{F}$ an $\mathscr{A}$-module, $U \mapsto \wedge^p\Gamma(U, \mathscr{F})$ is a presheaf whose associated sheaf is an $\mathscr{A}$-module denoted $\wedge^p\mathscr{F}$ and is called the *p-th exterior power of $\mathscr{F}$*; we verify easily that the canonical map of the presheaf $U \mapsto \wedge^p\Gamma(U, \mathscr{F})$ to the associated sheaf $\wedge^p\mathscr{F}$ is *injective*, and for each $x \in X$, $(\wedge^p\mathscr{F})_x = \wedge^p(\mathscr{F}_x)$. It is clear that $\wedge^p\mathscr{F}$ is a covariant functor in $\mathscr{F}$.

(4.1.6). Suppose that $\mathscr{A}$ is a sheaf of not-necessarily-commutative rings, $\mathscr{J}$ a left sheaf of ideals of $\mathscr{A}$, $\mathscr{F}$ an left $\mathscr{A}$-module; we then denote by $\mathscr{J}\mathscr{F}$ the $\mathscr{A}$-submodule of $\mathscr{F}$, the image of $\mathscr{J} \otimes_\mathbf{Z} \mathscr{F}$ (where $\mathbf{Z}$ is the sheaf associated to the constant presheaf $U \mapsto \mathbf{Z}$) under the canonical map $\mathscr{J} \otimes_\mathbf{Z} \mathscr{F} \to \mathscr{F}$; it is clear that for each $x \in X$, we have $(\mathscr{J}\mathscr{F})_x = \mathscr{J}_x\mathscr{F}_x$. When $\mathscr{A}$ is commutative, $\mathscr{J}\mathscr{F}$ is also the canonical image of $\mathscr{J} \otimes_\mathscr{A} \mathscr{F} \to \mathscr{F}$. It is immediate that $\mathscr{J}\mathscr{F}$ is also the $\mathscr{A}$-module associated to the presheaf $U \mapsto \Gamma(U, \mathscr{J})\Gamma(U, \mathscr{F})$. If $\mathscr{J}_1$, $\mathscr{J}_2$ are two left sheaves of ideals of $\mathscr{A}$, we have $\mathscr{J}_1(\mathscr{J}_2\mathscr{F}) = (\mathscr{J}_1\mathscr{J}_2)\mathscr{F}$.

(4.1.7). Let $(X_\lambda, \mathscr{A}_\lambda)_{\lambda\in L}$ be a family of ringed spaces; for each couple (λ, μ), suppose we are given an open subset $V_{\lambda\mu}$ of X_λ, and an isomorphism of ringed spaces $\phi_{\lambda\mu} : (V_{\mu\lambda}, \mathscr{A}_\mu|V_{\lambda\mu}) \simeq (V_{\lambda\mu}, \mathscr{A}_\lambda|V_{\lambda\mu})$, with $V_{\lambda\lambda} = X_\lambda$, $\phi_{\lambda\lambda}$ being the identity. Furthermore, suppose that, for each triple (λ, μ, ν), if we denote by $\phi'_{\mu\lambda}$ the restriction of $\phi_{\mu\lambda}$ to $V_{\lambda\mu} \cap V_{\lambda\nu}$, $\phi'_{\mu\lambda}$ is an isomorphism from $(V_{\lambda\mu} \cap V_{\lambda\nu}, \mathscr{A}_\lambda|(V_{\lambda\mu} \cap V_{\lambda\nu}))$ to $(V_{\mu\nu} \cap V_{\mu\lambda}, \mathscr{A}_\mu|(V_{\mu\nu} \cap V_{\mu\lambda}))$ and that we have $\phi'_{\lambda\nu} = \phi'_{\lambda\mu} \circ \phi'_{\mu\nu}$ (*gluing condition* for the $\phi_{\lambda\mu}$).

We can first consider the topological space obtained by gluing (by means of the $\phi_{\lambda\mu}$) of the X_λ along the $V_{\lambda\mu}$; if we identify X_λ with the corresponding open subset X'_λ in X, the hypotheses imply that the three sets $V_{\lambda\mu} \cap V_{\lambda\nu}$, $V_{\mu\nu} \cap V_{\mu\lambda}$, $V_{\nu\lambda} \cap V_{\nu\mu}$ identify with $X'_\lambda \cap X'_\mu \cap X'_\nu$. We can also transport to X'_λ the ringed space structure of X_λ, and if $\mathscr{A}'_\lambda$ are the transported sheaves of rings corresponding to the $\mathscr{A}_\lambda$, the $\mathscr{A}'_\lambda$ satisfy the gluing condition (3.3.1) and therefore define a sheaf of rings $\mathscr{A}$ on X; we say that $(X, \mathscr{A})$ is the ringed space obtained by *gluing the* $(X_\lambda, \mathscr{A}_\lambda)$ *along the* $V_{\lambda\mu}$, by means of the $\phi_{\lambda\mu}$. $\mathbf{0_I}$ | 39

4.2. Direct image of an $\mathscr{A}$-module

(4.2.1). Let $(X, \mathscr{A})$, $(Y, \mathscr{B})$ be two ringed spaces, $\Psi = (\psi, \theta)$ a morphism $(X, \mathscr{A}) \to (Y, \mathscr{B})$; $\psi_*(\mathscr{A})$ is then a sheaf of rings on Y, and θ a homomorphism $\mathscr{B} \to \psi_*(\mathscr{A})$ of sheaves of rings. Then let $\mathscr{F}$ be an $\mathscr{A}$-module; the direct image $\psi_*(\mathscr{F})$ is a sheaf of abelian groups on Y. In addition, for each open $U \subset Y$,

$$\Gamma(U, \psi_*(\mathscr{F})) = \Gamma(\psi^{-1}(U), \mathscr{F})$$

is equipped with the structure of a module over the ring $\Gamma(U, \psi_*(\mathscr{A})) = \Gamma(\psi^{-1}(U), \mathscr{A})$; the bilinear maps which define these structures are compatible with the restriction operations, defining on $\psi_*(\mathscr{F})$ the structure of a $\psi_*(\mathscr{A})$-module. The homomorphism $\theta : \mathscr{B} \to \psi_*(\mathscr{A})$ then defines also on $\psi_*(\mathscr{F})$ a $\mathscr{B}$-*module* structure; we say that this $\mathscr{B}$-module is the *direct image of* $\mathscr{F}$ *under the morphism* Ψ, and we denote it by $\Psi_*(\mathscr{F})$. If $\mathscr{F}_1$, $\mathscr{F}_2$ are two $\mathscr{A}$-modules over X and u an $\mathscr{A}$-homomorphism $\mathscr{F}_1 \to \mathscr{F}_2$, it is immediate (by considering the sections over the open subsets of Y) that $\psi_*(u)$ is a $\psi_*(\mathscr{A})$-homomorphism $\psi_*(\mathscr{F}_1) \to \psi_*(\mathscr{F}_2)$, and *a fortiori* a $\mathscr{B}$-homomorphism $\Psi_*(\mathscr{F}_1) \to \Psi_*(\mathscr{F}_2)$; as a $\mathscr{B}$-homomorphism, we denote it by $\Psi_*(u)$. So we see that Ψ_* is a *covariant functor* from the category of $\mathscr{A}$-modules to that of $\mathscr{B}$-modules. In addition, it is immediate that this functor is *left exact* (G, II, 2.12).

On $\psi_*(\mathscr{A})$, the structure of a $\mathscr{B}$-module and the structure of a sheaf of rings define a $\mathscr{B}$-algebra structure; we denote by $\Psi_*(\mathscr{A})$ this $\mathscr{B}$-algebra.

(4.2.2). Let $\mathscr{M}$, $\mathscr{N}$ be two $\mathscr{A}$-modules. For each open set U of Y, we have a canonical map

$$\Gamma(\psi^{-1}(U), \mathscr{M}) \times \Gamma(\psi^{-1}(U), \mathscr{N}) \longrightarrow \Gamma(\psi^{-1}(U), \mathscr{M} \otimes_{\mathscr{A}} \mathscr{N})$$

which is bilinear over the ring $\Gamma(\psi^{-1}(U), \mathscr{A}) = \Gamma(U, \psi_*(\mathscr{A}))$, and *a fortiori* over $\Gamma(U, \mathscr{B})$; it therefore defines a homomorphism

$$\Gamma(U, \Psi_*(\mathscr{M})) \otimes_{\Gamma(U,\mathscr{B})} \Gamma(U, \Psi_*(\mathscr{N})) \longrightarrow \Gamma(U, \Psi_*(\mathscr{M} \otimes_{\mathscr{A}} \mathscr{N}))$$

and as we check immediately that these homomorphisms are compatible with the restriction operations, they give a canonical functorial homomorphism of $\mathscr{B}$-modules

$$\Psi_*(\mathscr{M}) \otimes_{\mathscr{B}} \Psi_*(\mathscr{N}) \longrightarrow \Psi_*(\mathscr{M} \otimes_{\mathscr{A}} \mathscr{N}) \tag{4.2.2.1}$$

which is in general neither injective nor surjective. If $\mathscr{P}$ is a third $\mathscr{A}$-module, we check immediately that the diagram $\mathbf{0_I}$ | 40

$$\begin{tikzcd} \Psi_*(\mathscr{M}) \otimes_{\mathscr{B}} \Psi_*(\mathscr{N}) \otimes_{\mathscr{B}} \Psi_*(\mathscr{P}) \arrow[r] \arrow[d] & \Psi_*(\mathscr{M} \otimes_{\mathscr{A}} \mathscr{N}) \otimes_{\mathscr{B}} \Psi_*(\mathscr{P}) \arrow[d] \\ \Psi_*(\mathscr{M}) \otimes_{\mathscr{B}} \Psi_*(\mathscr{N} \otimes_{\mathscr{A}} \mathscr{P}) \arrow[r] & \Psi_*(\mathscr{M} \otimes_{\mathscr{A}} \mathscr{N} \otimes_{\mathscr{A}} \mathscr{P}) \end{tikzcd} \tag{4.2.2.2}$$

is commutative.

(4.2.3). Let $\mathscr{M}$, $\mathscr{N}$ be two $\mathscr{A}$-modules. For each open $U \subset Y$, we have by definition that $\Gamma(\psi^{-1}(U), \mathscr{H}om_{\mathscr{A}}(\mathscr{M}, \mathscr{N})) = \mathrm{Hom}_{\mathscr{A}|V}(\mathscr{M}|V, \mathscr{N}|V)$, where we put $V = \psi^{-1}(U)$; the map $u \mapsto \Psi_*(u)$ is a homomorphism

$$\mathrm{Hom}_{\mathscr{A}|V}(\mathscr{M}|V, \mathscr{N}|V) \longrightarrow \mathrm{Hom}_{\mathscr{B}|U}(\Psi_*(\mathscr{M})|U, \Psi_*(\mathscr{N})|U)$$

on the $\Gamma(U, \mathscr{B})$-module structures; these homomorphisms are compatible with the restriction operations, hence they define a canonical functorial homomorphism of $\mathscr{B}$-modules

$$\Psi_*(\mathscr{H}om_{\mathscr{A}}(\mathscr{M}, \mathscr{N})) \longrightarrow \mathscr{H}om_{\mathscr{B}}(\Psi_*(\mathscr{M}), \Psi_*(\mathscr{N})). \tag{4.2.3.1}$$

(4.2.4). If $\mathscr{C}$ is an $\mathscr{A}$-algebra, the composite homomorphism

$$\Psi_*(\mathscr{C}) \otimes_{\mathscr{B}} \Psi_*(\mathscr{C}) \longrightarrow \Psi_*(\mathscr{C} \otimes_{\mathscr{A}} \mathscr{C}) \longrightarrow \Psi_*(\mathscr{C})$$

defines on $\Psi_*(\mathscr{C})$ the structure of a *$\mathscr{B}$-algebra*, as a result of (4.2.2.2). We see similarly that if $\mathscr{M}$ is a $\mathscr{C}$-module, $\Psi_*(\mathscr{M})$ is canonically equipped with the structure of a $\Psi_*(\mathscr{C})$-module.

(4.2.5). Consider in particular the case where X is a *closed* subspace of Y and where ψ is the canonical injection $j : X \to Y$. If $\mathscr{B}' = \mathscr{B}|X = j^*(\mathscr{B})$ is the restriction of the sheaf of rings $\mathscr{B}$ to X, an $\mathscr{A}$-module $\mathscr{M}$ can be considered as a $\mathscr{B}'$-module by means of the homomorphism $\theta^\sharp : \mathscr{B}' \to \mathscr{A}$; then $\Psi_*(\mathscr{M})$ is the $\mathscr{B}$-module which induces $\mathscr{M}$ on X and 0 elsewhere. If $\mathscr{N}$ is a second $\mathscr{A}$-module, $\Psi_*(\mathscr{M}) \otimes_{\mathscr{B}} \Psi_*(\mathscr{N})$ canonically identifies with $\Psi_*(\mathscr{M} \otimes_{\mathscr{B}'} \mathscr{N})$ and $\mathscr{H}om_{\mathscr{B}}(\Psi_*(\mathscr{M}), \Psi_*(\mathscr{N}))$ with $\Psi_*(\mathscr{H}om_{\mathscr{B}'}(\mathscr{M}, \mathscr{N}))$.

(4.2.6). Let $(Z, \mathscr{C})$ be a third ringed space, $\Psi' = (\psi', \theta')$ a morphism $(Y, \mathscr{B}) \to (Z, \mathscr{C})$; if Ψ'' is the composite morphism $\Psi' \circ \Psi$, it is clear that we have $\Psi''_* = \Psi'_* \circ \Psi_*$.

4.3. Inverse image of an $\mathscr{A}$-module

(4.3.1). The hypotheses and notation being the same as (4.2.1), let $\mathscr{G}$ be a $\mathscr{B}$-module and $\psi^*(\mathscr{G})$ the inverse image (3.7.1) which is therefore a sheaf of abelian groups on X. The definition of sections of $\psi^*(\mathscr{G})$ and of $\psi^*(\mathscr{B})$ (3.7.1) shows that $\psi^*(\mathscr{G})$ is canonically equipped with a $\psi^*(\mathscr{B})$-module structure. On the other hand, the homomorphism $\theta^\sharp : \psi^*(\mathscr{B}) \to \mathscr{A}$ endows $\mathscr{A}$ with the a $\psi^*(\mathscr{B})$-module structure, which we denote by $\mathscr{A}_{[\theta]}$ when necessary to avoid confusion; the tensor product $\psi^*(\mathscr{G}) \otimes_{\psi^*(\mathscr{B})} \mathscr{A}_{[\theta]}$ is then equipped with an $\mathscr{A}$-module structure. We say that this $\mathscr{A}$-module is *the inverse image of $\mathscr{G}$ under the morphism* Ψ and we denote it by $\Psi^*(\mathscr{G})$. If $\mathscr{G}_1, \mathscr{G}_2$ are two $\mathscr{B}$-modules over Y, v a $\mathscr{B}$-homomorphism $\mathscr{G}_1 \to \mathscr{G}_2$, then $\psi^*(v)$, as we check immediately, is a $\psi^*(\mathscr{B})$-homomorphism from $\psi^*(\mathscr{G}_1)$ to $\psi^*(\mathscr{G}_2)$; as a result $\psi^*(v) \otimes 1$ is an $\mathscr{A}$-homomorphism $\Psi^*(\mathscr{G}_1) \to \Psi^*(\mathscr{G}_2)$, which we denote by $\Psi^*(v)$. So we define Ψ^* as a *covariant functor* from the category of $\mathscr{B}$-modules to that of $\mathscr{A}$-modules. Here, this functor (contrary to ψ^*) is no longer exact in general, but only *right exact*, the tensorization by $\mathscr{A}$ being a right exact functor to the category of $\psi^*(\mathscr{B})$-modules. $\mathbf{0_I}$ | 41

For each $x \in X$, we have $(\Psi^*(\mathscr{G}))_x = \mathscr{G}_{\psi(x)} \otimes_{\mathscr{B}_{\psi(x)}} \mathscr{A}_x$, according to (3.7.2). The support of $\Psi^*(\mathscr{G})$ is thus contained in $\psi^{-1}(\operatorname{Supp}(\mathscr{G}))$.

(4.3.2). Let $(\mathscr{G}_\lambda)$ be an inductive system of $\mathscr{B}$-modules, and let $\mathscr{G} = \varinjlim \mathscr{G}_\lambda$ be its inductive limit. The canonical homomorphisms $\mathscr{G}_\lambda \to \mathscr{G}$ define the $\psi^*(\mathscr{B})$-homomorphisms $\psi^*(\mathscr{G}_\lambda) \to \psi^*(\mathscr{G})$, which give a canonical homomorphism $\varinjlim \psi^*(\mathscr{G}_\lambda) \to \psi^*(\mathscr{G})$. As the stalk at a point of an inductive limit of sheaves is the inductive limit of the stalks at the same point (G, II, 1.11), the preceding canonical homomorphism is *bijective* (3.7.2). In addition, the tensor product commutes with inductive limits of sheaves, and we thus have a *canonical functorial isomorphism* $\varinjlim \Psi^*(\mathscr{G}_\lambda) \simeq \Psi^*(\varinjlim \mathscr{G}_\lambda)$ of $\mathscr{A}$-modules.

On the other hand, for a finite direct sum $\bigoplus_i \mathscr{G}_i$ of $\mathscr{B}$-modules, it is clear that $\psi^*(\bigoplus_i \mathscr{G}_i) = \bigoplus_i \psi^*(\mathscr{G}_i)$, therefore, by tensoring with $\mathscr{A}_{[\theta]}$,

$$\Psi^*\Big(\bigoplus_i \mathscr{G}_i\Big) = \bigoplus_i \Psi^*(\mathscr{G}_i). \tag{4.3.2.1}$$

By passing to the inductive limit, we deduce, in light of the above, that the above equality is still true for *any* direct sum.

(4.3.3). Let $\mathscr{G}_1$, $\mathscr{G}_2$ be two $\mathscr{B}$-modules; from the definition of the inverse images of sheaves of abelian groups (3.7.1), we obtain immediately a canonical homomorphism $\psi^*(\mathscr{G}_1) \otimes_{\psi^*(\mathscr{B})} \psi^*(\mathscr{G}_2) \to \psi^*(\mathscr{G}_1 \otimes_{\mathscr{B}} \mathscr{G}_2)$ of $\psi^*(\mathscr{B})$-modules, and the stalk at a point of a tensor product of sheaves being the tensor product of the stalks at this point (G, II, 2.8), we deduce from (3.7.2) that the above homomorphism is in fact a *isomorphism*. By tensoring with $\mathscr{A}$, we obtain a *canonical functorial isomorphism*

$$\Psi^*(\mathscr{G}_1) \otimes_{\mathscr{A}} \Psi^*(\mathscr{G}_2) \simeq \Psi^*(\mathscr{G}_1 \otimes_{\mathscr{B}} \mathscr{G}_2). \tag{4.3.3.1}$$

(4.3.4). Let $\mathscr{C}$ be a $\mathscr{B}$-algebra; the data of the algebra structure on $\mathscr{C}$ is the same as the data of a $\mathscr{B}$-homomorphism $\mathscr{C} \otimes_{\mathscr{B}} \mathscr{C} \to \mathscr{C}$ satisfying the associativity and commutativity conditions (conditions which are checked stalk-wise); the above isomorphism allows us to consider this homomorphism as a homomorphism of $\mathscr{A}$-modules $\Psi^*(\mathscr{C}) \otimes_{\mathscr{A}} \Psi^*(\mathscr{C}) \to \Psi^*(\mathscr{C})$ satisfying the same conditions, so $\Psi^*(\mathscr{C})$ is thus equipped with an $\mathscr{A}$-algebra structure. In particular, it follows immediately from the definitions that the $\mathscr{A}$-algebra $\Psi^*(\mathscr{B})$ is *equal to* $\mathscr{A}$ (up to a canonical isomorphism).

Similarly, if $\mathscr{M}$ is a $\mathscr{C}$-module, the data of this module structure is the same as that of a $\mathscr{B}$-homomorphism $\mathscr{C} \otimes_{\mathscr{B}} \mathscr{M} \to \mathscr{M}$ satisfying the associativity condition; hence we give a $\Psi^*(\mathscr{C})$-module structure on $\Psi^*(\mathscr{M})$. $\mathbf{0_I}$ | 42

(4.3.5). Let $\mathscr{J}$ be a sheaf of ideals of $\mathscr{B}$; as the functor ψ^* is exact, the $\psi^*(\mathscr{B})$-module $\psi^*(\mathscr{J})$ canonically identifies with a sheaf of ideals of $\psi^*(\mathscr{B})$; the canonical injection $\psi^*(\mathscr{J}) \to \psi^*(\mathscr{B})$ then gives a homomorphism of $\mathscr{A}$-modules $\Psi^*(\mathscr{J}) = \psi^*(\mathscr{J}) \otimes_{\psi^*(\mathscr{B})} \mathscr{A}_{[\theta]} \to \mathscr{A}$; we denote by $\Psi^*(\mathscr{J})\mathscr{A}$, or $\mathscr{J}\mathscr{A}$ if there is no fear of confusion, the image of $\Psi^*(\mathscr{J})$ under this homomorphism. So we have by definition $\mathscr{J}\mathscr{A} = \theta^\sharp(\psi^*(\mathscr{J}))\mathscr{A}$ and in particular, for each $x \in X$, $(\mathscr{J}\mathscr{A})_x = \theta_x^\sharp(\mathscr{J}_{\psi(x)})\mathscr{A}_x$, taking into account the canonical identification between the stalks of $\psi^*(\mathscr{J})$ and those of $\mathscr{J}$ (3.7.2). If $\mathscr{J}_1$, $\mathscr{J}_2$ are two sheaves of ideals of $\mathscr{B}$, then we have $(\mathscr{J}_1\mathscr{J}_2)\mathscr{A} = \mathscr{J}_1(\mathscr{J}_2\mathscr{A}) = (\mathscr{J}_1\mathscr{A})(\mathscr{J}_2\mathscr{A})$.

If $\mathscr{F}$ is an $\mathscr{A}$-module, we set $\mathscr{J}\mathscr{F} = (\mathscr{J}\mathscr{A})\mathscr{F}$.

(4.3.6). Let $(Z, \mathscr{C})$ be a third ringed space, $\Psi' = (\psi', \theta')$ a morphism $(Y, \mathscr{B}) \to (Z, \mathscr{C})$; if Ψ'' is the composite morphism $\Psi' \circ \Psi$, it follows from the definition (4.3.1) and from (4.3.3.1) that we have $\Psi''^* = \Psi^* \circ \Psi'^*$.

4.4. Relation between direct and inverse images

(4.4.1). The hypotheses and notation being the same as in (4.2.1), let $\mathscr{G}$ be a $\mathscr{B}$-module. By definition, a homomorphism $u : \mathscr{G} \to \Psi_*(\mathscr{F})$ of $\mathscr{B}$-modules is still called a Ψ*-morphisms from* $\mathscr{G}$ *to* $\mathscr{F}$, or simply a *homomorphism from* $\mathscr{G}$ *to* $\mathscr{F}$ and we write it as $u : \mathscr{G} \to \mathscr{F}$ when no confusion will occur. To give such a homomorphism is the same as giving, for each pair (U, V) where U is an open set of X, V an open set of Y such that $\psi(U) \subset V$, a *homomorphism* $u_{U,V} : \Gamma(V, \mathscr{G}) \to \Gamma(U, \mathscr{F})$ *of* $\Gamma(V, \mathscr{B})$-*modules*, $\Gamma(U, \mathscr{F})$ being considered as a $\Gamma(V, \mathscr{B})$-module by means of the ring homomorphism $\theta_{U,V} : \Gamma(V, \mathscr{B}) \to \Gamma(U, \mathscr{A})$; the $u_{U,V}$ must in addition render commutative the diagrams (3.5.1.1). It suffices, moreover, to define u by the data of the $u_{U,V}$ when U (resp. V) varies over a basis $\mathfrak{B}$ (resp. $\mathfrak{B}'$) for the topology of X (resp. Y) and to check the commutativity of (3.5.1.1) for these restrictions.

(4.4.2). Under the hypotheses of (4.2.1) and (4.2.6), let $\mathscr{H}$ be a $\mathscr{C}$-module, $v : \mathscr{H} \to \Psi'_*(\mathscr{G})$ a Ψ'-morphism; then $w : \mathscr{H} \xrightarrow{v} \Psi'_*(\mathscr{G}) \xrightarrow{\Psi'_*(u)} \Psi'_*(\Psi_*(\mathscr{F}))$ is a Ψ''-morphism which we call the *composition* of u and v.

(4.4.3). We will now see that we can define a canonical *isomorphism* of *bifunctors* in $\mathscr{F}$ and $\mathscr{G}$

$$\mathrm{Hom}_{\mathscr{A}}(\Psi^*(\mathscr{G}), \mathscr{F}) \simeq \mathrm{Hom}_{\mathscr{B}}(\mathscr{G}, \Psi_*(\mathscr{F})) \tag{4.4.3.1}$$

which we denote by $v \mapsto v_\theta^\flat$ (or simply $v \mapsto v^\flat$ if there is no chance of confusion); we denote by $u \mapsto u_\theta^\sharp$, or $u \mapsto u^\sharp$, the inverse isomorphism. This definition is the following: by composing $v : \Psi^*(\mathscr{G}) \to \mathscr{F}$ with the canonical map $\psi^*(\mathscr{G}) \to \Psi^*(\mathscr{G})$, we obtain a homomorphism of sheaves of groups $v' : \psi^*(\mathscr{G}) \to \mathscr{F}$, which is also a homomorphism of $\psi^*(\mathscr{B})$-modules. We obtain (3.7.1) a homomorphism $v'^\flat : \mathscr{G} \to \psi_*(\mathscr{F}) = \Psi_*(\mathscr{F})$, which is also a homomorphism of $\mathscr{B}$-modules as we check easily; we take $v_\theta^\flat = v'^\flat$. Similarly, for $u : \mathscr{G} \to \Psi_*(\mathscr{F})$, which is a homomorphism of $\mathscr{B}$-modules, we obtain (3.7.1) a homomorphism $u^\sharp : \psi^*(\mathscr{G}) \to \mathscr{F}$ of $\psi^*(\mathscr{B})$-modules, hence by tensoring with $\mathscr{A}$ we have a homomorphism of $\mathscr{A}$-modules $\Psi^*(\mathscr{G}) \to \mathscr{F}$, which we denote by $u_\theta^\sharp$. It is immediate to check that $(u_\theta^\sharp)_\theta^\flat = u$ and $(v_\theta^\flat)_\theta^\sharp = v$, so we have established the functorial nature in $\mathscr{F}$ of the isomorphism $v \mapsto v_\theta^\flat$. The functorial nature in $\mathscr{G}$ of $u \mapsto u_\theta^\sharp$ is then formally shown as in (3.5.4) (reasoning that would also prove the functorial nature of Ψ^* established in (4.3.1) directly). $\mathbf{0_I}$ | 43

If we take for v the identity homomorphism of $\Psi^*(\mathscr{B})$, $v_\theta^\flat$ is a homomorphism

$$\rho_{\mathscr{G}} : \mathscr{G} \longrightarrow \Psi_*(\Psi^*(\mathscr{G})); \tag{4.4.3.2}$$

if we take for u the identity homomorphism of $\Psi_*(\mathscr{F})$, $u_\theta^\sharp$ is a homomorphism

$$\sigma_{\mathscr{F}} : \Psi^*(\Psi_*(\mathscr{F})) \longrightarrow \mathscr{F}; \tag{4.4.3.3}$$

these homomorphisms will be called *canonical*. They are in general neither injective or surjective. We have canonical factorizations analogous to (3.5.3.3) and (3.5.4.4).

We note that if s is a section of $\mathscr{G}$ over an open set V of Y, $\rho_{\mathscr{G}}(s)$ is the section $s' \otimes 1$ of $\Psi^*(\mathscr{G})$ over $\psi^{-1}(V)$, s' being such that $s'_x = s_{\psi(x)}$ for all $x \in \psi^{-1}(V)$. We also note that if $u : \mathscr{G} \to \psi_*(\mathscr{F})$ is a homomorphism, it defines for all $x \in X$ a homomorphism $u_x : \mathscr{G}_{\psi(x)} \to \mathscr{F}_x$ on the stalks, obtained by composing $(u^\sharp)_x : (\Psi^*(\mathscr{G}))_x \to \mathscr{F}_x$ and the canonical homomorphism $s_x \mapsto s_x \otimes 1$ from $\mathscr{G}_{\psi(x)}$ to $(\Psi^*(\mathscr{G}))_x = \mathscr{G}_{\psi(x)} \otimes_{\mathscr{B}_{\psi(x)}} \mathscr{A}_x$. The homomorphism u_x is obtained also by passing to the inductive limit relative to the homomorphisms $\Gamma(V, \mathscr{G}) \xrightarrow{u} \Gamma(\psi^{-1}(V), \mathscr{F}) \to \mathscr{F}_x$, where V varies over the neighbourhoods of $\psi(x)$.

(4.4.4). Let $\mathscr{F}_1, \mathscr{F}_2$ be $\mathscr{A}$-modules, $\mathscr{G}_1, \mathscr{G}_2$ be $\mathscr{B}$-modules, u_i ($i = 1, 2$) a homomorphism from $\mathscr{G}_i$ to $\mathscr{F}_i$. We denote by $u_1 \otimes u_2$ the homomorphism $u : \mathscr{G}_1 \otimes_{\mathscr{B}} \mathscr{G}_2 \to \mathscr{F}_1 \otimes_{\mathscr{A}} \mathscr{F}_2$ such that $u^\sharp = (u_1)^\sharp \otimes (u_2)^\sharp$ (taking into account (4.3.3.1)); we check that u is also the composition $\mathscr{G}_1 \otimes_{\mathscr{B}} \mathscr{G}_2 \to \Psi_*(\mathscr{F}_1) \otimes_{\mathscr{B}} \Psi_*(\mathscr{F}_2) \to \Psi_*(\mathscr{F}_1 \otimes_{\mathscr{A}} \mathscr{F}_2)$, where the first arrow is the ordinary tensor product $u_1 \otimes_{\mathscr{B}} u_2$ and the second is the canonical homomorphism (4.2.2.1).

(4.4.5). Let $(\mathscr{G}_\lambda)_{\lambda \in L}$ be an inductive system of $\mathscr{B}$-modules, and, for each $\lambda \in L$, let u_λ be a homomorphism $\mathscr{G}_\lambda \to \Psi_*(\mathscr{F})$, form an inductive limit; we put $\mathscr{G} = \varinjlim \mathscr{G}_\lambda$ and $u = \varinjlim u_\lambda$; then the $(u_\lambda)^\sharp$ form an inductive system of homomorphisms $\Psi^*(\mathscr{G}_\lambda) \to \mathscr{F}$, and the inductive limit of this system is none other than $u^\sharp$.

(4.4.6). Let $\mathscr{M}$, $\mathscr{N}$ be two $\mathscr{B}$-modules, V an open set of Y, $U = \psi^{-1}(V)$; the map $v \mapsto \Psi^*(v)$ is a homomorphism

$$\mathrm{Hom}_{\mathscr{B}|V}(\mathscr{M}|V, \mathscr{N}|V) \longrightarrow \mathrm{Hom}_{\mathscr{A}|U}(\Psi^*(\mathscr{M})|U, \Psi^*(\mathscr{N})|U)$$

for the $\Gamma(V, \mathscr{B})$-module structures ($\mathrm{Hom}_{\mathscr{A}|U}(\Psi^*(\mathscr{M})|U, \Psi^*(\mathscr{N})|U)$ is normaly equipped with the a $\Gamma(U, \psi^*(\mathscr{B}))$-module structure, and thanks to the canonical homomorphism (3.7.2) $\Gamma(V, \mathscr{B}) \to$ **0_{I} | 44**
$\Gamma(U, \psi^*(\mathscr{B}))$, it is also a $\Gamma(V, \mathscr{B})$-module). We see immediately that these homomorphisms are compatible with the restriction morphisms, and as a result define a canonical functorial homomorphism

$$\gamma : \mathscr{H}om_{\mathscr{B}}(\mathscr{M}, \mathscr{N}) \longrightarrow \Psi_*(\mathscr{H}om_{\mathscr{A}}(\Psi^*(\mathscr{M}), \Psi^*(\mathscr{N}));$$

it also corresponds to this homomorphism the homomorphism

$$\gamma^\sharp : \Psi^*(\mathscr{H}om_{\mathscr{B}}(\mathscr{M}, \mathscr{N})) \longrightarrow \mathscr{H}om_{\mathscr{A}}(\Psi^*(\mathscr{M}), \Psi^*(\mathscr{N}))$$

and these canonical morphisms are functorial in $\mathscr{M}$ and $\mathscr{N}$.

(4.4.7). Suppose that $\mathscr{F}$ (resp. $\mathscr{G}$) is an $\mathscr{A}$-algebra (resp. a $\mathscr{B}$-algebra). If $u : \mathscr{G} \to \Psi_*(\mathscr{F})$ is a homomorphism of $\mathscr{B}$-algebras, $u^\sharp$ is a homomorphism $\Psi^*(\mathscr{G}) \to \mathscr{F}$ of $\mathscr{A}$-algebras; this follows from the commutativity of the diagram

$$\begin{tikzcd}
\mathscr{G} \otimes_{\mathscr{B}} \mathscr{G} \arrow[r] \arrow[d] & \mathscr{G} \arrow[d, "u"] \\
\Psi_*(\mathscr{F} \otimes_{\mathscr{A}} \mathscr{F}) \arrow[r] & \Psi_*(\mathscr{F})
\end{tikzcd}$$

and from (4.4.4). Similarly, if $v : \Psi^*(\mathscr{G}) \to \mathscr{F}$ is a homomorphism of $\mathscr{A}$-algebras, $v^\flat : \mathscr{G} \to \Psi_*(\mathscr{F})$ is a homomorphism of $\mathscr{B}$-algebras.

(4.4.8). Let $(Z, \mathscr{C})$ be a third ringed space, $\Psi' = (\psi', \theta')$ a morphism $(Y, \mathscr{B}) \to (Z, \mathscr{C})$, and $\Psi'' : (X, \mathscr{A}) \to (Z, \mathscr{C})$ the composite morphism $\Psi' \circ \Psi$. Let $\mathscr{H}$ be a $\mathscr{C}$-module, v' a homomorphism from $\mathscr{H}$ to $\mathscr{G}$; the composition $v'' = v \circ v'$ is by definition the homomorphism from $\mathscr{H}$ to $\mathscr{F}$ defined by $\mathscr{H} \xrightarrow{v'} \Psi'_*(\mathscr{G}) \xrightarrow{\Psi'_*(v)} \Psi'_*(\Psi_*(\mathscr{F}))$; we check that $v''^\sharp$ is the homomorphism

$$\Psi^*(\Psi'^*(\mathscr{H})) \xrightarrow{\Psi^*(v'^\sharp)} \Psi^*(\mathscr{G}) \xrightarrow{v^\sharp} \mathscr{F}.$$

§5. Quasi-coherent and coherent sheaves

5.1. Quasi-coherent sheaves

(5.1.1). Let $(X, \mathscr{O}_X)$ be a ringed space, $\mathscr{F}$ an $\mathscr{O}_X$-module. The data of a homomorphism $u : \mathscr{O}_X \to \mathscr{F}$ of $\mathscr{O}_X$-modules is equivalent to that of the section $s = u(1) \in \Gamma(X, \mathscr{F})$. Indeed, when s is given, for each section $t \in \Gamma(U, \mathscr{O}_X)$, we necessarily have $u(t) = t \cdot (s|U)$; we say that u is *defined by the section* s. If now I is any set of indices, consider the direct sum sheaf $\mathscr{O}_X^{(I)}$, and for each $i \in I$, let h_i be the canonical injection of the i-th factor into $\mathscr{O}_X^{(I)}$; we know that $u \mapsto (u \circ h_i)$ is an isomorphism from $\mathrm{Hom}_{\mathscr{O}_X}(\mathscr{O}_X^{(I)}, \mathscr{F})$ to the product $(\mathrm{Hom}_{\mathscr{O}_X}(\mathscr{O}_X, \mathscr{F}))^I$. So there is a canonical one-to-one correspondence between the homomorphisms $u : \mathscr{O}_X^{(I)} \to \mathscr{F}$ and the *families of sections* $(s_i)_{i \in I}$ *of* $\mathscr{F}$ *over* X. The homomorphism u corresponding to (s_i) sends an element $(a_i) \in (\Gamma(U, \mathscr{O}_X))^{(I)}$ to $\sum_{i \in I} a_i \cdot (s_i|U)$.

We say that $\mathscr{F}$ is *generated by the family* (s_i) if the homomorphism $\mathscr{O}_X^{(I)} \to \mathscr{F}$ defined for each family is *surjective* (in other words, if, for each $x \in X$, $\mathscr{F}_x$ is an $\mathscr{O}_x$-module generated by the $(s_i)_x$). **0_{I} | 45**
We say that $\mathscr{F}$ is *generated by its sections over* X if it is generated by the family of all these sections (or by a subfamily), in other words, if there exists a surjective homomorphism $\mathscr{O}_X^{(I)} \to \mathscr{F}$ for a suitable I.

We note that an $\mathscr{O}_X$-module $\mathscr{F}$ can be such that there exists a point $x_0 \in X$ for which $\mathscr{F}|U$ is not generated by its sections over U, *regardless of the choice of neighbourhood* U *of* x_0: it suffices to take $X = \mathbf{R}$, for $\mathscr{O}_X$ the simple sheaf $\mathbf{Z}$, for $\mathscr{F}$ the algebraic subsheaf of $\mathscr{O}_X$ such that $\mathscr{F}_0 = \{0\}$, $\mathscr{F}_x = \mathbf{Z}$ for $x \neq 0$, and finally $x_0 = 0$: the only section of $\mathscr{F}|U$ over U is 0 for a neighbourhood U of 0.

(5.1.2). Let $f : X \to Y$ be a morphism of ringed spaces. If $\mathscr{F}$ is an $\mathscr{O}_X$-module generated by its sections over X, then the canonical homomorphism $f^*(f_*(\mathscr{F})) \to \mathscr{F}$ (4.4.3.3) is *surjective*; indeed, with the notation of (5.1.1), $s_i \otimes 1$ is a section of $f^*(f_*(\mathscr{F}))$ over X, and its image in $\mathscr{F}$ is s_i. The example in (5.1.1) where f is the identity shows that the inverse of this proposition is false in general.

If $\mathscr{G}$ is an $\mathscr{O}_Y$-module generated by its sections over Y, then $f^*(\mathscr{G})$ is generated by its sections over X, since f^* is a right exact functor. **$\mathbf{Err}_{\mathrm{II}}$**

(5.1.3). We say that an $\mathscr{O}_X$-module $\mathscr{F}$ is *quasi-coherent* if for each $x \in X$ there is an open neighbourhood U of x such that $\mathscr{F}|U$ is isomorphic to the *cokernel* of a homomorphism of the form $\mathscr{O}_X^{(I)}|U \to \mathscr{O}_X^{(J)}|U$, where I and J are sets of arbitrary indices. It is clear that $\mathscr{O}_X$ is itself a quasi-coherent $\mathscr{O}_X$-module, and that any direct sum of quasi-coherent $\mathscr{O}_X$-modules is again a quasi-coherent $\mathscr{O}_X$-module. We say that an $\mathscr{O}_X$-*algebra* $\mathscr{A}$ is *quasi-coherent* if it is quasi-coherent as an $\mathscr{O}_X$-module.

(5.1.4). Let $f : X \to Y$ be a morphism of ringed spaces. If $\mathscr{G}$ is a quasi-coherent $\mathscr{O}_Y$-module, then $f^*(\mathscr{G})$ is a quasi-coherent $\mathscr{O}_X$-module. Indeed, for each $x \in X$, there is an open neighbourhood V of $f(x)$ in Y such that $\mathscr{G}|V$ is the cokernel of a homomorphism $\mathscr{O}_Y^{(I)}|V \to \mathscr{O}_Y^{(J)}|V$. If $U = f^{-1}(V)$, and if f_U is the restriction of f to U, then we have $f^*(\mathscr{G})|U = f_U^*(\mathscr{G}|V)$; as f_U^* is right exact and commutes with direct sums, $f_U^*(\mathscr{G}|V)$ is the cokernel of a homomorphism $\mathscr{O}_X^{(I)}|U \to \mathscr{O}_X^{(J)}|U$.

5.2. Sheaves of finite type

(5.2.1). We say that an $\mathscr{O}_X$-module $\mathscr{F}$ is *of finite type* if for each $x \in X$ there exists an open neighbourhood U of x such that $\mathscr{F}|U$ is generated by a *finite* family of sections over U, or if it is isomorphic to a sheaf quotient of a sheaf of the form $(\mathscr{O}_X|U)^p$ where p is finite. Each sheaf quotient of a sheaf of finite type is again a sheaf of finite type, as well as each finite direct sum and each finite tensor product of sheaves of finite type. An $\mathscr{O}_X$-module of finite type is not necessarily quasi-coherent, as we can see for the $\mathscr{O}_X$-module $\mathscr{O}_X/\mathscr{F}$, where $\mathscr{F}$ is the example in (5.1.1). If $\mathscr{F}$ is of finite type, then $\mathscr{F}_x$ is an $\mathscr{O}_x$-module of finite type for each $x \in X$, but the example in (5.1.1) shows that this condition is necessary but not sufficient in general.

(5.2.2). Let $\mathscr{F}$ be an $\mathscr{O}_X$-module *of finite type*. If s_i $(1 \leqslant i \leqslant n)$ are the sections of $\mathscr{F}$ over an open neighbourhood U of a point $x \in X$ and the $(s_i)_x$ generate $\mathscr{F}_x$, then there exists an open neighbourhood $V \subset U$ of x such that the $(s_i)_y$ generate $\mathscr{F}_y$ for all $y \in Y$ (FAC, I, 2, 12, prop. 1). In particular, we conclude that the support of $\mathscr{F}$ is *closed*.

Similarly, if $u : \mathscr{F} \to \mathscr{G}$ is a homomorphism such that $u_x = 0$, then there exists a neighbourhood U of x such that $u_y = 0$ for all $y \in U$. **0_I** | 46

(5.2.3). Suppose that X is *quasi-compact*, and let $\mathscr{F}$ and $\mathscr{G}$ be two $\mathscr{O}_X$-modules such that $\mathscr{G}$ is *of finite type*, $u : \mathscr{F} \to \mathscr{G}$ a *surjective* homomorphism. In addition, suppose that $\mathscr{F}$ is the inductive limit of an inductive system $(\mathscr{F}_\lambda)$ of $\mathscr{O}_X$-modules. Then there exists an index μ such that the homomorphism $\mathscr{F}_\mu \to \mathscr{G}$ is *surjective*. Indeed, for each $x \in X$, there exists a finite system of sections s_i of $\mathscr{G}$ over an open neighbourhood $U(x)$ of x such that the $(s_i)_y$ generate $\mathscr{G}_y$ for all $y \in U(x)$; there is then an open neighbourhood $V(x) \subset U(x)$ of x and n sections t_i of $\mathscr{F}$ over $V(x)$ such that $s_i|V(s) = u(t_i)$ for all i; we can also suppose that the t_i are the canonical images of sections of a similar sheaf $\mathscr{F}_{\lambda(x)}$ over $V(x)$. We then cover X with a finite number of neighbourhoods $V(x_k)$, and let μ be the maximal index of the $\lambda(x_k)$; it is clear that this index gives the answer.

Suppose still that X is quasi-compact, and let $\mathscr{F}$ be an $\mathscr{O}_X$-module of finite type generated by its sections over X (5.1.1); then $\mathscr{F}$ is generated by a *finite* subfamily of these sections: indeed, it suffices to cover X by a finite number of open neighbourhoods U_k such that, for each k, there is a finite number of sections s_{ik} of $\mathscr{F}$ over X whose restrictions to U_k generate $\mathscr{F}|U_k$; it is clear that the s_{ik} then generate $\mathscr{F}$.

(5.2.4). Let $f : X \to Y$ be a morphism of ringed spaces. If $\mathscr{G}$ is an $\mathscr{O}_Y$-module of finite type, then $f^*(\mathscr{G})$ is an $\mathscr{O}_X$-module of finite type. Indeed, for each $x \in X$, there is an open neighbourhood V of $f(x)$ in Y and a surjective homomorphism $v : \mathscr{O}_Y^p|V \to \mathscr{G}|V$. If $U = f^{-1}(V)$ and if f_U is the restriction of f to U, then we have $f^*(\mathscr{G})|U = f_U^*(\mathscr{G}|V)$; since f_U^* is right exact (4.3.1) and commutes **Err_II** with direct sums (4.3.2), $f_U^*(v)$ is a surjective homomorphism $\mathscr{O}_X^p|U \to f^*(\mathscr{G})|U$.

(5.2.5). We say that an $\mathscr{O}_X$-module $\mathscr{F}$ *admits a finite presentation* if for each $x \in X$ there exists an open neighbourhood U of x such that $\mathscr{F}|U$ is isomorphic to a *cokernel of a* $(\mathscr{O}_X|U)$-*homomorphism* $\mathscr{O}_X^p|U \to \mathscr{O}_X^q|U$, p and q being two integers > 0. Such an $\mathscr{O}_X$-module is therefore of finite type and quasi-coherent. If $f : X \to Y$ is a morphism of ringed spaces, and if $\mathscr{G}$ is an $\mathscr{O}_Y$-module admitting a finite presentation, then $f^*(\mathscr{G})$ admits a finite presentation, as shown in the argument of (5.1.4).

(5.2.6). Let $\mathscr{F}$ be an $\mathscr{O}_X$-module admitting a finite presentation (5.2.5); then, for each $\mathscr{O}_X$-module $\mathscr{H}$, the canonical functorial homomorphism

$$(\mathscr{H}om_{\mathscr{O}_X}(\mathscr{F},\mathscr{H}))_x \longrightarrow \mathrm{Hom}_{\mathscr{O}_x}(\mathscr{F}_x,\mathscr{H}_x)$$

is *bijective* (T, 4.1.1).

(5.2.7). Let $\mathscr{F}$ and $\mathscr{G}$ be two $\mathscr{O}_X$-modules admitting a finite presentation. If for some $x \in X$, $\mathscr{F}_x$ and $\mathscr{G}_x$ are *isomorphic* as $\mathscr{O}_x$-modules, then there exists an open neighbourhood U of x such that $\mathscr{F}|U$ and $\mathscr{G}|U$ are *isomorphic*. Indeed, if $\phi : \mathscr{F}_x \to \mathscr{G}_x$ and $\psi : \mathscr{G}_x \to \mathscr{F}_x$ are an isomorphism and its inverse isomorphism, then there exists, according to (5.2.6), an open neighbourhood V of x and a section u (resp. v) of $\mathscr{H}om_{\mathscr{O}_X}(\mathscr{F},\mathscr{G})$ (resp. $\mathscr{H}om_{\mathscr{O}_X}(\mathscr{G},\mathscr{F})$) over V such that $u_x = \phi$ (resp. $v_x = \psi$). As $(u \circ v)_x$ **0_I** | 47 and $(v \circ u)_x$ are the identity automorphisms, there exists an open neighbourhood $U \subset V$ of x such that $(u \circ v)|U$ and $(v \circ u)|U$ are the identity automorphisms, hence the proposition.

5.3. Coherent sheaves

(5.3.1). We say that an $\mathscr{O}_X$-module $\mathscr{F}$ is *coherent* if it satisfies the two following conditions:

(a) $\mathscr{F}$ is of finite type.
(b) for each open $U \subset X$, integer $n > 0$, and homomorphism $u : \mathscr{O}_X^n|U \to \mathscr{F}|U$, the kernel of u is of finite type.

We note that these two conditions are of a *local* nature.

For most of the proofs of the properties of coherent sheaves in what follows, cf. (FAC, I, 2).

(5.3.2). Each coherent $\mathscr{O}_X$-module admits a finite presentation (5.2.5); the inverse is not necessarily true, since $\mathscr{O}_X$ itself is not necessarily a coherent $\mathscr{O}_X$-module.

Each $\mathscr{O}_X$-submodule *of finite type* of a coherent $\mathscr{O}_X$-module is coherent; each *finite* direct sum of coherent $\mathscr{O}_X$-modules is a coherent $\mathscr{O}_X$-module.

(5.3.3). If $0 \to \mathscr{F} \to \mathscr{G} \to \mathscr{H} \to 0$ is an exact sequence of $\mathscr{O}_X$-modules and if two of these $\mathscr{O}_X$-modules are coherent, then so is the third.

(5.3.4). If $\mathscr{F}$ and $\mathscr{G}$ are two coherent $\mathscr{O}_X$-modules, $u : \mathscr{F} \to \mathscr{G}$ a homomorphism, then $\operatorname{Im}(u)$, $\operatorname{Ker}(u)$, and $\operatorname{Coker}(u)$ are coherent $\mathscr{O}_X$-modules. In particular, if $\mathscr{F}$ and $\mathscr{G}$ are $\mathscr{O}_X$-submodules of a coherent $\mathscr{O}_X$-module, then $\mathscr{F} + \mathscr{G}$ and $\mathscr{F} \cap \mathscr{G}$ are coherent.

If $\mathscr{A} \to \mathscr{B} \to \mathscr{C} \to \mathscr{D} \to \mathscr{E}$ is an exact sequence of $\mathscr{O}_X$-modules, and if $\mathscr{A}$, $\mathscr{B}$, $\mathscr{D}$, $\mathscr{E}$ are coherent, then $\mathscr{C}$ is coherent. **Err$_{\mathrm{II}}$**

(5.3.5). If $\mathscr{F}$ and $\mathscr{G}$ are two coherent $\mathscr{O}_X$-modules, then so are $\mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{G}$ are $\mathscr{H}om_{\mathscr{O}_X}(\mathscr{F}, \mathscr{G})$.

(5.3.6). Let $\mathscr{F}$ be a coherent $\mathscr{O}_X$-module, $\mathscr{J}$ a coherent sheaf of ideals of $\mathscr{O}_X$. Then the $\mathscr{O}_X$-module $\mathscr{J}\mathscr{F}$ is coherent, as the image of $\mathscr{J} \otimes_{\mathscr{O}_X} \mathscr{F}$ under the canonical homomorphism $\mathscr{J} \otimes_{\mathscr{O}_X} \mathscr{F} \to \mathscr{F}$ ((5.3.4) and (5.3.5)).

(5.3.7). We say that an $\mathscr{O}_X$-algebra $\mathscr{A}$ is *coherent* if it is coherent as an $\mathscr{O}_X$-module. In particular, $\mathscr{O}_X$ is a *coherent sheaf of rings* if and only if for each open $U \subset X$ and each homomorphism of the form $u : \mathscr{O}_X^p|U \to \mathscr{O}_X|U$, the kernel of u is an $(\mathscr{O}_X|U)$-module of finite type.

If $\mathscr{O}_X$ is a coherent sheaf of rings, then each $\mathscr{O}_X$-module $\mathscr{F}$ admitting a finite presentation (5.2.5) is coherent, according to (5.3.4).

The *annihilator* of an $\mathscr{O}_X$-module $\mathscr{F}$ is the kernel $\mathscr{J}$ of the canonical homomorphism $\mathscr{O}_X \to \mathscr{H}om_{\mathscr{O}_X}(\mathscr{F}, \mathscr{F})$ which sends each section $s \in \Gamma(U, \mathscr{O}_X)$ to the multiplication by s map in $\operatorname{Hom}(\mathscr{F}|U, \mathscr{F}|U)$; if $\mathscr{O}_X$ is coherent and if $\mathscr{F}$ is a coherent $\mathscr{O}_X$-module, then $\mathscr{J}$ is coherent ((5.3.4) and (5.3.5)) and for each $x \in X$, $\mathscr{J}_x$ is the annihilator of $\mathscr{F}_x$ (5.2.6).

(5.3.8). Suppose that $\mathscr{O}_X$ is coherent; let $\mathscr{F}$ be a coherent $\mathscr{O}_X$-module, x a point of X, M a submodule of finite type of $\mathscr{F}_x$; then there exists an open neighbourhood U of x and a coherent $(\mathscr{O}_X|U)$-submodule $\mathscr{G}$ of $\mathscr{F}|U$ such that $\mathscr{G}_x = M$ (T, 4.1, Lemma 1). **$\mathbf{0_I}$ | 48**

This result, along with the properties of the $\mathscr{O}_X$-submodules of a coherent $\mathscr{O}_X$-module, impose the necessary conditions on the rings $\mathscr{O}_x$ such that $\mathscr{O}_X$ is coherent. For example (5.3.4), the intersection of two ideals of finite type of $\mathscr{O}_x$ must still be an ideal of finite type.

(5.3.9). Suppose that $\mathscr{O}_X$ is coherent, and let M be an $\mathscr{O}_x$-module admitting a finite presentation, therefore isomorphic to a cokernel of a homomorphism $\phi : \mathscr{O}_x^p \to \mathscr{O}_x^q$; then there exists an open neighbourhood U of X and a coherent $(\mathscr{O}_X|U)$-module $\mathscr{F}$ such that $\mathscr{F}_x$ is isomorphic to M. Indeed, according to (5.2.6), there exists a section u of $\mathscr{H}om_{\mathscr{O}_X}(\mathscr{O}_X^p, \mathscr{O}_X^q)$ over an open neighbourhood U of x such that $u_x = \phi$; the cokernel $\mathscr{F}$ of the homomorphism $u : \mathscr{O}_X^p|U \to \mathscr{O}_X^q|U$ gives the answer (5.3.4).

(5.3.10). Suppose that $\mathscr{O}_X$ is coherent, and let $\mathscr{J}$ be a coherent sheaf of ideals of $\mathscr{O}_X$. For a $(\mathscr{O}_X/\mathscr{J})$-module $\mathscr{F}$ to be coherent, it is necessary and sufficient for it to be coherent as an $\mathscr{O}_X$-module. In particular, $\mathscr{O}_X/\mathscr{J}$ is a coherent sheaf of rings.

(5.3.11). Let $f : X \to Y$ be a morphism of ringed spaces, and suppose that $\mathscr{O}_X$ is coherent; then, for each coherent $\mathscr{O}_Y$-module $\mathscr{G}$, $f^*(\mathscr{G})$ is a coherent $\mathscr{O}_X$-module. Indeed, with the notation of (5.2.4), we can assume that $\mathscr{G}|V$ is the cokernel of a homomorphism $v : \mathscr{O}_Y^q|V \to \mathscr{O}_Y^p|V$; as f_U^* is right exact, $f^*(\mathscr{G})|U = f_U^*(\mathscr{G}|V)$ is the cokernel of the homomorphism $f_U^*(v) : \mathscr{O}_X^q|U \to \mathscr{O}_X^p|U$, hence our assertion.

(5.3.12). Let Y be a closed subset of X, $j : Y \to X$ the canonical injection, $\mathscr{O}_Y$ a sheaf of rings on Y, and set $\mathscr{O}_X = j_*(\mathscr{O}_Y)$. For an $\mathscr{O}_Y$-module $\mathscr{G}$ to be of finite type (resp. quasi-coherent, coherent), it is necessary and sufficient for $j_*(\mathscr{G})$ to be an $\mathscr{O}_X$-module of finite type (resp. quasi-coherent, coherent).

5.4. Locally free sheaves

(5.4.1). Let X be a ringed space. We say that an $\mathscr{O}_X$-module $\mathscr{F}$ is *locally free* if for each $x \in X$ there exists an open neighbourhood U of x such that $\mathscr{F}|U$ is isomorphic to a $(\mathscr{O}_X|U)$-module of the form $\mathscr{O}_X^{(I)}|U$, where I can depend on U. If for each U, I is finite, then we say that $\mathscr{F}$ is *of finite rank*; if for each U, I has the same finite number of elements n, we say that $\mathscr{F}$ is *of rank* n. A locally free $\mathscr{O}_X$-module of rank 1 is called *invertible* (cf. (5.4.3)). If $\mathscr{F}$ is a locally free $\mathscr{O}_X$-module of finite rank, then for each $x \in X$, $\mathscr{F}_x$ is a free $\mathscr{O}_x$-module of finite rank $n(x)$, and there exists a neighbourhood U of x such that $\mathscr{F}|U$, is of rank $n(x)$; if X is connected, then $n(x)$ is *constant*.

It is clear that each locally free sheaf is quasi-coherent, and if $\mathscr{O}_X$ is a coherent sheaf of rings, then each locally free $\mathscr{O}_X$-module of finite rank is coherent.

If $\mathscr{L}$ is locally free, then $\mathscr{L} \otimes_{\mathscr{O}_X} \mathscr{F}$ is an *exact* functor in $\mathscr{F}$ to the category of $\mathscr{O}_X$-modules.

We will mostly consider locally free $\mathscr{O}_X$-modules of finite rank, and when we speak of locally free $\mathbf{0_I}$ | 49
sheaves without specifying, it will be understood that they are of *finite rank*.

Suppose that $\mathscr{O}_X$ is *coherent*, and let $\mathscr{F}$ be a *coherent* $\mathscr{O}_X$-module. Then, if at a point $x \in X$, $\mathscr{F}_x$ is an $\mathscr{O}_x$-module *free of rank* n, there exists a neighbourhood U of x such that $\mathscr{F}|U$ is *locally free of rank* n; in fact, $\mathscr{F}_x$ is then isomorphic to $\mathscr{O}_x^n$, and the proposition follows from (5.2.7). $\mathbf{Err_{II}}$

(5.4.2). If $\mathscr{L}$, $\mathscr{F}$ are two $\mathscr{O}_X$-modules, we have a canonical functorial homomorphism

(5.4.2.1) $$\mathscr{L}^\vee \otimes_{\mathscr{O}_X} \mathscr{F} = \mathscr{H}om_{\mathscr{O}_X}(\mathscr{L}, \mathscr{O}_X) \otimes_{\mathscr{O}_X} \mathscr{F} \longrightarrow \mathscr{H}om_{\mathscr{O}_X}(\mathscr{L}, \mathscr{F})$$

defined in the following way: for each open set U, send any pair (u, t), where

$$u \in \Gamma(U, \mathscr{H}om_{\mathscr{O}_X}(\mathscr{L}, \mathscr{O}_X)),$$
$$\Gamma(U, \mathscr{H}om_{\mathscr{O}_X}(\mathscr{L}, \mathscr{O}_X)) = \mathrm{Hom}(\mathscr{L}|U, \mathscr{O}_X|U),$$
$$t \in \Gamma(U, \mathscr{F}),$$

to the element of $\mathrm{Hom}(\mathscr{L}|U, \mathscr{F}|U)$ which, for each $x \in U$, sends $s_x \in \mathscr{L}_x$ to the element $u_x(s_x)t_x$ of $\mathscr{F}_x$. If $\mathscr{L}$ is *locally free of finite rank*, then this homomorphism is *bijective*; the property being local, we can in fact reduce to the case where $\mathscr{L} = \mathscr{O}_X^n$; as for each $\mathscr{O}_X$-module $\mathscr{G}$, $\mathscr{H}om_{\mathscr{O}_X}(\mathscr{O}_X^n, \mathscr{G})$ is canonically isomorphic to $\mathscr{G}^n$, we have reduced to the case $\mathscr{L} = \mathscr{O}_X$, which is immediate.

(5.4.3). If $\mathscr{L}$ is invertible, then so is its dual $\mathscr{L}^\vee = \mathscr{H}om_{\mathscr{O}_X}(\mathscr{L}, \mathscr{O}_X)$, since we can immediately reduce (as the question is local) to the case $\mathscr{L} = \mathscr{O}_X$. In addition, we have a canonical isomorphism

(5.4.3.1) $$\mathscr{H}om_{\mathscr{O}_X}(\mathscr{L}, \mathscr{O}_X) \otimes_{\mathscr{O}_X} \mathscr{L} \simeq \mathscr{O}_X$$

as, according to (5.3.2), it suffices to define a canonical isomorphism $\mathscr{H}om_{\mathscr{O}_X}(\mathscr{L}, \mathscr{L}) \simeq \mathscr{O}_X$. For *each* $\mathscr{O}_X$-module $\mathscr{F}$, we have a canonical homomorphism $\mathscr{O}_X \simeq \mathscr{H}om_{\mathscr{O}_X}(\mathscr{F}, \mathscr{F})$ (5.3.7). It remains to prove that if $\mathscr{F} = \mathscr{L}$ is invertible, then this homomorphism is bijective, and as the question is local, it reduces to the case $\mathscr{L} = \mathscr{O}_X$, which is immediate.

Due to the above, we put $\mathscr{L}^{-1} = \mathscr{H}om_{\mathscr{O}_X}(\mathscr{L}, \mathscr{O}_X)$, and we say that $\mathscr{L}^{-1}$ is the *inverse* of $\mathscr{L}$. The terminology "invertible sheaf" can be justified in the following way when X is a point and $\mathscr{O}_X$ is a *local* ring A with maximal ideal $\mathfrak{m}$; if M and M' are two A-modules (M being of finite type) such that $M \otimes_A M'$ is isomorphic to A, then as $(A/\mathfrak{m}) \otimes_A (M \otimes_A M')$ identifies with $(M/\mathfrak{m}M) \otimes_{A/\mathfrak{m}} (M'/\mathfrak{m}M')$, this latter tensor product of vector spaces over the field $A/\mathfrak{m}$ is isomorphic to $A/\mathfrak{m}$, which requires $M/\mathfrak{m}M$ and $M'/\mathfrak{m}M'$ to be of dimension 1. For each element $z \in M$ not in $\mathfrak{m}M$, we have $M = Az + \mathfrak{m}M$, which implies that $M = Az$ according to Nakayama's Lemma, M being of finite type. Moreover, as the annihilator of z kills $M \otimes_A M'$, which is isomorphic to A, this annihilator is $\{0\}$, and as a result M is *isomorphic to* A. In the general case, this shows that $\mathscr{L}$ is an $\mathscr{O}_X$-module of finite type, such that there exists an $\mathscr{O}_X$-module $\mathscr{F}$ for which $\mathscr{L} \otimes_{\mathscr{O}_X} \mathscr{F}$ is isomorphic to $\mathscr{O}_X$, and if in addition the rings $\mathscr{O}_x$ are local rings, then $\mathscr{L}_x$ is an $\mathscr{O}_x$-module isomorphic to $\mathscr{O}_x$ for each $x \in X$. If $\mathscr{O}_X$ and $\mathscr{L}$ are assumed to be *coherent*, then we conclude that $\mathscr{L}$ is invertible according to (5.2.7).

(5.4.4). If $\mathscr{L}$ and $\mathscr{L}'$ are two invertible $\mathscr{O}_X$-modules, then so is $\mathscr{L} \otimes_{\mathscr{O}_X} \mathscr{L}'$, since the question is local, we can assume that $\mathscr{L} = \mathscr{O}_X$, and the result is then trivial. For each integer $n \geqslant 1$, we denote by

$\mathscr{L}^{\otimes n}$ the tensor product of n copies of the sheaf $\mathscr{L}$; we set by convention $\mathscr{L}^{\otimes 0} = \mathscr{O}_X$, and for $n \geqslant 1$, $\mathscr{L}^{\otimes(-n)} = (\mathscr{L}^{-1})^{\otimes n}$. With these notation, there is then a *canonical functorial isomorphism* $\mathbf{0_I}$ | 50

(5.4.4.1) $$\mathscr{L}^{\otimes m} \otimes_{\mathscr{O}_X} \mathscr{L}^{\otimes n} \simeq \mathscr{L}^{\otimes(n+m)}$$

for any rational integers m and n: indeed, by definition, we immediately reduce to the case where $m = -1$, $n = 1$, and the isomorphism in question is then that defined in (5.4.3).

(5.4.5). Let $f : Y \to X$ be a morphism of ringed spaces. If $\mathscr{L}$ is a locally free (resp. invertible) $\mathscr{O}_X$-module, then $f^*(\mathscr{L})$ is a locally free (resp. invertible) $\mathscr{O}_Y$-module: this follows immediately from that the inverse images of two locally isomorphic $\mathscr{O}_X$-modules are locally isomorphic, that f^* commutes with finite direct sums, and that $f^*(\mathscr{O}_X) = \mathscr{O}_Y$ (4.3.4). In addition, we know that we have a canonical functorial homomorphism $f^*(\mathscr{L}^\vee) \to (f^*(\mathscr{L}))^\vee$ (4.4.6), and when $\mathscr{L}$ is locally free, this homomorphism is *bijective*: indeed, we again reduce to the case where $\mathscr{L} = \mathscr{O}_X$ which is trivial. We conclude that if $\mathscr{L}$ is invertible, then $f^*(\mathscr{L}^{\otimes n})$ canonically identifies with $(f^*(\mathscr{L}))^{\otimes n}$ for each rational integer n.

(5.4.6). Let $\mathscr{L}$ be an invertible $\mathscr{O}_X$-module; we denote by $\Gamma_\bullet(X, \mathscr{L})$ or simply $\Gamma_\bullet(\mathscr{L})$ the abelian group direct sum $\bigoplus_{n\in\mathbf{Z}} \Gamma(X, \mathscr{L}^{\otimes n})$; we equip it with the structure of a *graded ring*, by corresponding to a pair (s_n, s_m), where $s_n \in \Gamma(X, \mathscr{L}^{\otimes n})$, $s_m \in \Gamma(X, \mathscr{L}^{\otimes m})$, the section of $\mathscr{L}^{\otimes(n+m)}$ over X which corresponds canonically (5.4.4.1) to the section $s_n \otimes s_m$ of $\mathscr{L}^{\otimes n} \otimes_{\mathscr{O}_X} \mathscr{L}^{\otimes m}$; the associativity of this multiplication is verified in an immediate way. It is clear that $\Gamma_\bullet(X, \mathscr{L})$ is a covariant functor in $\mathscr{L}$, with values in the category of graded rings.

If now $\mathscr{F}$ is any $\mathscr{O}_X$-module, then we set

$$\Gamma_\bullet(\mathscr{L}, \mathscr{F}) = \bigoplus_{n\in\mathbf{Z}} \Gamma(X, \mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{L}^{\otimes n}).$$

We equip this abelian group with the structure of a *graded module* over the graded ring $\Gamma_\bullet(\mathscr{L})$ in the following way: to a pair (s_n, u_m), where $s_n \in \Gamma(X, \mathscr{L}^{\otimes n})$ and $u_m \in \Gamma(X, \mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{L}^{\otimes m})$, we associate the section of $\mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{L}^{\otimes(m+n)}$ which canonically corresponds (5.4.4.1) to $s_n \otimes u_m$; the verification of the module axioms are immediate. For X and $\mathscr{L}$ fixed, $\Gamma_\bullet(\mathscr{L}, \mathscr{F})$ is a covariant functor in $\mathscr{F}$ with values in the category of graded $\Gamma_\bullet(\mathscr{L})$-modules; for X and $\mathscr{F}$ fixed, it is a covariant functor in $\mathscr{L}$ with values in the category of abelian groups.

If $f : Y \to X$ is a morphism of ringed spaces, the canonical homomorphism (4.4.3.2) $\rho : \mathscr{L}^{\otimes n} \to f_*(f^*(\mathscr{L}^{\otimes n}))$ defines a homomorphism of abelian groups $\Gamma(X, \mathscr{L}^{\otimes n}) \to \Gamma(Y, f^*(\mathscr{L}^{\otimes n}))$, and as $f^*(\mathscr{L}^{\otimes n}) = (f^*(\mathscr{L}))^{\otimes n})$, it follows from the definitions of the canonical homomorphisms (4.4.3.2) and (5.4.4.1) that the above homomorphisms define a *functorial homomorphism of graded rings* $\Gamma_\bullet(\mathscr{L}) \to \Gamma_\bullet(f^*(\mathscr{L}))$. The same canonical homomorphism (4.4.3) similarly defines a homomorphism of abelian groups $\Gamma(X, \mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{L}^{\otimes n}) \to \Gamma(Y, f^*(\mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{L}^{\otimes n}))$, and as

$$f^*(\mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{L}^{\otimes n}) = f^*(\mathscr{F}) \otimes_{\mathscr{O}_Y} (f^*(\mathscr{L}))^{\otimes n} \quad (4.3.3.1),$$

these homomorphism (for n variable) define a *di-homomorphism of graded modules* $\Gamma_\bullet(\mathscr{L}, \mathscr{F}) \to \Gamma_\bullet(f^*(\mathscr{L}), f^*(\mathscr{F}))$. $\mathbf{0_I}$ | 51

(5.4.7). One can show that there exists a *set* $\mathfrak{M}$ (also denoted $\mathfrak{M}(X)$) of invertible $\mathscr{O}_X$-modules such that each invertible $\mathscr{O}_X$-module is isomorphic to a unique element of $\mathfrak{M}$ [8]; we define on $\mathfrak{M}$ a composition law by sending two elements $\mathscr{L}$ and $\mathscr{L}'$ of $\mathfrak{M}$ to the unique element of $\mathfrak{M}$ isomorphic to $\mathscr{L} \otimes_{\mathscr{O}_X} \mathscr{L}'$. With this composition law, $\mathfrak{M}$ *is a group isomorphic to the cohomology group* $\mathrm{H}^1(X, \mathscr{O}_X^*)$, where $\mathscr{O}_X^*$ is the subsheaf of $\mathscr{O}_X$ such that $\Gamma(U, \mathscr{O}_X^*)$ is the group of invertible elements of the ring $\Gamma(U, \mathscr{O}_X)$ for each open $U \subset X$ ($\mathscr{O}_X^*$ is therefore a sheaf of *multiplicative* abelian groups).

We will note that for all open $U \subset X$, the group of sections $\Gamma(U, \mathscr{O}_X^*)$ canonically identifies with the *automorphism group* of the $(\mathscr{O}_X|U)$-module $\mathscr{O}_X|U$, the identification sending a section ε of $\mathscr{O}_X^*$ over U to the automorphism u of $\mathscr{O}_X|U$ such that $u_x(s_x) = \varepsilon_x s_x$ for all $x \in X$ and all $s_x \in \mathscr{O}_x$. Then let $\mathfrak{U} = (U_\lambda)$ be an open cover of X; the data, for each pair of indices (λ, μ), of an automorphism $\theta_{\lambda\mu}$ of $\mathscr{O}_X|(U_\lambda \cap U_\mu)$ is the same as giving a 1-*cochain* of the cover $\mathfrak{U}$, with values in $\mathscr{O}_X^*$, and say that the $\theta_{\lambda\mu}$ satisfy the gluing condition (3.3.1), meaning that the corresponding cochain is a *cocycle*. Similarly,

[8] See the book in preparation cited in the introduction.

the data, for each λ, of an automorphism ω_λ of $\mathscr{O}_X|U_\lambda$ is the same as the data of a 0-cochain of the cover $\mathfrak{U}$, with values in $\mathscr{O}_X^*$, and its *coboundary* corresponds to the family of automorphisms $(\omega_\lambda|U_\lambda \cap U_\mu) \circ (\omega_\mu|U_\lambda \cap U_\mu)^{-1}$. We can send each 1-cocycle of $\mathfrak{U}$ with values in $\mathscr{O}_X^*$ to the element of $\mathfrak{M}$ isomorphic to an invertible $\mathscr{O}_X$-module obtained by gluing with respect to the family of automorphisms $(\theta_{\lambda\mu})$ corresponding to this cocycle, and to two cohomologous coycles correspond two equal elements of $\mathfrak{M}$ (3.3.2); in other words, we thus define a map $\phi_{\mathfrak{U}} : \mathrm{H}^1(\mathfrak{U}, \mathscr{O}_X^*) \to \mathfrak{M}$. In addition, if $\mathfrak{B}$ is a second open cover of X, finer than $\mathfrak{U}$, then the diagram

$$\begin{tikzcd}
\mathrm{H}^1(\mathfrak{U}, \mathscr{O}_X^*) \arrow[dd] \arrow[dr, "\phi_{\mathfrak{U}}"] & \\
& \mathfrak{M} \\
\mathrm{H}^1(\mathfrak{B}, \mathscr{O}_X^*) \arrow[ur, "\phi_{\mathfrak{B}}"'] &
\end{tikzcd}$$

where the vertical arrow is the canonical homomorphism (G, II, 5.7), is commutative, as a result of (3.3.3). By passing to the inductive limit, we therefore obtain a map $\mathrm{H}^1(X, \mathscr{O}_X^*) \to \mathfrak{M}$, the Čech cohomology group $\check{\mathrm{H}}^1(X, \mathscr{O}_X^*)$ identifying as we know with the first cohomology group $\mathrm{H}^1(X, \mathscr{O}_X^*)$ (G, II, 5.9, Cor. of Thm. 5.9.1). This map is *surjective*: indeed, by definition, for each invertible $\mathscr{O}_X$-module $\mathscr{L}$, there is an open cover (U_λ) of X such that $\mathscr{L}$ is obtained by gluing the sheaves $\mathscr{O}_X|U_\lambda$ (3.3.1). It is also *injective*, since it suffices to prove for the maps $\mathrm{H}^1(\mathfrak{U}, \mathscr{O}_X^*) \to \mathfrak{M}$, and this follows from (3.3.2). It remains to show that the bijection thus defined is a group homomorphism. $\mathbf{0_I}$ | 52
Given two invertible $\mathscr{O}_X$-modules $\mathscr{L}$ and $\mathscr{L}'$, there is an open cover (U_λ) such that $\mathscr{L}|U_\lambda$ and $\mathscr{L}'|U_\lambda$ are isomorphic to $\mathscr{O}_X|U_\lambda$ for each λ; so there is for each index λ an element a_λ (resp. a'_λ) of $\Gamma(U_\lambda, \mathscr{L})$ (resp. $\Gamma(U_\lambda, \mathscr{L}')$) such that the elements of $\Gamma(U_\lambda, \mathscr{L})$ (resp. $\Gamma(U_\lambda, \mathscr{L}')$) are the $s_\lambda \cdot a_\lambda$ (resp. $s_\lambda \cdot a'_\lambda$), where s_λ varies over $\Gamma(U_\lambda, \mathscr{O}_X)$. The corresponding cocycles $(\varepsilon_{\lambda\mu})$, $(\varepsilon'_{\lambda\mu})$ are such that $s_\lambda \cdot a_\lambda = s_\mu \cdot a_\mu$ (resp. $s_\lambda \cdot a'_\lambda = s_\mu \cdot a'_\mu$) over $U_\lambda \cap U_\mu$ is equivalent to $s_\lambda = \varepsilon_{\lambda\mu} s_\mu$ (resp. $s_\lambda = \varepsilon'_{\lambda\mu} s_\mu$) over $U_\lambda \cap U_\mu$. As the sections of $\mathscr{L} \otimes_{\mathscr{O}_X} \mathscr{L}'$ over U_λ are the finite sums of the $s_\lambda s'_\lambda \cdot (a_\lambda \otimes a'_\lambda)$ where s_λ and s'_λ vary over $\Gamma(U_\lambda, \mathscr{O}_X)$, it is clear that the cocycle $(\varepsilon_{\lambda\mu}, \varepsilon'_{\lambda\mu})$ corresponds to $\mathscr{L} \otimes_{\mathscr{O}_X} \mathscr{L}'$, which finishes the proof. [9]

(5.4.8). Let $f = (\psi, \omega)$ be a morphism $Y \to X$ of ringed spaces. The functor $f^*(\mathscr{L})$ to the category of free $\mathscr{O}_X$-modules defines a map (which we still denote f^* by abuse of language) from the set $\mathfrak{M}(X)$ to the set $\mathfrak{M}(Y)$. Second, we have a canonical homomorphism (T, 3.2.2)

$$\mathrm{H}^1(X, \mathscr{O}_X^*) \longrightarrow \mathrm{H}^1(Y, \mathscr{O}_Y^*). \tag{5.4.8.1}$$

When we canonically identify (5.4.7) $\mathfrak{M}(X)$ and $\mathrm{H}^1(X, \mathscr{O}_X^*)$ (resp. $\mathfrak{M}(Y)$ and $\mathrm{H}^1(Y, \mathscr{O}_Y^*)$), the homomorphism (5.4.8.1) *identifies with the map* f^*. Indeed, if $\mathscr{L}$ comes from a cocycle $(\varepsilon_{\lambda\mu})$ corresponding to an open cover (U_λ) of X, then it suffices to show that $f^*(\mathscr{L})$ comes from a cocycle whose cohomology class is the image under (5.4.8.1) of $(\varepsilon_{\lambda\mu})$. If $\theta_{\lambda\mu}$ is the automorphism of $\mathscr{O}_X|(U_\lambda \cap U_\mu)$ which corresponds to $\varepsilon_{\lambda\mu}$, then it is clear that $f^*(\mathscr{L})$ is obtained by gluing the $\mathscr{O}_Y|\psi^{-1}(U_\lambda)$ by means of the automorphisms $f^*(\theta_{\lambda\mu})$, and it then suffices to check that these latter automorphisms corresponds to the cocycle $(\omega^\sharp(\varepsilon_{\lambda\mu}))$, which follows immediately from the definitions (we can identify $\varepsilon_{\lambda\mu}$ with its canonical image under ρ (3.7.2), a section of $\psi^*(\mathscr{O}_X^*)$ over $\psi^{-1}(U_\lambda \cap U_\mu)$).

(5.4.9). Let $\mathscr{E}$ and $\mathscr{F}$ be two $\mathscr{O}_X$-modules, $\mathscr{F}$ assumed to be *locally free*, and let $\mathscr{G}$ be an $\mathscr{O}_X$*-module extension of* $\mathscr{F}$ *by* $\mathscr{E}$, in other words there exists an exact sequence $0 \to \mathscr{E} \xrightarrow{i} \mathscr{G} \xrightarrow{p} \mathscr{F} \to 0$. Then, for each $x \in X$, there exists an open neighbourhood U of x such that $\mathscr{G}|U$ is isomorphic to the *direct sum* $\mathscr{E}|U \oplus \mathscr{F}|U$. We can reduce to the case where $\mathscr{F} = \mathscr{O}_X^n$; let e_i $(1 \leqslant i \leqslant n)$ be the canonical sections (5.5.5) of $\mathscr{O}_X^n$; there then exists an open neighbourhood U of x and n sections s_i of $\mathscr{G}$ over U such that $p(s_i|U) = e_i|U$ for $1 \leqslant i \leqslant n$. That being so, let f be the homomorphism $\mathscr{F}|U \to \mathscr{G}|U$ defined by

[9] For a general form of this result, see the book cited in the note on p. 51.

the sections $s_i|U$ (5.1.1). It is immediate that for each open $V \subset U$, and each section $s \in \Gamma(V, \mathscr{G})$ we have $s - f(p(s)) \in \Gamma(V, \mathscr{E})$, hence our assertion.

(5.4.10). Let $f : X \to Y$ be a morphism of ringed spaces, $\mathscr{F}$ an $\mathscr{O}_X$-module, and $\mathscr{L}$ a locally free $\mathscr{O}_Y$-module of finite rank. Then there exists a canonical isomorphism

(5.4.10.1) $$f_*(\mathscr{F}) \otimes_{\mathscr{O}_Y} \mathscr{L} \simeq f_*(\mathscr{F} \otimes_{\mathscr{O}_X} f^*(\mathscr{L})).$$

Indeed, for each $\mathscr{O}_Y$-module $\mathscr{L}$, we have a canonical homomorphism $\mathbf{0_I}$ | 53

$$f_*(\mathscr{F}) \otimes_{\mathscr{O}_Y} \mathscr{L} \xrightarrow{1\otimes\rho} f_*(\mathscr{F}) \otimes_{\mathscr{O}_Y} f_*(f^*(\mathscr{L})) \xrightarrow{\alpha} f_*(\mathscr{F} \otimes_{\mathscr{O}_X} f^*(\mathscr{L})),$$

ρ the homomorphism (4.4.3.2) and α the homomorphism (4.2.2.1). To show that when $\mathscr{L}$ is locally free, this homomorphism is bijective, it suffices, since the questions is local, to consider the case where $\mathscr{L} = \mathscr{O}_X^n$; in addition, f_* and f^* commute with finite direct sums, so we can assume $n = 1$, and in this case the proposition follows immediately from the definitions and from the relation $f^*(\mathscr{O}_Y) = \mathscr{O}_X$.

5.5. Sheaves on a locally ringed space

(5.5.1). We say that a ringed space $(X, \mathscr{O}_X)$ is a *locally ringed space* if for each $x \in X$, $\mathscr{O}_x$ is a local ring; these ringed spaces will be by far the most frequent ringed spaces that we will consider in this work. We then denote by $\mathfrak{m}_x$ the *maximal ideal* of $\mathscr{O}_x$, by $k(x)$ the *residue field* $\mathscr{O}_x/\mathfrak{m}_x$; for each $\mathscr{O}_X$-module $\mathscr{F}$, each open set U of X, each point $x \in U$, and each section $f \in \Gamma(U, \mathscr{F})$, we denote by $f(x)$ the *class* of the germ $f_x \in \mathscr{F}_x$ mod. $\mathfrak{m}_x\mathscr{F}_x$, and we say that this is the *value* of f at the point x. The relation $f(x) = 0$ then means that $f_x \in \mathfrak{m}_x\mathscr{F}_x$; when this is so, we say (by abuse of language) that f *is zero at* x. We will take care not to confuse this relation with $f_x = 0$.

(5.5.2). Let X be a locally ringed space, $\mathscr{L}$ an invertible $\mathscr{O}_X$-module, and f a section of $\mathscr{L}$ over X. There is then an *equivalence* between the three following properties for a point $x \in X$:

(a) *f_x is a generator of $\mathscr{L}_x$;*
(b) $f_x \notin \mathfrak{m}_x\mathscr{L}_x$ (in other words, $f(x) \neq 0$);
(c) *there exists a section g of $\mathscr{L}^{-1}$ over an open neighbourhood V of x such that the canonical image of $f \otimes g$ in $\Gamma(V, \mathscr{O}_X)$ (5.4.3) is the unit section.*

Indeed, since the questions is local, we can reduce to the case where $\mathscr{L} = \mathscr{O}_X$; the equivalence of (a) and (b) are then evident, and it is clear that (c) implies (b). Conversely, if $f_x \notin \mathfrak{m}_x$, then f_x is invertible in $\mathscr{O}_x$, say $f_x g_x = 1_x$. By definition of germs of sections, this means that there exists a neighbourhood V of x and a section g of $\mathscr{O}_X$ over V such that $fg = 1$ in V, hence (c).

It follows immediately from the condition (c) that the set X_f of x satisfying the equivalent conditions (a), (b), (c) is *open* in X; following the terminology introduced in (5.5.1), this is the set of the x for which f *does not vanish*.

(5.5.3). Under the hypotheses of (5.5.2), let $\mathscr{L}'$ be a second invertible $\mathscr{O}_X$-module; then, if $f \in \Gamma(X, \mathscr{L})$, $g \in \Gamma(X, \mathscr{L}')$, we have

$$X_f \cap X_g = X_{f\otimes g}.$$

We can in fact reduce immediately to the case where $\mathscr{L} = \mathscr{L}' = \mathscr{O}_X$ (since the questions is local); as $f \otimes g$ then canonically identifies with the product fg, the proposition is evident.

$\mathbf{0_I}$ | 54

(5.5.4). Let $\mathscr{F}$ be a locally free $\mathscr{O}_X$ of rank n; it is immediate that $\wedge^p \mathscr{F}$ is a locally free $\mathscr{O}_X$-module of rank $\binom{n}{p}$ if $p \leqslant n$ and 0 if $p > n$, since the question is local and we can reduce to the case where $\mathscr{F} = \mathscr{O}_X^n$; in addition, for each $x \in X$, $(\wedge^p \mathscr{F})_x/\mathfrak{m}_x(\wedge^p \mathscr{F})_x$ is a vector space of dimension $\binom{n}{p}$ over $k(x)$, which canonically identifies with $\wedge^p(\mathscr{F}_x/\mathfrak{m}_x\mathscr{F}_x)$. Let $s_1, \ldots, s_p$ be the sections of $\mathscr{F}$ over an open subset U of X, and let $s = s_1 \wedge \cdots \wedge s_p$, which is a section of $\wedge^p \mathscr{F}$ over U (4.1.5); we have $s(x) = s_1(x) \wedge \cdots \wedge s_p(x)$, and as a result, we say that the $s_1(x), \ldots, s_p(x)$ are *linearly dependent* means $s(x) = 0$. We conclude that the *set of the $x \in X$ such that $s_1(x), \ldots, s_p(x)$ are linearly independent is open in* X: it suffices in fact, by reducing to the case where $\mathscr{F} = \mathscr{O}_X^n$, to apply (5.5.2) to the section image of s under one of the projections of $\wedge^p \mathscr{F} = \mathscr{O}_X^{\binom{n}{p}}$ to the $\binom{n}{p}$ factors.

In particular, if $s_1, \ldots, s_n$ are n sections of $\mathscr{F}$ over U such that $s_1(x), \ldots, s_n(x)$ are linearly independent for each point $x \in U$, then the homomorphism $u : \mathscr{O}_X^n|U \to \mathscr{F}|U$ defined by the s_i (5.1.1) is an *isomorphism*: indeed, we can restrict to the case where $\mathscr{F} = \mathscr{O}_X^n$ and where we canonically identify $\wedge^n \mathscr{F}$ and $\mathscr{O}_X$; $s = s_1 \wedge \cdots \wedge s_n$ is then an *invertible* section of $\mathscr{O}_X$ over U, and we define an inverse homomorphism for u by means of the Cramer formulas.

(5.5.5). Let $\mathscr{E}$ and $\mathscr{F}$ be two locally free $\mathscr{O}_X$-modules (of finite rank), and let $u : \mathscr{E} \to \mathscr{F}$ be a homomorphism. For there to exist a neighbourhood U of $x \in X$ such that $u|U$ is *injective* and that $\mathscr{F}|U$ is *the direct sum of the* $u(\mathscr{E})|U$ *and of a locally free* $(\mathscr{O}_X|U)$*-submodule* $\mathscr{G}$, it is necessary and sufficient that $u_x : \mathscr{E}_x \to \mathscr{F}_x$ gives, by passing to quotients, an *injective* homomorphism of vector spaces $\mathscr{E}_x/\mathfrak{m}_x\mathscr{E}_x \to \mathscr{F}_x/\mathfrak{m}_x\mathscr{F}_x$. The condition is indeed *necessary*, since $\mathscr{F}_x$ is then the direct sum of the free $\mathscr{O}_x$-modules $u_x(\mathscr{E}_x)$ and $\mathscr{G}_x$, so $\mathscr{F}_x/\mathfrak{m}_x\mathscr{F}_x$ is the direct sum of $u_x(\mathscr{E}_x)/\mathfrak{m}_x u_x(\mathscr{E}_x)$ and of $\mathscr{G}_x/\mathfrak{m}_x\mathscr{G}_x$. The condition is *sufficient*, since we can reduce to the case where $\mathscr{E} = \mathscr{O}_X^m$; let $s_1, \ldots, s_m$ be the images under u of the sections e_i of $\mathscr{O}_X^m$ such that $(e_i)_y$ is equal to the i-th element of the canonical basis of $\mathscr{O}_y^m$ for each $y \in Y$ (*canonical sections* of $\mathscr{O}_X^m$); by hypothesis, the $s_1(x), \ldots, s_m(x)$ are linearly independent, so if $\mathscr{F}$ is of rank n, then there exist $n - m$ sections $s_{m+1}, \ldots, s_n$ of $\mathscr{F}$ over a neighbourhood V of x such that the $s_i(x)$ $(1 \leqslant i \leqslant n)$ form a basis for $\mathscr{F}_x/\mathfrak{m}_x\mathscr{F}_x$. There then exists (5.5.4) a neighbourhood $U \subset V$ of x such that the $s_i(y)$ $(1 \leqslant i \leqslant n)$ form a basis for $\mathscr{F}_y/\mathfrak{m}_y\mathscr{F}_y$ for each $y \in V$, and we conclude (5.5.4) that there is an isomorphism from $\mathscr{F}|U$ to $\mathscr{O}_X^n|U$, sending the $s_i|U$ $(1 \leqslant i \leqslant m)$ to the $e_i|U$, which finishes the proof.

§6. Flatness

(6.0). The notion of flatness is due to J.-P. Serre [Ser56]; in the following, we omit the proofs of the results which are presented in the *Algèbre commutative* of N. Bourbaki, to which we refer the reader. We assume that all rings are commutative.[10]

If M, N are two A-modules, M' (resp. N') a submodule of M (resp. N), we denote by $\mathrm{Im}(M' \otimes_A$ **0_I | 55**
$N')$ the submodule of $M \otimes_A N$, the image under the canonical map $M' \otimes_A N' \to M \otimes_A N$.

6.1. Flat modules

(6.1.1). Let M be an A-module. The following conditions are equivalent:

(a) The functor $M \otimes_A N$ is exact in N on the category of A-modules;
(b) $\mathrm{Tor}_i^A(M, N) = 0$ for each $i > 0$ and for each A-module N;
(c) $\mathrm{Tor}_1^A(M, N) = 0$ for each A-module N.

When M satisfies these conditions, we say that M is a *flat* A*-module*. It is clear that each free A-module is flat.

For M to be a flat A-module, it suffices that for each ideal $\mathfrak{J}$ of A, *of finite type*, the canonical map $M \otimes_A \mathfrak{J} \to M \otimes_A A = M$ is *injective*.

(6.1.2). Each inductive limit of flat A-modules is a flat A-module. For a direct sum $\bigoplus_{\lambda \in L} M_\lambda$ of A-modules to be a flat A-modules, it is necessary and sufficient that each of the A-modules M_λ is flat. In particular, every projective A-module is flat.

Let $0 \to M' \to M \to M'' \to 0$ be an exact sequence of A-modules, such that M'' is *flat*. Then, for each A-module N, the sequence

$$0 \longrightarrow M' \otimes_A N \longrightarrow M \otimes_A N \longrightarrow M'' \otimes_A N \longrightarrow 0$$

is exact. In addition, for M to be flat, is it necessary and sufficient that M' is (but it can be that M and M' are flat without $M'' = M/M'$ being so).

(6.1.3). Let M be a flat A-module, N any A-module; for two submodules N' N'' of N, we then have

$$\mathrm{Im}(M \otimes_A (N' + N'')) = \mathrm{Im}(M \otimes_A N') + \mathrm{Im}(M \otimes_A N''),$$

$$\mathrm{Im}(M \otimes_A (N' \cap N'')) = \mathrm{Im}(M \otimes_A N') \cap \mathrm{Im}(M \otimes_A N'')$$

(images taken in $M \otimes_A N$).

[10] See the exposé cited of N. Bourbaki for the generalization from most of the results to the noncommutative case.

(6.1.4). Let M and N be two A-modules, M' (resp. N') a submodule of M (resp. N), and suppose that one of the modules M/M', N/N' is flat. Then we have $\operatorname{Im}(M' \otimes_A N') = \operatorname{Im}(M' \otimes_A N) \cap (M \otimes_A N')$ (images in $M \otimes_A N$). In particular, if $\mathfrak{J}$ is an ideal of A and if M/M' is flat, then we have $\mathfrak{J}M' = M' \cap \mathfrak{J}M$.

6.2. Change of ring When an additive group M is equipped with multiple modules structures relative to the rings A, B, ..., we say that M is flat as an A-module, B-module, ..., we sometimes also say that M is *A-flat*, *B-flat*, ...

(6.2.1). Let A and B be two rings, M an A-module, N an (A, B)-bimodule. If M is flat and if N is B-flat, then $M \otimes_A N$ is B-flat. In particular, if M and N are two flat A-modules, then $M \otimes_A N$ is a flat A-module. If B is an A-algebra and if M is a flat A-module, then the B-module $M_{(B)} = M \otimes_A B$ $\mathbf{0_I}$ | 56
is flat. Finally, if B is an A-algebra which is flat as an A-module, and if N is a flat B-module, then N is also A-flat.

(6.2.2). Let A be a ring, B an A-algebra which is flat as an A-module. Let M, N be two A-modules, such that M admits a finite presentation; then the canonical homomorphism

$$\operatorname{Hom}_A(M, N) \otimes_A B \longrightarrow \operatorname{Hom}_B(M \otimes_A B, N \otimes_A B) \tag{6.2.2.1}$$

(sending $u \otimes b$ to the homomorphism $m \otimes b' \mapsto u(m) \otimes b'b$) is an isomorphism.

(6.2.3). Let $(A_\lambda, \phi_{\mu\lambda})$ be a filtered inductive system of rings; let $A = \varinjlim A_\lambda$. On the other hand, for each λ, let M_λ be an A_λ-module, and for $\lambda \leqslant \mu$ let $\theta_{\mu\lambda} : M_\lambda \to M_\mu$ be a $\phi_{\mu\lambda}$-homomorphism, such that $(M_\lambda, \theta_{\mu\lambda})$ is an inductive system; $M = \varinjlim M_\lambda$ is then an A-module. This being so, if for each λ, M_λ is a *flat* A_λ-module, then M is a *flat* A-module. Indeed, let $\mathfrak{J}$ be an ideal *of finite type* of A; by definition of the inductive limit, there exists an index λ and an ideal $\mathfrak{J}_\lambda$ of A_λ such that $\mathfrak{J} = \mathfrak{J}_\lambda A$. If we put $\mathfrak{J}'_\mu = \mathfrak{J}_\lambda A_\mu$ for $\mu \geqslant \lambda$, we also have $\mathfrak{J} = \varinjlim \mathfrak{J}'_\mu$ (where μ varies over the indices $\geqslant \lambda$), hence (the functor $\varinjlim$ being exact and commuting with tensor products)

$$M \otimes_A \mathfrak{J} = \varinjlim (M_\mu \otimes_{A_\mu} \mathfrak{J}'_\mu) = \varinjlim \mathfrak{J}'_\mu M_\mu = \mathfrak{J}M.$$

6.3. Local nature of flatness

(6.3.1). If A is a ring, S a multiplicative subset of A, $S^{-1}A$ is a *flat A-module*. Indeed, for each A-module N, $N \otimes_A S^{-1}A$ identifies with $S^{-1}N$ (1.2.5) and we know (1.3.2) that $S^{-1}N$ is an exact functor in N.

If now M is a flat A-module, $S^{-1}M = M \otimes_A S^{-1}A$ is a flat $S^{-1}A$-module (6.2.1), so it is also A-flat according to the above and from (6.2.1). In particular, if P is an $S^{-1}A$-module, we can consider it as an A-module isomorphic to $S^{-1}P$; for P to be A-flat, it is necessary and sufficient that it is $S^{-1}A$-flat.

(6.3.2). Let A be a ring, B an A-algebra, and T a multiplicative subset of B. If P is a B-module which is *A-flat*, $T^{-1}P$ is *A-flat*. Indeed, for each A-module N, we have $(T^{-1}P) \otimes_A N = (T^{-1}B \otimes_B P) \otimes_A N$ $= T^{-1}B \otimes_B (P \otimes_A N) = T^{-1}(P \otimes_A N)$; $T^{-1}(P \otimes_A N)$ is an exact functor in N, being the composition of the two exact functors $P \otimes_A N$ (in N) and $T^{-1}Q$ (in Q). If S is a multiplicative subset of A such that its image in B is *contained in* T, then $T^{-1}P$ is equal to $S^{-1}(T^{-1}P)$, so it is also $S^{-1}A$-flat according to (6.3.1).

(6.3.3). Let $\phi : A \to B$ be a ring homomorphism, M a B-module. The following properties are equivalent:

(a) M is a flat A-module.
(b) For each maximal ideal $\mathfrak{n}$ of B, $M_\mathfrak{n}$ is a flat A-module.
(c) For each maximal ideal $\mathfrak{n}$ of B, by setting $\mathfrak{m} = \phi^{-1}(\mathfrak{n})$, $M_\mathfrak{n}$ is a flat $A_\mathfrak{m}$-module.

Indeed, as $M_\mathfrak{n} = (M_\mathfrak{n})_\mathfrak{m}$, the equivalence of (b) and (c) follows from (6.3.1), and the fact that (a)
implies (b) is a particular case of (6.3.2). It remains to see that (b) implies (a), that is to say, that for $\mathbf{0_I}$ | 57
each injective homomorhism $u : N' \to N$ of A-modules, the homomorphism $v = 1 \otimes u : M \otimes_A N' \to M \otimes_A N$ is injective. We have that v is also a homomorphism of B-modules, and we know that for it to be injective, it suffices that for each maximal ideal $\mathfrak{n}$ of B, $v_\mathfrak{n} : (M \otimes_A N')_\mathfrak{n} \to (M \otimes_A N)_\mathfrak{n}$ is injective. But as

$$(M \otimes_A N)_\mathfrak{n} = B_\mathfrak{n} \otimes_B (M \otimes_A N) = M_\mathfrak{n} \otimes_A N,$$

$v_{\mathfrak{n}}$ is none other that the homomorphism $1 \otimes u : M_{\mathfrak{n}} \otimes_A N' \to M_{\mathfrak{n}} \otimes_A N$, which is injective since $M_{\mathfrak{n}}$ is A-flat.

In particular (by taking $B = A$), for an A-module M to be flat, it is necessary and sufficient that $M_{\mathfrak{m}}$ is $A_{\mathfrak{m}}$-flat for each maximal ideal $\mathfrak{m}$ of A.

(6.3.4). Let M be an A-module; if M is flat, and if $f \in A$ does not divide 0 in A, f does not kill any element $\neq 0$ in M, since the homomorphism $m \mapsto f \cdot m$ is expressed as $1 \otimes u$, where u is the multiplication $a \mapsto f \cdot a$ on A and M is identified with $M \otimes_A A$; if u is injective, it is the same for $1 \otimes u$ since M is flat. In particular, if A is *integral*, M is *torsion-free*.

Conversely, suppose that A is integral, M is torsion-free, and suppose that for each maximal ideal $\mathfrak{m}$ of A, $A_{\mathfrak{m}}$ is a *discrete valuation ring*; then M is *A-flat*. Indeed, it suffices (6.3.3) to prove that $M_{\mathfrak{m}}$ is $A_{\mathfrak{m}}$-flat, and we can therefore suppose that A is already a discrete valuation ring. But as M is the inductive limit of its submodules of finite type, and these latter submodules are torsion-free, we can in addition reduce to the case where M is of finite type (6.1.2). The proposition follows in this case from that M is a free A-module.

In particular, if A is an *integral* ring, $\phi : A \to B$ a ring homomorphism making B a *flat* A-module and $\neq \{0\}$, ϕ is necessarily *injective*. Conversely, if B is integral, A a subring of B, and if for each maximal ideal $\mathfrak{m}$ of A, $A_{\mathfrak{m}}$ is a discrete valuation ring, then B is *A-flat*.

6.4. Faithfully flat modules

(6.4.1). For an A-module M, the following four properties are equivalent:

(a) For a sequence $N' \to N \to N''$ of A-modules to be exact, it is necessary and sufficient that the sequence $M \otimes_A N' \to M \otimes_A N \to M \otimes_A N''$ is exact;
(b) M is flat for each A-module N, the relation $M \otimes_A N = 0$ implies $N = 0$;
(c) M is flat for each homomorphism $v : N \to N'$ of A-modules, the relation $1_M \otimes v = 0$, 1_M being the identity automorphism of M;
(d) M is flat for each maximal ideal $\mathfrak{m}$ of A, $\mathfrak{m}M \neq M$.

When M satisfies these conditions, we say that M is a *faithfully flat* A-module; M is then necessarily a *faithful* module. In addition, if $u : N \to N'$ is a homomorphism of A-modules, then for u to be injective (resp. surjective, bijective), it is necessary and sufficient that $1 \otimes u : M \otimes_A N \to M \otimes_A N'$ is so.

$\mathbf{0_I}$ | 58

(6.4.2). A free module $\neq \{0\}$ is faithfully flat; it is the same for the direct sum of a flat module and a faithfully flat module. If S is a multiplicative subset of A, then $S^{-1}A$ is a faithfully flat A-module if S consists of invertible elements (so $S^{-1}A = A$).

(6.4.3). Let $0 \to M' \to M \to M'' \to 0$ be an exact sequence of A-modules; if M' and M'' are flat, and if one of the two is faithfully flat, then M is also faithfully flat.

(6.4.4). Let A and B be two rings, M an A-module, N an (A, B)-bimodule. If M is faithfully flat and if N is a faithfully flat B-module, then $M \otimes_A N$ is a faithfully flat B-module. In particular, if M and N are two faithfully flat A-modules, then so is $M \otimes_A N$. If B is an A-algebra and if M is a faithfully flat A-module, the B-module $M_{(B)}$ is faithfully flat.

(6.4.5). If M is a faithfully flat A-modules and if S is a multiplicative subset of A, $S^{-1}M$ is a faithfully flat $S^{-1}A$-module, since $S^{-1}M = M \otimes_A (S^{-1}A)$ (6.4.4). Conversely, if for each maximal ideal $\mathfrak{m}$ of A, $M_{\mathfrak{m}}$ is a faithfully flat $A_{\mathfrak{m}}$-module, then M is a faithfully flat A-module, since M is A-flat (6.3.3), and we have

$$M_{\mathfrak{m}}/\mathfrak{m}M_{\mathfrak{m}} = (M \otimes_A A_{\mathfrak{m}}) \otimes_{A_{\mathfrak{m}}} (A_{\mathfrak{m}}/\mathfrak{m}A_{\mathfrak{m}}) = M \otimes_A (A/\mathfrak{m}) = M/\mathfrak{m}M,$$

so the hypotheses imply that $M/\mathfrak{m}M \neq 0$ for each maximal ideal $\mathfrak{m}$ of A, which proves our assertion (6.4.1).

6.5. Restriction of scalars

(6.5.1). Let A be a ring, $\phi : A \to B$ a ring homomorphism making B an A-algebra. Suppose that there exists a B-module N which is a *faithfully flat* A-module. Then, for each A-module M, the homomorphism $x \mapsto 1 \otimes x$ from M to $B \otimes_A M = M_{(B)}$ is *injective*. In particular, ϕ is injective; for each ideal $\mathfrak{a}$ of A, we have $\phi^{-1}(\mathfrak{a}B) = \mathfrak{a}$; for each maximal (resp. prime) ideal $\mathfrak{m}$ of A, there exists a maximal (resp. prime) ideal $\mathfrak{n}$ of B such that $\phi^{-1}(\mathfrak{n}) = \mathfrak{m}$.

(6.5.2). When the conditions of (6.5.1) are satisfied, we identify A with the subring of B by ϕ and more generally, for each A-module M, we identify M with an A-submodule of $M_{(B)}$. We note that if B is also *Noetherian*, then so is A, since the map $\mathfrak{a} \mapsto \mathfrak{a}B$ is an increasing injection from the set of ideals of A to the set of ideals of B; the existence of an infinite strictly increasing sequence of ideals of A thus implies the existence of an analogous sequence of ideals of B.

6.6. Faithfully flat rings

(6.6.1). Let $\phi : A \to B$ be a ring homomorphism making B an A-algebra. The following five properties are equivalent:

(a) B is a faithfully flat A-module (in other words, $M_{(B)}$ is an *exact* and *faithful* functor in M).
(b) The homomorphism ϕ is injective and the A-module $B/\phi(A)$ is flat. $\mathbf{0_I}$ | 59
(c) The A-module B is flat (in other words, the functor $M_{(B)}$ is *exact*), and for each A-module M. the homomorphism $x \mapsto 1 \otimes x$ from M to $M_{(B)}$ is injective.
(d) The A-module B is flat and for each ideal $\mathfrak{a}$ of A, we have $\phi^{-1}(\mathfrak{a}B) = \mathfrak{a}$.
(e) The A-module B is flat and for each maximal ideal $\mathfrak{m}$ of A, there exists a maximal ideal $\mathfrak{n}$ of B such that $\phi^{-1}(\mathfrak{n}) = \mathfrak{m}$.

When these conditions are satisfied, we identify A with a subring of B.

(6.6.2). Let A be a *local* ring, $\mathfrak{m}$ its maximal ideal, and B an A-algebra such that $\mathfrak{m}B \neq B$ (which is so when for example B is a local ring and $A \to B$ is a *local* homomorphism). If B is a *flat* A-module, B is a *faithfully flat* A-module. Indeed, this follows from (6.4.1, (d)). Under the indicated conditions, we thus see that if B is Noetherian, then so too is A (6.5.2). $\mathbf{Err_{II}}$

(6.6.3). Let B be an A-algebra which is a faithfully flat A-module. For each A-module M and each A-submodule M' of M, we have (by identifying M with an A-submodule of $M_{(B)}$) $M' = M \cap M'_{(B)}$. For M to be a flat (resp. faithfully flat) A-module, it is necessary and sufficient that $M_{(B)}$ is a flat (resp. faithfully flat) B-module.

(6.6.4). Let B be an A-algebra, N a faithfully flat B-module. For B to be a flat (resp. faithfully flat) A-module, it is necessary and sufficient that N is.

In particular, let C be a B-algebra; if the ring C is faithfully flat over B and B is faithfully flat over A, then C is faithfully flat over A; if C is faithfully flat over B and over A, then B is faithfully flat over A.

6.7. Flat morphisms of ringed spaces

(6.7.1). Let $f : X \to Y$ be a morphism of ringed spaces, and let $\mathscr{F}$ be an $\mathscr{O}_X$-module. We say that $\mathscr{F}$ is *f-flat* (or *Y-flat* when there is no chance of confusion with f) *at a point* $x \in X$ if $\mathscr{F}_x$ is a flat $\mathscr{O}_{f(x)}$-module; we say that $\mathscr{F}$ is *f-flat over* $y \in Y$ if $\mathscr{F}$ is f-flat for all the points $x \in f^{-1}(y)$; we say that $\mathscr{F}$ is *f-flat* if $\mathscr{F}$ is f-flat at all the points of X. We say that the morphism f is *flat at* $x \in X$ (resp. *flat over* $y \in Y$, resp. *flat*) if $\mathscr{O}_X$ is f-flat at x (resp. f-flat over y, resp. f-flat). If f is a flat morphism, we then say that X is *flat over* Y, or *Y-flat*. $\mathbf{Err_{II}}$

(6.7.2). With the notation of (6.7.1), if $\mathscr{F}$ is f-flat at x, for each open neighbourhood U of $y = f(x)$, the functor $(f^*(\mathscr{G}) \otimes_{\mathscr{O}_X} \mathscr{F})_x$ in $\mathscr{G}$ is *exact* on the category of $(\mathscr{O}_Y|U)$-modules; indeed, this stalk canonically identifies with $\mathscr{G}_y \otimes_{\mathscr{O}_y} \mathscr{F}_x$, and our assertion follows from the definition. In particular, if f is a *flat* morphism, the functor f^* is *exact* on the category of $\mathscr{O}_Y$-modules.

(6.7.3). Conversely, suppose the sheaf of rings $\mathscr{O}_Y$ is *coherent*, and suppose that for *each* open neighbourhood U of y, the functor $(f^*(\mathscr{G}) \otimes_{\mathscr{O}_X} \mathscr{F})_x$ is exact in $\mathscr{G}$ on the category of *coherent* $(\mathscr{O}_Y|U)$-modules. Then $\mathscr{F}$ is *f-flat at* x. In fact, it suffices to prove that for each ideal of finite type $\mathfrak{J}$ of $\mathscr{O}_y$,

the canonical homomorphism $\mathfrak{J} \otimes_{\mathscr{O}_y} \mathscr{F}_x \to \mathscr{F}_x$ is injective (6.1.1). We know (5.3.8) that there then exists an open neighbourhood U of y and a coherent sheaf of ideals $\mathscr{J}$ of $\mathscr{O}_Y|U$ such that $\mathscr{J}_y = \mathfrak{J}$, $\mathbf{0_I}$ | 60
hence the conclusion.

(6.7.4). The results of (6.1) for flat modules are immediately translated into propositions for sheaves with are f-flat at a point:

If $0 \to \mathscr{F}' \to \mathscr{F} \to \mathscr{F}'' \to 0$ is an exact sequence of $\mathscr{O}_X$-modules and if $\mathscr{F}''$ is f-flat at a point $x \in X$, then, for each open neighbourhood U of $y = f(x)$ and each $(\mathscr{O}_Y|U)$-module $\mathscr{G}$, the sequence

$$0 \longrightarrow (f^*(\mathscr{G}) \otimes_{\mathscr{O}_X} \mathscr{F}')_x \longrightarrow (f^*(\mathscr{G}) \otimes_{\mathscr{O}_X} \mathscr{F})_x \longrightarrow (f^*(\mathscr{G}) \otimes_{\mathscr{O}_X} \mathscr{F}'')_x \longrightarrow 0$$

is exact. For $\mathscr{F}$ to be f-flat at x, it is necessary and sufficient that $\mathscr{F}'$ is. We have similar statements for the corresponding notions of a f-flat $\mathscr{O}_X$-modules over $y \in Y$, or of a f-flat $\mathscr{O}_X$-module.

(6.7.5). Let $f : X \to Y$, $g : Y \to Z$ be two morphisms of ringed spaces; let $x \in X$, $y = f(x)$, and $\mathscr{F}$ be an $\mathscr{O}_X$-module. If $\mathscr{F}$ is f-flat at the point x and if the morphism g is flat at the point y, then $\mathscr{F}$ is $(g \circ f)$-flat at x (6.2.1). In particular, if f and g are flat morphisms, then $g \circ f$ is flat.

(6.7.6). Let X, Y be two ringed spaces, $f : X \to Y$ a *flat* morphism. Then the canonical homomorphism of bifunctors (4.4.6)

(6.7.6.1) $$f^*(\mathscr{H}om_{\mathscr{O}_Y}(\mathscr{F},\mathscr{G})) \longrightarrow \mathscr{H}om_{\mathscr{O}_X}(f^*(\mathscr{F}), f^*(\mathscr{G}))$$

is an *isomorphism* when $\mathscr{F}$ admits a *finite presentation* (5.2.5).

Indeed, since the questions is local, we can assume that there exists an exact sequence $\mathscr{O}_Y^m \to \mathscr{O}_Y^n \to \mathscr{F} \to 0$. The two sides of (6.7.6.1) are right exact functors in $\mathscr{F}$ according to the hypotheses on f; we then have reduced to proving the proposition in the case where $\mathscr{F} = \mathscr{O}_Y$, in which the result is trivial.

(6.7.8). We say that a morphism $f : X \to Y$ of ringed spaces is *faithfully flat* if f is *surjective* and if, for each $x \in X$, $\mathscr{O}_x$ is a *faithfully flat* $\mathscr{O}_{f(x)}$-module. When X and Y are locally ringed spaces (5.5.1), it is equivalent to say that the morphism f is *surjective* and *flat* (6.6.2). When f is faithfully flat, f^* is an *exact* and *faithful* functor on the category of $\mathscr{O}_Y$-modules (6.6.1, a), and for an $\mathscr{O}_Y$-module $\mathscr{G}$ to be Y-flat, it is necessary and sufficient that $f^*(\mathscr{G})$ is (6.6.3).

§7. Adic rings

7.1. Admissible rings

(7.1.1). Recall that in a topological ring A (not necessarily separated), we say that an element x is *topologically nilpotent* if 0 is *a* limit of the sequence $(x^n)_{n\geqslant 0}$. We say that a topological ring A is *linearly topologized* if there exists a fundamental system of neighbourhoods of 0 in A of (necessarily *open*) *ideals*.

Definition (7.1.2). — In a linearly topologized ring A, we say that an ideal $\mathfrak{J}$ is an *ideal of definition* if $\mathfrak{J}$ is open and if, for each neighbourhood V of 0, there exists a integer $n > 0$ such that $\mathfrak{J}^n \subset V$ $\mathbf{0_I}$ | 61
(which we express, by abuse of language, by saying that the sequence $(\mathfrak{J}^n)$ tends to 0*).* We say that a linearly topologized ring A is *preadmissible* if there exists in A an ideal of definition; we say that A is *admissible* if it is preadmissible and if in addition it is separated and complete.

It is clear that if $\mathfrak{J}$ is an ideal of definition, $\mathfrak{L}$ an open ideal of A, then $\mathfrak{J} \cap \mathfrak{L}$ is also an ideal of definition; the ideals of definition of a preadmissible ring A thus form a *fundamental system of neighbourhoods of* 0.

Lemma (7.1.3). — *Let A be a linearly topologized ring.*

(i) *For $x \in A$ to be topologically nilpotent, it is necessary and sufficient that for each open ideal $\mathfrak{J}$ of A, the canonical image of x in $A/\mathfrak{J}$ is nilpotent. The set $\mathfrak{T}$ of topologically nilpotent elements of A is an ideal.*
(ii) *Suppose that in addition A is preadmissible, and let $\mathfrak{J}$ be an ideal of definition for A. For $x \in A$ to be topologically nilpotent, it is necessary and sufficient that its canonical image in $A/\mathfrak{J}$ is nilpotent; the ideal $\mathfrak{T}$ is the inverse image of the nilradical of $A/\mathfrak{J}$ and is thus open.*

Proof. (i) follows immediately from the definitions. To prove (ii), it suffices to note that for each neighbourhood V of 0 in A, there exists an $n > 0$ such that $\mathfrak{J}^n \subset V$; if $x \in A$ is such that $x^m \in \mathfrak{J}$, we have $x^{mq} \in V$ for $q \geqslant n$, so x is topologically nilpotent. □

Proposition (7.1.4). — *Let A be a preadmissible ring, $\mathfrak{J}$ an ideal of definition for A.*

(i) *For an ideal $\mathfrak{J}'$ of A to be contained in an ideal of definition, it is necessary and sufficient that there exists an integer $n > 0$ such that $\mathfrak{J}'^n \subset \mathfrak{J}$.*
(ii) *For an $x \in A$ to be contained in an ideal of definition, it is necessary and sufficient that it is topologically nilpotent.*

Proof.

(i) If $\mathfrak{J}'^n \subset \mathfrak{J}$, then for each open neighbourhood V of 0 in A, there exists an m such that $\mathfrak{J}^m \subset V$, thus $\mathfrak{J}'^{mn} \subset V$.
(ii) The condition is evidently necessary; it is sufficient, since if it satisfied, then there exists an n such that $x^n \in \mathfrak{J}$, so $\mathfrak{J}' = \mathfrak{J} + Ax$ is an ideal of definition, because it is open, and $\mathfrak{J}'^n \subset \mathfrak{J}$.

□

Corollary (7.1.5). — *In a preadmissible ring A, an open prime ideal contains all the ideals of definition.*

Corollary (7.1.6). — *The notation and hypotheses being that of (7.1.4), the following properties of an ideal $\mathfrak{J}_0$ of A are equivalent:*

(a) *$\mathfrak{J}_0$ is the largest ideal of definition of A;*
(b) *$\mathfrak{J}_0$ is a maximal ideal of definition;*
(c) *$\mathfrak{J}_0$ is an ideal of definition such that the ring $A/\mathfrak{J}_0$ is reduced.*

For there to exist an ideal $\mathfrak{J}_0$ to have these properties, it is necessary and sufficient that the nilradical of $A/\mathfrak{J}$ to be nilpotent; $\mathfrak{J}_0$ is then equal to the ideal $\mathfrak{T}$ of topologically nilpotent elements of A.

Proof. It is clear that (a) implies (b), and (b) implies (c) according to (7.1.4, ii), and (7.1.3, ii); for the same reason, (c) implies (a). The latter assertion follows from (7.1.4, i) and (7.1.3, ii). □

When $\mathfrak{T}/\mathfrak{J}$, the nilradical of $A/\mathfrak{J}$, is nilpotent, and we denote by A_{red} the (reduced) quotient ring $A/\mathfrak{T}$.

$\mathbf{0_I}$ | 62

Corollary (7.1.7). — *A preadmissible Noetherian ring admits a largest ideal of definition.*

Corollary (7.1.8). — *If a preadmissible ring A is such that, for an ideal of definition $\mathfrak{J}$, the powers $\mathfrak{J}^n$ ($n > 0$) form a fundamental system of neighbourhoods of 0, it is the same for the powers $\mathfrak{J}'^n$ for each ideal of definition $\mathfrak{J}'$ of A.*

Definition (7.1.9). — We say that a preadmissible ring A is *preadic* if there exists an ideal of definition $\mathfrak{J}$ for A such that the $\mathfrak{J}^n$ form a fundamental system of neighbourhoods of 0 in A *(or equivalently, such that the $\mathfrak{J}^n$ are* open*)*. We call a ring *adic* if it is a separated and complete preadic ring.

If $\mathfrak{J}$ is an ideal of definition for a preadic (resp. adic) ring A, we say that A is a $\mathfrak{J}$-*preadic* (resp. $\mathfrak{J}$-*adic*) ring, and that its topology is the $\mathfrak{J}$-*preadic* (resp. $\mathfrak{J}$-*adic*) topology. More generally, if M is an A-module, the topology on M having for a fundamental system of neighbourhoods of 0 the submodules $\mathfrak{J}^n M$ is called the $\mathfrak{J}$-*preadic* (resp. $\mathfrak{J}$-*adic*) topology. According to (7.1.8), these topologies are independent of the choice of the ideal of definition $\mathfrak{J}$.

Proposition (7.1.10). — *Let A be an admissible ring, $\mathfrak{J}$ an ideal of definition for A. Then $\mathfrak{J}$ is contained in the radical of A.*

This statement is equivalent to any of the following corollaries:

Corollary (7.1.11). — *For each $x \in \mathfrak{J}$, $1 + x$ is invertible in A.*

Corollary (7.1.12). — *For $f \in A$ to be invertible in A, it is necessary and sufficient that its canonical image in $A/\mathfrak{J}$ is invertible in $A/\mathfrak{J}$.*

Corollary (7.1.13). — *For each A-module M of finite type, the relation $M = \mathfrak{J}M$ (equivalent to $M \otimes_A (A/\mathfrak{J}) = 0$) implies that $M = 0$.*

Corollary (7.1.14). — *Let $u : M \to N$ be a homomorphism of A-modules, N being of finite type; for u to be surjective, it is necessary and sufficient that $u \otimes 1 : M \otimes_A (A/\mathfrak{J}) \to N \otimes_A (A/\mathfrak{J})$ is.*

Proof. The equivalence of (7.1.10) and (7.1.11) follows from Bourbaki, *Alg.*, chap. VIII, §6, no. 3, th. 1, and the equivalence of (7.1.10) and (7.1.10) and (7.1.13) follows from *loc. cit.*, th. 2; the fact that (7.1.10) implies (7.1.14) follows from *loc. cit.*, cor. 4 of the prop. 6; on the other hand, (7.1.14) implies (7.1.13) by applying the zero homomorphism. Finally, (7.1.10) implies that if f is invertible in $A/\mathfrak{J}$, then f is not contained in any maximal ideal of A, thus f is invertible in A, in other words, (7.1.10) implies (7.1.12); conversely, (7.1.12) implies (7.1.11).

It therefore remains to prove (7.1.11). Now as A is separated and complete, and the sequence $(\mathfrak{J}^n)$ tends to 0, it is immediate that the series $\sum_{n=0}^{\infty}(-1)^n x^n$ is convergent in A, and that if y is its sum, then we have $y(1+x) = 1$. □

7.2. Adic rings and projective limits

(7.2.1). Each projective limit of *discrete* rings is evidently a linearly topologized ring, separated and compact. Conversely, let A be a linearly topologized ring, and let $(\mathfrak{J}_\lambda)$ be a fundamental system of open neighbourhoods of 0 in A consisting of ideals. The canonical maps $\phi_\lambda : A \to A/\mathfrak{J}_\lambda$ form a projective system of continuous representations and therefore define a continuous representation $\phi : A \to \varprojlim A/\mathfrak{J}_\lambda$; if A is *separated*, then ϕ is a topological isomorphism from A to an everywhere-dense subring of $\varprojlim A/\mathfrak{J}_\lambda$; if in addition A is *complete*, then ϕ is a topological isomorphism from A to $\varprojlim A/\mathfrak{J}_\lambda$. $\mathbf{0_I}$ | 63

Lemma (7.2.2). — *For a linearly topologized ring to be admissible, it is necessary and sufficient that it is isomorphic to a projective limit $A = \varprojlim A_\lambda$, where $(A_\lambda, \mu_{\lambda\mu})$ is a projective limit of discrete rings having for the set of indices a filtered ordered (by $\leqslant$) L which admits a smallest element denoted 0 and satisfies the following conditions: 1st. the $u_\lambda : A \to A_\lambda$ are sujective; 2nd. the kernel $\mathfrak{J}_\lambda$ of $u_{0\lambda} : A_\lambda \to A_0$ is nilpotent. When this is so, the kernel $\mathfrak{J}$ of $u_0 : A \to A_0$ is equal to $\varprojlim \mathfrak{J}_\lambda$.*

Proof. The necessity of the condition follows from (7.2.1), by choosing $(\mathfrak{J}_\lambda)$ to be a fundamental system of neighbourhoods of 0 consisting of ideals of definitions contained in an ideal of definition $\mathfrak{J}_0$ and by applying (7.1.4, i). The converse follows from the definition of the projective limit and from (7.2.1), and the latter assertion is immediate. □

(7.2.3). Let A be an *admissible* topological ring, $\mathfrak{J}$ an ideal of A contained in an ideal of definition (in other words (7.1.4) such that $(\mathfrak{J}^n)$ tends to 0); we can consider on A the ring topology having for a fundamental system of neighbourhoods of 0 the powers $\mathfrak{J}^n$ $(n > 0)$; we call again this the $\mathfrak{J}$-*preadic* topology. The hypothesis that A is admissible implies that $\bigcup_n \mathfrak{J}^n = 0$, therefore the $\mathfrak{J}$-preadic topology on A is *separated*; let $\widehat{A} = \varprojlim A/\mathfrak{J}^n$ be the completion of A for this topology (where the $A/\mathfrak{J}^n$ are equipped with the discrete topology), and denote by u the (not necessarily continuous) ring homomorphism $A \to \widehat{A}$, the projective limit of the sequence of homomorphisms $u_n : A \to A/\mathfrak{J}^n$. On the other hand, the $\mathfrak{J}$-preadic topology on A is finer than the given topology $\mathscr{T}$ on A; as A is separated and complete for $\mathscr{T}$, we can extend by continuity the identity map of A (equipped with the $\mathfrak{J}$-preadic topology) to A equipped with $\mathscr{T}$; this gives a continuous representation $v : \widehat{A} \to A$.

Proposition (7.2.4). — *If A is an admissible ring and $\mathfrak{J}$ is contained in an ideal of definition of A, then A is separated and complete for the $\mathfrak{J}$-preadic topology.*

Proof. With the notation of (7.2.3), it is immediate that $v \circ u$ is the identity map of A. On the other hand, $u_n \circ v : \widehat{A} \to A/\mathfrak{J}^n$ is the extension by continuity (for the $\mathfrak{J}$-preadic topology on A and the discrete topology on $A/\mathfrak{J}^n$) of the canonical map u_n; in other words, it is the canonical map from $\widehat{A} = \varprojlim_k A/\mathfrak{J}^k$ to $A/\mathfrak{J}^n$; $u \circ v$ is therefore the projective limit of this sequence of maps, which is by definition the identity map of $\widehat{A}$; this proves the proposition. □

Corollary (7.2.5). — *Under the hypotheses of (7.2.3), the following conditions are equivalent:*

(a) *the homomorphism u is continuous;* $\mathbf{0_I}$ | 64
(b) *the homomorphism v is bicontinous;*
(c) *A is a $\mathfrak{J}$-adic ring.*

Corollary (7.2.6). — *Let A be an admissible ring A, $\mathfrak{J}$ an ideal of definition for A. For A to be Noetherian, it is necessary and sufficient for $A/\mathfrak{J}$ to be Noetherian and for $\mathfrak{J}/\mathfrak{J}^2$ to be an $A/\mathfrak{J}$-module of finite type.*

These conditions are evidently necessary. Conversely, suppose the conditions are satisfied; as according to (7.2.4) A is complete for the $\mathfrak{J}$-preadic topology, for it to be Noetherian, it is necessary and sufficient that the associated graded ring $\operatorname{grad}(A)$ (for the filtration on the $\mathfrak{J}^n$) is ([CC, p .18–07, th. 4]). Now, let $a_1, \ldots, a_n$ be the elements of $\mathfrak{J}$ whose classes mod. $\mathfrak{J}^2$ are the generators of $\mathfrak{J}/\mathfrak{J}^2$ as a $A/\mathfrak{J}$-module. It is immediate by induction that the classes mod. $\mathfrak{J}^{m+1}$ of the monomials of total degree m in the a_i ($1 \leqslant i \leqslant n$) form a system of generators for the $A/\mathfrak{J}$-module $\mathfrak{J}^m/\mathfrak{J}^{m+1}$. We conclude that $\operatorname{grad}(A)$ is a ring isomorphic to a quotient of $(A/\mathfrak{J})[T_1, \ldots, T_n]$ (T_i indeterminates), which finishes the proof.

Proposition (7.2.7). — *Let (A_i, u_{ij}) be a projective system ($i \in \mathbf{N}$) of discrete rings, and for each integer i, let $\mathfrak{J}_i$ be the kernel in A_i of the homomorphism $u_{0i} : A_i \to A_0$. We suppose that:*

(a) *For $i \leqslant j$, u_{ij} is surjective and its kernel is $\mathfrak{J}_j^{i+1}$* (therefore A_i is isomorphic to $A_j/\mathfrak{J}_j^{i+1}$).

(b) *$\mathfrak{J}_1/\mathfrak{J}_1^2$ ($= \mathfrak{J}_1$) is a module of finite type over $A_0 = A_1/\mathfrak{J}_1$.*

Let $A = \varprojlim_i A_i$, and for each integer $n \geqslant 0$, let u_n be the canonical homomorphism $A \to A_n$, and let $\mathfrak{J}^{(n+1)} \subset A$ be its kernel. Then we have these conditions:

(i) *A is an adic ring, having $\mathfrak{J} = \mathfrak{J}^{(1)}$ for an ideal of definition.*

(ii) *We have $\mathfrak{J}^{(n)} = \mathfrak{J}^n$ for each $n \geqslant 1$.*

(iii) *$\mathfrak{J}/\mathfrak{J}^2$ is isomorphic to $\mathfrak{J}_1 = \mathfrak{J}_1/\mathfrak{J}_1^2$, and as a result is a module of finite type over $A_0 = A/\mathfrak{J}$.*

Proof. The hypothesis of surjectivity on the u_{ij} implies that u_n is surjective; in addition, the hypothesis (a) implies that $\mathfrak{J}_j^{j+1} = 0$, therefore A is an admissible ring (7.2.2); by definition, the $\mathfrak{J}^{(n)}$ form a fundamental system of neighbourhoods of 0 in A, so (ii) implies (i). In addition, we have $\mathfrak{J} = \varprojlim_i \mathfrak{J}_i$ and the maps $\mathfrak{J} \to \mathfrak{J}_i$ are surjective, so (ii) implies (iii), and it remains to prove (ii). By definition, $\mathfrak{J}^{(n)}$ consists of the elements $(x_k)_{k \geqslant 0}$ of A such that $x_k = 0$ for $k < n$, therefore $\mathfrak{J}^{(n)}\mathfrak{J}^{(m)} \subset \mathfrak{J}^{(n+m)}$, in other words the $\mathfrak{J}^{(n)}$ form a *filtration* of A. On the other hand, $\mathfrak{J}^{(n)}/\mathfrak{J}^{(n+1)}$ is isomorphic to the projection from $\mathfrak{J}^{(n)}$ to A_n; as $\mathfrak{J}^{(n)} = \varprojlim_{i>n} \mathfrak{J}_i^n$, this projection is none other than $\mathfrak{J}_n^n$, which is a module over $A_0 = A_n/\mathfrak{J}_n$. Now let $a_j = (a_{jk})_{k \geqslant 0}$ be r elements of $\mathfrak{J} = \mathfrak{J}^{(1)}$ such that $a_{11}, \ldots, a_{r1}$ form a system of generators for $\mathfrak{J}_1$ over A_0; we will see that the set S_n of monomials of total degree n and the a_j generate the ideal $\mathfrak{J}^{(n)}$ of A. As $\mathfrak{J}_i^{i+1} = 0$, it is clear first of all that $S_n \subset \mathfrak{J}^{(n)}$; since A is complete for the filtration $(\mathfrak{J}^{(m)})$, it suffices to prove that the set $\overline{S}_n$ of classes mod. $\mathfrak{J}^{(n+1)}$ of elements of S_n generate the graded module $\operatorname{grad}(\mathfrak{J}^{(n)})$ over the graded ring $\operatorname{grad}(A)$ for the above filtration ([CC, p. 18–06, lemme]); according to the definition of the multiplication on $\operatorname{grad}(A)$, it suffices to prove $\mathbf{0_I}$ | 65
that for each m, $\overline{S}_m$ is a system of generators for the A_0-module $\mathfrak{J}^{(m)}/\mathfrak{J}^{(m+1)}$, or that $\mathfrak{J}_m^m$ is generated by the monomials of degree m in the a_{jm} ($1 \leqslant j \leqslant r$). For this, it remains to show that $\mathfrak{J}_m$ is generated (as an A_m-module) by the monomials of degree $\leqslant m$ with respect to to a_{jm}; the proposition being evident by definition for $m = 1$, we argue by induction on m, and let $\mathfrak{J}'_m$ be the A_m-submodule of $\mathfrak{J}_m$ generated by these monomials. The relation $\mathfrak{J}_{m-1} = \mathfrak{J}_m/\mathfrak{J}_m^m$ and the induction hypothesis prove that $\mathfrak{J}_m = \mathfrak{J}'_m + \mathfrak{J}_m^m$, hence, since $\mathfrak{J}_m^{m+1} = 0$, we have $\mathfrak{J}_m^m = {\mathfrak{J}'_m}^m$, and finally $\mathfrak{J}_m = \mathfrak{J}'_m$. □

Corollary (7.2.8). — *Under the conditions of Proposition (7.2.7), for A to be Noetherian, it is necessary and sufficient that A_0 is.*

Proof. This follows immediately from Corollary (7.2.6). □

Proposition (7.2.9). — *Suppose the hypotheses of Proposition (7.2.7): for each integer i, let M_i be an A_i-module, and for $i \leqslant j$, let $v_{ij} : M_j \to M_i$ be a u_{ij}-homomorphism, such that (M_i, v_{ij}) is a projective system. In addition, suppose that M_0 is an A_0-module of finite type and that the v_{ij} are surjective with kernel $\mathfrak{J}_j^{i+1} M_j$. Then $M = \varprojlim M_i$ is an A-module of finite type, and the kernel of the surjective u_n-homomorphism $v_n : M \to M_n$ is $\mathfrak{J}^{n+1}M$* (such that M_n identifies with $M/\mathfrak{J}^{n+1}M = M \otimes_A (A/\mathfrak{J}^{n+1})$).

Proof. Let $z_h = (z_{hk})_{k \geqslant 0}$ be a system of s elements of M such that the z_{h0} ($1 \leqslant h \leqslant s$) forms a system of generators for M_0; we will show that the z_h generate the A-module M. The A-module M is separated and complete for the filtration by the $M^{(n)}$, where $M^{(n)}$ is the set of $y = (y_k)_{k \geqslant 0}$ in M such that $y_k = 0$ for $k < n$; it is clear that we have $\mathfrak{J}^{(n)} M \subset M^{(n)}$ and that $M^{(n)}/M^{(n+1)} = \mathfrak{J}_n^n M_n$. We therefore have reduced to showing that the classes of the z_h modulo $M^{(1)}$ generate the graded module $\operatorname{grad}(M)$ (by the above filtration) over the graded ring $\operatorname{grad}(A)$ [CC, p. 18–06, lemme]; for this, we observe that it suffices to prove that the z_{hn} ($1 \leqslant h \leqslant s$) generate the A_n-module M_n. We argue by induction on n, the proposition being evident by definition for $n = 0$; the relation $M_{n-1} = M_n/\mathfrak{J}_n^n M_n$ and the induction hypothesis show that if M'_n is the submodule of M_n generated by the z_{hn}, we have that $M_n = M'_n + \mathfrak{J}_n^n M_n$, and as $\mathfrak{J}_n$ is nilpotent, this implies that $M_n = M'_n$. Similarly, passing to the associated graded modules shows that the canonical map from $\mathfrak{J}^{(n)}$ to $M^{(n)}$ is surjective (thus bijection), in other words that $\mathfrak{J}^{(n)} M = \mathfrak{J}^n M$ is the kernel of $M \to M_{n-1}$. □ **Err$_{\text{II}}$**

Corollary (7.2.10). — *Let (N_i, w_{ij}) be a second projective system of A_i-modules satisfying the conditions of Proposition (7.2.9), and let $N = \varprojlim N_i$. There is a bijective correspondence between the projective systems (h_i) of A_i-homomorphisms $h_i : M_i \to N_i$ and the homomorphisms of A-modules $h : M \to N$ (which is necessarily continuous for the $\mathfrak{J}$-adic topologies).*

Proof. It is clear that if $h : M \to N$ is an A-homomorphism, then we have $h(\mathfrak{J}^n M) \subset \mathfrak{J}^n N$, hence the continuity of h; by passing to quotients, there corresponds to h a projective system of A_i-homomorphisms $h_i : M_i \to N_i$, whose projective limit is h, hence the corollary. □

Remark (7.2.11). — Let A be an adic ring with an ideal of definition $\mathfrak{J}$ such that $\mathfrak{J}/\mathfrak{J}^2$ is an $A/\mathfrak{J}$-module of finite type; it is clear that the $A_i = A/\mathfrak{J}^{i+1}$ satisfy the conditions of Proposition (7.2.7); as **0_{I} | 66**
A is the projective limit of the A_i, we see that Proposition (7.2.7) gives the description of *all* the adic rings of the type considered (and in particular of all the *adic Noetherian* rings).

Example (7.2.12). — Let B be a ring, $\mathfrak{J}$ an ideal of B such that $\mathfrak{J}/\mathfrak{J}^2$ is a module of finite type over $B/\mathfrak{J}$ (or over B, equivalently); set $A = \varprojlim_n B/\mathfrak{J}^{n+1}$; A is the separated completion of B equipped with the $\mathfrak{J}$-preadic topology. If $A_n = B/\mathfrak{J}^{n+1}$, then it is immediate that the A_n satisfy the conditions of Proposition (7.2.7); therefore A is an adic ring and if $\overline{\mathfrak{J}}$ is the closure in A of the canonical image of $\mathfrak{J}$, then $\overline{\mathfrak{J}}$ is an ideal of definition for A, $\overline{\mathfrak{J}^n}$ is the closure of the canonical image of $\mathfrak{J}^n$, $A/\overline{\mathfrak{J}^n}$ identifies with $B/\mathfrak{J}^n$ and $\overline{\mathfrak{J}}/\overline{\mathfrak{J}^2}$ is isomorphic to $\mathfrak{J}/\mathfrak{J}^2$ as an $A/\overline{\mathfrak{J}}$-module. Similarly, if N is such that $N/\mathfrak{J}N$ is a B-module of finite type, and if we set $M_i = N/\mathfrak{J}^{i+1}N$, then $M = \varprojlim M_i$ is an A-module of finite type, isomorphic to the separated completion of N for the $\mathfrak{J}$-preadic topology, and $\overline{\mathfrak{J}^n}M$ identifies with the closure of the canonical image of $\mathfrak{J}^n N$, and $M/\overline{\mathfrak{J}^n}M$ identifies with $N/\mathfrak{J}^n N$.

7.3. Preadic Noetherian rings

(7.3.1). Let A be a ring, $\mathfrak{J}$ an ideal of A, and M an A-module; we denote by $\widehat{A} = \varprojlim_n A/\mathfrak{J}^n$ (resp. $\widehat{M} = \varprojlim_n M/\mathfrak{J}^n M$) the separated completion of A (resp. M) for the $\mathfrak{J}$-preadic topology. Let $M' \xrightarrow{u} M \xrightarrow{v} M'' \to 0$ be an exact sequence of A-modules; as $M/\mathfrak{J}^n M = M \otimes_A (A/\mathfrak{J}^n)$, the sequence

$$M'/\mathfrak{J}^n M' \xrightarrow{u_n} M/\mathfrak{J}^n M \xrightarrow{v_n} M''/\mathfrak{J}^n M'' \longrightarrow 0$$

is exact for each n. In addition, as $v(\mathfrak{J}^n M) = \mathfrak{J}^n v(M) = \mathfrak{J}^n M''$, $\widehat{v} = \varprojlim v_n$ is surjective (Bourbaki, *Top. gén.*, Chap. IX, 2nd ed., p. 60, Cor. 2). On the other hand, if $z = (z_k)$ is an element of the kernel of $\widehat{v}$, then for each integer k, there exists a $z'_k \in M'/\mathfrak{J}^k M'$ such that $u_k(z'_k) = z_k$; we conclude that there exists a $z' = (z'_n) \in \widehat{M'}$ such that the first k components of $\widehat{u}(z')$ coincide with the z; in other words, the image of $\widehat{M'}$ under $\widehat{u}$ is *dense* in the kernel of $\widehat{v}$.

If we suppose that A is *Noetherian*, then so is $\widehat{A}$, according to (7.2.12), $\mathfrak{J}/\mathfrak{J}^2$ is then an A-module of finite type. In addition, we have the following theorem.

Theorem (7.3.2). — (Krull's Theorem). *Let A be a* Noetherian *ring, $\mathfrak{J}$ an ideal of A, M an A-module* of finite type, *and M' a submodule of M; then the induced topology on M' by the $\mathfrak{J}$-preadic topology of M is identical to the $\mathfrak{J}$-preadic topology of M'.*

This follows immediately from

Lemma (7.3.2.1). — (Artin–Rees Lemma). *Under the hypotheses of (7.3.2), there exists an integer p such that, for $n \geqslant p$, we have*

$$M' \cap \mathfrak{J}^n M = \mathfrak{J}^{n-p}(M' \cap \mathfrak{J}^p M).$$

For the proof, see [CC, p. 2–04]. $\mathbf{0}_{\mathbf{I}}$ | 67

Corollary (7.3.3). — *Under the hypotheses of (7.3.2), the canonical map $M \otimes_A \widehat{A} \to \widehat{M}$ is bijective, and the functor $M \otimes_A \widehat{A}$ is exact in M on the category of A-modules of finite type; as a result, the separated $\mathfrak{J}$-adic completion $\widehat{A}$ is a flat A-module (6.1.1).*

Proof. We first note that $\widehat{M}$ is an *exact* functor in M on the category of A-modules of finite type. Indeed, let $0 \to M' \xrightarrow{u} M \xrightarrow{v} M'' \to 0$ be an exact sequence; we have seen that $\widehat{v} : \widehat{M} \to \widehat{M''}$ is surjective (7.3.1); on the other hand, if i is the canonical homomorphism $M \to \widehat{M}$, it follows from Krull's Theorem (7.3.2) that the closure of $i(u(M'))$ in $\widehat{M}$ identifies with the separated completion of M' for the $\mathfrak{J}$-preadic topology; thus $\widehat{u}$ is injective, and according to (7.3.1), the image of $\widehat{u}$ is equal to the kernel of $\widehat{v}$.

This being so, the canonical map $M \otimes_A \widehat{A} \to \widehat{M}$ is obtained by passing to the projective limit of the maps $M \otimes_A \widehat{A} \to M \otimes_A (A/\mathfrak{J}^n) = M/\mathfrak{J}^n M$. It is clear that this map is bijective when M is of the form A^p. If M is an A-module of finite type, then we have an exact sequence $A^p \to A^q \to M \to 0$, hence, by virtue of the *right* exactness of the functors $M \otimes_A \widehat{A}$ and $\widehat{M}$ (in M) on the category of A-modules of finite type, we have the commutative diagram

$$\begin{tikzcd}
A^p \otimes_A \widehat{A} \arrow[r] \arrow[d] & A^q \otimes_A \widehat{A} \arrow[r] \arrow[d] & M \otimes_A \widehat{A} \arrow[r] \arrow[d] & 0 \\
\widehat{A}^p \arrow[r] & \widehat{A}^q \arrow[r] & \widehat{M} \arrow[r] & 0
\end{tikzcd}$$

where the two rows are exact and the first two vertical arrows are isomorphisms; this immediately finishes the proof. ☐

Corollary (7.3.4). — *Let A be a Noetherian ring, $\mathfrak{J}$ an ideal of A, M and N two A-modules of finite type; we have the canonical functorial isomorphisms*

$$(M \otimes_A N)^\wedge \simeq \widehat{M} \otimes_{\widehat{A}} \widehat{N}, \ (\mathrm{Hom}_A(M,N))^\wedge \simeq \mathrm{Hom}_{\widehat{A}}(\widehat{M}, \widehat{N}).$$

Proof. This follows from Corollary (7.3.3), (6.2.1), and (6.2.2). ☐

Corollary (7.3.5). — *Let A be a Noetherian ring, $\mathfrak{J}$ an ideal of A. The following conditions are equivalent:*

(a) *$\mathfrak{J}$ is contained in the radical of A.*
(b) *$\widehat{A}$ is a faithfully flat A-module (6.4.1).*
(c) *Each A-module of finite type is separated for the $\mathfrak{J}$-preadic topology.*
(d) *Each submodule of an A-module of finite type is closed for the $\mathfrak{J}$-preadic topology.*

Proof. As $\widehat{A}$ is a flat A-module, the conditions (b) and (c) are equivalent, since (b) is equivalent to saying that if M is an A-module of finite type, then the canonical map $M \to \widehat{M} = M \otimes_A \widehat{A}$ is injective (6.6.1, c). It is immediate that (c) implies (d), since if N is a submodule of an A-module M of finite type, then M/N is separated for the $\mathfrak{J}$-preadic topology, so N is closed in M. We show that (d) implies (a): if $\mathfrak{m}$ is a maximal ideal of A, then $\mathfrak{m}$ is closed in A for the $\mathfrak{J}$-preadic topology, so $\mathfrak{m} = \bigcap_{p \geqslant 0}(\mathfrak{m} + \mathfrak{J}^p)$, and as $\mathfrak{m} + \mathfrak{J}^p$ is necessarily equal to A or to $\mathfrak{m}$, we have that $\mathfrak{m} + \mathfrak{J}^p = \mathfrak{m}$ for large enough p, hence $\mathfrak{J}^p \subset \mathfrak{m}$, and $\mathfrak{J} \subset \mathfrak{m}$ when $\mathfrak{m}$ is prime. Finally, (a) implies (b): indeed, let $\mathbf{0}_{\mathbf{I}}$ | 68
P be the closure of $\{0\}$ in an A-module M of finite type, for the $\mathfrak{J}$-preadic topology; according to Krull's Theorem (7.3.2), the topology induced on P by the $\mathfrak{J}$-preadic topology of M is the $\mathfrak{J}$-preadic topology of P, so $\mathfrak{J}P = P$; as P is of finite type, it follows from Nakayama's Lemma that $P = 0$ ($\mathfrak{J}$ being contained in the radical of A). ☐

We note that the conditions of Corollary (7.3.5) are satisfied when A is a *local Noetherian ring* and $\mathfrak{J} \neq A$ is any ideal of A.

Corollary (7.3.6). — *If A is a $\mathfrak{J}$-preadic Noetherian ring, then each A-module of finite type is separated and complete for the $\mathfrak{J}$-preadic topology.*

Proof. As we then have $\widehat{A} = A$, this follows immediately from Corollary (7.3.3). □

We conclude that Proposition (7.2.9) gives the description of *all* the modules of finite type over an adic Noetherian ring.

Corollary (7.3.7). — *Under the hypotheses of (7.3.2), the kernel of the canonical map $M \to \widehat{M} = M \otimes_A \widehat{A}$ is the set of the $x \in M$ killed by an element of $1 + \mathfrak{J}$.*

Proof. For each $x \in M$ in this kernel, it is necessary and sufficient that the separated completion of the submodule Ax is 0 (by Krull's Theorem (7.3.2)), in other words, that $x \in \mathfrak{J}x$. □

7.4. Quasi-finite modules over local rings

Definition (7.4.1). — Given a local ring A, with maximal ideal $\mathfrak{m}$, we say that an A-module M is quasi-finite (over A) if $M/\mathfrak{m}M$ is of finite rank over the residue field $k = A/\mathfrak{m}$.

When A is *Noetherian*, the separated completion $\widehat{M}$ of M for the $\mathfrak{m}$-preadic topology is then an *$\widehat{A}$-module of finite type*; indeed, as $\mathfrak{m}/\mathfrak{m}^2$ is then an A-module of finite type, this follows from Example (7.2.12) and from the hypothesis on $M/\mathfrak{m}M$.

In particular, if we suppose that in addition A is *complete* and M is *separated* for the $\mathfrak{m}$-preadic topology (in other words, $\bigcap_n \mathfrak{m}^n M = 0$), then M is also an *A-module of finite type*: indeed, $\widehat{M}$ is then an A-module of finite type, and as M identifies with a submodule of $\widehat{M}$, M is also of finite type (and is indeed identical to its completion according to Corollary (7.3.6)).

Proposition (7.4.2). — *Let A, B be two local rings, $\mathfrak{m}$, $\mathfrak{n}$ their maximal ideals, and suppose that B is Noetherian. Let $\phi : A \to B$ be a local homomorphism, M a B-module of finite type. If M is a quasi-finite A-module, then the $\mathfrak{m}$-preadic and $\mathfrak{n}$-preadic topologies on M are identical, thus separated.*

Proof. We note that by hypothesis $M/\mathfrak{m}M$ is of *finite length* as an A-module, thus also *a fortiori* as a B-module. We conclude that $\mathfrak{n}$ is the *unique prime ideal* of B containing the annihilator of $M/\mathfrak{m}M$: indeed, we immediately reduce (according to (1.7.4) and (1.7.2)) to the case where $M/\mathfrak{m}M$ is *simple*, thus necessarily isomorphic to $B/\mathfrak{n}$, and our assertion is evident in this case. On the other hand, as M is a B-module of finite type, the prime ideals which contain the annihilator of $M/\mathfrak{m}M$ are those which contain $\mathfrak{m}B + \mathfrak{b}$, where we denote by $\mathfrak{b}$ the annihilator of the B-module M (1.7.5). As B is Noetherian, we conclude ([Sam53b, p. 127, Cor. 4]) that $\mathfrak{m}B + \mathfrak{b}$ is an ideal of definition for B, in $\mathbf{0_I}$ | 69
other words there exists a $k > 0$ such that $\mathfrak{n}^k \subset \mathfrak{m}B + \mathfrak{b} \subset \mathfrak{n}$; as a result, for each $h > 0$, we have

$$\mathfrak{n}^{hk} M \subset (\mathfrak{m}B + \mathfrak{b})^h M = \mathfrak{m}^h M \subset \mathfrak{n}^h M,$$

which proves that the $\mathfrak{m}$-preadic and $\mathfrak{n}$-preadic topologies on M are the same; the second is separated according to Corollary (7.3.5). □

Corollary (7.4.3). — *Under the hypotheses of Proposition (7.4.2), if in addition A is Noetherian and complete for the $\mathfrak{m}$-preadic topology, then M is an A-module of finite type.*

Proof. Indeed, M is then separated for the $\mathfrak{m}$-preadic topology, and our assertion follows from the remark after Definition (7.4.1). □

(7.4.4). The most important case of Proposition (7.4.2) is when B is a quasi-finite A-module, i.e., $B/\mathfrak{m}B$ is an *algebra of finite rank over $k = A/\mathfrak{m}$*; furthermore, by virtue of what precedes, this condition can be broken down into the conjunction of the following two conditions:

(i) *$\mathfrak{m}B$ is an ideal of definition for B;*
(ii) *$B/\mathfrak{n}$ is an extension of finite rank of the field $A/\mathfrak{m}$.*

When this is so, every B-module of finite type is evidently a quasi-finite A-module.

Corollary (7.4.5). — *Under the hypotheses of Proposition (7.4.2), if $\mathfrak{b}$ is the annihilator of the B-module M, then $B/\mathfrak{b}$ is a quasi-finite A-module.*

Proof. Suppose $M \neq 0$ (otherwise the corollary is evident). We can consider M as a module over the local Noetherian ring $B/\mathfrak{b}$; its annihilator then being 0, the proof of Proposition (7.4.2) shows that $\mathfrak{m}(B/\mathfrak{b})$ is an ideal of definition for $B/\mathfrak{b}$. On the other hand, $M/\mathfrak{n}M$ is a vector space of finite rank over $A/\mathfrak{m}$, being a quotient of $M/\mathfrak{m}M$, which is by hypothesis of finite rank over $A/\mathfrak{m}$; as $M \neq 0$, we have $M \neq \mathfrak{n}M$ by virtue of Nakayama's Lemma; as $M/\mathfrak{n}M$ is a vector space $\neq 0$ over $B/\mathfrak{n}$, the fact that it is of finite rank over $A/\mathfrak{m}$ implies that $B/\mathfrak{n}$ is also of finite rank over $A/\mathfrak{m}$; the conclusion follows from (7.4.4) applied to the ring $B/\mathfrak{b}$. □

7.5. Rings of restricted formal series

(7.5.1). Let A be a topological ring, linearly topologized, separated and complete; let $(\mathfrak{J}_\lambda)$ be a fundamental system of neighbourhoods of 0 in A consisting of (open) ideals, such that A canonically identifies with $\varprojlim A/\mathfrak{J}_\lambda$ (7.2.1). For each λ, let $B_\lambda = (A/\mathfrak{J}_\lambda)[T_1, \ldots, T_r]$, where the T_i are indeterminates; it is clear that the B_λ form a projective system of discrete rings. We set $\varprojlim B_\lambda = A\{T_1, \ldots, T_r\}$, and we will see that this topological ring is independent of the fundamental system of ideals $(\mathfrak{J}_\lambda)$ considered. More precisely, let A' be the subring of the ring of formal series $A[\![T_1, \ldots, T_r]\!]$ consisting of formal series $\sum_\alpha c_\alpha T^\alpha$ (with $\alpha = (\alpha_1, \ldots, \alpha_r) \in \mathbf{N}^r$) such that $\lim c_\alpha = 0$ (according to the filter by complements of finite subsets of $\mathbf{N}^r$); we say that these series are the *restricted* formal series in the T_i, with coefficients in A. For each neighbourhood V of 0 in A, let V' be the set of $x = \sum_\alpha c_\alpha T^\alpha \in A'$ $\mathbf{0_I}$ | 70
such that $c_\alpha \in V$ for all α. We verify immediately that the V' form a fundamental system of neighbourhoods of 0 defining on A' a *separated* ring topology; we will canonically define a *topological isomorphism* from the ring $A\{T_1, \ldots, T_r\}$ to A'. For each $\alpha \in \mathbf{N}^r$ and each λ, let $\phi_{\lambda,\alpha}$ be the map from $(A/\mathfrak{J}_\lambda)[T_1, \ldots, T_r]$ to $A/\mathfrak{J}_\lambda$ which sends each polynomial in the first ring to the coefficient of T^α in that polynomial. It is clear that the $\phi_{\lambda,\alpha}$ form a projective system of homomorphisms of $A/\mathfrak{J}_\lambda$-modules, so their projective limit is a continuous homomorphism $\phi_\alpha : A\{T_1, \ldots, T_r\} \to A$; we will see that, for each $y \in A\{T_1, \ldots, T_r\}$, the formal series $\sum_\alpha \phi_\alpha(y) T^\alpha$ is *restricted*. Indeed, if y_λ is the component of y in B_λ, and if we denote by H_λ the finite set of the $\alpha \in \mathbf{N}^r$ for which the coefficients of the polynomial y_λ are nonzero, then we have $\phi_{\lambda,\alpha}(y_\mu) \in \mathfrak{J}_\lambda$ for $\mathfrak{J}_\mu \subset \mathfrak{J}_\lambda$ and $\alpha \notin H_\lambda$, and by passing to the limit, $\phi_\alpha(y) \in \mathfrak{J}_\lambda$ for $\alpha \notin H_\lambda$. We thus define a ring homomorphism $\phi : A\{T_1, \ldots, T_r\} \to A'$ by setting $\phi(y) = \sum_\alpha \phi_\alpha(y) T^\alpha$, and it is immediate that ϕ is continuous. Conversely, if θ_λ is the canonical homomorphism $A \to A/\mathfrak{J}_\lambda$, then for each element $z = \sum_\alpha c_\alpha T^\alpha \in A'$ and each λ, there are only a finite number of indices α such that $\theta_\lambda(c_\alpha) \neq 0$, and as a result $\psi_\lambda(z) = \sum_\alpha \theta_\lambda(c_\alpha) T^\alpha$ is in B_λ; the ψ_λ are continuous and form a projective system of homomorphisms whose projective limit is a continuous homomorphism $\psi : A' \to A\{T_1, \ldots, T_r\}$; it remains to verify that $\phi \circ \psi$ and $\psi \circ \phi$ are the identity automorphisms, which is immediate.

(7.5.2). We identify $A\{T_1, \ldots, T_r\}$ with the ring A' of restricted formal series by means of the isomorphisms defined in (7.5.1). The canonical isomorphisms

$$((A/\mathfrak{J}_\lambda)[T_1, \ldots, T_r])[T_{r+1}, \ldots, T_s] \simeq (A/\mathfrak{J}_\lambda)[T_1, \ldots, T_s]$$

define, by passing to the projective limit, a canonical isomorphism

$$(A\{T_1, \ldots, T_r\})\{T_{r+1}, \ldots, T_s\} \simeq A\{T_1, \ldots, T_s\}.$$

(7.5.3). For every continuous homomorphism $u : A \to B$ from A to a linearly topologized ring B, separated and complete, and each system $(b_1, \ldots, b_r)$ of r elements of B, there exists *a unique continuous homomorphism* $\overline{u} : A\{T_1, \ldots, T_r\} \to B$, such that $\overline{u}(a) = u(a)$ for all $a \in A$ and $\overline{u}(T_j) = b_j$ for $1 \leqslant j \leqslant r$. It suffices to set

$$\overline{u}\Big(\sum_\alpha c_\alpha T^\alpha\Big) = \sum_\alpha u(c_\alpha) b_1^{\alpha_1} \cdots b_r^{\alpha_r};$$

the verification of the fact that the family $(u(c_\alpha) b_1^{\alpha_1} \cdots b_r^{\alpha_r})$ is summable in B and that $\overline{u}$ is continuous are immediate and left to the reader. We note that this property (for arbitrary B and b_j) *characterizes* the topological ring $A\{T_1, \ldots, T_r\}$ up to unique isomorphism.

Proposition (7.5.4). —

(i) *If A is an admissible ring, then so is $A' = A\{T_1, \ldots, T_r\}$.*

(ii) *Let A be an adic ring, $\mathfrak{J}$ an ideal of definition for A such that $\mathfrak{J}/\mathfrak{J}^2$ is of finite type over $A/\mathfrak{J}$. If we set $\mathfrak{J}' = \mathfrak{J}A'$, then A' is also a $\mathfrak{J}'$-adic ring, and $\mathfrak{J}'/\mathfrak{J}'^2$ is of finite type over $A'/\mathfrak{J}'$. If in addition A is Noetherian, then so is A'.* $\mathbf{0_I}$ | 71

Proof.

(i) If $\mathfrak{J}$ is an ideal of A, $\mathfrak{J}'$ the ideal of A' consisting of the $\sum_\alpha c_\alpha T^\alpha$ such that $c_\alpha \in \mathfrak{J}$ for all α, then $(\mathfrak{J}')^n \subset (\mathfrak{J}^n)'$; if $\mathfrak{J}$ is an ideal of definition for A, then $\mathfrak{J}'$ is also an ideal of definition for A'.

(ii) Set $A_i = A/\mathfrak{J}^{i+1}$, and for $i \leqslant j$, let u_{ij} be the canonical homomorphism $A/\mathfrak{J}^{j+1} \to A/\mathfrak{J}^{i+1}$; set $A'_i = A_i[T_1, \ldots, T_r]$, and let u'_{ij} be the homomorphism $A'_j \to A'_i$ ($i \leqslant j$) obtained by applying u_{ij} to the coefficients of the polynomials in A'_j. We will show that the projective system (A'_i, u'_{ij}) satisfies the conditions of Proposition (7.2.7); as $\mathfrak{J}'$ is the kernel of $A' \to A'_0$, this proves the first assertion of (ii). It is clear that the u'_{ij} are surjective; the kernel $\mathfrak{J}'_i$ of u'_{0i} is the set of polynomials in $A_i[T_1, \ldots, T_r]$ whose coefficients are in $\mathfrak{J}/\mathfrak{J}^{i+1}$; in particular, $\mathfrak{J}'_1$ is the set of polynomials in $A_1[T_1, \ldots, T_r]$ whose coefficients are in $\mathfrak{J}/\mathfrak{J}^2$. As $\mathfrak{J}/\mathfrak{J}^2$ is of finite type over $A_1 = A/\mathfrak{J}^2$, we see that $\mathfrak{J}'_1/\mathfrak{J}'^2_1$ is a module of finite type over A'_1 (or equivalently, over $A'_0 = A'_1/\mathfrak{J}'_1$). We will now show that the kernel of u'_{ij} is $\mathfrak{J}'^{i+1}_j$. It is evident that $\mathfrak{J}'^{i+1}_j$ is contained in this kernel. On the other hand, let $a_1, \ldots, a_m$ be the elements of $\mathfrak{J}$ whose classes mod $\mathfrak{J}^2$ generate $\mathfrak{J}/\mathfrak{J}^2$; we verify immediately that the classes mod $\mathfrak{J}^{j+1}$ of monomials of degree $\leqslant j$ in the a_k ($1 \leqslant k \leqslant m$) generate $\mathfrak{J}/\mathfrak{J}^{j+1}$, and the classes of monomials of degree $> i$ and $\leqslant j$ generate $\mathfrak{J}^{i+1}/\mathfrak{J}^{j+1}$; a monomial in the T_k having such an element for a coefficient is thus a product of $i+1$ elements of $\mathfrak{J}'_j$, which establishes our assertion. Finally, if A is Noetherian, then so is $A'/\mathfrak{J}' = (A/\mathfrak{J})[T_1, \ldots, T_r]$, hence A' is Noetherian (7.2.8).

□

Proposition (7.5.5). — *Let A be a Noetherian $\mathfrak{J}$-adic ring, B an admissible topological ring, $\phi : A \to B$ a continuous homomorphism, making B an A-algebra. The following conditions are equivalent:*

(a) *B is Noetherian and $\mathfrak{J}B$-adic, and $B/\mathfrak{J}B$ is an algebra of finite type over $A/\mathfrak{J}$.*

(b) *B is topologically A-isomorphic to $\varprojlim B_n$, where $B_n = B_m/\mathfrak{J}^{n+1}B_m$ for $m \geqslant n$, and B_1 is an algebra of finite type over $A_1 = A/\mathfrak{J}^2$.*

(c) *B is topologically A-isomorphic to a quotient of an algebra of the form $A\{T_1, \ldots, T_r\}$ by an ideal (necessarily closed according to Corollary (7.3.6) and Proposition (7.5.4, ii)).*

Proof. As A is Noetherian, so is $A' = A\{T_1, \ldots, T_r\}$ (7.5.4), so (c) implies that B is Noetherian; as $\mathfrak{J}' = \mathfrak{J}A'$ is an open neighbourhood of 0 in A' such that the $\mathfrak{J}'^n$ form a fundamental system of neighbourhoods of 0, the images $\mathfrak{J}^nB$ of the $\mathfrak{J}'^n$ form a fundamental system of neighbourhoods of 0 in B, and as B is separated and complete, B is a $\mathfrak{J}B$-adic ring. Finally, $B/\mathfrak{J}B$ is an algebra (over $A/\mathfrak{J}$) that is a quotient of $A'/\mathfrak{J}A' = (A/\mathfrak{J})[T_1, \ldots, T_r]$, so it is of finite type, which proves that (c) implies (a).

If B is $\mathfrak{J}B$-adic and Noetherian, then B is isomorphic to $\varprojlim B_n$, where $B_n = B/\mathfrak{J}^{n+1}B$ (7.2.11), and $\mathfrak{J}B/\mathfrak{J}^2B$ is a module of finite type over $B/\mathfrak{J}B$. Let $(a_j)_{1 \leqslant j \leqslant s}$ be a system of generators for the $B/\mathfrak{J}B$-module $\mathfrak{J}B/\mathfrak{J}^2B$, and let $(c_i)_{1 \leqslant i \leqslant r}$ be a system of elements of $B/\mathfrak{J}^2B$ such that the classes mod $\mathfrak{J}B/\mathfrak{J}^2B$ form a system of generators for the $A/\mathfrak{J}$-algebra $B/\mathfrak{J}B$; we see immediately that the c_i, a_j form a system of generators for the $A/\mathfrak{J}^2$-algebra $B/\mathfrak{J}^2B$, hence (a) implies (b). $\mathbf{0_I}$ | 72

It remains to prove that (b) implies (c). The hypotheses imply that B_1 is a Noetherian ring, and as $B_1 = B_2/\mathfrak{J}^2B_2$, we have $\mathfrak{J}^2B_1 = 0$, hence $\mathfrak{J}B_1 = \mathfrak{J}B_1/\mathfrak{J}^2B_1$ is a B_0-module of finite type. The conditions of Proposition (7.2.7) are thus satisfied by the projective system (B_n) and B is a $\mathfrak{J}B$-adic ring. Let $(c_i)_{1 \leqslant i \leqslant r}$ be a finite system of elements of B whose classes mod $\mathfrak{J}B$ generate the $A/\mathfrak{J}$-algebra $B/\mathfrak{J}B$, and whose linear combinations with coefficients in $\mathfrak{J}$ are such that their classes mod $\mathfrak{J}^2B$ generate the B_0-module $\mathfrak{J}B/\mathfrak{J}^2B$. There exists a continuous A-homomorphism u from $A' = A\{T_1, \ldots, T_r\}$ to B which reduces to ϕ on A and is such that $u(T_i) = c_i$ for $1 \leqslant i \leqslant r$ (7.5.3); if we prove that u is *surjective*, then (c) will be established, since from $u(A') = B$ we deduce that $u(\mathfrak{J}^nA') = \mathfrak{J}^nB$, in other words that u is a strict morphism of topological rings and B is thus isomorphic to a quotient of A' by a closed ideal. As B is complete for the $\mathfrak{J}B$-adic topology, it suffices ([CC, p. 18–07]) to show that the homomorphism $\operatorname{grad}(A') \to \operatorname{grad}(B)$, induced canonically by u for the $\mathfrak{J}$-adic filtrations on A' and B, is surjective. But by definition, the homomorphisms $A'/\mathfrak{J}A' \to B/\mathfrak{J}B$ and $\mathfrak{J}A'/\mathfrak{J}^2A' \to \mathfrak{J}B/\mathfrak{J}^2B$ induced by u are surjective; by induction on n, we immediately deduce that so is $\mathfrak{J}A'/\mathfrak{J}^nA' \to \mathfrak{J}B/\mathfrak{J}^nB$, and *a fortiori* so is $\mathfrak{J}^nA'/\mathfrak{J}^{n+1}A' \to \mathfrak{J}^nB/\mathfrak{J}^{n+1}B$, which finishes the proof. □

7.6. Completed rings of fractions

(7.6.1). Let A be a linearly topologized ring, $(\mathfrak{J}_\lambda)$ a fundamental system of neighbourhoods of 0 in A consisting of ideals, S a multiplicative subset of A. Let u_λ be the canonical homomorphism $A \to A_\lambda = A/\mathfrak{J}_\lambda$, and for $\mathfrak{J}_\mu \subset \mathfrak{J}_\lambda$, let $u_{\lambda\mu}$ be the canonical homomorphism $A_\mu \to A_\lambda$. Set $S_\lambda = u_\lambda(S)$, so that $u_{\lambda\mu}(S_\mu) = S_\lambda$. The $u_{\lambda\mu}$ canonically induce surjective homomorphisms $S_\mu^{-1}A_\mu \to S_\lambda^{-1}A_\lambda$, for which these rings form a projective system; we denote by $A\{S^{-1}\}$ the projective limit of this system. This definition does not depend on the fundamental system of neighbourhoods $(\mathfrak{J}_\lambda)$ chosen; indeed:

Proposition (7.6.2). — *The ring $A\{S^{-1}\}$ is topologically isomorphic to the separated completion of the ring $S^{-1}A$ for the topology which has a fundamental system of neighbourhoods of* 0 *consisting of the $S^{-1}\mathfrak{J}_\lambda$.*

Proof. If v_λ is the canonical homomorphism $S^{-1}A \to S_\lambda^{-1}A_\lambda$ induced by u_λ, then the kernel of v_λ is $S^{-1}\mathfrak{J}_\lambda$ and v_λ is surjective, hence the proposition (7.2.1). □

Corollary (7.6.3). — *If S' is the canonical image of S in the separated completion $\widehat{A}$ of A, then $A\{S^{-1}\}$ canonically identifies with $\widehat{A}\{S'^{-1}\}$.*

We note that if A is separated and complete, then it is not necessarily the same for $S^{-1}A$ with the topology defined by the $S^{-1}\mathfrak{J}_\lambda$, as we see for example by taking S to be the set of the f^n ($n \geqslant 0$), where f is topologically nilpotent but not nilpotent: indeed, $S^{-1}A$ is not 0 and on the other hand, for each λ there exists an n such that $f^n \in \mathfrak{J}_\lambda$, so $1 = f^n/f^n \in S^{-1}\mathfrak{J}_\lambda$ and $S^{-1}\mathfrak{J}_\lambda = S^{-1}A$.

$\mathbf{0_I}$ | 73

Corollary (7.6.4). — *If, in A,* 0 *is not adherent to S, then the ring $A\{S^{-1}\}$ is not* 0*.*

Proof. Indeed, 0 is not adherent to $\{1\}$ in the ring $S^{-1}A$; otherwise, we would have that $1 \in S^{-1}\mathfrak{J}_\lambda$ for each open ideal $\mathfrak{J}_\lambda$ of A, and it follows that $\mathfrak{J}_\lambda \cap S \neq \varnothing$ for all λ, contradicting the hypothesis. □

(7.6.5). We say that $A\{S^{-1}\}$ is the *completed ring of fractions* of A with denominators in S. With the above notation, it is clear that the inverse image of $S^{-1}\mathfrak{J}_\lambda$ in A contains $\mathfrak{J}_\lambda$, hence the canonical map $A \to S^{-1}A$ is continuous, and if we compose it with the canonical map $S^{-1}A \to A\{S^{-1}\}$, we obtain a canonical continuous homomorphism $A \to A\{S^{-1}\}$, the projective limit of the homomorphisms $A \to S_\lambda^{-1}A_\lambda$.

(7.6.6). The couple consisting of $A\{S^{-1}\}$ and the canonical homomorphism $A \to A\{S^{-1}\}$ is characterized by the following *universal property*: every continuous homomorphism u from A to a linearly topologized ring B, separated and complete, such that $u(S)$ consists of invertible elements in B, uniquely factorizes as $A \to A\{S^{-1}\} \xrightarrow{u'} B$, where u' is continuous. Indeed, u uniquely factorizes as $A \to S^{-1}A \xrightarrow{v'} B$; as for each open ideal $\mathfrak{K}$ of B we have that $u^{-1}(\mathfrak{K})$ contains a $\mathfrak{J}_\lambda$, $v'^{-1}(\mathfrak{K})$ necessarily contains $S^{-1}\mathfrak{J}_\lambda$, so v' is continuous; since B is separated and complete, v' uniquely factorizes as $S^{-1}A \to A\{S^{-1}\} \xrightarrow{u'} B$, where u' is continuous; hence our assertion.

(7.6.7). Let B be a second linearly topologized ring, T a multiplicative subset of B, $\phi : A \to B$ a continuous homomorphism such that $\phi(S) \subset T$. According to the above, the continuous homomorphism $A \xrightarrow{\phi} B \to B\{T^{-1}\}$ uniquely factorizes as $A \to A\{S^{-1}\} \xrightarrow{\phi'} B\{T^{-1}\}$, where ϕ' is continuous. In particular, if $B = A$ and if ϕ is the identity, we see that for $S \subset T$ we have a continuous homomorphism $\rho^{T,S} : A\{S^{-1}\} \to A\{T^{-1}\}$ obtained by passing to the separated completion from $S^{-1}A \to T^{-1}A$; if U is a third multiplicative subset of A such that $S \subset T \subset U$, then we have $\rho^{U,S} = \rho^{U,T} \circ \rho^{T,S}$.

(7.6.8). Let S_1, S_2 be two multiplicative subsets of A, and let S_2' be the canonical image of S_2 in $A\{S_1^{-1}\}$; we then have a canonical topological isomorphism $A\{(S_1S_2)^{-1}\} \simeq A\{S_1^{-1}\}\{S_2'^{-1}\}$, as we see from the canonical isomorphism $(S_1S_2)^{-1}A \simeq S_2''^{-1}(S_1^{-1}A)$ (where S_2'' is the canonical image of S_2 in $S_1^{-1}A$), which is bicontinuous.

(7.6.9). Let $\mathfrak{a}$ be an *open* ideal of A; we can assume that $\mathfrak{J}_\lambda \subset \mathfrak{a}$ for all λ, and as a result $S^{-1}\mathfrak{J}_\lambda \subset S^{-1}\mathfrak{a}$ in the ring $S^{-1}A$, in other words, $S^{-1}\mathfrak{a}$ is an *open* ideal of $S^{-1}A$; we denote by $\mathfrak{a}\{S^{-1}\}$ its separated completion, equal to $\varprojlim(S^{-1}\mathfrak{a}/S^{-1}\mathfrak{J}_\lambda)$, which is an *open* ideal of $A\{S^{-1}\}$, isomorphic to the closure of the canonical image of $S^{-1}\mathfrak{a}$. In addition, *the discrete ring* $A\{S^{-1}\}/\mathfrak{a}\{S^{-1}\}$ *is canonically isomorphic to* $S^{-1}A/S^{-1}\mathfrak{a} = S^{-1}(A/\mathfrak{a})$. Conversely, if $\mathfrak{a}'$ is an open ideal of $A\{S^{-1}\}$, then $\mathfrak{a}'$ contains an ideal of the form $\mathfrak{J}_\lambda\{S^{-1}\}$ which is the inverse image of an ideal of $S^{-1}A/S^{-1}\mathfrak{J}_\lambda$, which is necessarily (1.2.6) of the form $S^{-1}\mathfrak{a}$, where $\mathfrak{a} \supset \mathfrak{J}_\lambda$. We conclude that $\mathfrak{a}' = \mathfrak{a}\{S^{-1}\}$. In particular (1.2.6):

Proposition (7.6.10). — *The map* $\mathfrak{p} \mapsto \mathfrak{p}\{S^{-1}\}$ *is an increasing bijection from the set of* open prime *ideals* $\mathfrak{p}$ *of* A *such that* $\mathfrak{p} \cap S = \varnothing$ *to the set of* open prime *ideals of* $A\{S^{-1}\}$*; in addition, the field of fractions of* $A\{S^{-1}\}/\mathfrak{p}\{S^{-1}\}$ *is canonically isomorphic to that of* $A/\mathfrak{p}$. **0_I** | 74

Proposition (7.6.11). —

(i) *If* A *is an admissible ring, then so is* $A' = A\{S^{-1}\}$*, and for every ideal of definition* $\mathfrak{J}$ *for* A*,* $\mathfrak{J}' = \mathfrak{J}\{S^{-1}\}$ *is an ideal of definition for* A'.

(ii) *Let* A *be an adic ring,* $\mathfrak{J}$ *an ideal of definition for* A *such that* $\mathfrak{J}/\mathfrak{J}^2$ *is of finite type over* $A/\mathfrak{J}$*; then* A' *is a* $\mathfrak{J}'$*-adic ring and* $\mathfrak{J}'/\mathfrak{J}'^2$ *is of finite type over* $A'/\mathfrak{J}'$*. If in addition* A *is Noetherian, then so is* A'.

Proof.

(i) If $\mathfrak{J}$ is an ideal of definition for A, then it is clear that $S^{-1}\mathfrak{J}$ is an ideal of definition for the topological ring $S^{-1}A$, since we have $(S^{-1}\mathfrak{J})^n = S^{-1}\mathfrak{J}^n$. Let A'' be the separated ring associated to $S^{-1}A$, $\mathfrak{J}''$ the image of $S^{-1}\mathfrak{J}$ in A''; the image of $S^{-1}\mathfrak{J}^n$ is $\mathfrak{J}''^n$, so $\mathfrak{J}''^n$ tends to 0 in A''; as $\mathfrak{J}'$ is the closure of $\mathfrak{J}''$ in A', $\mathfrak{J}'^n$ is contained in the closure of $\mathfrak{J}''^n$, hence tends to 0 in A'.

(ii) Set $A_i = A/\mathfrak{J}^{i+1}$, and for $i \leqslant j$, let u_{ij} be the canonical homomorphism $A/\mathfrak{J}^{j+1} \to A/\mathfrak{J}^{i+1}$; let S_i be the canonical image of S in A_i, and set $A'_i = S_i^{-1}A_i$; finally, let $u'_{ij} : A'_j \to A'_i$ be the homomorphism canonically induced by u_{ij}. We show that the projective system (A'_i, u'_{ij}) satisfies the conditions of Proposition (7.2.7): it is clear that the u'_{ij} are surjective; on the other hand, the kernel of u'_{ij} is $S_j^{-1}(\mathfrak{J}^{i+1}/\mathfrak{J}^{j+1})$ (1.3.2), equal to $\mathfrak{J}_j'^{i+1}$, where $\mathfrak{J}'_j = S_j^{-1}(\mathfrak{J}/\mathfrak{J}^{j+1})$; finally, $\mathfrak{J}'_1/\mathfrak{J}_1'^2 = S_1^{-1}(\mathfrak{J}/\mathfrak{J}^2)$, and as $\mathfrak{J}/\mathfrak{J}^2$ is of finite type over $A/\mathfrak{J}^2$, $\mathfrak{J}'_1/\mathfrak{J}_1'^2$ is of finite type over A'_1. Finally, if A is Noetherian, then so is $A'_0 = S_0^{-1}(A/\mathfrak{J})$, which, by Corollary (7.2.8), completes the proof of Proposition (7.6.11).[11]

□

Corollary (7.6.12). — *Under the hypotheses of Proposition (7.6.11, ii), we have* $(\mathfrak{J}\{S^{-1}\})^n = \mathfrak{J}^n\{S^{-1}\}$.

Proof. This follows from Proposition (7.2.7) and the proof of Proposition (7.6.11). □

Proposition (7.6.13). — *Let* A *be an adic Noetherian ring,* S *a multiplicative subset of* A*; then* $A\{S^{-1}\}$ *is a flat* A*-module.*

Proof. If $\mathfrak{J}$ is an ideal of definition for A, then $A\{S^{-1}\}$ is the separated completion of the Noetherian ring $S^{-1}A$ equipped with the $S^{-1}\mathfrak{J}$-preadic topology; as a result (7.3.3) $A\{S^{-1}\}$ is a flat $S^{-1}A$-module; as $S^{-1}A$ is a flat A-module (6.3.1), the proposition follows from the transitivity of flatness (6.2.1). □

Corollary (7.6.14). — *Under the hypotheses of Proposition (7.6.13), let* $S' \subset S$ *be a second multiplicative subset of* A*; then* $A\{S^{-1}\}$ *is a flat* $A\{S'^{-1}\}$*-module.*

Proof. By (7.6.8), $A\{S^{-1}\}$ canonically identifies with $A\{S'^{-1}\}\{S_0^{-1}\}$, where S_0 is the canonical image of S in $A\{S'^{-1}\}$, and $A\{S'^{-1}\}$ is Noetherian (7.6.11). □

[11] The French source places "(7.2.8)" after "proposition", making it read as the proposition proved; context shows that it is the corollary invoked.

(7.6.15). For each element f of a linearly topologized ring A, we denote by $A_{\{f\}}$ the completed ring of fractions $A\{S_f^{-1}\}$, where S_f is the multiplicative set of the f^n ($n \geqslant 0$); for each open ideal $\mathfrak{a}$ of A, we write $\mathfrak{a}_{\{f\}}$ for $\mathfrak{a}\{S_f^{-1}\}$. If g is a second element of A, then we have a canonical continuous homomorphism $A_{\{f\}} \to A_{\{fg\}}$ (7.6.7). When f varies over a multiplicative subset S of A, the $A_{\{f\}}$ form a filtered inductive system with the above homomorphisms; we set $A_{\{S\}} = \varinjlim_{f\in S} A_{\{f\}}$. For every $f \in S$, we have a homomorphism $A_{\{f\}} \to A\{S^{-1}\}$ (7.6.7), and these homomorphisms form $\mathbf{0_I}$ | 75
an inductive system; by passing to the inductive limit, they thus define a canonical homomorphism $A_{\{S\}} \to A\{S^{-1}\}$.

Proposition (7.6.16). — *If A is a Noetherian ring, then $A\{S^{-1}\}$ is a flat module over $A_{\{S\}}$.*

Proof. By (7.6.14), $A\{S^{-1}\}$ is flat over each of the rings $A_{\{f\}}$ for $f \in S$, and the conclusion follows from (6.2.3). □

Proposition (7.6.17). — *Let $\mathfrak{p}$ be an open prime ideal in an admissible ring A, and let $S = A - \mathfrak{p}$. Then the rings $A\{S^{-1}\}$ and $A_{\{S\}}$ are local rings, the canonical homomorphism $A_{\{S\}} \to A\{S^{-1}\}$ is local, and the residue fields of $A_{\{S\}}$ and $A\{S^{-1}\}$ are canonically isomorphic to the field of fractions of $A/\mathfrak{p}$.*

Proof. Let $\mathfrak{J} \subset \mathfrak{p}$ be an ideal of definition for A; we have $S^{-1}\mathfrak{J} \subset S^{-1}\mathfrak{p} = \mathfrak{p}A_{\mathfrak{p}}$, so $A_{\mathfrak{p}}/S^{-1}\mathfrak{J}$ is a local ring; we conclude from Corollary (7.1.12), (7.6.9), and Proposition (7.6.11, i) that $A\{S^{-1}\}$ is a local ring. Set $\mathfrak{m} = \varinjlim_{f\in S} \mathfrak{p}_{\{f\}}$, which is an ideal in $A_{\{S\}}$; we will see that each element in $A_{\{S\}}$ not in $\mathfrak{m}$ is invertible. Indeed, such an element is the image in $A_{\{S\}}$ of an element $z \in A_{\{f\}}$ not in $\mathfrak{p}_{\{f\}}$, for an $f \in S$; its canonical image z_0 in $A_{\{f\}}/\mathfrak{J}_{\{f\}} = S_f^{-1}(A/\mathfrak{J})$ therefore is not in $S_f^{-1}(\mathfrak{p}/\mathfrak{J})$ (7.6.9), which means that $z_0 = \overline{x}/\overline{f}^k$, where $x \notin \mathfrak{p}$ and $\overline{x}$, $\overline{f}$ are the classes of x, f mod $\mathfrak{J}$. As $x \in S$, we have $g = xf \in S$, and in $S_g^{-1}A$, the canonical image $y_0 = x^{k+1}/g^k$ of $x/f^k \in S_f^{-1}A$ admits an inverse $x^{k-1}f^{2k}/g^k$. This implies *a fortiori* that the image of y_0 in $S_g^{-1}A/S_g^{-1}\mathfrak{J}$ is invertible, so ((7.6.9) and Corollary (7.1.12)) the canonical image y of z in $A_{\{g\}}$ is invertible; the image of z in $A_{\{S\}}$ (equal to that of y) is as a result invertible. We thus see that $A_{\{S\}}$ is a local ring with maximal ideal $\mathfrak{m}$; in addition, the image of $\mathfrak{p}_{\{f\}}$ in $A\{S^{-1}\}$ is contained in the maximal ideal $\mathfrak{p}\{S^{-1}\}$ of this ring; *a fortiori*, the image of $\mathfrak{m}$ in $A\{S^{-1}\}$ is contained in $\mathfrak{p}\{S^{-1}\}$, so the canonical homomorphism $A_{\{S\}} \to A\{S^{-1}\}$ is local. Finally, as each element of $A\{S^{-1}\}/\mathfrak{p}\{S^{-1}\}$ is the image of an element in the ring $S_f^{-1}A$ for a suitable $f \in S$, the homomorphism $A_{\{S\}} \to A\{S^{-1}\}/\mathfrak{p}\{S^{-1}\}$ is surjective, and gives an isomorphism of the residue fields by passing to quotients. □

Corollary (7.6.18). — *Under the hypotheses of Proposition (7.6.17), if we suppose also that A is an adic Noetherian ring, then the local rings $A\{S^{-1}\}$ and $A_{\{S\}}$ are Noetherian, and $A\{S^{-1}\}$ is a faithfully flat $A_{\{S\}}$-module.*

Proof. We already know from (7.6.11, ii) that $A\{S^{-1}\}$ is Noetherian and $A_{\{S\}}$-flat (7.6.16); as the homomorphism $A_{\{S\}} \to A\{S^{-1}\}$ is local, we conclude that $A\{S^{-1}\}$ is a faithfully flat $A_{\{S\}}$-module (6.6.2), and as a result that $A_{\{S\}}$ is Noetherian (6.5.2). □

7.7. Completed tensor products

(7.7.1). Let A be a linearly topologized ring, M, N two linearly topologized A-modules. Let $\mathfrak{J}$, V, W be open neighbourhoods of 0 in A, M, N respectively, which are A-modules, and such that $\mathfrak{J}M \subset V$, $\mathfrak{J}N \subset W$, so that M/V and N/W can be considered as $A/\mathfrak{J}$-modules. When $\mathfrak{J}$, V, W vary over the systems of open neighbourhoods satisfying these properties, it is immediate that the modules $(M/V) \otimes_{A/\mathfrak{J}} (N/W)$ form a projective system of modules over the projective system of rings $A/\mathfrak{J}$; $\mathbf{0_I}$ | 76
by passing to the projective limit, we thus obtain a module over the separated completion $\widehat{A}$ of A, which we call the *completed tensor product* of M and N and denote by $(M \otimes_A N)^\wedge$. If we note that M/V is canonically isomorphic to $\widehat{M}/\overline{V}$, where $\widehat{M}$ is the separated completion of M and $\overline{V}$ the closure in $\widehat{M}$ of the image of V, then we see that the completed tensor product $(M \otimes_A N)^\wedge$ canonically identifies with $(\widehat{M} \otimes_{\widehat{A}} \widehat{N})^\wedge$, which we denote by $\widehat{M}\widehat{\otimes}_{\widehat{A}}\widehat{N}$.

(7.7.2). With the above notation, the tensor products $(M/V) \otimes_A (N/W)$ and $(M/V) \otimes_{A/\mathfrak{J}} (N/W)$ identify canonically; they identify with $(M \otimes_A N)/(\mathrm{Im}(V \otimes_A N) + \mathrm{Im}(M \otimes_A W))$. We conclude that $(M \otimes_A N)^\wedge$ is *the separated completion of the A-module $M \otimes_A N$, equipped with the topology for which the submodules*

$$\mathrm{Im}(V \otimes_A N) + \mathrm{Im}(M \otimes_A W)$$

form a fundamental system of neighbourhoods of 0 (V and W varying over the set of open submodules of M and N respectively); we say for brevity that this topology is the *tensor product* of the given topologies on M and N.

(7.7.3). Let M', N' be two linearly topologized A-modules, $u : M \to M'$, $v : N \to N'$ two continuous homomorphisms; it is immediate that $u \otimes v$ is continuous for the tensor product topologies on $M \otimes_A N$ and $M' \otimes_A N'$ respectively; by passing to the separated completions, we obtain a continuous homomorphism $(M \otimes_A N)^\wedge \to (M' \otimes_A N')^\wedge$, which we denote by $u \widehat{\otimes} v$; $(M \otimes_A N)^\wedge$ is thus a *bifunctor* in M and N in the category of linearly topologized A-modules.

(7.7.4). We similarly define the completed tensor product of any finite number of linearly topologized A-modules; it is immediate that this product has the usual properties of associativity and commutativity.

(7.7.5). If B, C are two linearly topologized A-algebras, then the tensor product topology on $B \otimes_A C$ has for a fundamental system of neighbourhoods of 0 the *ideals* $\mathrm{Im}(\mathfrak{K} \otimes_A C) + \mathrm{Im}(B \otimes_A \mathfrak{L})$ of the algebra $B \otimes_A C$, $\mathfrak{K}$ (resp. $\mathfrak{L}$) varying over the set of open ideals of B (resp. C). As a result, $(B \otimes_A C)^\wedge$ is equipped with the structure of a *topological $\widehat{A}$-algebra*, the projective limit of the projective system of $A/\mathfrak{J}$-algebras $(B/\mathfrak{K}) \otimes_{A/\mathfrak{J}} (C/\mathfrak{L})$ ($\mathfrak{J}$ an open ideal of A such that $\mathfrak{J}B \subset \mathfrak{K}$, $\mathfrak{J}C \subset \mathfrak{L}$; such an ideal always exists). We say that this algebra is the *completed tensor product* of the algebras B and C.

(7.7.6). The A-algebra homomorphisms $b \mapsto b \otimes 1$, $c \mapsto 1 \otimes c$ from B and C to $B \otimes_A C$ are continuous when we equip the latter algebra with the tensor product topology; by composing with the canonical homomorphism from $B \otimes_A C$ to its separated completion, they give *canonical homomorphisms* $\rho : B \to (B \otimes_A C)^\wedge$, $\sigma : C \to (B \otimes_A C)^\wedge$. The algebra $(B \otimes_A C)^\wedge$ and the homomorphisms ρ and σ have in addition the following *universal property*: for every linearly topologized A-algebra D, separated and complete, and each pair of continuous A-homomorphisms $u : B \to D$, $v : C \to D$, there exists a unique continuous A-homomorphism $w : (B \otimes_A C)^\wedge \to D$ such that $u = w \circ \rho$ and $v = w \circ \sigma$.[12] Indeed, there already exists a unique A-homomorphism $w_0 : B \otimes_A C \to D$ such that $u(b) = w_0(b \otimes 1)$ and $v(c) = w_0(1 \otimes c)$, and it remains to prove that w_0 is *continuous*, since it then gives a continuous homomorphism w by passing to the separated completion. If $\mathfrak{M}$ is an open ideal $\mathbf{0_I}$ | 77
of D, then there exists by hypothesis open ideals $\mathfrak{K} \subset B$, $\mathfrak{L} \subset C$ such that $u(\mathfrak{K}) \subset \mathfrak{M}$, $v(\mathfrak{L}) \subset \mathfrak{M}$; the image under w_0 of $\mathrm{Im}(\mathfrak{K} \otimes_A C) + \mathrm{Im}(B \otimes_A \mathfrak{L})$ is again contained in $\mathfrak{M}$, hence our assertion.

Proposition (7.7.7). — *If B and C are two preadmissible A-algebras, then $(B \otimes_A C)^\wedge$ is admissible, and if $\mathfrak{K}$ (resp. $\mathfrak{L}$) is an ideal of definition for B (resp. C), then the closure in $(B \otimes_A C)^\wedge$ of the canonical image of $\mathfrak{H} = \mathrm{Im}(\mathfrak{K} \otimes_A C) + \mathrm{Im}(B \otimes_A \mathfrak{L})$ is an ideal of definition.*

Proof. It suffices to show that $\mathfrak{H}^n$ tends to 0 for the tensor product topology, which follows immediately from the inclusion

$$\mathfrak{H}^{2n} \subset \mathrm{Im}(\mathfrak{K}^n \otimes_A C) + \mathrm{Im}(B \otimes_A \mathfrak{L}^n).$$

□

Proposition (7.7.8). — *Let A be a preadic ring, $\mathfrak{J}$ an ideal of definition for A, M an A-module* of finite type, *equipped with the $\mathfrak{J}$-preadic topology. For every topological adic Noetherian A-algebra B, $B \otimes_A M$ identifies with the completed tensor product $(B \otimes_A M)^\wedge$.*

Proof. If $\mathfrak{K}$ is an ideal of definition for B, there exists by hypothesis an integer m such that $\mathfrak{J}^m B \subset \mathfrak{K}$, so $\mathrm{Im}(B \otimes_A \mathfrak{J}^{nm} M) = \mathrm{Im}(\mathfrak{J}^{nm} B \otimes_A M) \subset \mathrm{Im}(\mathfrak{K}^n B \otimes_A M) = \mathfrak{K}^n (B \otimes_A M)$; we conclude that on $B \otimes_A M$, the tensor product of the topologies of B and M is the $\mathfrak{K}$-preadic topology. As $B \otimes_A M$ is a B-module of finite type, the proposition follows from Corollary (7.3.6). □

[12] The French source repeats “et un seul” (“and unique”) in this clause; the English states the intended uniqueness once. [EG-EGA-I-P76-776-DUPLICATE-ET-UN-SEUL-SRC-001]

7.8. Topologies on modules of homomorphisms

(7.8.1). Let A be a *Noetherian* $\mathfrak{J}$*-adic* ring, M and N two A-modules of finite type, equipped with the $\mathfrak{J}$-preadic topology; we know (7.3.6) that they are separated and complete; in addition, every A-homomorphism $M \to N$ is automatically continuous, and the A-module $\mathrm{Hom}_A(M,N)$ is of finite type. For every integer $i \geqslant 0$, set $A_i = A/\mathfrak{J}^{i+1}$, $M_i = M/\mathfrak{J}^{i+1}M$, $N_i = N/\mathfrak{J}^{i+1}N$; for $i \leqslant j$, every homomorphism $u_j : M_j \to N_j$ maps $\mathfrak{J}^{i+1}M_j$ to $\mathfrak{J}^{i+1}N_j$, thus giving by passage to quotients a homomorphism $u_i : M_i \to N_i$, which defines a canonical homomorphism $\mathrm{Hom}_{A_j}(M_j,N_j) \to \mathrm{Hom}_{A_i}(M_i,N_i)$; in addition, the $\mathrm{Hom}_{A_i}(M_i,N_i)$ form a *projective system* for these homomorphisms, and it follows from Corollary (7.2.10) that there is a canonical isomorphism $\phi : \mathrm{Hom}_A(M,N) \to \varprojlim_i \mathrm{Hom}_{A_i}(M_i,N_i)$. In addition:

Proposition (7.8.2). — *If M and N are modules of finite type over a $\mathfrak{J}$-adic Noetherian ring A, then the submodules* $\mathrm{Hom}_A(M,\mathfrak{J}^{i+1}N)$ *form a fundamental system of neighbourhoods of* 0 *in* $\mathrm{Hom}_A(M,N)$ *for the $\mathfrak{J}$-adic topology, and the canonical isomorphism* $\phi : \mathrm{Hom}_A(M,N) \to \varprojlim_i \mathrm{Hom}_{A_i}(M_i,N_i)$ *is a topological isomorphism.*

Proof. We can consider M as the quotient of a free A-module L of finite type, and as a result identify $\mathrm{Hom}_A(M,N)$ as a submodule of $\mathrm{Hom}_A(L,N)$; in this identification, $\mathrm{Hom}_A(M,\mathfrak{J}^{i+1}N)$ is the intersection of $\mathrm{Hom}_A(M,N)$ and $\mathrm{Hom}_A(L,\mathfrak{J}^{i+1}N)$; as the induced topology on $\mathrm{Hom}_A(M,N)$ by the $\mathfrak{J}$-adic topology of $\mathrm{Hom}_A(L,N)$ is the $\mathfrak{J}$-adic topology (7.3.2), we have reduced to proving the first assertion for $M = L = A^m$; but then $\mathrm{Hom}_A(L,N) = N^m$, $\mathrm{Hom}_A(L,\mathfrak{J}^{i+1}N) = (\mathfrak{J}^{i+1}N)^m =$ $\mathbf{0}_{\mathbf{I}}$ | 78
$\mathfrak{J}^{i+1}N^m$ and the result is evident. To establish the second assertion, we note that the image of $\mathrm{Hom}_A(M,\mathfrak{J}^{i+1}N)$ in $\mathrm{Hom}_{A_j}(M_j,N_j)$ is zero for $j \leqslant i$, hence ϕ is continuous; conversely, the inverse image in $\mathrm{Hom}_A(M,N)$ of 0 of $\mathrm{Hom}_{A_i}(M_i,N_i)$ is $\mathrm{Hom}_A(M,\mathfrak{J}^{i+1}N)$, so ϕ is bicontinuous. □

If we only suppose that A is a *Noetherian* $\mathfrak{J}$*-preadic* ring, M and N two A-modules of finite type, separated for the $\mathfrak{J}$-preadic topology, then the preceding proof shows that the first assertion of Proposition (7.8.2) remains valid, and that ϕ is a topological isomorphism from $\mathrm{Hom}_A(M,N)$ to a submodule of $\varprojlim_i \mathrm{Hom}_{A_i}(M_i,N_i)$.

Proposition (7.8.3). — *Under the hypotheses of Proposition (7.8.2), the set of injective (resp. surjective, bijective) homomorphisms from M to N is an open subset of* $\mathrm{Hom}_A(M,N)$.

Proof. According to Corollaries (7.3.5) and (7.1.14), for u to be surjective, it is necessary and sufficient that the corresponding homomorphism $u_0 : M/\mathfrak{J}M \to N/\mathfrak{J}N$ is, and the set of surjective homomorphisms from M to N is thus the inverse image under the continuous map $\mathrm{Hom}_A(M,N) \to \mathrm{Hom}_{A_0}(M_0,N_0)$ of a subset of a discrete space. We now show that the set of injective homomorphisms is open; let v be such a homomorphism and set $M' = v(M)$; by the Artin–Rees Lemma (7.3.2.1), there exists an integer $k \geqslant 0$ such that $M' \cap \mathfrak{J}^{m+k}N \subset \mathfrak{J}^m M'$ for all $m > 0$; we will see that for all $w \in \mathfrak{J}^{k+1}\mathrm{Hom}_A(M,N)$, $u = v + w$ is injective, which will finish the proof. Indeed, let $x \in M$ be such that $u(x) = 0$; we prove that for every $i \geqslant 0$ the relation $x \in \mathfrak{J}^i M$ implies that $x \in \mathfrak{J}^{i+1}M$; it will then follow that $x \in \bigcap_{i\geqslant 0}\mathfrak{J}^i M = (0)$. Indeed, we then have $w(x) \in \mathfrak{J}^{i+k+1}N$, and as a result $w(x) = -v(x) \in M'$, so $v(x) \in M' \cap \mathfrak{J}^{i+k+1}N \subset \mathfrak{J}^{i+1}M'$, and as v is an isomorphism from M to M', $x \in \mathfrak{J}^{i+1}M$; q.e.d. □

§8. Representable functors

8.1. Representable functors $\mathbf{0}_{\mathbf{III}}$ | 5

(8.1.1). We denote by `Set` the category of sets. Let `C` be a category; for two objects X, Y of `C`, we set $h_X(Y) = \mathrm{Hom}(Y,X)$; for each morphism $u : Y \to Y'$ in `C`, we denote by $h_X(u)$ the map $v \mapsto vu$ from $\mathrm{Hom}(Y',X)$ to $\mathrm{Hom}(Y,X)$. It is immediate that with these definitions, $h_X : \mathtt{C} \to \mathtt{Set}$ is a *contravariant functor*, i.e., an object of the category $\mathtt{Hom}(\mathtt{C}^{\mathrm{op}},\mathtt{Set})$, of covariant functors from the category $\mathtt{C}^{\mathrm{op}}$ (the dual of the category `C`) to the category `Set` (T, 1.7, (d) and [Carb]).

(8.1.2). Now let $w : X \to X'$ be a morphism in $\mathtt{C}$; for each $Y \in \mathtt{C}$ and each $v \in \mathrm{Hom}(Y, X) = h_X(Y)$, we have $wv \in \mathrm{Hom}(Y, X') = h_{X'}(Y)$; we denote by $h_w(Y)$ the map $v \mapsto wv$ from $h_X(Y)$ to $h_{X'}(Y)$. It is immediate that for each morphism $u : Y \to Y'$ in $\mathtt{C}$, the diagram

$$\begin{tikzcd} h_X(Y') \arrow[r, "h_X(u)"] \arrow[d, "h_w(Y')"'] & h_X(Y) \arrow[d, "h_w(Y)"] \\ h_{X'}(Y') \arrow[r, "h_{X'}(u)"'] & h_{X'}(Y) \end{tikzcd}$$

is commutative; in other words, h_w is a *natural transformation (or functorial morphism)* $h_X \to h_{X'}$ (T, 1.2), also a morphism in the category $\mathtt{Hom}(\mathtt{C}^{\mathrm{op}}, \mathtt{Set})$ (T, 1.7, (d)). The definitions of h_X and of h_w therefore constitute the definition of a *canonical covariant functor*

(8.1.2.1) $$h : \mathtt{C} \longrightarrow \mathtt{Hom}(\mathtt{C}^{\mathrm{op}}, \mathtt{Set}), \quad X \longmapsto h_X.$$

(8.1.3). Let X be an object in $\mathtt{C}$, F a contravariant functor from $\mathtt{C}$ to $\mathtt{Set}$ (an object of $\mathtt{Hom}(\mathtt{C}^{\mathrm{op}}, \mathtt{Set})$). Let $g : h_X \to F$ be a *natural transformation*: for all $Y \in \mathtt{C}$, $g(Y)$ is thus a map $h_X(Y) \to F(Y)$ such that $\mathbf{0_{III}}$ | 6
for each morphism $u : Y \to Y'$ in $\mathtt{C}$, the diagram

(8.1.3.1) $$\begin{tikzcd} h_X(Y') \arrow[r, "h_X(u)"] \arrow[d, "g(Y')"'] & h_X(Y) \arrow[d, "g(Y)"] \\ F(Y') \arrow[r, "F(u)"'] & F(Y) \end{tikzcd}$$

is commutative. In particular, we have a map $g(X) : h_X(X) = \mathrm{Hom}(X, X) \to F(X)$, hence an element

(8.1.3.2) $$\alpha(g) = (g(X))(1_X) \in F(X)$$

and as a result a canonical map

(8.1.3.3) $$\alpha : \mathrm{Hom}(h_X, F) \longrightarrow F(X).$$

Conversely, consider an element $\xi \in F(X)$; for each morphism $v : Y \to X$ in $\mathtt{C}$, $F(v)$ is a map $F(X) \to F(Y)$; consider the map

(8.1.3.4) $$v \longmapsto (F(v))(\xi)$$

from $h_X(Y)$ to $F(Y)$; if we denote by $(\beta(\xi))(Y)$ this map,

(8.1.3.5) $$\beta(\xi) : h_X \longrightarrow F$$

is a *natural transformation*, since for each morphism $u : Y \to Y'$ in $\mathtt{C}$ we have $(F(vu))(\xi) = (F(u) \circ F(v))(\xi)$, which makes (8.1.3.1) commutative for $g = \beta(\xi)$. We have thus defined a canonical map

(8.1.3.6) $$\beta : F(X) \longrightarrow \mathrm{Hom}(h_X, F).$$

Proposition (8.1.4). — *The maps α and β are the inverse bijections of each other.*

Proof. We calculate $\alpha(\beta(\xi))$ for $\xi \in F(X)$; for each $Y \in \mathtt{C}$, $(\beta(\xi))(Y)$ is a map $g_1(Y) : v \mapsto (F(v))(\xi)$ from $h_X(Y)$ to $F(Y)$. We thus have

$$\alpha(\beta(\xi)) = (g_1(X))(1_X) = (F(1_X))(\xi) = 1_{F(X)}(\xi) = \xi.$$

We now calculate $\beta(\alpha(g))$ for $g \in \mathrm{Hom}(h_X, F)$; for each $Y \in \mathtt{C}$, $(\beta(\alpha(g)))(Y)$ is the map $v \mapsto (F(v))((g(X))(1_X))$; according to the commutativity of (8.1.3.1), this map is none other than $v \mapsto (g(Y))((h_X(v))(1_X)) = (g(Y))(v)$ by definition of $h_X(v)$, in other words, it is equal to $g(Y)$, which finishes the proof. □

(8.1.5). Recall that a *subcategory* $\mathtt{C}'$ of a category $\mathtt{C}$ is defined by the condition that its objects are objects of $\mathtt{C}$, and that if X', Y' are two objects of $\mathtt{C}'$, then the set $\mathrm{Hom}_{\mathtt{C}'}(X', Y')$ of morphisms $X' \to Y'$ *in* $\mathtt{C}'$ is a subset of the set $\mathrm{Hom}_{\mathtt{C}}(X', Y')$ of morphisms $X' \to Y'$ *in* $\mathtt{C}$, the canonical map of "composition of morphisms"

$$\mathrm{Hom}_{\mathtt{C}'}(X', Y') \times \mathrm{Hom}_{\mathtt{C}'}(Y', Z') \longrightarrow \mathrm{Hom}_{\mathtt{C}'}(X', Z')$$

being the restriction of the canonical map $\mathbf{0}_{\text{III}}$ | 7

$$\mathrm{Hom}_{\mathtt{C}}(X', Y') \times \mathrm{Hom}_{\mathtt{C}}(Y', Z') \longrightarrow \mathrm{Hom}_{\mathtt{C}}(X', Z').$$

We say that $\mathtt{C}'$ is a *full* subcategory of $\mathtt{C}$ if $\mathrm{Hom}_{\mathtt{C}'}(X', Y') = \mathrm{Hom}_{\mathtt{C}}(X', Y')$ for every pair of objects in $\mathtt{C}'$. The subcategory $\mathtt{C}''$ of $\mathtt{C}$ consisting of the objects of $\mathtt{C}$ isomorphic to objects of $\mathtt{C}'$ is then again a full subcategory of $\mathtt{C}$, *equivalent* (T, 1.2) to $\mathtt{C}'$ as we verify easily.

A covariant functor $F : \mathtt{C}_1 \to \mathtt{C}_2$ is called *fully faithful* if for every pair of objects X_1, Y_1 of $\mathtt{C}_1$, the map $u \mapsto F(u)$ from $\mathrm{Hom}(X_1, Y_1)$ to $\mathrm{Hom}(F(X_1), F(Y_1))$ is *bijective*; this implies that the subcategory $F(\mathtt{C}_1)$ of $\mathtt{C}_2$ is *full*. In addition, if two objects X_1, X_1' have the same image X_2, then there exists a unique isomorphism $u : X_1 \to X_1'$ such that $F(u) = 1_{X_2}$. For each object X_2 of $F(\mathtt{C}_1)$, let $G(X_2)$ be one of the objects X_1 of $\mathtt{C}_1$ such that $F(X_1) = X_2$ (G is defined by means of the axiom of choice); for each morphism $v : X_2 \to Y_2$ in $F(\mathtt{C}_1)$, $G(v)$ will be the unique morphism $u : G(X_2) \to G(Y_2)$ such that $F(u) = v$; G is then a *functor* from $F(\mathtt{C}_1)$ to $\mathtt{C}_1$; FG is the identity functor on $F(\mathtt{C}_1)$, and the above shows that there exists an isomorphism of functors $\phi : 1_{\mathtt{C}_1} \to GF$ such that F, G, ϕ, and the identity $1_{F(\mathtt{C}_1)} \to FG$ define an *equivalence* between the category $\mathtt{C}_1$ and the full subcategory $F(\mathtt{C}_1)$ of $\mathtt{C}_2$ (T, 1.2).

(8.1.6). We apply Proposition (8.1.4) to the case where F is $h_{X'}$, X' being any object of $\mathtt{C}$; the map $\beta : \mathrm{Hom}(X, X') \to \mathrm{Hom}(h_X, h_{X'})$ is none other than the map $w \mapsto h_w$ defined in (8.1.2); this map being *bijective*, we see with the terminology of (8.1.5) that:

Proposition (8.1.7). — *The canonical functor $h : \mathtt{C} \to \mathtt{Hom}(\mathtt{C}^{\mathrm{op}}, \mathtt{Set})$ is fully faithful.*

(8.1.8). Let F be a contravariant functor from $\mathtt{C}$ to $\mathtt{Set}$; we say that F is *representable* if there exists an object $X \in \mathtt{C}$ such that F is *isomorphic* to h_X; it follows from Proposition (8.1.7) that the data of an $X \in \mathtt{C}$ and an isomorphism of functors $g : h_X \to F$ determines X up to unique isomorphism. Proposition (8.1.7) then implies that h defines an *equivalence* between $\mathtt{C}$ and the full subcategory of $\mathtt{Hom}(\mathtt{C}^{\mathrm{op}}, \mathtt{Set})$ consisting of the *contravariant representable functors*. It follows from Proposition (8.1.4) that the data of a natural transformation $g : h_X \to F$ is equivalent to that of an element $\xi \in F(X)$; to say that g is an *isomorphism* is equivalent to the following condition on ξ: *for every object Y of $\mathtt{C}$ the map $v \mapsto (F(v))(\xi)$ from $\mathrm{Hom}(Y, X)$ to $F(Y)$ is bijective*. When ξ satisfies this condition, we say that the pair (X, ξ) *represents* the representable functor F. By abuse of language, we also say that the object $X \in \mathtt{C}$ represents F if there exists a $\xi \in F(X)$ such that (X, ξ) represents F, in other words if h_X is isomorphic to F.

Let F, F' be two contravariant representable functors from $\mathtt{C}$ to $\mathtt{Set}$, $h_X \to F$ and $h_{X'} \to F'$ two isomorphisms of functors. Then it follows from (8.1.6) that there is a canonical bijective correspondence between $\mathrm{Hom}(X, X')$ and the set $\mathrm{Hom}(F, F')$ of natural transformations $F \to F'$.

(8.1.9). *Example I. Projective limits*. The notion of a contravariant representable functor covers in particular the "dual" notion of the usual notion of a "solution to a universal problem". More $\mathbf{0}_{\text{III}}$ | 8
generally, we will see that the notion of the *projective limit* is a special case of the notion of a representable functor. Recall that in a category $\mathtt{C}$, we define a *projective system* by the data of a preordered set I, a family $(A_\alpha)_{\alpha \in I}$ of objects of $\mathtt{C}$, and for every pair of indices (α, β) such that $\alpha \leqslant \beta$, a morphism $u_{\alpha\beta} : A_\beta \to A_\alpha$. A *projective limit* of this system in $\mathtt{C}$ consists of an object B of $\mathtt{C}$ (denoted $\varprojlim A_\alpha$), and for each $\alpha \in I$, a morphism $u_\alpha : B \to A_\alpha$ such that: 1st. $u_\alpha = u_{\alpha\beta} u_\beta$ for $\alpha \leqslant \beta$; 2nd. for every object X of $\mathtt{C}$ and every family $(v_\alpha)_{\alpha \in I}$ of morphisms $v_\alpha : X \to A_\alpha$ such that $v_\alpha = u_{\alpha\beta} v_\beta$ for $\alpha \leqslant \beta$, there exists a unique morphism $v : X \to B$ (denoted $\varprojlim v_\alpha$) such that $v_\alpha = u_\alpha v$ for all $\alpha \in I$ (T, 1.8). This can be interpreted in the following way: the $u_{\alpha\beta}$ canonically define maps

$$\overline{u}_{\alpha\beta} : \mathrm{Hom}(X, A_\beta) \longrightarrow \mathrm{Hom}(X, A_\alpha)$$

which define a *projective system* of sets $(\mathrm{Hom}(X, A_\alpha), \overline{u}_{\alpha\beta})$, and (v_α) is by definition an element of the set $\varprojlim \mathrm{Hom}(X, A_\alpha)$; it is clear that $X \mapsto \varprojlim \mathrm{Hom}(X, A_\alpha)$ is a *contravariant functor* from $\mathtt{C}$ to $\mathtt{Set}$, and the existence of the projective limit B is equivalent to saying that $(v_\alpha) \mapsto \varprojlim v_\alpha$ is an *isomorphism* of functors in X

$$\varprojlim \mathrm{Hom}(X, A_\alpha) \simeq \mathrm{Hom}(X, B), \tag{8.1.9.1}$$

in other words, that the functor $X \mapsto \varprojlim \mathrm{Hom}(X, A_\alpha)$ is *representable*.

(8.1.10). *Example II. Final objects.* Let $\mathtt{C}$ be a category, $\{a\}$ a singleton set. Consider the contravariant functor $F : \mathtt{C} \to \mathtt{Set}$ which sends every object X of $\mathtt{C}$ to the set $\{a\}$, and every morphism $X \to X'$ in $\mathtt{C}$ to the unique map $\{a\} \to \{a\}$. To say that this functor is *representable* means that there exists an object $e \in \mathtt{C}$ such that for every $Y \in \mathtt{C}$, $\mathrm{Hom}(Y, e) = h_e(Y)$ is a *singleton set*; we say that e is an *final object* of $\mathtt{C}$, and it is clear that two final objects of $\mathtt{C}$ are isomorphic (which allows us to define, in general with the axiom of choice, *one* final object of $\mathtt{C}$ which we then denote $e_{\mathtt{C}}$). For example, in the category $\mathtt{Set}$, the final objects are the singleton sets; in the category of *augmented algebras* over a field K (where the morphisms are the algebra homomorphisms compatible with the augmentation), K is a final object; in the category of *S-preschemes* (**I**, 2.5.1), S is a final object.

(8.1.11). For two objects X and Y of a category $\mathtt{C}$, set $h'_X(Y) = \mathrm{Hom}(X, Y)$, and for every morphism $u : Y \to Y'$, let $h'_X(u)$ be the map $v \mapsto uv$ from $\mathrm{Hom}(X, Y)$ to $\mathrm{Hom}(X, Y')$; h'_X is then a *covariant functor* $\mathtt{C} \to \mathtt{Set}$, so we deduce as in (8.1.2) the definition of a canonical covariant functor $h' : \mathtt{C}^{\mathtt{op}} \to \mathtt{Hom}(\mathtt{C}, \mathtt{Set})$; a *covariant* functor F from $\mathtt{C}$ to $\mathtt{Set}$, in other words an object of $\mathtt{Hom}(\mathtt{C}, \mathtt{Set})$, is then *representable* if there exists an object $X \in \mathtt{C}$ (necessarily unique up to unique isomorphism) such that F is *isomorphic to* h'_X; we leave it to the reader to develop the "dual" notions of the above, which this time cover the notion of an *inductive limit*, and in particular the usual notion of a "solution to a universal problem".

8.2. Algebraic structures in categories

(8.2.1). Given two contravariant functors F and F' from $\mathtt{C}$ to $\mathtt{Set}$, recall that for every object $Y \in \mathtt{C}$, $\mathbf{0}_{\mathbf{III}}$ | 9
we set $(F \times F')(Y) = F(Y) \times F'(Y)$, and for every morphism $u : Y \to Y'$ in $\mathtt{C}$, we set $(F \times F')(u) = F(u) \times F'(u)$, which is the map $(t, t') \mapsto (F(u)(t), F'(u)(t'))$ from $F(Y') \times F'(Y')$ to $F(Y) \times F'(Y)$; $F \times F' : \mathtt{C} \to \mathtt{Set}$ is thus a *contravariant functor* (which is none other than the *product* of the objects F and F' in the category $\mathtt{Hom}(\mathtt{C}^{\mathtt{op}}, \mathtt{Set})$). Given an object $X \in \mathtt{C}$, we call an *internal composition law* on X a *natural transformation*

(8.2.1.1) $$\gamma_X : h_X \times h_X \longrightarrow h_X.$$

In other words (T, 1.2), for every object $Y \in \mathtt{C}$, $\gamma_X(Y)$ is a map $h_X(Y) \times h_X(Y) \to h_X(Y)$ (thus by definition an *internal composition law* on the set $h_X(Y)$) with the condition that for every morphism $u : Y \to Y'$ in $\mathtt{C}$, the diagram

$$\begin{tikzcd} h_X(Y') \times h_X(Y') \arrow[r, "h_X(u) \times h_X(u)"] \arrow[d, "\gamma_X(Y')"'] & h_X(Y) \times h_X(Y) \arrow[d, "\gamma_X(Y)"] \\ h_X(Y') \arrow[r, "h_X(u)"'] & h_X(Y) \end{tikzcd}$$

is commutative; this implies that for the composition laws $\gamma_X(Y)$ and $\gamma_X(Y')$, $h_X(u)$ is a *homomorphism* from $h_X(Y')$ to $h_X(Y)$.

In a similar way, given two objects Z and X of $\mathtt{C}$, we call an *external composition law on X, with Z as its domain of operators* a natural transformation

(8.2.1.2) $$\omega_{X,Z} : h_Z \times h_X \longrightarrow h_X.$$

We see as above that for every $Y \in \mathtt{C}$, $\omega_{X,Z}(Y)$ is an external composition law on $h_X(Y)$, with $h_Z(Y)$ as its domain of operators and such that for every morphism $u : Y \to Y'$, $h_X(u)$ and $h_Z(u)$ form a *di-homomorphism* from $(h_Z(Y'), h_X(Y'))$ to $(h_Z(Y), h_X(Y))$.

(8.2.2). Let X' be a second object of $\mathtt{C}$, and suppose we are given an internal composition law $\gamma_{X'}$ on X'; we say that a morphism $w : X \to X'$ in $\mathtt{C}$ is a *homomorphism* for the composition laws if for every $Y \in \mathtt{C}$, $h_w(Y) : h_X(Y) \to h_{X'}(Y)$ is a *homomorphism* for the composition laws $\gamma_X(Y)$ and $\gamma_{X'}(Y)$. If X'' is a third object of $\mathtt{C}$ equipped with an internal composition law $\gamma_{X''}$ and $w' : X' \to X''$ is a morphism $\mathbf{0}_{\mathbf{III}}$ | 10
in $\mathtt{C}$ which is a homomorphism for $\gamma_{X'}$ and $\gamma_{X''}$, then it is clear that the morphism $w'w : X \to X''$ is a homomorphism for the composition laws γ_X and $\gamma_{X''}$. An isomorphism $w : X \simeq X'$ in $\mathtt{C}$ is called

an *isomorphism for the composition laws* γ_X *and* $\gamma_{X'}$ if w is a homomorphism for these composition laws, and if its inverse morphism w^{-1} is a homomorphism for the composition laws $\gamma_{X'}$ and γ_X.

We define in a similar way the *di-homomorphisms* for pairs of objects of $\mathtt{C}$ equipped with external composition laws.

(8.2.3). When an internal composition law γ_X on an object $X \in \mathtt{C}$ is such that $\gamma_X(Y)$ is a *group law* on $h_X(Y)$ for *every* $Y \in \mathtt{C}$, we say that X, equipped with this law, is a $\mathtt{C}$-*group* or a *group object in* $\mathtt{C}$. We similarly define $\mathtt{C}$-*rings*, $\mathtt{C}$-*modules*, etc.

(8.2.4). Suppose that the *product* $X \times X$ of an object $X \in \mathtt{C}$ by itself exists in $\mathtt{C}$; by definition, we then have $h_{X\times X} = h_X \times h_X$ up to canonical isomorphism, since it is a particular case of the projective limit (8.1.9); an internal composition law on X can thus be considered as a functorial morphism $\gamma_X : h_{X\times X} \to h_X$, and thus canonically determines (8.1.6) an element $c_X \in \operatorname{Hom}(X \times X, X)$ such that $h_{c_X} = \gamma_X$; in this case, the data of an internal composition law on X is equivalent to the data of a morphism $X \times X \to X$; when $\mathtt{C}$ is the category $\mathtt{Set}$, we recover the classical notion of an internal composition law on a set. We have an analogous result for an external composition law when the product $Z \times X$ exists in $\mathtt{C}$.

(8.2.5). With the above notation, suppose that in addition $X \times X \times X$ exists in $\mathtt{C}$; the characterization of the product as an object representing a functor (8.1.9) implies the existence of canonical isomorphisms

$$(X \times X) \times X \simeq X \times X \times X \simeq X \times (X \times X);$$

if we canonically identify $X \times X \times X$ with $(X \times X) \times X$, then the map $\gamma_X(Y) \times 1_{h_X(Y)}$ identifies with $h_{c_X \times 1_X}(Y)$ for all $Y \in \mathtt{C}$. As a result, it is equivalent to say that for every $Y \in \mathtt{C}$, the internal law $\gamma_X(Y)$ is associative, or that the diagram of maps

$$\begin{tikzcd}
h_X(Y) \times h_X(Y) \times h_X(Y) \arrow[r, "\gamma_X(Y)\times 1"] \arrow[d, "1\times\gamma_X(Y)"'] & h_X(Y) \times h_X(Y) \arrow[d, "\gamma_X(Y)"] \\
h_X(Y) \times h_X(Y) \arrow[r, "\gamma_X(Y)"'] & h_X(Y)
\end{tikzcd}$$

is commutative, or that the diagram of morphisms **0_{III} | 11**

$$\begin{tikzcd}
X \times X \times X \arrow[r, "c_X\times 1_X"] \arrow[d, "1_X\times c_X"'] & X \times X \arrow[d, "c_X"] \\
X \times X \arrow[r, "c_X"'] & X
\end{tikzcd}$$

is commutative.

(8.2.6). Under the hypotheses of (8.2.5), if we want to express, for every $Y \in \mathtt{C}$, the internal law $\gamma_X(Y)$ as a *group law*, then it is first necessary that it is associative, and second that there exists a map $\alpha_X(Y) : h_X(Y) \to h_X(Y)$ having the properties of the *inverse* operation of a group; as for every morphism $u : Y \to Y'$ in $\mathtt{C}$, we have seen that $h_X(u)$ must be a group homomorphism $h_X(Y') \to h_X(Y)$, we first see that $\alpha_X : h_X \to h_X$ must be a *natural transformation*. On the other hand, one can express the characteristic properties of the inverse $s \mapsto s^{-1}$ of a group G without involving the identity element: it suffices to check that the two composite maps

$$(s,t) \longmapsto (s, s^{-1}, t) \longmapsto (s, s^{-1}t) \longmapsto s(s^{-1}t),$$

$$(s,t) \longmapsto (s, s^{-1}, t) \longmapsto (s, ts^{-1}) \longmapsto (ts^{-1})s$$

are equal to the second projection $(s,t) \mapsto t$ from $G \times G$ to G. By (8.1.3), we have $\alpha_X = h_{a_X}$, where $a_X \in \mathrm{Hom}(X,X)$; the first condition above then expresses that the composite morphism

$$X \times X \xrightarrow{(1_X, a_X)\times 1_X} X \times X \times X \xrightarrow{1_X \times c_X} X \times X \xrightarrow{c_X} X$$

is the second projection $X \times X \to X$ in $\mathtt{C}$, and the second condition is similar.

(8.2.7). Now suppose that there exists a *final object* e (8.1.10) in $\mathtt{C}$. Let us always assume that $\gamma_X(Y)$ is a group law on $h_X(Y)$ for every $Y \in \mathtt{C}$, and denote by $\eta_X(Y)$ the identity element of $\gamma_X(Y)$. As, for every morphism $u : Y \to Y'$ in $\mathtt{C}$, $h_X(u)$ is a group homomorphism, we have $\eta_X(Y) = (h_X(u))(\eta_X(Y'))$; taking in particular $Y' = e$, in which case u is the unique element ε of $\mathrm{Hom}(Y,e)$, we see that the element $\eta_X(e)$ completely determines $\eta_X(Y)$ for every $Y \in \mathtt{C}$. Set $e_X = \eta_X(X)$, the identity element of the group $h_X(X) = \mathrm{Hom}(X,X)$; the commutativity of the diagram

$$\begin{tikzcd} h_X(e) \arrow[r, "h_X(\varepsilon)"] \arrow[d, "h_{e_X}(e)"'] & h_X(Y) \arrow[d, "h_{e_X}(Y)"] \\ h_X(e) \arrow[r, "h_X(\varepsilon)"'] & h_X(Y) \end{tikzcd}$$

(cf. (8.1.2)) shows that, on the set $h_X(Y)$, the map $h_{e_X}(Y)$ is none other than $s \mapsto \eta_X(Y)$ sending every element to the identity element. We then verify that the fact that $\eta_X(Y)$ is the identity element of $\gamma_X(Y)$ for every $Y \in \mathtt{C}$ is equivalent to saying that the composite morphism **0**$_{\mathbf{III}}$ | 12

$$X \xrightarrow{(1_X, 1_X)} X \times X \xrightarrow{1_X \times e_X} X \times X \xrightarrow{c_X} X,$$

and the analog in which we swap 1_X and e_X, are both *equal* to 1_X.

(8.2.8). One could of course easily extend the examples of algebraic structures in categories. The example of groups was treated with enough detail, but later on we will usually leave it to the reader to develop analogous notions for the examples of algebraic structures we will encounter.

§9. Constructible sets

9.1. Constructible sets

Definition (9.1.1). — We say that a continuous map $f : X \to Y$ is *quasi-compact* if for every quasi-compact open subset U of Y, $f^{-1}(U)$ is quasi-compact. We say that a subset Z of a topological space X is *retrocompact* in X if the canonical injection $Z \to X$ is quasi-compact, in other words, if for every quasi-compact open subset U of X, $U \cap Z$ is quasi-compact.

A *closed* subset of X is retrocompact in X, but a quasi-compact subset of X is not necessarily retrocompact in X. If X is quasi-compact, every retrocompact open subset of X is quasi-compact. It is clear that every *finite* union of retrocompact sets in X is retrocompact in X, as every finite union of quasi-compact sets is quasi-compact. Every finite intersection of retrocompact open sets in X is a retrocompact open set in X. In a *locally Noetherian* space X, every quasi-compact set is a Noetherian subspace, and as a result *every subset* of X is retrocompact in X.

Definition (9.1.2). — Given a topological space X, we say that a subset of X is *constructible* if it belongs to the smallest set of subsets $\mathfrak{F}$ of X containing all the retrocompact open subsets of X and stable under finite intersections and complements (which implies that $\mathfrak{F}$ is also stable under finite unions).

Proposition (9.1.3). — *For a subset of X to be constructible, it is necessary and sufficient for it to be a finite union of sets of the form $U \cap \complement V$, where U and V are retrocompact open sets in X.*

Proof. It is clear that the condition is sufficient. To see that it is necessary, consider the set $\mathfrak{G}$ of finite unions of sets of the form $U \cap \complement V$, where U and V are retrocompact open sets in X; it suffices to see that every complement of a set in $\mathfrak{G}$ is in $\mathfrak{G}$. Let $Z = \bigcup_{i \in I}(U_i \cap \complement V_i)$, where I is finite, U_i and V_i retrocompact open sets in X; we have $\complement Z = \bigcap_{i\in I}(V_i \cup \complement U_i)$, so $\complement Z$ is a finite union of sets which are intersections of a certain number of the V_i and of a certain number of the $\complement U_i$, thus of the form

$V \cap \complement U$, where U is the union of a certain number of the U_i and V is the intersection of a certain number of the V_i; but we have noted above that finite unions and intersections of retrocompact open sets in X are retrocompact open sets in X, hence the conclusion. □ $\mathbf{0}_{\mathbf{III}}$ | 13

Corollary (9.1.4). — *Every constructible subset of X is retrocompact in X.*

Proof. It suffices to show that if U and V are retrocompact open sets in X, then $U \cap \complement V$ is retrocompact in X; if W is a quasi-compact open set in X, then $W \cap U \cap \complement V$ is closed in the quasi-compact space $W \cap U$, hence it is quasi-compact. □

In particular:

Corollary (9.1.5). — *For an open subset U of X to be constructible, it is necessary and sufficient for it to be retrocompact in X. For a closed subset F of X to be constructible, it is necessary and sufficient for the open set $\complement F$ to be retrocompact.*

(9.1.6). An important case is when every quasi-compact open subset of X is retrocompact, in other words, when the intersection of two quasi-compact open subsets of X is quasi-compact (cf. (**I**, 5.5.6)). When X is also quasi-compact, this implies that the retrocompact open subsets of X are identical to the quasi-compact open subsets of X, and the constructible subsets of X are finite unions of sets of the form $U \cap \complement V$, where U and V are quasi-compact open sets.

Corollary (9.1.7). — *For a subset of a Noetherian space X to be constructible, it is necessary and sufficient for it to be a finite union of locally closed subsets of X.*

Proposition (9.1.8). — *Let X be a topological space, U an open subset of X.*

(i) *If T is a constructible subset of X, then $T \cap U$ is a constructible subset of U.*
(ii) *In addition, suppose that U is retrocompact in X. For a subset Z of U to be constructible in X, it is necessary and sufficient for it to be constructible in U.*

Proof.

(i) Using Proposition (9.1.3), we reduce to showing that if T is a retrocompact open set in X, then $T \cap U$ is a retrocompact open set in U, in other words, for every quasi-compact open $W \subset U$, $T \cap U \cap W = T \cap W$ is quasi-compact, which immediately follows from the hypothesis.
(ii) The condition is necessary by (i), so it remains to show that it is sufficient. By Proposition (9.1.3), it suffices to consider the case where Z is a retrocompact open set *in U*, because it will then follow that $U - Z$ is constructible in X, and if Z and Z' are two retrocompact opens *in* U, then $Z \cap (U - Z')$ will be constructible in X. If W is a quasi-compact open set in X and Z a retrocompact open set in U, then we have $Z \cap W = Z \cap (W \cap U)$, and by hypothesis $W \cap U$ is a quasi-compact open set in U; so $W \cap Z$ is quasi-compact, and as a result Z is a retrocompact open set in X, and *a fortiori* constructible in X.

□

Corollary (9.1.9). — *Let X be a topological space, $(U_i)_{i \in I}$ a finite cover of X by retrocompact open sets in X. For a subset Z of X to be constructible in X, it is necessary and sufficient for $Z \cap U_i$ to be constructible in U_i for all $i \in I$.*

(9.1.10). In particular, suppose that X is quasi-compact and every point of X admits a fundamental system of retrocompact open neighbourhoods in X (and *a fortiori* quasi-compact); then the condition for a subset Z of X to be constructible in X is of a *local* nature, in other words, it is necessary and sufficient that for every $x \in X$, there exists an open neighbourhood V of x such that $V \cap Z$ is constructible in V. Indeed, if this condition is satisfied, then there exists for every $x \in X$ an open neighbourhood V of x which is *retrocompact in* X and such that $V \cap Z$ is constructible in V, by the hypotheses on X and by Proposition (9.1.8, i); it then suffices to cover X by a finite number of these neighbourhoods and to apply Corollary (9.1.9). $\mathbf{0}_{\mathbf{III}}$ | 14

Definition (9.1.11). — Let X be a topological space. We say that a subset T of X is *locally constructible* in X if for every $x \in X$ there exists an open neighbourhood V of x such that $T \cap V$ is constructible in V.

It follows from Proposition (9.1.8, i) that if V is such that $V \cap T$ is constructible in V, then for every open $W \subset V$, $W \cap T$ is constructible in W. If T is locally constructible in X, then for every open set U in X, $T \cap U$ is locally constructible in U, as a result of the above remark. The same remark shows that the set of locally constructible subsets of X is stable under finite unions and finite intersections; on the other hand, it is clear that it is also stable under taking complements.

Proposition (9.1.12). — *Let X be a topological space. Every constructible set in X is locally constructible in X. The converse is true if X is quasi-compact and if its topology admits a basis formed by the retrocompact sets in X.*

Proof. The first assertion follows from Definition (9.1.11) and the second from (9.1.10). □

Corollary (9.1.13). — *Let X be a topological space whose topology admits a basis formed by the retrocompact sets in X. Then every locally constructible subset T of X is retrocompact in X.*

Proof. Let U be a quasi-compact open set in X; $T \cap U$ is locally constructible in U, hence constructible in U by Proposition (9.1.12), and as a result quasi-compact by Corollary (9.1.4). □

9.2. Constructible subsets of Noetherian spaces

(9.2.1). We have seen (9.1.7) that in a Noetherian space X, the constructible subsets of X are the *finite unions of locally closed subsets of X*.

The inverse image of a constructible set in X by a continuous map from a Noetherian space X' to X is constructible in X'. If Y is a constructible subset of a Noetherian space X, then the subsets of Y which are constructible as subspaces of Y are identical to those which are constructible as subspaces of X.

Proposition (9.2.2). — *Let X be an irreducible Noetherian space, E a constructible subset of X. For E to be everywhere dense in X, it is necessary and sufficient for E to contain a nonempty open subset of X.*

Proof. The condition is evidently sufficient, as every nonempty open set is dense in X. Conversely, $\mathbf{0}_{\mathrm{III}}$ | 15
let $E = \bigcup_{i=1}^{n}(U_i \cap F_i)$ be a constructible subset of X, the U_i being nonempty open sets and the F_i closed in X; we then have $\overline{E} \subset \bigcup_i F_i$. As a result, if $\overline{E} = X$, then X is equal to one of the F_i, hence $E \supset U_i$, which finishes the proof. □

When X admits a generic point x (**0**, 2.1.2), the condition of Proposition (9.2.2) is equivalent to the relation $x \in E$.

Proposition (9.2.3). — *Let X be a Noetherian space. For a subset E of X to be constructible, it is necessary and sufficient that, for every irreducible closed subset Y of X, $E \cap Y$ is rare in Y or contains a nonempty open subset of Y.*

Proof. The necessity of the condition follows from the fact that $E \cap Y$ must be a constructible subset of Y and from Proposition (9.2.2), since a nondense subset of Y is necessarily rare in the irreducible space Y (**0**, 2.1.1). To prove that the condition is sufficient, apply the principle of Noetherian induction (**0**, 2.2.2) to the set $\mathfrak{F}$ of closed subsets Y of X such that $Y \cap E$ is constructible (with respect to Y or with respect to X, which are equivalent): we can thus assume that for every closed subset $Y \neq X$ of X, $E \cap Y$ is constructible. First suppose that X is not irreducible, and let X_i $(1 \leqslant i \leqslant m)$ be its irreducible components, necessarily of finite number (**0**, 2.2.5); by hypothesis the $E \cap X_i$ are constructible, hence their union E is as well. Suppose now that X is irreducible; then by hypothesis, if E is rare, then $\overline{E} \neq X$ and $E = E \cap \overline{E}$ is constructible; if E contains a nonempty open subset U of X, then it is the union of U and $E \cap (X - U)$; but $X - U$ is a closed set distinct from X, so $E \cap (X - U)$ is constructible; as a result, E is itself constructible, which finishes the proof. □

Corollary (9.2.4). — *Let X be a Noetherian space, (E_α) an increasing filtered family of constructible subsets of X, such that*

(1st) *X is the union of the family (E_α).*

(2nd) *Every irreducible closed subset of X is contained in the closure of one of the E_α.*

Then there exists an index α such that $X = E_\alpha$.

When every irreducible closed subset of X admits a generic point, the hypothesis (2nd) *can be omitted.*

Proof. We apply the principle of Noetherian induction (**0**, 2.2.2) to the set $\mathfrak{M}$ of closed subsets of X contained in at least one of the E_α; we can thus suppose that every closed subset $Y \neq X$ of X is contained in one of the E_α. The proposition is evident if X is not irreducible, because each of the irreducible components X_i of X ($1 \leqslant i \leqslant m$) is contained in an E_{α_i}, and there exists an E_α containing all of the E_{α_i}. Now suppose that X is irreducible. By hypothesis, there exists a β such that $X = \overline{E_\beta}$, so (9.2.2) E_β contains a nonempty open subset U of X. But then the closed set $X - U$ is contained in an E_γ, and it suffices to take an E_α containing E_β and E_γ. When every irreducible closed subset Y of X admits a generic point y, there exists α such that $y \in E_\alpha$, so $Y = \overline{\{y\}} \subset \overline{E_\alpha}$, and condition (2nd) is therefore a consequence of (1st). □ $\mathbf{0}_{\mathbf{III}}$ | 16

Proposition (9.2.5). — *Let X be a Noetherian space, x a point of X, and E a constructible subset of X. For E to be a neighbourhood of x, it is necessary and sufficient that for every irreducible closed subset Y of X containing x, $E \cap Y$ is dense in Y (if there exists a generic point y of Y, this also means (9.2.2) that $y \in E$).*

Proof. The condition is evidently necessary; we will prove that it is sufficient. Applying the principle of Noetherian induction to the set $\mathfrak{M}$ of closed subsets Y of X containing x and such that $E \cap Y$ is a neighbourhood of x in Y, we can assume that every closed subset $Y \neq X$ of X containing x belongs to $\mathfrak{M}$. If X is not irreducible, then each of the irreducible components X_i of X containing x is distinct from X, hence $E \cap X_i$ is a neighbourhood of x with respect to X_i; as a result, E is a neighbourhood of x in the union of the irreducible components of X containing x, and as this union is a neighbourhood of x in X, so is E. If X is irreducible, then E is dense in X by hypothesis, so it contains a nonempty open subset U of X (9.2.2); the proposition is then evident if $x \in U$; otherwise, by hypothesis, x is an interior point of $E \cap (X - U)$ relative to $X - U$, so the closure of $X - E$ in X does not contain x, and the complement of this closure is a neighbourhood of x contained in E, which finishes the proof. □

Corollary (9.2.6). — *Let X be a Noetherian space, E a subset of X. For E to be an open set in X, it is necessary and sufficient that for every irreducible closed subset Y of X intersecting E, $E \cap Y$ contains a nonempty open subset of Y.*

Proof. The condition is evidently necessary; conversely, if it is satisfied, then it implies that E is constructible by Proposition (9.2.3). In addition, Proposition (9.2.5) shows that E is then a neighbourhood of each of its points, hence the conclusion. □

9.3. Constructible functions

Definition (9.3.1). — Let h be a map from a topological space X to a set T. We say that h is *constructible* if $h^{-1}(t)$ is constructible for every $t \in T$, and empty except for finitely many values of t; then for every subset S of T, $h^{-1}(S)$ is constructible. We say that h is *locally constructible* if every $x \in X$ has an open neighbourhood V such that $h|V$ is constructible.

Every constructible function is locally constructible; the converse is true when X is quasi-compact and admits a basis formed by the retrocompact open sets in X (in particular, when X is Noetherian).

Proposition (9.3.2). — *Let h be a map from a Noetherian space X to a set T. For h to be constructible, it is necessary and sufficient that for every irreducible closed subset Y of X, there exists a nonempty subset U of Y, open with respect to Y, in which h is constant.*

Proof. The condition is necessary: indeed, by hypothesis, h takes only finitely many values t_i on Y, and each of the sets $h^{-1}(t_i) \cap Y$ is constructible in Y (9.2.1); as they can not all be rare subsets of the space Y, at least one of them contains a nonempty open set (9.2.3).

To see that the condition is sufficient, we apply the principle of Noetherian induction on the set $\mathfrak{M}$ of closed subsets Y of X such that the restriction $h|Y$ is constructible; we can thus assume that for every closed subset $Y \neq X$ of X, $h|Y$ is constructible. If X is not irreducible, then the restriction of h to each of the (finitely many) irreducible components X_i of X is constructible, and it then follows immediately from Definition (9.3.1) that h is constructible. If X is irreducible, then there exists by hypothesis a nonempty open subset U of X on which h is constant; on the other hand, the restriction of h to $X - U$ is constructible by hypothesis, and it follows immediately that h is constructible. □ $\mathbf{0}_{\mathbf{III}}$ | 17

Corollary (9.3.3). — *Let X be a Noetherian space in which every irreducible closed subset admits a generic point. If h is a map from X to a set T such that, for every $t \in T$, $h^{-1}(t)$ is constructible, then h is constructible.*

Proof. If Y is an irreducible closed subset of X and y its generic point, then $Y \cap h^{-1}(h(y))$ is constructible and contains y, hence (9.2.2) this set contains a nonempty open subset of Y, and it suffices to apply Proposition (9.3.2). ☐

Proposition (9.3.4). — *Let X be a Noetherian space in which every irreducible closed subset admits a generic point, h a constructible map from X to an ordered set. For h to be upper semi-continuous on X, it is necessary and sufficient that for every $x \in X$ and every generization* (**0**, 2.1.2) *x' of x, we have $h(x') \leqslant h(x)$.*

Proof. The function h takes only finitely many values; therefore, to say that it is upper semi-continuous means that for every $x \in X$, the set E of the $y \in X$ such that $h(y) \leqslant h(x)$ is a neighbourhood of x. By hypothesis, E is a constructible subset of X; on the other hand, to say that an irreducible closed subset Y of X contains x means that its generic point y is a generization of x; the conclusion then follows from Proposition (9.2.5). ☐

§10. Supplement on flat modules

For any proofs missing in (10.1) and (10.2), we refer the reader to Bourbaki, *Alg. comm.*, chap. II and III.

10.1. Relations between flat modules and free modules

(10.1.1). Let A be a ring, $\mathfrak{J}$ an ideal of A, and M an A-module; for every integer $p \geqslant 0$, we have a canonical homomorphism of $(A/\mathfrak{J})$-modules

$$\phi_p : (M/\mathfrak{J}M) \otimes_{A/\mathfrak{J}} (\mathfrak{J}^p/\mathfrak{J}^{p+1}) \longrightarrow \mathfrak{J}^p M/\mathfrak{J}^{p+1}M, \tag{10.1.1.1}$$

which is evidently *surjective*. We denote by $\operatorname{gr}(A) = \oplus_{p\geqslant 0}\mathfrak{J}^p/\mathfrak{J}^{p+1}$ the graded ring associated to A filtered by the $\mathfrak{J}^p$, and by $\operatorname{gr}(M) = \oplus_{p\geqslant 0}\mathfrak{J}^p M/\mathfrak{J}^{p+1}M$ the graded $\operatorname{gr}(A)$-module associated to M filtered by the $\mathfrak{J}^p M$; we then have $\operatorname{gr}_p(A) = \mathfrak{J}^p/\mathfrak{J}^{p+1}$, and $\operatorname{gr}_p(M) = \mathfrak{J}^p M/\mathfrak{J}^{p+1}M$; the ϕ define a *surjective* homomorphism of graded $\operatorname{gr}(A)$-modules

$$\phi : \operatorname{gr}_0(M) \otimes_{\operatorname{gr}_0(A)} \operatorname{gr}(A) \longrightarrow \operatorname{gr}(M). \tag{10.1.1.2}$$

0_III-1 | 18

(10.1.2). Suppose that *one* of the following hypotheses is satisfied:

(i) $\mathfrak{J}$ is nilpotent;
(ii) A is Noetherian, $\mathfrak{J}$ is contained in the radical of A, and M is of finite type.

Then the following properties are equivalent.

(a) M is a free A-module.
(b) $M/\mathfrak{J}M = M \otimes_A (A/\mathfrak{J})$ is a free $(A/\mathfrak{J})$-module, and $\operatorname{Tor}_1^A(M, A/\mathfrak{J}) = 0$.
(c) $M/\mathfrak{J}M$ is a free $(A/\mathfrak{J})$-module, and the canonical homomorphism (10.1.1.2) is injective (and thus bijective).

(10.1.3). Suppose that $A/\mathfrak{J}$ is a *field* (in other words, that $\mathfrak{J}$ is maximal), and that one of the hypotheses, (i) and (ii), of (10.1.2) is satisfied. Then the following properties are equivalent.

(a) M is a free A-module.
(b) M is a projective A-module.
(c) M is a flat A-module.
(d) $\operatorname{Tor}_1^A(M, A/\mathfrak{J}) = 0$.
(e) The canonical homomorphism (10.1.1.2) is bijective.

This result can be applied, in particular, to the following two cases:

(i) M is an *arbitrary* module, over a local ring A whose maximal ideal $\mathfrak{J}$ is *nilpotent* (for example, a local Artinian ring);
(ii) M is a module *of finite type* over a *local Noetherian* ring.

10.2. Local flatness criteria

(10.2.1). With the hypotheses and notation of (10.1.1), consider the following conditions.

(a) M is a flat A-module.
(b) $M/\mathfrak{J}M$ is a flat $(A/\mathfrak{J})$-module, and $\operatorname{Tor}_1^A(M, A/\mathfrak{J}) = 0$.
(c) $M/\mathfrak{J}M$ is a flat $(A/\mathfrak{J})$-module, and the canonical homomorphism (10.1.1.2) is bijective.
(d) For all $n \geqslant 1$, $M/\mathfrak{J}^n M$ is a flat $(A/\mathfrak{J}^n)$-module.

Then we have the implications

$$\text{(a)} \implies \text{(b)} \implies \text{(c)} \implies \text{(d)},$$

and, if $\mathfrak{J}$ is *nilpotent*, then the four conditions are *equivalent*. This is also the case if A is Noetherian and M is *ideally separated*, that is to say, for every ideal $\mathfrak{a}$ of A, the A-module $\mathfrak{a} \otimes_A M$ is *separated* for the $\mathfrak{J}$-preadic topology.

(10.2.2). Let A be a Noetherian ring, B a commutative Noetherian A-algebra, $\mathfrak{J}$ an ideal of A such that $\mathfrak{J}B$ is contained in the radical of B, and M a B-*module* of finite type. Then, when M is considered as an A-*module*, the four conditions of (10.2.1) are *equivalent*. This result applies first and foremost in the case where A and B are *local* Noetherian rings, with the homomorphism $A \to B$ being a *local* homomorphism. More specifically, if $\mathfrak{J}$ is then the *maximal* ideal of A, we can, in conditions *(b)* and *(c)*, remove the hypothesis that $M/\mathfrak{J}M$ is flat, since it is automatically satisfied, and condition *(d)* implies that the modules $M/\mathfrak{J}^n M$ are *free* over the $A/\mathfrak{J}^n$. $\mathbf{0}_{\mathbf{III\text{-}1}}$ | 19

(10.2.3). With the hypotheses on A, B, $\mathfrak{J}$, and M from the start of (10.2.2), let $\widehat{A}$ be the separated completion of A for the $\mathfrak{J}$-preadic topology, and $\widehat{M}$ the separated completion of M for the $\mathfrak{J}B$-preadic topology. Then, for M to be a flat A-module, it is necessary and sufficient for $\widehat{M}$ to be a flat $\widehat{A}$-module.

(10.2.4). Let $\rho : A \to B$ be a local homomorphism of local Noetherian rings, k the residue field of A, and M and N both B-modules of finite type, with N assumed to be A-*flat*. Let $u : M \to N$ be a B-homomorphism. Then the following conditions are equivalent.

(a) u is injective, and $\operatorname{Coker}(u)$ is a flat A-module.
(b) $u \otimes 1 : M \otimes_A k \to N \otimes_A k$ is injective.

(10.2.5). Let $\rho : A \to B$ and $\sigma : B \to C$ be local homomorphisms of local Noetherian rings, k the residue field of A, and M a C-module of finite type. Suppose that B is a *flat* A-module. Then the following conditions are equivalent.

(a) M is a flat B-module.
(b) M is a flat A-module, and $M \otimes_A k$ is a flat $(B \otimes_A k)$-module.

Proposition (10.2.6). — *Let A and B be local Noetherian rings, $\rho : A \to B$ a local homomorphism, $\mathfrak{J}$ an ideal of B contained in the maximal ideal, and M a B-module of finite type. Suppose that, for all $n \geqslant 0$, $M_n = M/\mathfrak{J}^{n+1}M$ is a flat A-module. Then M is a flat A-module.*

Proof. We have to prove that, for every injective homomorphism $u : N' \to N$ of A-modules of finite type, $v = 1 \otimes u : M \otimes_A N' \to M \otimes_A N$ is injective. But $M \otimes_A N'$ and $M \otimes_A N$ are B-modules of finite type, and thus separated for the $\mathfrak{J}$-preadic topology ($\mathbf{0}_\mathbf{I}$, 7.3.5); it thus suffices to prove that the homomorphism $\widehat{v} : \widehat{M \otimes_A N'} \to \widehat{M \otimes_A N}$ of the separated completions is injective. But $\widehat{v} = \varprojlim v_n$, where v_n is the homomorphism $1 \otimes u : M_n \otimes_A N' \to M_n \otimes_A N$; since, by hypothesis, M_n is A-flat, v_n is injective for all n, and thus so too is $\widehat{v}$, because the functor $\varprojlim$ is left exact. □

Corollary (10.2.7). — *Let A be a Noetherian ring, B a local Noetherian ring, $\rho : A \to B$ a homomorphism, f an element of the maximal ideal of B, and M a B-module of finite type. Suppose that the homothety $f_M : x \to fx$ on M is injective, and that M/fM is a flat A-module. Then M is a flat A-module.*

Proof. Let $M_i = f^i M$ for $i \geqslant 0$; since f_M is injective, M_i/M_{i+1} is isomorphic to M/fM, and thus A-flat for all $i \geqslant 0$; the exact sequence

$$0 \longrightarrow M_i/M_{i+1} \longrightarrow M/M_{i+1} \longrightarrow M/M_i \longrightarrow 0$$

gives us, by induction on i, that M/M_i is A-*flat* for all $i \geqslant 0$ ($\mathbf{0}_\mathbf{I}$, 6.1.2); we can thus apply (10.2.6). We can also argue directly as follows: for every A-module N of finite type, $M \otimes_A N$ is a B-module of finite type; since f belongs to the radical $\mathfrak{n}$ of B, the (f)-adic topology on $M \otimes_A N$ is finer than the $\mathfrak{n}$-adic topology, and we know that the latter is *separated* ($\mathbf{0}_{\mathrm{I}}$, 7.3.5). Now, since M/M_i is A-flat, we have that $\mathbf{0}_{\mathbf{III\text{-}1}}$ | 20

$$f^i(M \otimes_A N) = \operatorname{Im}(M_i \otimes_A N \longrightarrow M \otimes_A N) = \operatorname{Ker}(M \otimes_A N \longrightarrow (M/M_i) \otimes_A N)$$

by ($\mathbf{0}_{\mathrm{I}}$, 6.1.2). So let N be an A-module of finite type, and N' a submodule of N, with canonical injection $j : N' \to N$; in the commutative diagram

$$\begin{array}{ccc} M \otimes_A N' & \longrightarrow & (M/M_i) \otimes_A N' \\ {\scriptstyle 1_M \otimes j}\downarrow & & \downarrow{\scriptstyle 1_{M/M_i} \otimes j} \\ M \otimes_A N & \longrightarrow & (M/M_i) \otimes_A N \end{array}$$

$1_{M/M_i} \otimes j$ is injective, because M/M_i is A-flat; we thus conclude that

$$\operatorname{Ker}(M \otimes_A N' \longrightarrow M \otimes_A N) \subset \operatorname{Ker}(M \otimes_A N' \longrightarrow (M/M_i) \otimes_A N')$$

for any i; since the intersection of the latter kernels is 0, as we saw above, so too is the former kernel, and so M is A-flat. □

Proposition (10.2.8). — *Let A be a reduced Noetherian ring, and M an A-module of finite type. Suppose that, for every A-algebra B which is a discrete valuation ring, $M \otimes_A B$ is a flat B-module (and thus free (10.1.3)). Then M is a flat A-module.*

Proof. We know that, for M to be flat, it is necessary and sufficient for $M_{\mathfrak{m}}$ to be a flat $A_{\mathfrak{m}}$-module for every maximal ideal $\mathfrak{m}$ of A ($\mathbf{0}_{\mathrm{I}}$, 6.3.3); we can thus restrict to the case where A is *local* ($\mathbf{0}_{\mathrm{I}}$, 1.2.8). So let $\mathfrak{m}$ be the maximal ideal of A, $\mathfrak{p}_i$ $(1 \leqslant i \leqslant r)$ the minimal prime ideals of A, and k the residue field $A/\mathfrak{m}$. We know (**II**, 7.1.7) that there exists, for each i, a discrete valuation ring B_i that has the same field of fractions K_i as the integral domain $A/\mathfrak{p}_i$, and that, further, dominates $A/\mathfrak{p}_i$. Let $M_i = M \otimes_A B_i$. By hypothesis, M_i is free over B_i, and so, denoting by k_i the residue field of B_i, we have

$$\operatorname{rg}_{k_i}(M_i \otimes_{B_i} k_i) = \operatorname{rg}_{K_i}(M_i \otimes_{B_i} K_i). \tag{10.2.8.1}$$

But it is clear that the composite homomorphism $A \to A/\mathfrak{p}_i \to B_i$ is local, and so k_i is an extension of k, and that we have $M_i \otimes_{B_i} k_i = M \otimes_A k_i = (M \otimes_A k) \otimes_k k_i$, and also that $M_i \otimes_{B_i} K_i = M \otimes_A K_i$. Equation (10.2.8.1) thus implies that

$$\operatorname{rg}_k(M \otimes_A k) = \operatorname{rg}_{K_i}(M \otimes_A K_i) \quad \text{for } 1 \leqslant i \leqslant r$$

and since A is reduced, we know that this condition implies that M is a *free* A-module (Bourbaki, *Alg. comm.*, chap. II, § 3, n° 2, prop. 7). □

10.3. Existence of flat extensions of local rings

Proposition (10.3.1). — *Let A be a local Noetherian ring, with maximal ideal $\mathfrak{J}$, and residue field $k = A/\mathfrak{J}$. Let K be a field extension of k. Then there exists a local homomorphism from A to a local Noetherian ring B, such that $B/\mathfrak{J}B$ is k-isomorphic to K, and such that B is a flat A-module.*

The rest of this section is devoted to proving this proposition, step-by-step.

(10.3.1.1). First suppose that $K = k(T)$, where T is an indeterminate. In the ring of polynomials $A' = A[T]$, consider the prime ideal $\mathfrak{J}' = \mathfrak{J}A'$, consisting of the polynomials that have coefficients in the ideal $\mathfrak{J}$; it is clear that $A'/\mathfrak{J}'$ is canonically isomorphic to $k[T]$. We will show that the ring of fractions $B = A'_{\mathfrak{J}'}$ is that for which we are searching (that is, a ring which satisfies the conditions of the conclusion of the proposition); it is clearly a local Noetherian ring, with maximal ideal $\mathfrak{L} = \mathfrak{J}B$. Further, $B/\mathfrak{L} = (A'/\mathfrak{J}')_{\mathfrak{J}'} = (k[T])_{\mathfrak{J}'}$ is exactly the field of fractions K of $k[T]$. Finally, B is a flat A'-module, and A' is a free A-module, so B is a flat A-module ($\mathbf{0}_{\mathrm{I}}$, 6.2.1). $\mathbf{0}_{\mathbf{III\text{-}1}}$ | 21

(10.3.1.2). Now suppose that $K = k(t) = k[t]$, where t is algebraic over k; let $f \in k[T]$ be the minimal polynomial of t; there exists a monic polynomial $F \in A[T]$ whose canonical image in $k[T]$ is f. So let $A' = A[T]$, and let $\mathfrak{J}'$ be the ideal $\mathfrak{J}A' + (F)$ in A'. We will see that the quotient ring $B = A'/(F)$ is that for which we are searching. First of all, it is clear that B is a *free* A-module, and thus flat. The ring $A'/\mathfrak{J}'$ is isomorphic to

$$(A'/\mathfrak{J}A')/\big((\mathfrak{J}A' + (F))/\mathfrak{J}A'\big) = k[T]/(f) = K;$$

the image $\mathfrak{L}$ of $\mathfrak{J}'$ in B is thus maximal, and we evidently have that $\mathfrak{L} = \mathfrak{J}B$. Finally, B is a semi-local ring, because it is an A-module of finite type (Bourbaki, *Alg. comm.*, chap. IV, § 2, nº 5, cor. 3 of prop. 9), and its maximal ideals are in bijective correspondence with those of $B/\mathfrak{J}B$ ([SZ60, vol. I, p. 259]); the previous arguments then prove that B is a local ring.

Lemma (10.3.1.3). — *Let $(A_\lambda, f_{\mu\lambda})$ be a filtered inductive system of local rings, such that the $f_{\mu\lambda}$ are local homomorphisms; let $\mathfrak{m}_\lambda$ be the maximal ideal of A_λ, and let $K_\lambda = A_\lambda/\mathfrak{m}_\lambda$. Then $A' = \varinjlim A_\lambda$ is a local ring, with maximal ideal $\mathfrak{m}' = \varinjlim \mathfrak{m}_\lambda$, and residue field $K = \varinjlim K_\lambda$. Further, if $\mathfrak{m}_\mu = \mathfrak{m}_\lambda A_\mu$ with $\lambda < \mu$, then we have $\mathfrak{m}' = \mathfrak{m}_\lambda A'$ for all λ. If, further, for $\lambda < \mu$, A_μ is a flat A_λ-module, and if all the A_λ are Noetherian, then A' is Noetherian and is a flat A_λ-module for all λ.*

Proof. Since, by hypothesis, $f_{\mu\lambda}(\mathfrak{m}_\lambda) \subset \mathfrak{m}_\mu$ for $\lambda < \mu$, the $\mathfrak{m}_\lambda$ form an inductive system, and its limit $\mathfrak{m}'$ is evidently an ideal of A'. Further, if $x' \notin \mathfrak{m}'$, there exists a λ such that $x' = f_\lambda(x_\lambda)$ for some $x_\lambda \in A_\lambda$ (where $f_\lambda : A_\lambda \to A'$ denotes the canonical homomorphism); because $x' \notin \mathfrak{m}'$, we necessarily have that $x_\lambda \notin \mathfrak{m}_\lambda$, and so x_λ admits an inverse y_λ in A_λ, and $y' = f_\lambda(y_\lambda)$ is the inverse of x' in A', which proves that A' is a local ring with maximal ideal $\mathfrak{m}'$; the claim about K follows immediately from the fact that $\varinjlim$ is an exact functor. The hypothesis that $\mathfrak{m}_\mu = \mathfrak{m}_\lambda A_\mu$ implies that the canonical map $\mathfrak{m}_\lambda \otimes_{A_\lambda} A_\mu \to \mathfrak{m}_\mu$ is surjective; the equality $\mathfrak{m}' = \mathfrak{m}_\lambda A'$ then follows from, again, the fact that the functor $\varinjlim$ is exact and commutes with the tensor product.

Now suppose that, for $\lambda < \mu$, we have $\mathfrak{m}_\mu = \mathfrak{m}_\lambda A_\mu$, and that A_μ is a flat A_λ-module. Then A' is a flat A_λ-module for all λ, by $(\mathbf{0_I}, 6.2.3)$; since A' and A_λ are local rings, and since $\mathfrak{m}' = \mathfrak{m}_\lambda A'$, A' is even a *faithfully flat* A_λ-module $(\mathbf{0_I}, 6.6.2)$. Finally, suppose further that the A_λ are *Noetherian*; the $\mathfrak{m}_\lambda$-adic topologies are then separated $(\mathbf{0_I}, 7.3.5)$; we now show that, from this, it follows that the $\mathfrak{m}'$-adic topology on A' is *separated*. Indeed, if $x' \in A'$ belongs to all the $\mathfrak{m}'^n$ $(n > 0)$, then it is the image of some $x_\mu \in A_\mu$ for a specific index μ, and since the inverse image in A_μ of $\mathfrak{m}'^n = \mathfrak{m}_\mu^n A'$ is $\mathfrak{m}_\mu^n$ $(\mathbf{0_I}, 6.6.1)$, x_μ belongs to all the $\mathfrak{m}_\mu^n$, so $x_\mu = 0$, by hypothesis, and so $x' = 0$. Denote by $\widehat{A}'$ the completion of A' for the $\mathfrak{m}'$-adic topology; the above shows that we have $A' \subset \widehat{A}'$. We will now show that $\widehat{A}'$ is *Noetherian* and A_λ-*flat* for all λ; from this, it will follow that $\widehat{A}'$ is A'-flat $(\mathbf{0_I}, 6.2.3)$, $\mathbf{0_{III\text{-}1}}$ | 22
and since $\mathfrak{m}'\widehat{A}' \neq \widehat{A}'$, that $\widehat{A}'$ is a faithfully flat A'-module $(\mathbf{0_I}, 6.6.2)$, whence the final conclusion that A' is *Noetherian* $(\mathbf{0_I}, 6.5.2)$, which will finish the proof of the lemma.

We have $\widehat{A}' = \varprojlim_n A'/\mathfrak{m}'^n$; by the fact that A' is A_λ-flat, we have that

$$\mathfrak{m}'^n/\mathfrak{m}'^{n+1} = (\mathfrak{m}_\lambda^n/\mathfrak{m}_\lambda^{n+1}) \otimes_{A_\lambda} A' = (\mathfrak{m}_\lambda^n/\mathfrak{m}_\lambda^{n+1}) \otimes_{K_\lambda} (K_\lambda \otimes_{A_\lambda} A') = (\mathfrak{m}_\lambda^n/\mathfrak{m}_\lambda^{n+1}) \otimes_{K_\lambda} K;$$

since $\mathfrak{m}_\lambda^n/\mathfrak{m}_\lambda^{n+1}$ is a K_λ-vector space of finite dimension, $\mathfrak{m}'^n/\mathfrak{m}'^{n+1}$ is a K-vector space of finite dimension for all $n \geqslant 0$. It thus follows from $(\mathbf{0_I}, 7.2.12)$ and $(\mathbf{0_I}, 7.2.8)$ that $\widehat{A}'$ is *Noetherian*. We further know that the maximal ideal of $\widehat{A}'$ is $\mathfrak{m}'\widehat{A}'$, and that $\widehat{A}'/\mathfrak{m}'^n\widehat{A}'$ is isomorphic to $A'/\mathfrak{m}'^n$; since $A'/\mathfrak{m}'^n = (A_\lambda/\mathfrak{m}_\lambda^n) \otimes_{A_\lambda} A'$, we see that $A'/\mathfrak{m}'^n$ is a flat $(A_\lambda/\mathfrak{m}_\lambda^n)$-module $(\mathbf{0_I}, 6.2.1)$; criterion (10.2.2) is thus applicable to the Noetherian A_λ-algebra $\widehat{A}'$, and shows that $\widehat{A}'$ is A_λ-*flat*. □

(10.3.1.4). We now treat the general case. There exists an ordinal γ and, for every ordinal $\lambda \leqslant \gamma$, a subfield k_λ of K that contains k, such that (i) for all $\lambda < \gamma$, $k_{\lambda+1}$ is an extension of k_λ generated by a single element; (ii) for every limit ordinal μ, $k_\mu = \bigcup_{\lambda<\mu} k_\lambda$; and (iii) $K = k_\gamma$. In fact, it suffices to consider a bijection $\xi \mapsto t_\xi$ from the set of ordinals $\xi \leqslant \beta$ (for some suitable β) to K, and to define k_λ by transfinite induction (for $\lambda \leqslant \beta$) as the union of the k_μ for $\mu < \lambda$ if λ is a limit ordinal, and as $k_\nu(t_\xi)$ if $\lambda = \nu + 1$, where ξ is the smallest ordinal such that $t_\xi \notin k_\nu$; γ is then, by definition, the smallest ordinal $\leqslant \beta$ such that $k_\gamma = K$.

With this in mind, we will define, by transfinite induction, a family of local Noetherian rings A_λ for $\lambda \leqslant \gamma$, and local homomorphisms $f_{\mu\lambda} : A_\lambda \to A_\mu$ for $\lambda \leqslant \mu$, satisfying the following conditions:

(i) $(A_\lambda, f_{\mu\lambda})$ is an inductive system, and $A_0 = A$;
(ii) for all λ, we have a k-isomorphism $A_\lambda/\mathfrak{J}A_\lambda \simeq k_\lambda$;
(iii) for $\lambda \leqslant \mu$, A_μ is a flat A_λ-module.

So suppose that the A_λ and the $f_{\mu\lambda}$ are defined for $\lambda < \mu < \xi$, and suppose, first of all, that $\xi = \zeta + 1$, so that $k_\xi = k_\zeta(t)$. If t is transcendental over k_ζ, we define A_ξ, following the procedure of (10.3.1.1), to be equal to $(A_\zeta[t])_{\mathfrak{J}A_\zeta[t]}$; the canonical map is $f_{\xi\zeta}$, and, for $\lambda < \zeta$, we take $f_{\xi\lambda} = f_{\xi\zeta} \circ f_{\zeta\lambda}$; the verification of conditions (i) to (iii) is then immediate, given that what we have shown in (10.3.1.1). So now suppose that t is algebraic, and let h be its minimal polynomial in $k_\zeta[T]$, and H a monic polynomial in $A_\zeta[T]$ whose image in $k_\zeta[T]$ is h; we then take A_ξ to be equal to $A_\zeta[T]/(H)$, with the $f_{\xi\lambda}$ being defined as before; the verification of conditions (i) to (iii) then follows from what we have shown in (10.3.1.2).

Now suppose that ξ has no predecessor; we then take A_ξ to be the inductive limit of the inductive system of local rings $(A_\lambda, f_{\mu\lambda})$ for $\lambda < \xi$; we define $f_{\xi\lambda}$ as the canonical map for $\lambda < \xi$. The fact that A_ξ is local and Noetherian, that the $f_{\xi\lambda}$ are local homomorphisms, and that conditions (i) to (iii) are satisfied for $\lambda \leqslant \xi$ then follows from the induction hypothesis, and from Lemma (10.3.1.3). With this construction, it is clear that the ring $B = A_\gamma$ satisfies the conditions of (10.3.1). □ $\mathbf{0}_{\mathbf{III\text{-}1}}$ | 23

We note that, by (10.2.1, c), we have a canonical isomorphism

(10.3.1.5)
$$\operatorname{gr}(A) \otimes_k K \xrightarrow{\sim} \operatorname{gr}(B).$$

We can also replace B by its $\mathfrak{J}B$-adic completion $\widehat{B}$ without changing the conclusions of (10.3.1), because $\widehat{B}$ is a flat B-module ($\mathbf{0}_\mathbf{I}$, 7.3.3), and thus a flat A-module ($\mathbf{0}_\mathbf{I}$, 6.2.1).

We have also shown the following:

Corollary (10.3.2). — *If K is an extension of finite degree, then we can assume that B is a finite A-algebra.*

§11. Supplement on homological algebra

11.1. Review of spectral sequences

(11.1.1). In the following, we use a more general notion of a spectral sequence than that defined in (T, 2.4); keeping the notation of (T, 2.4), we call a *spectral sequence* in an abelian category C a system E consisting of the following parts:

(a) A family (E_r^{pq}) of objects of C defined for $p, q \in \mathbf{Z}$ and $r \geqslant 2$.

(b) A family of morphisms $d_r^{pq} : E_r^{pq} \to E_r^{p+r,q-r+1}$ such that $d_r^{p+r,q-r+1} d_r^{pq} = 0$. We set $Z_{r+1}(E_r^{pq}) = \operatorname{Ker}(d_r^{pq})$ and $B_{r+1}(E_r^{pq}) = \operatorname{Im}(d_r^{p-r,q+r-1})$, so that
$$B_{r+1}(E_r^{pq}) \subset Z_{r+1}(E_r^{pq}) \subset E_r^{pq}.$$

(c) A family of isomorphisms $\alpha_r^{pq} : Z_{r+1}(E_r^{pq})/B_{r+1}(E_r^{pq}) \simeq E_{r+1}^{pq}$.

We then define for $k \geqslant r+1$, by induction on k, the subobjects $B_k(E_r^{pq})$ and $Z_k(E_r^{pq})$ as the inverse images, under the canonical morphism $E_r^{pq} \to E_r^{pq}/B_{r+1}(E_r^{pq})$ of the subobjects of this quotient identified via α_r^{pq} with the subobjects $B_k(E_{r+1}^{pq})$ and $Z_k(E_{r+1}^{pq})$ respectively. It is clear that we then have, up to isomorphism,

(11.1.1.1)
$$Z_k(E_r^{pq})/B_k(E_r^{pq}) = E_k^{pq} \text{ for } k \geqslant r+1,$$

and, if we set $B_r(E_r^{pq}) = 0$ and $Z_r(E_r^{pq}) = E_r^{pq}$, then we have the inclusion relations

(11.1.1.2)
$$0 = B_r(E_r^{pq}) \subset B_{r+1}(E_r^{pq}) \subset B_{r+2}(E_r^{pq}) \subset \cdots \subset Z_{r+2}(E_r^{pq}) \subset Z_{r+1}(E_r^{pq}) \subset Z_r(E_r^{pq}) = E_r^{pq}.$$

The other parts of the data of E are then:

(d) Two subobjects $B_\infty(E_2^{pq})$ and $Z_\infty(E_2^{pq})$ of E_2^{pq} such that we have $B_\infty(E_2^{pq}) \subset Z_\infty(E_2^{pq})$ and, for every $k \geqslant 2$,
$$B_k(E_2^{pq}) \subset B_\infty(E_2^{pq}) \text{ and } Z_\infty(E_2^{pq}) \subset Z_k(E_2^{pq}).$$

We set

(11.1.1.1.3)
$$E_\infty^{pq} = Z_\infty(E_2^{pq})/B_\infty(E_2^{pq}).$$

(e) A family (E^n) of objects of C, each equipped with a *decreasing filtration* $(F^p(E^n))_{p\in\mathbf{Z}}$. As usual, we denote by $\operatorname{gr}(E^n)$ the graded object associated to the filtered object E^n, the direct sum of the $\operatorname{gr}_p(E^n) = F^p(E^n)/F^{p+1}(E^n)$. $\mathbf{0}_{\mathbf{III}}$ | 24

(f) For every pair $(p,q) \in \mathbf{Z} \times \mathbf{Z}$, an isomorphism $\beta^{pq} : E_\infty^{pq} \simeq \operatorname{gr}_p(E^{p+q})$.

The family (E^n), without the filtrations, is called the *abutment* (or *limit*) of the spectral sequence E.

Suppose that the category $\mathtt{C}$ admits infinite direct sums, or that for every $r \geqslant 2$ and every $n \in \mathbf{Z}$, there are finitely many pairs (p,q) such that $p+q=n$ and $E_r^{pq} \neq 0$ (it suffices for it to hold for $r=2$). Then the $E_r^{(n)} = \sum_{p+q=n} E_r^{pq}$ are defined, and if we denote by $d_r^{(n)}$ the morphism $E_r^{(n)} \to E_r^{(n+1)}$ whose restriction to E_r^{pq} is d_r^{pq} for every pair (p,q) such that $p+q=n$, then $d_r^{(n+1)} \circ d_r^{(n)} = 0$, in other words, $(E_r^{(n)})_{n\in\mathbf{Z}}$ is a *complex* $E_r^{(\bullet)}$ in $\mathtt{C}$, with differential of degree $+1$, and it follows from (c) that $\mathrm{H}^n(E_r^{(\bullet)})$ is *isomorphic to* $E_{r+1}^{(n)}$ for every $r \geqslant 2$.

(11.1.2). A *morphism* $u : E \to E'$ from a spectral sequence E to a spectral sequence $E' = (E_r'^{pq}, E'^n)$ consists of systems of morphisms $u_r^{pq} : E_r^{pq} \to E_r'^{pq}$ and $u^n : E^n \to E'^n$, the u^n compatible with the filtrations on E^n and E'^n, and the diagrams

$$\begin{tikzcd} E_r^{pq} \arrow[r, "d_r^{pq}"] \arrow[d, "u_r^{pq}"'] & E_r^{p+r,q-r+1} \arrow[d, "u_r^{p+r,q-r+1}"] \\ E_r'^{pq} \arrow[r, "d_r'^{pq}"'] & E_r'^{p+r,q-r+1} \end{tikzcd}$$

being commutative; in addition, by passing to quotients, u_r^{pq} gives a morphism $\overline{u}_r^{pq} : Z_{r+1}(E_r^{pq})/B_{r+1}(E_r^{pq}) \to Z_{r+1}(E_r'^{pq})/B_{r+1}(E_r'^{pq})$ and we must have $\alpha_r'^{pq} \circ \overline{u}_r^{pq} = u_{r+1}^{pq} \circ \alpha_r^{pq}$; finally, we must have $u_2^{pq}(B_\infty(E_2^{pq})) \subset B_\infty(E_2'^{pq})$ and $u_2^{pq}(Z_\infty(E_2^{pq})) \subset Z_\infty(E_2'^{pq})$; by passing to quotients, u_2^{pq} then gives a morphism $u_\infty^{pq} : E_\infty^{pq} \to E_\infty'^{pq}$, and the diagram

$$\begin{tikzcd} E_\infty^{pq} \arrow[r, "u_\infty^{pq}"] \arrow[d, "\beta^{pq}"'] & E_\infty'^{pq} \arrow[d, "\beta'^{pq}"] \\ \mathrm{gr}_p(E^{p+q}) \arrow[r, "\mathrm{gr}_p(u^{p+q})"'] & \mathrm{gr}_p(E'^{p+q}) \end{tikzcd}$$

must be commutative.

The above definitions show, by induction on r, that if the u_2^{pq} are *isomorphisms*, then so are the u_r^{pq} for $r \geqslant 2$; *if in addition we know that* $u_2^{pq}(B_\infty(E_2^{pq})) = B_\infty(E_2'^{pq})$ *and* $u_2^{pq}(Z_\infty(E_2^{pq})) = Z_\infty(E_2'^{pq})$ *and the* u^n *are isomorphisms*, then we can conclude that u is an *isomorphism*.

(11.1.3). Recall that if $(F^p(X))_{p\in\mathbf{Z}}$ is a (decreasing) *filtration* of an object $X \in \mathtt{C}$, then we say that this **0_{III}** | 25
filtration is *separated* if $\inf(F^p(X)) = 0$, *discrete* if there exists a p such that $F^p(X) = 0$, *exhaustive* (or *coseparated*) if $\sup(F^p(X)) = X$, *codiscrete* if there exists a p such that $F^p(X) = X$.

We say that a spectral sequence $E = (E_r^{pq}, E^n)$ is *weakly convergent* if we have $B_\infty(E_2^{pq}) = \sup_k(B_k(E_2^{pq}))$ and $Z_\infty(E_2^{pq}) = \inf_k(Z_k(E_2^{pq}))$ (in other words, the objects $B_\infty(E_2^{pq})$ and $Z_\infty(E_2^{pq})$ are determined from the data (a)–(c) of the spectral sequence E). We say that the spectral sequence E is *regular* if it is weakly convergent and if, in addition:

(1st) For every pair (p,q), the decreasing sequence $(Z_k(E_2^{pq}))_{k\geqslant 2}$ is *stable*; the hypothesis that E is weakly convergent then implies that $Z_\infty(E_2^{pq}) = Z_k(E_2^{pq})$ for k large enough (depending on p and q).

(2nd) For every n, the filtration $(F^p(E^n))_{p\in\mathbf{Z}}$ of E^n is *discrete* and *exhaustive*.

We say that the spectral sequence E is *coregular* if it is weakly convergent and if, in addition:

(3rd) For every pair (p,q), the increasing sequence $(B_k(E_2^{pq}))_{k\geqslant 2}$ is *stable*, which implies that $B_\infty(E_2^{pq}) = B_k(E_2^{pq})$, and as a result, $E_\infty^{pq} = \inf E_k^{pq}$.

(4th) For every n, the filtration of E^n is *codiscrete*.

Finally, we say that E is *biregular* if it is both regular and coregular, in other words if we have the following conditions:

(a) For every pair (p,q), the sequences $(B_k(E_2^{pq}))_{k\geqslant 2}$ and $(Z_k(E_2^{pq}))_{k\geqslant 2}$ are *stable* and we have $B_\infty(E_2^{pq}) = B_k(E_2^{pq})$ and $Z_\infty(E_2^{pq}) = Z_k(E_2^{pq})$ for k large enough (which implies that $E_\infty^{pq} = E_k^{pq}$).

(b) For every n, the filtration $(F^p(E^n))_{p\in\mathbf{Z}}$ is *discrete* and *codiscrete* (which we also call *finite*).

The spectral sequences defined in (T, 2.4) are thus biregular spectral sequences.

(11.1.4). Suppose that in the category $\mathtt{C}$, filtered inductive limits exist and the functor $\varinjlim$ is *exact* (which is equivalent to saying that the axiom (AB 5) of (T, 1.5) is satisfied (cf. T, 1.8)). The condition that the filtration $(F^p(X))_{p\in\mathbf{Z}}$ of an object $X\in\mathtt{C}$ is exhaustive is then expressed as $\varinjlim_{p\to-\infty} F^p(X) = X$. If a spectral sequence E is weakly convergent, then we have $B_\infty(E_2^{pq}) = \varinjlim_{k\to\infty} B_k(E_2^{pq})$; if in addition $u : E\to E'$ is a morphism from E to a weakly convergent spectral sequence E' in $\mathtt{C}$, then we have $u_2^{pq}(B_\infty(E_2^{pq})) = B_\infty(E_2'^{pq})$, by the exactness of $\varinjlim$. In addition:

Proposition (11.1.5). — *Let $\mathtt{C}$ be an abelian category in which filtered inductive limits are exact, E and E' two regular spectral sequences in $\mathtt{C}$, $u : E\to E'$ a morphism of spectral sequences. If the u_2^{pq} are isomorphisms, then so is u.*

Proof. We already know (11.1.2) that the u_r^{pq} are isomorphisms and that

$$u_2^{pq}(B_\infty(E_2^{pq})) = B_\infty(E_2'^{pq});$$

the hypothesis that E and E' are regular also implies that $u_2^{pq}(Z_\infty(E_2^{pq})) = Z_\infty(E_2'^{pq})$, and as u_2^{pq} is an isomorphism, so is u_∞^{pq}; we thus conclude that $\mathrm{gr}_p(u^{p+q})$ is also an isomorphism. But as the filtrations of the E^n and the E'^n are discrete and exhaustive, this implies that the u^n are also isomorphisms (Bourbaki, *Alg. comm.*, chap. III, §2, n°8, th. 1). □ $\mathbf{0_{III}}$ | 26

(11.1.6). It follows from (11.1.1.2) and the definition (11.1.1.3) that if, for a spectral sequence E, we have $E_r^{pq} = 0$, then we have $E_k^{pq} = 0$ for $k\geqslant r$ and $E_\infty^{pq} = 0$. We say that a spectral sequence *degenerates* if there exists an integer $r\geqslant 2$ and, for every integer $n\in\mathbf{Z}$, an integer $q(n)$ such that $E_r^{n-q,q} = 0$ *for every* $q\neq q(n)$. We first deduce from the previous remark that we also have $E_k^{n-q,q} = 0$ for $k\geqslant r$ (including $k=\infty$) and $q\neq q(n)$. In addition, the definition of E_{r+1}^{pq} shows that we have $E_{r+1}^{n-q(n),q(n)} = E_r^{n-q(n),q(n)}$; if E is *weakly convergent*, then we also have $E_\infty^{n-q(n),q(n)} = E_r^{n-q(n),q(n)}$; in other words, for every $n\in\mathbf{Z}$, $\mathrm{gr}_p(E^n) = 0$ for $p\neq q(n)$ and $\mathrm{gr}_{q(n)}(E^n) = E_r^{n-q(n),q(n)}$. If in addition the filtration of E^n is *discrete* and *exhaustive*, then the spectral sequence E is *regular*, and we have $E^n = E_r^{n-q(n),q(n)}$ up to isomorphism.

(11.1.7). Suppose that filtered inductive limits exist and are exact in the category $\mathtt{C}$, and let $(E_\lambda, u_{\mu\lambda})$ be an inductive system (over a filtered set of indices) of spectral sequences in $\mathtt{C}$. Then the *inductive limit* of this inductive system exists in the additive category of spectral sequences of objects of $\mathtt{C}$: to see this, it suffices to define E_r^{pq}, d_r^{pq}, α_r^{pq}, $B_\infty(E_2^{pq})$, $Z_\infty(E_2^{pq})$, E^n, $F^p(E^n)$, and β^{pq} as the respective inductive limits of the $E_{r,\lambda}^{pq}$, $d_{r,\lambda}^{pq}$, $\alpha_{r,\lambda}^{pq}$, $B_\infty(E_{2,\lambda}^{pq})$, $Z_\infty(E_{2,\lambda}^{pq})$, E_λ^n, $F^p(E_\lambda^n)$, and β_λ^{pq}; the verification of the conditions of (11.1.1) follows from the exactness of the functor $\varinjlim$ on $\mathtt{C}$.

Remark (11.1.8). — Suppose that the category $\mathtt{C}$ is the category of A-modules over a *Noetherian* ring A (resp. a ring A). Then the definitions of (11.1.1) show that if, for a given r, the E_r^{pq} are A-modules *of finite type* (resp. *of finite length*), then so are each of the modules E_s^{pq} for $s\geqslant r$, hence so is E_∞^{pq}. If in addition the filtration of the abutment (E^n) is *discrete* and *codiscrete* for all n, then we conclude that each of the E^n is also an A-module *of finite type* (resp. *of finite length*).

(11.1.9). We will have to consider conditions which ensure that a spectral sequence E is biregular in a "uniform" way in $p+q=n$. We will then use the following lemma:

Lemma (11.1.10). — *Let (E_r^{pq}) be a family of objects of $\mathtt{C}$ related by the data of* (a), (b), *and* (c) *of* (11.1.1). *For a fixed integer n, the following properties are equivalent:*

(a) *There exists an integer $r(n)$ such that for $r\geqslant r(n)$, $p+q=n$ or $p+q=n-1$, the morphisms d_r^{pq} are zero.*

(b) *There exists an integer $r(n)$ such that for $p+q=n$ or $p+q=n+1$, we have $B_r(E_2^{pq}) = B_s(E_2^{pq})$ for $s \geqslant r \geqslant r(n)$.*
(c) *There exists an integer $r(n)$ such that for $p+q=n$ or $p+q=n-1$, we have $Z_r(E_2^{pq}) = Z_s(E_2^{pq})$ for $s \geqslant r \geqslant r(n)$.*
(d) *There exists an integer $r(n)$ such that for $p+q=n$, we have $B_r(E_2^{pq}) = B_s(E_2^{pq})$ and $Z_r(E_2^{pq}) = Z_s(E_2^{pq})$ for $s \geqslant r \geqslant r(n)$.*

Proof. According to the conditions (a), (b), and (c) of (11.1.1), we have that saying $Z_{r+1}(E_2^{pq}) = Z_r(E_2^{pq})$ is equivalent to saying that $d_r^{pq} = 0$ and that saying $B_r(E_2^{p+r,q-r+1}) = B_{r+1}(E_2^{p+r,q-r+1})$ is equivalent to saying that $d_r^{pq} = 0$; the lemma immediately follows from this remark. □ $\mathbf{0_{III}}$ | 27

11.2. The spectral sequence of a filtered complex

(11.2.1). Given an abelian category C, we will agree to denote by notation such as $K^\bullet$ the *complexes* $(K^i)_{i\in\mathbf{Z}}$ of objects of C whose differential is of degree $+1$, and by the notation such as $K_\bullet$ the complexes $(K_i)_{i\in\mathbf{Z}}$ of objects of C whose differential is of degree -1. To each complex $K^\bullet = (K^i)$ whose differential d is of degree $+1$, we can associate a complex $K'_\bullet = (K'_i)$ by setting $K'_i = K^{-i}$, the differential $K'_i \to K'_{i-1}$ being the operator $d : K^{-i} \to K^{-i+1}$; and *vice versa*, which, depending on the circumstances, will allow one to consider either one of the types of complexes and translate any result from one type into results for the other. We similarly denote by notation such as $K^{\bullet\bullet} = (K^{ij})$ (resp. $K_{\bullet\bullet} = (K_{ij})$) the *bicomplexes* (or *double complexes*) of objects of C in which the *two* differentials are of degree $+1$ (resp. -1); we can still pass from one type to the other by changing the signs of the indices, and we have similar notation and remarks for any multicomplexes. The notation $K^\bullet$ and $K_\bullet$ will also be used for **Z**-*graded objects* of C, which are not necessarily complexes (they can be considered as such for the *zero* differentials); for example, we write $\mathrm{H}^\bullet(K^\bullet) = (\mathrm{H}^i(K^\bullet))_{i\in\mathbf{Z}}$ for the *cohomology* of a complex $K^\bullet$ whose differential is of degree $+1$, and $\mathrm{H}_\bullet(K_\bullet) = (\mathrm{H}_i(K_\bullet))_{i\in\mathbf{Z}}$ for the *homology* of a complex $K_\bullet$ whose differential is of degree -1; when we pass from $K^\bullet$ to $K'_\bullet$ by the method described above, we have $\mathrm{H}_i(K'_\bullet) = \mathrm{H}^{-i}(K^\bullet)$.

Recall in this case that for a complex $K^\bullet$ (resp. $K_\bullet$), we will write in general $Z^i(K^\bullet) = \mathrm{Ker}(K^i \to K^{i+1})$ ("object of cocycles") and $B^i(K^\bullet) = \mathrm{Im}(K^{i-1} \to K^i)$ ("object of coboundaries") (resp. $Z_i(K_\bullet) = \mathrm{Ker}(K_i \to K_{i-1})$ ("object of cycles") and $B_i(K_\bullet) = \mathrm{Im}(K_{i+1} \to K_i)$ ("object of boundaries")) so that $\mathrm{H}^i(K^\bullet) = Z^i(K^\bullet)/B^i(K^\bullet)$ (resp. $\mathrm{H}_i(K_\bullet) = Z_i(K_\bullet)/B_i(K_\bullet)$).

If $K^\bullet = (K^i)$ (resp. $K_\bullet = (K_i)$) is a complex in C and $T : \mathtt{C} \to \mathtt{C}'$ a functor from C to an abelian category C′, then we denote by $T(K^\bullet)$ (resp. $T(K_\bullet)$) the complex $(T(K^i))$ (resp. $(T(K_i))$) in C′.

We will not review the definition of the ∂-*functors* (T, 2.1), except to note that we *also* say ∂-functor in place of ∂*-functor when the morphism ∂ decreases the degree of a unit, the context clarifying this point if there is cause for confusion.

Finally, we say that a *graded object* $(A_i)_{i\in\mathbf{Z}}$ of C is *bounded below* (resp. *above*) if there exists an i_0 such that $A_i = 0$ for $i < i_0$ (resp. $i > i_0$).

(11.2.2). Let $K^\bullet$ be a complex in C whose differential d is of degree $+1$, and suppose it is equipped with a *filtration* $F(K^\bullet) = (F^p(K^\bullet))_{p\in\mathbf{Z}}$ consisting of *graded* subobjects of $K^\bullet$, in other words, $F^p(K^\bullet) =$ $\mathbf{0_{III}}$ | 28 $(K^i \cap F^p(K^\bullet))_{i\in\mathbf{Z}}$; in addition, we assume that $d(F^p(K^\bullet)) \subset F^p(K^\bullet)$ for every $p \in \mathbf{Z}$. Let us quickly recall how one *functorially* defines a spectral sequence $E(K^\bullet)$ from $K^\bullet$ (M, XV, 4 and G, I, 4.3). For $r \geqslant 2$, the canonical morphism $F^p(K^\bullet)/F^{p+r}(K^\bullet) \to F^p(K^\bullet)/F^{p+1}(K^\bullet)$ defines a morphism in cohomology

$$\mathrm{H}^{p+q}(F^p(K^\bullet)/F^{p+r}(K^\bullet)) \longrightarrow \mathrm{H}^{p+q}(F^p(K^\bullet)/F^{p+1}(K^\bullet)).$$

We denote by $Z_r^{pq}(K^\bullet)$ the image of this morphism. Similarly, from the exact sequence

$$0 \longrightarrow F^p(K^\bullet)/F^{p+1}(K^\bullet) \longrightarrow F^{p-r+1}(K^\bullet)/F^{p+1}(K^\bullet) \longrightarrow F^{p-r+1}(K^\bullet)/F^p(K^\bullet) \longrightarrow 0,$$

we deduce from the exact sequence in cohomology a morphism

$$\mathrm{H}^{p+q-1}(F^{p-r+1}(K^\bullet)/F^p(K^\bullet)) \longrightarrow \mathrm{H}^{p+q}(F^p(K^\bullet)/F^{p+1}(K^\bullet)),$$

and we denote by $B_r^{pq}(K^\bullet)$ the image of this morphism; we show that $B_r^{pq}(K^\bullet) \subset Z_r^{pq}(K^\bullet)$ and we take $E_r^{pq}(K^\bullet) = Z_r^{pq}(K^\bullet)/B_r^{pq}(K^\bullet)$; we will not specify the definition of the d_r^{pq} or the α_r^{pq}.

We note here that all the $Z_r^{pq}(K^\bullet)$ and $B_r^{pq}(K^\bullet)$, for p and q fixed, are subobjects of the same object $\mathrm{H}^{p+q}(F^p(K^\bullet)/F^{p+1}(K^\bullet))$, which we denote by $Z_1^{pq}(K^\bullet)$; we set $B_1^{pq}(K^\bullet) = 0$, so that the above definitions of $Z_r^{pq}(K^\bullet)$ and $B_r^{pq}(K^\bullet)$ also work for $r = 1$; we still set $E_1^{pq}(K^\bullet) = Z_1^{pq}(K^\bullet)$. We define d_1^{pq} and α_1^{pq} such that the conditions of (11.1.1) are satisfied for $r = 1$. On the other hand, we define the subobjects $Z_\infty^{pq}(K^\bullet)$ as the image of the morphism

$$\mathrm{H}^{p+q}(F^p(K^\bullet)) \longrightarrow \mathrm{H}^{p+q}(F^p(K^\bullet)/F^{p+1}(K^\bullet)) = E_1^{pq}(K^\bullet),$$

and $B_\infty^{pq}(K^\bullet)$ as the image of the morphism

$$\mathrm{H}^{p+q-1}(K^\bullet/F^p(K^\bullet)) \longrightarrow \mathrm{H}^{p+q}(F^p(K^\bullet)/F^{p+1}(K^\bullet)) = E_1^{pq}(K^\bullet),$$

induced as above from the exact sequence in cohomology. We set $Z_\infty(E_2^{pq}(K^\bullet))$ and $B_\infty(E_2^{pq}(K^\bullet))$ to be the canonical images in $E_2^{pq}(K^\bullet)$ of $Z_\infty^{pq}(K^\bullet)$ and $B_\infty^{pq}(K^\bullet)$.

Finally, we denote by $F^p(\mathrm{H}^n(K^\bullet))$ the image in $\mathrm{H}^n(K^\bullet)$ of the morphism $\mathrm{H}^n(F^p(K^\bullet)) \to \mathrm{H}^n(K^\bullet)$ induced from the canonical injection $F^p(K^\bullet) \to K^\bullet$; by the exact sequence in cohomology, this is also the kernel of the morphism $\mathrm{H}^n(K^\bullet) \to \mathrm{H}^n(K^\bullet/F^p(K^\bullet))$. This defines a filtration on $E^n(K^\bullet) = \mathrm{H}^n(K^\bullet)$; we will not give here the definition of the isomorphisms β^{pq}.

(11.2.3). The *functorial* nature of $E(K^\bullet)$ is understood in the following way: given two *filtered* complexes $K^\bullet$ and $K'^\bullet$ in $\mathtt{C}$ and a morphism of complexes $u : K^\bullet \to K'^\bullet$ that is *compatible with the filtrations*, we induce in an evident way the morphisms u_r^{pq} (for $r \geqslant 1$) and u^n, and we show that these morphisms are compatible with the d_r^{pq}, α_r^{pq}, and β^{pq} in the sense of (11.1.2), and thus define a well-defined morphism $E(u) : E(K^\bullet) \to E(K'^\bullet)$ of spectral sequences. In addition, we show that if u and v are morphisms $K^\bullet \to K'^\bullet$ of the above type, *homotopic in degree* $\leqslant k$, then $u_r^{pq} = v_r^{pq}$ for $r > k$ and $u^n = v^n$ for all n (M, XV, 3.1).

(11.2.4). Suppose that filtered inductive limits in $\mathtt{C}$ are exact. Then if the filtration $(F^p(K^\bullet))$ of $K^\bullet$ is *exhaustive*, then so is the filtration $(F^p(\mathrm{H}^n(K^\bullet)))$ for all n, since by hypothesis we have $K^\bullet = \varinjlim_{p\to-\infty} F^p(K^\bullet)$ and since the hypothesis on $\mathtt{C}$ implies that cohomology commutes with inductive limits. In addition, for the same reason, we have $B_\infty(E_2^{pq}(K^\bullet)) = \sup_k B_k(E_2^{pq}(K^\bullet))$. We say that the filtration $(F^p(K^\bullet))$ of $K^\bullet$ is *regular* if for every n there exists an integer $u(n)$ such that $\mathrm{H}^n(F^p(K^\bullet)) = 0$ for $p > u(n)$. This is particularly the case when the filtration of $K^\bullet$ is *discrete*. When the filtration of $K^\bullet$ is regular and exhaustive, and filtered inductive limits are exact in $\mathtt{C}$, we have (M, XV, 4) that the spectral sequence $E(K^\bullet)$ is *regular*. $\mathbf{0}_{\mathbf{III}}$ | 29

11.3. The spectral sequences of a bicomplex

(11.3.1). With regard to the conventions for bicomplexes, we follow those of (T, 2.4) rather than those of (M), the two differentials d' and d'' (of degree $+1$) of such a bicomplex $K^{\bullet\bullet} = (K^{ij})$ thus being assumed to be *permutable*. Suppose that *one* of the following two conditions is satisfied:

(1) *Infinite direct sums* exist in $\mathtt{C}$;

(2) For all $n \in \mathbf{Z}$, there is only a *finite* number of pairs (p, q) such that $p + q = n$ and $K^{pq} \neq 0$.

Then the bicomplex $K^{\bullet\bullet}$ defines a (simple) *complex* $(K'^n)_{n\in\mathbf{Z}}$ with $K'^n = \sum_{i+j=n} K^{ij}$, the differential d (of degree $+1$) of this complex being given by $dx = d'x + (-1)^i d''x$ for $x \in K^{ij}$. When we later speak of the (simple) *complex defined by a bicomplex* $K^{\bullet\bullet}$, it will always be understood that one of the above conditions is satisfied. We adopt the analogous conventions for multicomplexes.

We denote by $K^{i,\bullet}$ (resp. $K^{\bullet,j}$) the simple complex $(K^{ij})_{j\in\mathbf{Z}}$ (resp. $(K^{ij})_{i\in\mathbf{Z}}$), by $Z_{\mathrm{II}}^p(K^{i,\bullet})$, $B_{\mathrm{II}}^p(K^{i,\bullet})$, $\mathrm{H}_{\mathrm{II}}^p(K^{i,\bullet})$ (resp. $Z_{\mathrm{I}}^p(K^{\bullet,j})$, $B_{\mathrm{I}}^p(K^{\bullet,j})$, $\mathrm{H}_{\mathrm{I}}^p(K^{\bullet,j})$) its p objects of cocycles, of coboundaries, and of cohomology, respectively; the differential $d' : K^{i,\bullet} \to K^{i+1,\bullet}$ is a morphism of complexes, which thus gives an operator on the cocycles, coboundaries, and cohomology,

$$d' : Z_{\mathrm{II}}^p(K^{i,\bullet}) \longrightarrow Z_{\mathrm{II}}^p(K^{i+1,\bullet})$$
$$d' : B_{\mathrm{II}}^p(K^{i,\bullet}) \longrightarrow B_{\mathrm{II}}^p(K^{i+1,\bullet})$$
$$d' : \mathrm{H}_{\mathrm{II}}^p(K^{i,\bullet}) \longrightarrow \mathrm{H}_{\mathrm{II}}^p(K^{i+1,\bullet})$$

and it is clear that for these operators, $(Z_{\mathrm{II}}^p(K^{i,\bullet}))_{i\in\mathbf{Z}}$, $(B_{\mathrm{II}}^p(K^{i,\bullet}))_{i\in\mathbf{Z}}$, and $(\mathrm{H}_{\mathrm{II}}^p(K^{i,\bullet}))_{i\in\mathbf{Z}}$ are complexes; we denote the complex $(\mathrm{H}_{\mathrm{II}}^p(K^{i,\bullet}))_{i\in\mathbf{Z}}$ by $\mathrm{H}_{\mathrm{II}}^p(K^{\bullet\bullet})$, and its q objects of cocycles, coboundaries, and cohomology by $Z^q_{\mathrm{I}}(\mathrm{H}^p_{\mathrm{II}}(K^{\bullet\bullet}))$, $B^q_{\mathrm{I}}(\mathrm{H}^p_{\mathrm{II}}(K^{\bullet\bullet}))$, and $\mathrm{H}^q_{\mathrm{I}}(\mathrm{H}^p_{\mathrm{II}}(K^{\bullet\bullet}))$. We similarly define the complexes $\mathrm{H}^p_{\mathrm{I}}(K^{\bullet\bullet})$ and their cohomology objects $\mathrm{H}^q_{\mathrm{II}}(\mathrm{H}^p_{\mathrm{I}}(K^{\bullet\bullet}))$. Recall, however, that $\mathrm{H}^n(K^{\bullet\bullet})$ denotes the n-th object of the cohomology of the *(simple)* complex defined by $K^{\bullet\bullet}$.

(11.3.2). On the complex defined by a bicomplex $K^{\bullet\bullet}$, we can consider two canonical filtrations, $(F^p_{\mathrm{I}}(K^{\bullet\bullet}))$ and $(F^p_{\mathrm{II}}(K^{\bullet\bullet}))$, given by

(11.3.2.1) $$F^p_{\mathrm{I}}(K^{\bullet\bullet}) = \left(\sum_{i+j=n, i\geqslant p} K^{ij}\right)_{n\in\mathbf{Z}} \quad\text{and}\quad F^p_{\mathrm{II}}(K^{\bullet\bullet}) = \left(\sum_{i+j=n, j\geqslant p} K^{ij}\right)_{n\in\mathbf{Z}}$$

which, by definition, are graded subobjects of the (simple) complex defined by $K^{\bullet\bullet}$, and thus make this complex a filtered complex; moreover, it is clear that these filtrations are *exhaustive* and *separated*. $\mathbf{0_{III}}$ | 30

There corresponds to each of these filtrations a spectral sequence (11.2.2); we denote by $'E(K^{\bullet\bullet})$ and $''E(K^{\bullet\bullet})$ the spectral sequences corresponding to $(F^p_{\mathrm{I}}(K^{\bullet\bullet}))$ and $(F^p_{\mathrm{II}}(K^{\bullet\bullet}))$ respectively, called the *spectral sequence of the bicomplex* $K^{\bullet\bullet}$, and both having as their abutment the cohomology $(\mathrm{H}^n(K^{\bullet\bullet}))$. We can further show (M, XV, 6) that we have

(11.3.2.2) $$'E^{pq}_2(K^{\bullet\bullet}) = \mathrm{H}^p_{\mathrm{I}}(\mathrm{H}^q_{\mathrm{II}}(K^{\bullet\bullet})) \quad\text{and}\quad ''E^{pq}_2(K^{\bullet\bullet}) = \mathrm{H}^q_{\mathrm{II}}(\mathrm{H}^p_{\mathrm{I}}(K^{\bullet\bullet})).$$

Every morphism $u : K^{\bullet\bullet} \to K'^{\bullet\bullet}$ of bicomplexes is *ipso facto* compatible with the filtrations of the same type of $K^{\bullet\bullet}$ and $K'^{\bullet\bullet}$, thus defines a morphism for each of the two spectral sequences; in addition, two *homotopic* morphisms define a homotopy *of order* $\leqslant 1$ of the corresponding filtered (simple) complexes, thus the *same* morphism for each of the two spectral sequences (M, XV, 6.1).

Proposition (11.3.3). — *Let $K^{\bullet\bullet} = (K^{ij})$ be a bicomplex in an abelian category* $\mathtt{C}$.

- (i) *If there exist i_0 and j_0 such that $K^{ij} = 0$ for $i < i_0$ or $j < j_0$ (resp. $i > i_0$ or $j > j_0$), then the two spectral sequences $'E(K^{\bullet\bullet})$ and $''E(K^{\bullet\bullet})$ are biregular.*
- (ii) *If there exist i_0 and i_1 such that $K^{ij} = 0$ for $i < i_0$ or $i > i_1$ (resp. if there exist j_0 and j_1 such that $K^{ij} = 0$ for $j < j_0$ or $j > j_1$), then the two spectral sequences $'E(K^{\bullet\bullet})$ and $''E(K^{\bullet\bullet})$ are biregular.*

Suppose in addition that filtered inductive limits exist and are exact in $\mathtt{C}$. *Then:*

- (iii) *If there exists i_0 such that $K^{ij} = 0$ for $i > i_0$ (resp. if there exists j_0 such that $K^{ij} = 0$ for $j < j_0$), then the spectral sequence $'E(K^{\bullet\bullet})$ is regular.*
- (iv) *If there exists i_0 such that $K^{ij} = 0$ for $i < i_0$ (resp. if there exists j_0 such that $K^{ij} = 0$ for $j > j_0$), then the spectral sequence $''E(K^{\bullet\bullet})$ is regular.*

Proof. The proposition follows immediately from the definitions (11.1.3) and from (11.2.4), as well as from the following observations relating to the filtration F_{I} (and similar observations that we can deduce for F_{II} by exchanging the roles of the two indices in $K^{\bullet\bullet}$):

1° If there exists i_0 such that $K^{ij} = 0$ for $i > i_0$, then the filtration $F_{\mathrm{I}}(K^{\bullet\bullet})$ is *discrete*.

2° If there exists i_0 such that $K^{ij} = 0$ for $i < i_0$, then the filtration $F_{\mathrm{I}}(K^{\bullet\bullet})$ is *co-discrete*. We can then immediately deduce that it is the same for the corresponding filtration $F_{\mathrm{I}}(\mathrm{H}^n(K^{\bullet\bullet}))$ for all n. Furthermore, the definition of the B^{pq}_r corresponding to the filtration $F_{\mathrm{I}}(K^{\bullet\bullet})$ (11.2.2) shows that for any pair (p,q), the sequence $(B^{pq}_r)_{r\geqslant 2}$ is stable.

3° If there exists j_0 such that $K^{ij} = 0$ for $j < j_0$, then we have
$$F^{p+r}_{\mathrm{I}}(K^{\bullet\bullet}) \cap (\sum_{i+j=n} K^{ij}) = 0$$
as soon as $p + r + j_0 > n$, so $Z^{pq}_r = Z_\infty(E^{pq}_2)$ for $r > q - j_0 + 1$. On the other hand, $\mathrm{H}^n(F^p_{\mathrm{I}}(K^{\bullet\bullet})) = 0$ for $p > n - j_0 + 1$.

4° If there exists j_0 such that $K^{ij} = 0$ for $j > j_0$, then we have
$$F^{p-r+1}_{\mathrm{I}}(K^{\bullet\bullet}) \cap (\sum_{i+j=n} K^{ij}) = \sum_{i+j=n} K^{ij}$$
as soon as $p - r + 1 + j_0 < n$, so $B^{pq}_r = B_\infty(E^{pq}_2)$ for $r > j_0 - q + 1$. On the other hand, $\mathrm{H}^n(F^p_{\mathrm{I}}(K^{\bullet\bullet})) = \mathrm{H}^n(K^{\bullet\bullet})$ for $p + j_0 < n - 1$. $\mathbf{0_{III}}$ | 31

□

(11.3.4). Suppose that the bicomplex $K^{\bullet\bullet} = (K^{ij})$ is such that $K^{ij} = 0$ for $i < 0$ or $j < 0$. We know that we can define, for all $p \in \mathbf{Z}$, a canonical "edge-homomorphism".

$$'E_2^{p0}(K^{\bullet\bullet}) \to \mathrm{H}^p(K^{\bullet\bullet}) \tag{11.3.4.1}$$

(M, XV, 6). Recall that this is due to, on the one hand, the spectral sequence $'E(K^{\bullet\bullet})$, since $Z_r^{p0} = Z_{\mathrm{I}}^p(Z_{\mathrm{II}}^0(K^{\bullet\bullet}))$ for $2 \leqslant r \leqslant +\infty$, and on the other hand, that $\mathrm{H}^p(F_{\mathrm{I}}^{p+1}(K^{\bullet\bullet})) = 0$, so that the isomorphism $\beta^{p0} : {}'E_\infty^{p0} \xrightarrow{\sim} \mathrm{H}^p(F_{\mathrm{I}}^p)/\mathrm{H}^p(F_{\mathrm{I}}^{p+1})$ gives a homomorphism $'E_\infty^{p0} \to \mathrm{H}^p(F_{\mathrm{I}}^p(K^{\bullet\bullet})) \to \mathrm{H}^p(K^{\bullet\bullet})$. The equality of all the Z_r^{p0} allows us to define canonical homomorphisms $'E_r^{p0} \to' E_s^{p0}$ for $r \leqslant s$, and in particular a homomorphism $'E_2^{p0} \to' E_\infty^{p0}$, whence by composition the edge-homomorphism $'E_2^{p0}(K^{\bullet\bullet}) \to \mathrm{H}^p(K^{\bullet\bullet})$. Furthermore, we can immediately verify that the edge-homomorphism thus defined sends the class modulo B_2^{p0} of an element $z \in Z_{\mathrm{II}}^0(K^{\bullet\bullet}) \subset K^{p0}$ such that $d'z = 0$ to the class of z modulo B_∞^{p0} in $'E_\infty^{p0}$, and then to the cohomology class of z in $\mathrm{H}^p(K^{\bullet\bullet})$. We therefore finally see that the *edge-homomorphism* (11.3.4.1) *comes from, by passing to cohomology, the canonical injection* $Z_{\mathrm{II}}^0(K^{\bullet\bullet}) \to K^{\bullet\bullet}$ (where $K^{\bullet\bullet}$ is considered as simple complex). We naturally interpret the edge-homomorphism in the same way

$$''E_2^{p0}(K^{\bullet\bullet}) \to \mathrm{H}^p(K^{\bullet\bullet}) \tag{11.3.4.2}$$

as coming from the canonical injection $Z_{\mathrm{I}}^0(K^{\bullet\bullet}) \to K^{\bullet\bullet}$.

(11.3.5). Now let $K_{\bullet\bullet} = (K_{ij})$ be a bicomplex in $\mathtt{C}$ whose two differential operators are of degrees -1. We then write $K_{i,\bullet}$ (resp. $K_{\bullet,j}$) to mean the simple complex $(K_{ij})_{j\in\mathbf{Z}}$ (resp. $(K_{ij})_{i\in\mathbf{Z}}$), $\mathrm{H}_p^{\mathrm{II}}(K_{i,\bullet})$ (resp. $\mathrm{H}_p^{\mathrm{I}}(K_{\bullet,j})$) to mean the p-th homology object, $\mathrm{H}_p^{\mathrm{II}}(K_{\bullet\bullet})$ (resp. $\mathrm{H}_p^{\mathrm{I}}(K_{\bullet\bullet})$) to mean the complex $(\mathrm{H}_p^{\mathrm{II}}(K_{i,\bullet}))_{i\in\mathbf{Z}}$ (resp. $(\mathrm{H}_p^{\mathrm{I}}(K_{\bullet,j}))_{j\in\mathbf{Z}}$), and $\mathrm{H}_q^{\mathrm{I}}(\mathrm{H}_p^{\mathrm{II}}(K_{\bullet\bullet}))$ (resp. $\mathrm{H}_q^{\mathrm{II}}(\mathrm{H}_p^{\mathrm{I}}(K_{\bullet\bullet}))$) to mean the q-th homology object; we use analogous notation for the objects of cycles and objects of boundaries; finally, we will denote by $\mathrm{H}_n(K_{\bullet\bullet})$ the n-th homology object (when it exists) of the simple complex (with a differential operator of degree -1) defined by $K_{\bullet\bullet}$. Let $K'^{\bullet\bullet} = (K'^{ij})$, with $K'^{ij} = K_{-i,-j}$, be the bicomplex with differential operators of degrees $+1$ associated to $K_{\bullet\bullet}$. By definition, the *spectral sequences* of $K_{\bullet\bullet}$ are those of $K'^{\bullet\bullet}$, that we write as $'E(K_{\bullet\bullet})$ and $''E(K_{\bullet\bullet})$, where, however, we change the notation, by putting

$$'E_{pq}^r(K_{\bullet\bullet}) =' E_r^{-p,-q}(K'^{\bullet\bullet}) \quad \text{and} \quad ''E_{pq}^r(K_{\bullet\bullet}) ='' E_r^{-p,-q}(K'^{\bullet\bullet}),$$

for $2 \leqslant r \leqslant \infty$. With this notation, we have

$$'E_{pq}^2(K_{\bullet\bullet}) = \mathrm{H}_p^{\mathrm{I}}(\mathrm{H}_q^{\mathrm{II}}(K_{\bullet\bullet})) \quad \text{and} \quad ''E_{pq}^2(K_{\bullet\bullet}) = \mathrm{H}_q^{\mathrm{II}}(\mathrm{H}_p^{\mathrm{I}}(K_{\bullet\bullet})).$$

To avoid sign errors, it will be preferable in general to return to the complex $K'^{\bullet\bullet}$ for the relations between these spectral sequences and their abutments. We note, however, the criteria corresponding to (11.3.3):

(11.3.6). The spectral sequences $'E(K_{\bullet\bullet})$ and $''E(K_{\bullet\bullet})$ are *biregular* in the following cases:

(a) There exist i_0 and j_0 such that $K_{ij} = 0$ for $i > i_0$ or $j > j_0$ (resp. for $i < i_0$ or $j < j_0$); $\mathbf{0_{III}}$ | 32
(b) There exist i_0 and i_1 such that $K_{ij} = 0$ for $i < i_0$ and $i > i_1$;
(c) There exist j_0 and j_1 such that $K_{ij} = 0$ for $j < j_0$ and $j > j_1$.

The sequence $'E(K_{\bullet\bullet})$ is *regular* if there exists i_0 such that $K_{ij} = 0$ for $i < i_0$, or if there exists j_0 such that $K_{ij} = 0$ for $j > j_0$.

The sequence $''E(K_{\bullet\bullet})$ is *regular* if there exists i_0 such that $K_{ij} = 0$ for $i > i_0$, or if there exists j_0 such that $K_{ij} = 0$ for $j < j_0$.

11.4. Hypercohomology of a functor with respect to a complex $K^\bullet$

(11.4.1). Let $\mathtt{C}$ be an abelian category. Recall that we defined the *right resolution* (or *cohomological resolution*) of an object A in $\mathtt{C}$ to be a complex of objects in $\mathtt{C}$, whose differential operator is of degree $+1$,

$$0 \to L^0 \to L^1 \to L^2 \to \ldots$$

endowed with a morphism $\varepsilon : A \to L^0$, called the *augmentation* of the resolution, which we can consider as a morphism of complexes

$$\begin{tikzcd} 0 \arrow[r] & A \arrow[r] \arrow[d, "\varepsilon"'] & 0 \arrow[r] \arrow[d] & 0 \arrow[r] \arrow[d] & \ldots \\ 0 \arrow[r] & L^0 \arrow[r] & L^1 \arrow[r] & L^2 \arrow[r] & \ldots \end{tikzcd}$$

such that the sequence

$$0 \to A \xrightarrow{\varepsilon} L^0 \to L^1 \ldots$$

is exact. Similarly, a *left resolution* (or *homological resolution*) of A is a complex $0 \leftarrow L_0 \leftarrow L_1 \leftarrow L_2 \ldots$ of objects in $\mathtt{C}$, whose differential operator is of degree -1, endowed with an *augmentation* $L_0 \xrightarrow{\varepsilon} A$ such that the sequence

$$0 \leftarrow A \xleftarrow{\varepsilon} L_0 \leftarrow L_1 \ldots$$

is exact.

When the right resolution $(L_i)_{i\geqslant 0}$ of an object A is such that $L_i = 0$ for $i \geqslant n+1$, we say that this resolution is *of length* $\leqslant n$. We define a left resolution of length $\leqslant n$ similarly. A resolution which is of length $\leqslant n$ for some integer n is said to be *finite*.

A resolution of A is called *projective* (resp. *injective*) if the objects of $\mathtt{C}$, apart from A, of which it is composed are *projective* (resp. *injective*). When $\mathtt{C}$ is the category of (left, say) modules over a ring, we say that a resolution of A is *flat* (resp. *free*) when the modules, apart from A, of which it is composed are *flat* (resp. *free*).

(11.4.2). Let $K^\bullet = (K^i)_{i\in\mathbf{Z}}$ be a complex of objects of $\mathtt{C}$, whose differential operator is of degree $+1$. We define the *right Cartan–Eilenberg resolution* of $K^\bullet$ to be a pair consisting of a bicomplex $L^{\bullet\bullet} = (L^{ij})$ with differential operator of degree $+1$ and such that $L^{ij} = 0$ for $j < 0$, and a morphism of simple complexes $\varepsilon : K^\bullet \to L^{\bullet,0}$, such that the following conditions are fulfilled: $\mathbf{0}_{\mathbf{III}}$ | 33

(i) For each index i, the sequences

$$0 \to K^i \xrightarrow{\varepsilon} L^{i0} \to L^{i1} \to \ldots$$
$$0 \to B^i(K^\bullet) \xrightarrow{\varepsilon} B^i_{\mathrm{I}}(L^{\bullet,0}) \to B^i_{\mathrm{I}}(L^{\bullet,1}) \to \ldots$$
$$0 \to Z^i(K^\bullet) \xrightarrow{\varepsilon} Z^i_{\mathrm{I}}(L^{\bullet,0}) \to Z^i_{\mathrm{I}}(L^{\bullet,1}) \to \ldots$$
$$0 \to \mathrm{H}^i(K^\bullet) \xrightarrow{\varepsilon} \mathrm{H}^i_{\mathrm{I}}(L^{\bullet,0}) \to \mathrm{H}^i_{\mathrm{I}}(L^{\bullet,1}) \to \ldots$$

are exact, or, in other words, $(L^{i,\bullet}), (B^i_{\mathrm{I}}(L^{\bullet\bullet})), (Z^i_{\mathrm{I}}(L^{\bullet\bullet}))$ and $(\mathrm{H}^i_{\mathrm{I}}(L^{\bullet\bullet}))$ are *resolutions* of $K^i, B^i(K^\bullet), Z^i(K^\bullet)$ and $\mathrm{H}^i(K^\bullet)$ (respectively).

(ii) For each j, the simple complex $L^{\bullet,j}$ is *split*, or, in other words, the exact sequences

(11.4.2.1) $$0 \to B^i_{\mathrm{I}}(L^{\bullet,j}) \to Z^i_{\mathrm{I}}(L^{\bullet,j}) \to \mathrm{H}^i_{\mathrm{I}}(L^{\bullet,j}) \to 0$$

(11.4.2.2) $$0 \to Z^i_{\mathrm{I}}(L^{\bullet,j}) \to L^{ij} \to B^{i+1}_{\mathrm{I}}(L^{\bullet,j}) \to 0$$

are *split*.

We can prove (M, XVII, 1.2) that if every object of $\mathtt{C}$ is a subobject of an injective object, then every complex $K^\bullet$ of $\mathtt{C}$ admits an *injective* Cartan–Eilenberg resolution, i.e. consisting of injective objects L^{ij} (the condition (ii) above then implying that the $(B^i_{\mathrm{I}}(L^{\bullet,j})), (Z^i_{\mathrm{I}}(L^{\bullet,j}))$ and $(\mathrm{H}^i_{\mathrm{I}}(L^{\bullet,j}))$ also consist of injective objects). Furthermore, for any morphism $f : K^\bullet \to K'^\bullet$ of complexes of $\mathtt{C}$, any Cartan–Eilenberg resolution $L^{\bullet\bullet}$ of $K^\bullet$, and any *injective* Cartan–Eilenberg resolution $L'^{\bullet\bullet}$ of $K'^\bullet$, there exists a morphism of bicomplexes $F : L^{\bullet\bullet} \to L'^{\bullet\bullet}$ that is compatible with f and its augmentation, and if f

and g are homotopic morphisms from $K^\bullet$ to $K'^\bullet$, then the corresponding morphisms from $L^{\bullet\bullet}$ to $L'^{\bullet\bullet}$ are also homotopic *(loc. cit.)*.

When $K^\bullet$ is *bounded below* (resp. *bounded above*), we can take $L^{\bullet\bullet}$ to be such that $L^{ij} = 0$ for $i < i_0$ (resp. $i > i_0$) if $K^i = 0$ for $i < i_0$ (resp. $i > i_0$) (M, XVII, 1.3).

Suppose, on the other hand, that there exists an integer n such that every object of $\mathtt{C}$ admits a *injective resolution of length* $\leqslant n$; then we can assume that we have $L^{ij} = 0$ for $j > n$ (M, XVII, 1.4).

(11.4.3). Now let T be an *additive covariant functor* from $\mathtt{C}$ to an abelian category $\mathtt{C}'$. Given a complex $K^\bullet$ of $\mathtt{C}$ and an *injective* Cartan–Eilenberg resolution $L^{\bullet\bullet}$ of $K^\bullet$, suppose that the (simple) complex defined by the bicomplex $T(L^{\bullet\bullet})$ exists (11.3.1); then the two spectral sequences ${}'E(T(L^{\bullet\bullet}))$ and ${}''E(T(L^{\bullet\bullet}))$ of this bicomplex are called the *hypercohomology spectral sequences* of T with respect to $K^\bullet$; by (11.4.2) and (11.3.2), they depend only on the complex $K^\bullet$, not on the choice of the injective Cartan–Eilenberg resolution $L^{\bullet\bullet}$; furthermore, they depend *functorially* on $K^\bullet$. They have the same abutment $\mathrm{H}^\bullet(T(L^{\bullet\bullet}))$, also called the *hypercohomology* of T with respect to $K^\bullet$, and denoted by $\mathrm{R}^\bullet T(K^\bullet)$. We can show that the E_2 terms of the two spectral sequences above are given by

$$ {}'E_2^{pq} = \mathrm{H}^p(\mathrm{R}^q T(K^\bullet)) \tag{11.4.3.1} $$

$$ {}''E_2^{pq} = \mathrm{R}^p T(\mathrm{H}^q(K^\bullet)) \tag{11.4.3.2} $$

where $\mathrm{R}^p T$ denotes, as usual, the p-th *derived functor* of T for $p \in \mathbf{Z}$; $\mathrm{R}^q T(K^\bullet)$ denotes the complexes $(\mathrm{R}^q T(K^i))_{i\in\mathbf{Z}}$. Unless explicitly otherwise mentioned, we will henceforth assume that every object of $\mathtt{C}$ is a subobject of an injective object of $\mathtt{C}$, so that injective Cartan–Eilenberg resolutions exist for any complex of $\mathtt{C}$. Since $L^{ij} = 0$ for $j < 0$, the criteria of (11.3.3) show that the *two* hypercohomology spectral sequences of T with respect to $K^\bullet$ exist and are *biregular* in each of the following two cases: $\mathbf{0_{III}}$ | 34

(1) $K^\bullet$ is bounded below;
(2) Every object of $\mathtt{C}$ admits an injective resolution of length at most n, for some integer n independent of the object in question.

Indeed, we can suppose, in the first case, by (11.4.2), that there exists i_0 such that $L^{ij} = 0$ for $i < i_0$, and, in the second case, that there exists j_1 such that $L^{ij} = 0$ for $j > j_1$; in each of these two cases, it is furthermore clear that, for any given n, there exist only a finite number of pairs (i, j) such that $L^{ij} \neq 0$ and $i + j = n$, which proves our claims.

If we assume that filtrant inductive limits exist in $\mathtt{C}'$ and are exact (which implies, in particular, the existence of infinite direct sums in $\mathtt{C}'$), then the complex defined by the bicomplex $T(L^{\bullet\bullet})$ exists, and criterion (11.3.3) shows that the sequence ${}'E(T(L^{\bullet\bullet}))$ is always *regular*.

If $K^\bullet$ is a complex such that all the K^i are zero except for a single K^{i_0}, then $\mathrm{R}^n T(K^\bullet)$ is isomorphic to $\mathrm{R}^{n-i_0} T(K^{i_0})$, as follows immediately from the definitions by taking a Cartan–Eilenberg resolution $L^{\bullet\bullet}$ such that $L^{ij} = 0$ for $i \neq i_0$.

If $K^\bullet$ and $K'^\bullet$ are two complexes of $\mathtt{C}$, and f and g are homotopic morphisms from $K^\bullet$ to $K'^\bullet$, then the morphisms $\mathrm{R}^\bullet T(K^\bullet) \to \mathrm{R}^\bullet T(K'^\bullet)$ induced by f and g are identical, and the same is true for the morphisms of the cohomology spectral sequences.

Proposition (11.4.5). — *Suppose that filtrant inductive limits exist in* $\mathtt{C}'$ *and are exact. If* $\mathrm{R}^n T(K^i) = 0$ *for all* $n > 0$ *and all* $i \in \mathbf{Z}$*, then we have functorial isomorphisms*

$$ \mathrm{R}^i T(K^\bullet) \xrightarrow{\sim} \mathrm{H}^i(T(K^\bullet)) \tag{11.4.5.1} $$

for all $i \in \mathbf{Z}$.

Proof. Indeed, the only non-zero E_2 terms of the first spectral sequence (11.4.3.1) are then ${}'E_2^{p0} = \mathrm{H}^p(T(K^\bullet))$; in other words, this sequence is *degenerate*; since it is regular (11.4.4), the conclusion follows from (11.1.6). □

(11.4.6). Now consider, for example, a covariant bifunctor $(M, N) \to T(M, N)$ from $\mathtt{C} \times \mathtt{C}'$ to $\mathtt{C}''$, where $\mathtt{C}$, $\mathtt{C}'$, and $\mathtt{C}''$ are three abelian categories; we assume, for simplicity, that T is additive in each of its arguments, and furthermore that every object of $\mathtt{C}$ and every object of $\mathtt{C}'$ are subobjects of an injective object, and that filtered inductive limits exist in $\mathtt{C}''$ and are exact. We then define the *hypercohomology* of T with respect to the complexes $K^\bullet$ and $K'^\bullet$ of $\mathtt{C}$ and $\mathtt{C}'$ (respectively), with differential operators of degree $+1$, by replacing $K^\bullet$ (resp. $K'^\bullet$) by an injective Cartan–Eilenberg resolution $L^{\bullet\bullet}$ (resp. $L'^{\bullet\bullet}$); then $T(L^{\bullet\bullet}, L'^{\bullet\bullet})$ is a quadricomplex of $\mathtt{C}''$, which we consider as a *bicomplex* of $\mathtt{C}''$, with the degree of $T(L^{ij}, L'^{hk})$ being the integers $i+h$ and $j+k$. The *hypercohomology* of T with respect to $K^\bullet$ and $K'^\bullet$ is by definition the cohomology $\mathrm{H}^\bullet(T(L^{\bullet\bullet}, L'^{\bullet\bullet}))$ of this bicomplex (in other words, that of the associated simple complex) and is denoted by $\mathrm{R}^\bullet T(K^\bullet, K'^\bullet)$; it is the abutment of two spectral sequences whose E_2 terms are given by **0**$_{\mathbf{III}}$ | 35

(11.4.6.1) $$'E_2^{pq} = \mathrm{H}^p(\mathrm{R}^q T(K^\bullet, K'^\bullet))$$

(11.4.6.2) $$''E_2^{pq} = \sum_{q'+q''=q} \mathrm{R}^p T(\mathrm{H}^{q'}(K^\bullet), \mathrm{H}^{q''}(K'^\bullet))$$

(cf. M, XVII, 2).

Here $\mathrm{R}^q T(K^\bullet, K'^\bullet)$ is the bicomplex $\left(\mathrm{R}^q T(K^i, K'^j)\right)_{(i,j)\in\mathbf{Z}\times\mathbf{Z}}$, and the right-hand side of (11.4.6.1) is its cohomology when we consider it as a simple complex.

Furthermore, the first spectral sequence is always regular, and the two spectral sequences are biregular when there exists n such that every object of $\mathtt{C}$ and every object of $\mathtt{C}'$ admit an injective resolution of length $\leqslant n$, or when $K^\bullet$ and $K'^\bullet$ are bounded below; in the latter case, we can furthermore omit the hypothesis that inductive limits exist in $\mathtt{C}$ and $\mathtt{C}'$.

If $K_1^\bullet$ and $K_1'^\bullet$ are two other complexes of $\mathtt{C}$ and $\mathtt{C}'$ (respectively), f and g *homotopic* morphisms from $K^\bullet$ to $K_1^\bullet$, and f' and g' *homotopic* morphisms from $K'^\bullet$ to $K_1'^\bullet$, then the morphisms $\mathrm{R}^\bullet T(K^\bullet, K'^\bullet) \to \mathrm{R}^\bullet T(K_1^\bullet, K_1'^\bullet)$ induced by f and f' on the one hand, and by g and g' on the other hand, are identical, and the same is true for the morphisms of the hypercohomology spectral sequences.

We can generalize easily to any additive covariant multifunctor.

Proposition (11.4.7). — *Suppose that for any injective object* $\mathtt{I}$ *of* $\mathtt{C}$ *(resp.* $\mathtt{I}'$ *of* $\mathtt{C}'$*),* $\mathtt{A}' \mapsto T(\mathtt{I}, \mathtt{A}')$ *(resp.* $\mathtt{A} \mapsto T(\mathtt{A}, \mathtt{I}')$*) is an exact functor. Then, with the notation of (11.4.6), we have a canonical isomorphism*

$$\mathrm{R}^\bullet T(K^\bullet, K'^\bullet) \xrightarrow{\sim} \mathrm{H}^\bullet(T(L^{\bullet\bullet}, K'^\bullet)) \xrightarrow{\sim} \mathrm{H}^\bullet(T(K^\bullet, L'^{\bullet\bullet}))$$

where the last two terms are the cohomology of simple complexes defined by the tricomplexes $T(L^{\bullet\bullet}, K'^\bullet)$ *and* $T(K^\bullet, L'^{\bullet\bullet})$ *(respectively).*

Proof. Let us define, for example, the first of these isomorphisms. The quadricomplex $T(L^{\bullet\bullet}, L'^{\bullet\bullet})$ can be considered as a bicomplex, where the degrees of $T(L^{ij}, L'^{hk})$ are the integers $i+j+h$ and k. Since, for each h, $L'^{h,\bullet}$ is a *resolution* of K'^h, we have, for this bicomplex, by virtue of the hypotheses on T, $\mathrm{H}_{\mathrm{II}}^q(T(L^{\bullet\bullet}, L'^{\bullet\bullet})) = 0$ for $q \neq 0$, and $\mathrm{H}_{\mathrm{II}}^0(T(L^{\bullet\bullet}, L'^{\bullet\bullet})) = T(L^{\bullet\bullet}, K'^\bullet)$; the first spectral sequence of this bicomplex is thus *degenerate*; since $L'^{hk} = 0$ for $k < 0$, this sequence is also regular (11.3.3), and the conclusion then follows from (11.1.6). □

We have similar results for a covariant multifunctor of any number n of arguments: in the calculation of the hypercohomology, it is not necessary to replace *all* the complexes by a Cartan–Eilenberg resolution, but only $n-1$ of them, provided that, when we fix $n-1$ arbitrary arguments by taking them to be *injective* objects, the covariant functor in the remaining argument is *exact*.

11.5. Passage to the inductive limit in the hypercohomology

Lemma (11.5.1). — *Let* $K^\bullet = (K^i)_{i\in\mathbf{Z}}$ *be a complex of* $\mathtt{C}$*, and, for every integer* $r \in \mathbf{Z}$*, let* $K_{(r)}^\bullet$ *be the complex such that* $K_{(r)}^i = 0$ *for* $i < r$ *and* $K_{(r)}^i = K^i$ *for* $i \geqslant r$*. Let* T *be an additive covariant functor from* $\mathtt{C}$ *to* $\mathtt{C}'$ *that commutes with inductive limits; we suppose that filtered inductive limits exist and are exact in* $\mathtt{C}$ *and* $\mathtt{C}'$*. Then* $\mathrm{R}^\bullet T(K^\bullet)$ *is isomorphic to the inductive limit* **0**$_{\mathbf{III}}$ | 36

$$\varinjlim_{r\to-\infty} \mathrm{R}^\bullet T(K_{(r)}^\bullet).$$

An injective Cartan–Eilenberg resolution of $K^\bullet$ is constructed by choosing arbitrarily, for every i, an injective resolution $(X_{\mathrm{B}}^{ij})_{j\geqslant 0}$ of $\mathrm{B}^i(K^\bullet)$ and an injective resolution $(X_{\mathrm{H}}^{ij})_{j\geqslant 0}$ of $\mathrm{H}^i(K^\bullet)$. Once this is done, the construction shows that the injective resolution $(L^{ij})_{j\geqslant 0}$ of K^i and the differential operators $L^{i,j} \to L^{i+1,j}$ depend only on the resolutions $(X_{\mathrm{B}}^{i,\bullet})$, $(X_{\mathrm{H}}^{i,\bullet})$, and $(X_{\mathrm{B}}^{i+1,\bullet})$ (M, XVII, 1.2).

Now it is clear that $\mathrm{B}^i(K^\bullet_{(r)}) = \mathrm{B}^i(K^\bullet)$ and $\mathrm{H}^i(K^\bullet_{(r)}) = \mathrm{H}^i(K^\bullet)$ for $i \geqslant r+1$. On the other hand, for every r there is a canonical injection

$$\varphi^\bullet_{r-1,r} : K^\bullet_{(r)} \longrightarrow K^\bullet_{(r-1)},$$

where $\varphi^i_{r-1,r}$ is the identity for $i \neq r-1$. The preceding observation shows that, if $L^{\bullet\bullet} = (L^{ij})$ is an injective Cartan–Eilenberg resolution of $K^\bullet$, then for every r one can define an injective Cartan–Eilenberg resolution $L^{\bullet\bullet}_{(r)} = (L^{ij}_{(r)})$ of $K^\bullet_{(r)}$ such that $L^{ij}_{(r)} = 0$ for $i < r$ and $L^{ij}_{(r)} = L^{ij}$ for $i \geqslant r+1$. One can also define a morphism of bicomplexes

$$\Phi^{\bullet\bullet}_{r-1,r} : L^{\bullet\bullet}_{(r)} \longrightarrow L^{\bullet\bullet}_{(r-1)}$$

corresponding to $\varphi^\bullet_{r-1,r}$; the construction of this morphism (*loc. cit.*) again shows that it can be chosen so that $\Phi^{ij}_{r-1,r}$ is the identity for $i \neq r$ and $i \neq r-1$.

We have thus defined an inductive system $(L^{\bullet\bullet}_{(r)})$ of bicomplexes of $\mathtt{C}$ whose inductive limit, as r tends to $-\infty$, is evidently $L^{\bullet\bullet}$. Since direct sums commute with inductive limits, the simple complex associated with $L^{\bullet\bullet}$ is likewise the inductive limit of the simple complexes associated with the $L^{\bullet\bullet}_{(r)}$. By hypothesis T commutes with inductive limits, and so does cohomology, because the functor $\varinjlim$ is exact. Consequently, up to isomorphism,

$$\mathrm{H}^\bullet(T(L^{\bullet\bullet})) = \varinjlim_{r\to-\infty} \mathrm{H}^\bullet(T(L^{\bullet\bullet}_{(r)})).$$

Lemma (11.5.1) allows one, by passage to the inductive limit, to extend to arbitrary complexes $K^\bullet$ properties that hold for complexes *bounded below*. As a first example, we prove the following.

Proposition (11.5.2). — *Under the hypotheses of (11.5.1) concerning $\mathtt{C}$, $\mathtt{C}'$, and T, the functor $\mathrm{R}^\bullet T(K^\bullet)$ is a cohomological functor on the abelian category of complexes of $\mathtt{C}$.*

Proof. We first show that it is enough to treat complexes bounded below. Given an exact sequence

$$0 \longrightarrow K'^\bullet \longrightarrow K^\bullet \longrightarrow K''^\bullet \longrightarrow 0$$

of complexes, for every r it induces an exact sequence

$$0 \longrightarrow K'^\bullet_{(r)} \longrightarrow K^\bullet_{(r)} \longrightarrow K''^\bullet_{(r)} \longrightarrow 0.$$

By hypothesis, the latter gives an exact sequence

$$\cdots \longrightarrow \mathrm{R}^n T(K'^\bullet_{(r)}) \longrightarrow \mathrm{R}^n T(K^\bullet_{(r)}) \longrightarrow \mathrm{R}^n T(K''^\bullet_{(r)}) \xrightarrow{\partial} \mathrm{R}^{n+1} T(K'^\bullet_{(r)}) \longrightarrow \cdots.$$

These exact sequences form an inductive system. Lemma (11.5.1) and the exactness of $\varinjlim$ therefore give an exact sequence

$$\cdots \longrightarrow \mathrm{R}^n T(K'^\bullet) \longrightarrow \mathrm{R}^n T(K^\bullet) \longrightarrow \mathrm{R}^n T(K''^\bullet) \xrightarrow{\partial} \mathrm{R}^{n+1} T(K'^\bullet) \longrightarrow \cdots.$$

□

To treat complexes bounded below, it is enough to consider those for which $K^i = 0$ when $i < 0$; these plainly form an abelian category, which we denote by $\mathtt{K}$.

Lemma (11.5.2.1). — *In $\mathtt{K}$, let $\mathfrak{J}$ be the class of complexes $Q^\bullet = (Q^i)_{i\geqslant 0}$ having the following properties:* **0_III** | 37

(1) *every Q^i is an injective object of $\mathtt{C}$;*

(2) *for every $i \geqslant 0$, $\mathrm{Z}^i(Q^\bullet) = \mathrm{B}^i(Q^\bullet)$, and $\mathrm{Z}^i(Q^\bullet)$ is a direct summand of Q^i.*

Then:

(i) *every $Q^\bullet \in \mathfrak{J}$ is an injective object of $\mathtt{K}$;*

(ii) *every object of $\mathtt{K}$ is isomorphic to a subcomplex of a complex belonging to $\mathfrak{J}$.*

Proof. (i) Let $A^\bullet = (A^i)$ be an object of $\mathtt{K}$, let $A'^\bullet = (A'^i)$ be a subobject of $A^\bullet$, let $Q^\bullet = (Q^i)$ belong to $\mathfrak{J}$, and suppose that a morphism

$$f = (f^i) : A'^\bullet \longrightarrow Q^\bullet$$

is given. We must extend it to a morphism $g = (g^i) : A^\bullet \to Q^\bullet$. For simplicity, we use the language of the category of modules (cf. [27]).

Identify Q^i with $\mathrm{B}^i(Q^\bullet) \oplus \mathrm{B}^{i+1}(Q^\bullet)$. We proceed by induction on i. Suppose that g^j has been defined for $j < i$, compatibly with the differentials $d^j : A^j \to A^{j+1}$ and $d'^j : Q^j \to Q^{j+1}$ for $j < i-1$, and that in addition:

(1) $g^{i-1}(\mathrm{Z}^{i-1}(A^\bullet)) \subset \mathrm{Z}^{i-1}(Q^\bullet)$;

(2) if $C^j = (d^j)^{-1}(A'^{j+1})$ for every j, then $d'^{i-1} \circ g^{i-1}$ coincides with $f^i \circ d^{i-1}$ on C^{i-1}.

By composing $f^i : A'^i \to Q^i$ with the two projections, we obtain morphisms

$$f'^i : A'^i \longrightarrow \mathrm{B}^i(Q^\bullet), \qquad f''^i : A'^i \longrightarrow \mathrm{B}^{i+1}(Q^\bullet).$$

Since $d'^{i-1} \circ g^{i-1}$ maps A^{i-1} into $\mathrm{B}^i(Q^\bullet)$ and vanishes on $\mathrm{Z}^{i-1}(A^\bullet)$, it defines a morphism

$$h^i : \mathrm{B}^i(A^\bullet) \longrightarrow \mathrm{B}^i(Q^\bullet).$$

Condition (2) says that h^i coincides with f'^i on $\mathrm{B}^i(A^\bullet) \cap A'^i$. Because $\mathrm{B}^i(Q^\bullet)$ is a direct summand of Q^i, it is injective; hence there is a morphism

$$g'^i : A^i \longrightarrow \mathrm{B}^i(Q^\bullet)$$

that coincides with h^i on $\mathrm{B}^i(A^\bullet)$ and with f'^i on A'^i.

On the other hand, consider the morphism

$$f''^{i+1} \circ d^i : C^i \longrightarrow \mathrm{B}^{i+1}(Q^\bullet),$$

which vanishes on $\mathrm{Z}^i(A^\bullet)$. Since $\mathrm{B}^{i+1}(Q^\bullet)$ is injective, there is a morphism

$$g''^i : A^i \longrightarrow \mathrm{B}^{i+1}(Q^\bullet)$$

that coincides with $f''^{i+1} \circ d^i$ on C^i and with zero on $\mathrm{Z}^i(A^\bullet)$. Taking $g^i = g'^i + g''^i$ allows the induction to continue.

(ii) To embed $A^\bullet = (A^i)$ in a complex belonging to $\mathfrak{J}$, choose for every $i \geqslant 1$ an injective object Q'^i of $\mathtt{C}$ and an injection $f'^i : A^i \to Q'^i$. Set

$$Q^i = 0 \quad (i < 0), \qquad Q^0 = Q'^1, \qquad Q^i = Q'^i \oplus Q'^{i+1} \quad (i \geqslant 1),$$

with the evident differential. For every i, set

$$f^i = f'^i + (f'^{i+1} \circ d^i),$$

where $f'^i = 0$ for $i \leqslant 0$. It is immediate that every f^i is injective and that the f^i commute with the differentials. $\square$

Corollary (11.5.2.2). — *Every object $K^\bullet$ of $\mathtt{K}$ admits a right resolution formed of objects of $\mathfrak{J}$. If $L^{\bullet\bullet}$ is such a resolution, then for every resolution $L'^{\bullet\bullet}$ of $K^\bullet$ formed of objects of $\mathtt{K}$, there is a morphism of bicomplexes*

$$F : L'^{\bullet\bullet} \longrightarrow L^{\bullet\bullet}$$

compatible with the augmentations, and any two such morphisms F, F' are homotopic.

Proof. This is precisely (M, V, 1.1 a)) applied to the abelian category $\mathtt{K}$. $\square$

(11.5.2.3). Having established these preliminaries, let $L'^{\bullet\bullet}$ be an injective Cartan–Eilenberg resolution of $K^\bullet$ and let $L^{\bullet\bullet}$ be a resolution of $K^\bullet$ formed of objects of $\mathfrak{J}$. We show that there is an isomorphism

$$\mathrm{H}^\bullet(T(L'^{\bullet\bullet})) \xrightarrow{\sim} \mathrm{H}^\bullet(T(L^{\bullet\bullet})).$$

Corollary (11.5.2.2) gives a morphism of bicomplexes

$$T(L'^{\bullet\bullet}) \longrightarrow T(L^{\bullet\bullet}),$$

and hence a morphism

$$'E(T(L'^{\bullet\bullet})) \longrightarrow {}'E(T(L^{\bullet\bullet}))$$

between their first spectral sequences. By (11.3.3), these spectral sequences are regular, so by (11.1.5) it is enough to check that this morphism is an isomorphism on the E_2 terms. Equivalently, one must show that

$$\mathrm{H}^q_{\mathrm{II}}(T(L^{i,\bullet})) = \mathrm{R}^q T(K^i).$$

Since $L^{i,\bullet}$ is a right resolution of K^i, this reduces the question to the following lemma.

Lemma (11.5.2.4). — *Let $L^\bullet = (L^i)_{i\in\mathbf{Z}}$ be a right resolution of an object A of $\mathtt{C}$ such that $\mathrm{R}^n T(L^i) = 0$ for every $i \in \mathbf{Z}$ and every $n > 0$. Then*

$$\mathrm{H}^\bullet(T(L^\bullet)) = \mathrm{R}^\bullet T(A).$$

Proof. This is a special case of (T, 2.5.2). □

(11.5.2.5). The proof of (11.5.2) now follows immediately, since $L'^{\bullet\bullet}$ is an injective resolution of $K^\bullet$ in the abelian category $\mathtt{K}$. In other words, the functor

$$K^\bullet \longmapsto \mathrm{H}^\bullet(T(L'^{\bullet\bullet}))$$

is precisely the right-derived cohomological functor of T in the category $\mathtt{K}$ (T, 2.3).

Proposition (11.5.3). — *Under the hypotheses of (11.5.1) concerning $\mathtt{C}$, $\mathtt{C}'$, and T, let $L^{\bullet\bullet} = (L^{ij})$ be a bicomplex such that $L^{ij} = 0$ for $j < 0$ and such that, for every i, $L^{i,\bullet}$ is a resolution of K^i. Suppose further that $\mathrm{R}^n T(L^{ij}) = 0$ for every pair (i, j) and every $n > 0$. Then there is a functorial isomorphism*

$$\mathrm{R}^\bullet T(K^\bullet) \xrightarrow{\sim} \mathrm{H}^\bullet(T(L^{\bullet\bullet})). \tag{11.5.3.1}$$

Proof. Let $L^{\bullet\bullet}_{(r)} = (L^{ij}_{(r)})$ be the bicomplex defined by

$$L^{ij}_{(r)} = 0 \quad (i < r), \qquad L^{ij}_{(r)} = L^{ij} \quad (i \geqslant r).$$

It is immediate that $L^{\bullet\bullet}$ is the inductive limit of the $L^{\bullet\bullet}_{(r)}$ as r tends to $-\infty$. By the hypothesis on T and by (11.5.1), it is therefore enough to prove the proposition when $K^\bullet$ is bounded below, say when $K^i = 0$ for $i < 0$, with $L^{ij} = 0$ for $i < 0$. Let $L'^{\bullet\bullet} = (L'^{ij})$ be a right resolution of $K^\bullet$ formed of objects of $\mathfrak{J}$, as in (11.5.2.2). There is a morphism of bicomplexes

$$L^{\bullet\bullet} \longrightarrow L'^{\bullet\bullet}$$

compatible with the augmentations, hence a morphism

$${}'E(T(L^{\bullet\bullet})) \longrightarrow {}'E(T(L'^{\bullet\bullet}))$$

between the first spectral sequences. Lemma (11.5.2.4) shows, exactly as in (11.5.2.3), that this morphism is an isomorphism, proving the assertion. □

Remark (11.5.4). — The preceding arguments show that the conclusions of (11.5.2) and (11.5.3) hold in the category of complexes $K^\bullet$ bounded below without assuming that T commutes with filtered inductive limits. Moreover, if one considers only the category $\mathtt{K}$ of complexes $K^\bullet$ such that $K^i = 0$ for $i < 0$, the characterization of $\mathrm{R}^\bullet T(K^\bullet)$ as the system of right-derived functors of T in $\mathtt{K}$ shows that this cohomological functor is *universal* (T, 2.3).

Another case in which (11.5.2) holds without any additional hypothesis on T is when there is an integer $m > 0$ such that every object of $\mathtt{C}$ admits an injective resolution of length at most m. Indeed, in the proof of (11.5.1), all the injective resolutions of objects of $\mathtt{C}$ that occur may be chosen of length at most m. It follows at once that, for a fixed total degree n and for r sufficiently large, the terms of total degree n in $T(L^{\bullet\bullet}_{(r)})$ are equal to those in $T(L^{\bullet\bullet})$ and are finite in number. Consequently,

$$\mathrm{H}^n(T(L^{\bullet\bullet})) = \mathrm{H}^n(T(L^{\bullet\bullet}_{(r)}))$$

for r sufficiently large. With the notation of (11.5.2), one likewise has

$$\mathrm{R}^n T(K^\bullet_{(r)}) = \mathrm{R}^n T(K^\bullet)$$

for r sufficiently large (depending on n), and similarly for $K'^\bullet$ and $K''^\bullet$, which proves the conclusion. In the same way, (11.5.3) holds without an additional condition on T when $\mathtt{C}$ satisfies the preceding hypothesis and the resolutions $L^{i,\bullet}$ are taken to have length at most m.

(11.5.5). The result of (11.5.2) extends to covariant multifunctors. Consider, for example, the situation of (11.4.6), in which filtered inductive limits are assumed to exist and to be exact in $\mathtt{C}$, $\mathtt{C}'$, and $\mathtt{C}''$, and T is assumed to commute with inductive limits. Then $\mathrm{R}^\bullet T(K^\bullet, K'^\bullet)$ is a bifunctor that is cohomological in each of the complexes $K^\bullet, K'^\bullet$. To see this, one reduces, as in (11.5.2), to the case in which $K^\bullet$ and $K'^\bullet$ are bounded below. Choosing injective resolutions of $K^\bullet$ and $K'^\bullet$ of the type described in (11.5.2.2), one is reduced to the general property proved in (M, V, 4.1). $\mathbf{0}_{\mathbf{III}}$ | 39

(11.5.6). Similarly, the results of (11.4.7) and (11.5.3) extend as follows. Under the hypotheses of (11.5.5), suppose that we are given two bicomplexes

$$L^{\bullet\bullet} = (L^{ij}), \qquad L'^{\bullet\bullet} = (L'^{ij})$$

such that $L^{ij} = L'^{ij} = 0$ for $j < 0$, such that, for every i, $L^{i,\bullet}$ is a resolution of K^i and $L'^{i,\bullet}$ is a resolution of K'^i, and such that

$$\mathrm{R}^n T(L^{ij}, L'^{hk}) = 0$$

for $n > 0$ and every system of indices (i, j, h, k). Then there is an isomorphism, functorial in $K^\bullet$ and $K'^\bullet$,

(11.5.6.1) $$\mathrm{R}^\bullet T(K^\bullet, K'^\bullet) \xrightarrow{\sim} \mathrm{H}^\bullet(T(L^{\bullet\bullet}, L'^{\bullet\bullet})).$$

This is proved as in (11.5.3), by reducing to the case in which $K^\bullet$ and $K'^\bullet$ are bounded below.

Suppose in addition that, for every pair (i, j) and every pair (h, k), the functors

$$A \longmapsto T(A, L'^{hk}), \qquad A' \longmapsto T(L^{ij}, A')$$

are exact in $\mathtt{C}$ and $\mathtt{C}'$, respectively. Then there are also functorial isomorphisms

(11.5.6.2) $$\mathrm{R}^\bullet T(K^\bullet, K'^\bullet) \xrightarrow{\sim} \mathrm{H}^\bullet(T(L^{\bullet\bullet}, K'^\bullet)) \xrightarrow{\sim} \mathrm{H}^\bullet(T(K^\bullet, L'^{\bullet\bullet})).$$

The proof is analogous to that of (11.4.7).

(11.5.7). The results of (11.5.5) and (11.5.6) also hold without assuming that T commutes with inductive limits, provided that one restricts to complexes $K^\bullet, K'^\bullet$ bounded below, or that one assumes that every object of $\mathtt{C}$ (respectively, of $\mathtt{C}'$) admits an injective resolution of bounded length and, in (11.5.6), that the second degrees of $L^{\bullet\bullet}$ and $L'^{\bullet\bullet}$ are bounded above.

11.6. Hyperhomology of a functor with respect to a complex $K_\bullet$

(11.6.1). Let $\mathtt{C}$ be an abelian category and let $K_\bullet = (K_i)_{i\in\mathbf{Z}}$ be a complex of objects of $\mathtt{C}$ whose differential has degree -1. A *left Cartan–Eilenberg resolution* of $K_\bullet$ consists of a bicomplex $L_{\bullet\bullet} = (L_{ij})$, whose differentials have degree -1 and for which $L_{ij} = 0$ when $j < 0$, together with a morphism of simple complexes

$$\varepsilon : L_{\bullet,0} \longrightarrow K_\bullet,$$

such that the conditions obtained from those of (11.4.2) by "reversing the arrows" are satisfied. If every object of $\mathtt{C}$ is a quotient of a projective object, then every complex $K_\bullet$ of $\mathtt{C}$ admits a *projective Cartan–Eilenberg resolution*, that is, one formed of projective objects L_{ij}; it has functorial properties similar to those of (11.4.2). Moreover, if $K_\bullet$ is bounded below (respectively, above), one may require $L_{ij} = 0$ for $i < i_0$ (respectively, $i > i_0$) whenever $K_i = 0$ for $i < i_0$ (respectively, $i > i_0$). If every object of $\mathtt{C}$ admits a projective resolution of length at most n, one may require $L_{ij} = 0$ for $j > n$.

(11.6.2). Suppose that T is an additive covariant functor from $\mathtt{C}$ to an abelian category $\mathtt{C}'$. The hyperhomology $\mathrm{L}_\bullet T(K_\bullet)$ and the *hyperhomology spectral sequences* of T with respect to a complex $K_\bullet$ of $\mathtt{C}$ (when they exist) are defined from (11.4.3), again by "reversing the arrows". The E^2 terms of the two spectral sequences so obtained are $\mathbf{0}_{\mathbf{III}}$ | 40

(11.6.2.1) $$'E^2_{pq} = \mathrm{H}_p(\mathrm{L}_q T(K_\bullet))$$

and

(11.6.2.2) $$''E^2_{pq} = \mathrm{L}_p T(\mathrm{H}_q(K_\bullet)),$$

where $\mathrm{L}_p T$ denotes the pth left-derived functor of T for $p \geqslant 0$, and zero for $p < 0$, while $\mathrm{L}_q T(K_\bullet)$ denotes the complex $(\mathrm{L}_q T(K_i))_{i\in\mathbf{Z}}$.

The properties of hyperhomology do not all follow from those of hypercohomology merely by "reversing the arrows" (unless additional hypotheses of type (AB 5*) from (T, 1.5) are imposed on $\mathtt{C}'$). The reason is the regularity conditions on the two preceding spectral sequences, to which one must now apply the criteria of (11.3.4). Those criteria show that, if filtered inductive limits exist and are exact in $\mathtt{C}'$, then the complex defined by the bicomplex $T(L_{\bullet\bullet})$ exists and the *second* spectral sequence $''E(T(L_{\bullet\bullet}))$ is regular. If either $K_\bullet$ is bounded below or there is an integer n such that every object of $\mathtt{C}$ admits a projective resolution of length at most n, then the *two* hyperhomology spectral sequences exist (without any hypothesis on $\mathtt{C}'$) and are biregular.

Proposition (11.6.3). — *Let* C *and* C' *be two abelian categories, and let* T *be an additive covariant functor from* C *to* C'. *Then:*

(i) The hyperhomology $\mathrm{L}_\bullet T(K_\bullet)$ is a homological functor on the abelian category of complexes of C that are bounded below.

(ii) Let $K_\bullet$ be a complex of C bounded below. If $\mathrm{L}_n T(K_i) = 0$ for every $n > 0$ and every $i \in \mathbf{Z}$, there are functorial isomorphisms

$$\mathrm{L}_i T(K_\bullet) \xrightarrow{\sim} \mathrm{H}_i(T(K_\bullet)) \qquad (i \in \mathbf{Z}). \tag{11.6.3.1}$$

(iii) Let $K_\bullet$ be a complex of C bounded below. Let $L_{\bullet\bullet} = (L_{ij})$ be a bicomplex such that $L_{ij} = 0$ for $j < 0$ and, for every i, $L_{i,\bullet}$ is a resolution of K_i. Suppose in addition that $\mathrm{L}_n T(L_{ij}) = 0$ for every pair (i,j) and every $n > 0$. Then there is a functorial isomorphism

$$\mathrm{L}_\bullet T(K_\bullet) \xrightarrow{\sim} \mathrm{H}_\bullet(T(L_{\bullet\bullet})). \tag{11.6.3.2}$$

The proofs proceed as those of (11.5.2), (11.4.5), and (11.5.3) in the case of complexes bounded below. We leave the details of these arguments to the reader.

(11.6.4). Entirely analogous results hold for covariant multifunctors that are additive in each argument. For example, for a bifunctor T, the two hyperhomology spectral sequences have E^2 terms $\mathbf{0_{III}}$ | 41

$${}'E^2_{pq} = \mathrm{H}_p(\mathrm{L}_q T(K_\bullet, K'_\bullet)) \tag{11.6.4.1}$$

and

$${}''E^2_{pq} = \sum_{q'+q''=q} \mathrm{L}_p T(\mathrm{H}_{q'}(K_\bullet), \mathrm{H}_{q''}(K'_\bullet)). \tag{11.6.4.2}$$

Here again it is the *second* spectral sequence that is regular. The two sequences are biregular when $K_\bullet$ and $K'_\bullet$ are bounded below, or when the objects of the abelian categories under consideration admit projective resolutions of a fixed length.

Moreover:

Proposition (11.6.5). — *Let* C, C', *and* C'' *be three abelian categories, and let* T *be a covariant biadditive bifunctor from* $\mathsf{C} \times \mathsf{C}'$ *to* C''.

(i) $\mathrm{L}_\bullet T(K_\bullet, K'_\bullet)$ is a bifunctor that is homological in each of the bounded-below complexes $K_\bullet, K'_\bullet$, formed respectively of objects of C and of C'.

(ii) Suppose that $K_\bullet$ and $K'_\bullet$ are bounded below. Let $L_{\bullet\bullet} = (L_{ij})$ and $L'_{\bullet\bullet} = (L'_{ij})$ be two bicomplexes such that $L_{ij} = L'_{ij} = 0$ for $j < 0$ and such that, for every i, $L_{i,\bullet}$ is a resolution of K_i and $L'_{i,\bullet}$ is a resolution of K'_i. Suppose finally that $\mathrm{L}_n T(L_{ij}, L'_{hk}) = 0$ for every $n > 0$ and every system of indices (i,j,h,k). Then there is a functorial isomorphism

$$\mathrm{L}_\bullet T(K_\bullet, K'_\bullet) \xrightarrow{\sim} \mathrm{H}_\bullet(T(L_{\bullet\bullet}, L'_{\bullet\bullet})). \tag{11.6.5.1}$$

(iii) Suppose in addition that, for every pair (i,j) and every pair (h,k), the functors

$$A \longmapsto T(A, L'_{hk}), \qquad A' \longmapsto T(L_{ij}, A')$$

are exact in C and C', respectively. Then there are functorial isomorphisms

$$\mathrm{L}_\bullet T(K_\bullet, K'_\bullet) \xrightarrow{\sim} \mathrm{H}_\bullet(T(L_{\bullet\bullet}, K'_\bullet)) \xrightarrow{\sim} \mathrm{H}_\bullet(T(K_\bullet, L'_{\bullet\bullet})). \tag{11.6.5.2}$$

The proofs are analogous to those of (11.5.5) and (11.5.6).

11.7. Hyperhomology of a functor with respect to a bicomplex $K_{\bullet\bullet}$

(11.7.1). Let C be an abelian category in which every object is a quotient of a projective object. Consider a bicomplex $K_{\bullet\bullet} = (K_{ij})$ of objects of C whose two degrees are bounded below. We may always restrict ourselves to the case where $K_{ij} = 0$ for $i < 0$ or $j < 0$, and we shall do so from now on. We may regard $K_{\bullet\bullet}$ as an ordinary complex consisting of the objects

$$K_{i,\bullet} = (K_{ij})_{j\geqslant 0}$$

of the abelian category K of nonnegative complexes of objects of C. It follows from Lemma (11.5.2.1) (or, more precisely, from the "dual" lemma obtained by "reversing the arrows") and from (M, V, 2.2) that $K_{\bullet\bullet}$ admits a *projective Cartan–Eilenberg resolution* in the category K. Such a resolution is a tricomplex $M_{\bullet\bullet\bullet} = (M_{ijk})$ in C, all of whose degrees are nonnegative and whose objects are projective, such that, for every i,

$$M_{i,\bullet\bullet}, \qquad \mathrm{B}_i^{\mathrm{I}}(M_{\bullet\bullet\bullet}), \qquad \mathrm{Z}_i^{\mathrm{I}}(M_{\bullet\bullet\bullet}), \qquad \mathrm{H}_i^{\mathrm{I}}(M_{\bullet\bullet\bullet})$$

are projective resolutions in K of, respectively,

$$K_{i,\bullet}, \qquad \mathrm{B}_i^{\mathrm{I}}(K_{\bullet\bullet}), \qquad \mathrm{Z}_i^{\mathrm{I}}(K_{\bullet\bullet}), \qquad \mathrm{H}_i^{\mathrm{I}}(K_{\bullet\bullet}).$$

In particular, for every pair (i,j), $M_{ij,\bullet}$ is a projective resolution of K_{ij} in C.

Proposition (11.7.2). — *Let T be an additive covariant functor from C to an abelian category C'. With the notation of (11.7.1), the homology*

$$\mathrm{H}_\bullet\big(T(M_{\bullet\bullet\bullet})\big)$$

of the simple complex associated with the tricomplex $T(M_{\bullet\bullet\bullet})$ is canonically isomorphic to the hyperhomology $\mathrm{L}_\bullet T(K_{\bullet\bullet})$ of the simple complex associated with $K_{\bullet\bullet}$ (11.6.2). It is also the common abutment of six biregular spectral sequences denoted ${}^{(t)}\mathrm{E}$, where $t = a, b, a', b', c$, or d, whose E^2 terms are $\mathbf{0}_{\mathbf{III}}$ | 42

$$
\begin{aligned}
{}^{(a)}\mathrm{E}^2_{pq} &= \mathrm{L}_p T\big(\mathrm{H}_q(K_{\bullet\bullet})\big),\\
{}^{(b)}\mathrm{E}^2_{pq} &= \mathrm{H}_p\big(\mathrm{L}_q^{\mathrm{II}} T(K_{\bullet\bullet})\big),\\
{}^{(a')}\mathrm{E}^2_{pq} &= \mathrm{L}_p T\big(\mathrm{H}_q^{\mathrm{I}}(K_{\bullet\bullet})\big),\\
{}^{(b')}\mathrm{E}^2_{pq} &= \mathrm{H}_p\big(\mathrm{L}_q T(K_{\bullet\bullet})\big),\\
{}^{(c)}\mathrm{E}^2_{pq} &= \mathrm{L}_p T\big(\mathrm{H}_q^{\mathrm{II}}(K_{\bullet\bullet})\big),\\
{}^{(d)}\mathrm{E}^2_{pq} &= \mathrm{H}_p\big(\mathrm{L}_q^{\mathrm{I}} T(K_{\bullet\bullet})\big).
\end{aligned}
$$

Recall that, for a complex $A_\bullet = (A_i)$, we use the notation $F(A_\bullet)$ for the complex whose objects are the $F(A_i)$. For example, $\mathrm{L}_q^{\mathrm{II}} T(K_{\bullet\bullet})$ denotes the complex

$$\big(\mathrm{L}_q^{\mathrm{II}} T(K_{i,\bullet})\big)_{i\geqslant 0},$$

where $\mathrm{L}_q^{\mathrm{II}} T(K_{i,\bullet})$ is the hyperhomology of index q of the functor T relative to the simple complex $K_{i,\bullet}$.

Proof. Let $L_\bullet$ denote the simple complex associated with $K_{\bullet\bullet}$, so that

$$L_i = \bigoplus_{r+s=i} K_{rs},$$

and set

$$N_{ij} = \bigoplus_{r+s=i} M_{rsj}.$$

It is clear that, for every i, $N_{i,\bullet}$ is a projective resolution of L_i in C. It follows from (11.6.3) and (11.6.4) that there is a functorial isomorphism

$$\mathrm{L}_\bullet T(L_\bullet) \simeq \mathrm{H}_\bullet\big(T(N_{\bullet\bullet})\big).$$

Since the simple complex associated with the bicomplex $T(N_{\bullet\bullet})$ is also the simple complex associated with the tricomplex $T(M_{\bullet\bullet\bullet})$, this proves the first assertion.

Moreover, $\mathrm{L}_\bullet T(L_\bullet)$ is the abutment of the two hyperhomology spectral sequences (11.6.2) of T relative to the simple complex $L_\bullet$. These are precisely ${}^{(b')}\mathrm{E}$ and ${}^{(a)}\mathrm{E}$, respectively.

Now regard $M_{\bullet\bullet\bullet}$ as a bicomplex $U_{\bullet\bullet}$, where

$$U_{ij} = \bigoplus_{r+s=j} M_{irs}.$$

The homology $\mathrm{H}_\bullet(T(M_{\bullet\bullet\bullet}))$ is also the abutment of the two spectral sequences of the bicomplex $T(U_{\bullet\bullet})$. For every i, the bicomplex $M_{i,\bullet\bullet}$ satisfies the hypotheses of (11.6.3) relative to the simple complex $K_{i,\bullet}$. Consequently,

$$\mathrm{H}^{\mathrm{II}}_q\big(T(U_{i,\bullet})\big) = \mathrm{L}^{\mathrm{II}}_q T(K_{i,\bullet}),$$

and the first spectral sequence of $T(U_{\bullet\bullet})$ is precisely ${}^{(b)}\mathrm{E}$.

On the other hand, for every r, $M_{\bullet,r,\bullet}$ is a Cartan–Eilenberg resolution of the simple complex $K_{\bullet,r}$. The calculation made in (M, XV, 2) shows that

$$\mathrm{H}^{\mathrm{I}}_q\big(T(M_{\bullet,rs})\big) = T\big(\mathrm{H}^{\mathrm{I}}_q(M_{\bullet,rs})\big),$$

and hence

$$\mathrm{H}^{\mathrm{I}}_q\big(T(U_{\bullet,j})\big) = \bigoplus_{r+s=j} T\big(\mathrm{H}^{\mathrm{I}}_q(M_{\bullet,rs})\big).$$

In other words, the simple complex $\mathrm{H}^{\mathrm{I}}_q(T(U_{\bullet\bullet}))$ is the simple complex associated with the bicomplex $T(\mathrm{H}^{\mathrm{I}}_q(M_{\bullet\bullet\bullet}))$. For every q, $\mathrm{H}^{\mathrm{I}}_q(M_{\bullet\bullet\bullet})$ is a projective resolution in $\mathtt{K}$ of the simple complex $\mathrm{H}^{\mathrm{I}}_q(K_{\bullet\bullet})$. Applying (11.6.3), we obtain

$$\mathrm{H}^{\mathrm{II}}_p\big(T(\mathrm{H}^{\mathrm{I}}_q(M_{\bullet\bullet\bullet}))\big) = \mathrm{L}_p T\big(\mathrm{H}^{\mathrm{I}}_q(K_{\bullet\bullet})\big),$$

and hence the spectral sequence ${}^{(a')}\mathrm{E}$. Finally, the spectral sequences ${}^{(c)}\mathrm{E}$ and ${}^{(d)}\mathrm{E}$ are obtained by interchanging the roles of the indices i and j in the definition of the tricomplex $M_{\bullet\bullet\bullet}$ and applying the preceding arguments to the resulting tricomplex. □

We call $\mathrm{L}_\bullet T(K_{\bullet\bullet})$ the *hyperhomology* of T relative to the bicomplex $K_{\bullet\bullet}$.

(11.7.3). *Remarks.*

(i) It follows from (11.6.3) that $\mathrm{L}_\bullet T(K_{\bullet\bullet})$ is a homological functor on the category of bicomplexes $K_{\bullet\bullet}$ in $\mathtt{C}$ that are bounded below in each degree.

$\mathbf{0_{III}}$ | 43

(ii) Let $M_{\bullet\bullet\bullet}$ be a tricomplex in $\mathtt{C}$ such that, for every pair (r,s), $M_{rs,\bullet}$ is a resolution of K_{rs}, and such that

$$\mathrm{L}_n T(M_{ijk}) = 0$$

for every triple (i,j,k) and every $n > 0$. Then there is an isomorphism

$$\mathrm{L}_\bullet T(K_{\bullet\bullet}) \simeq \mathrm{H}_\bullet\big(T(M_{\bullet\bullet\bullet})\big).$$

Indeed, with the notation used in the proof of (11.7.2), $N_{i,\bullet}$ is a resolution of L_i such that $\mathrm{L}_n T(N_{ij}) = 0$ for every $n > 0$ and every pair (i,j), so it is enough to apply (11.6.3), (iii).

(iii) The results of (11.7.2) immediately generalize to covariant multifunctors. For example, let $\mathtt{C}'$ be a second abelian category in which every object is a quotient of a projective object, let $K'_{\bullet\bullet}$ be a bicomplex in $\mathtt{C}'$ whose two degrees are bounded below, and let T be an additive covariant bifunctor from $\mathtt{C} \times \mathtt{C}'$ to an abelian category $\mathtt{C}''$. If $L_\bullet$ and $L'_\bullet$ are the simple complexes associated with $K_{\bullet\bullet}$ and $K'_{\bullet\bullet}$, respectively, we define the hyperhomology of T relative to the two bicomplexes $K_{\bullet\bullet}$ and $K'_{\bullet\bullet}$ to be

$$\mathrm{L}_\bullet T(L_\bullet, L'_\bullet).$$

Applying (11.6.4) and (11.6.5), we obtain, just as in (11.7.2), six spectral sequences abutting to this hyperhomology; we leave their explicit formulation to the reader.

11.8. Supplement on the cohomology of simplicial complexes

(11.8.1). Let A be a finite set, and let $\Sigma(A)$ be the set of finite sequences

$$\sigma = (\alpha_0, \ldots, \alpha_h)$$

of elements of A (the "simplices" of A); set $|\sigma| = \{\alpha_0, \ldots, \alpha_h\}$. Recall that the chain complex $\mathrm{C}_\bullet(A)$ is the graded free abelian group generated by the elements of $\Sigma(A)$, with $(\alpha_0, \ldots, \alpha_h)$ in degree h, and with differential

$$d(\alpha_0, \ldots, \alpha_h) = \sum_{j=0}^{h} (-1)^j (\alpha_0, \ldots, \widehat{\alpha}_j, \ldots, \alpha_h).$$

The subgroup $\mathrm{D}_\bullet(A)$ of $\mathrm{C}_\bullet(A)$ generated by those chains $\sigma = (\alpha_0, \ldots, \alpha_h)$ for which two of the α_i are equal, and by the chains

$$\pi(\sigma) - \varepsilon_\pi \sigma,$$

where, for every permutation π,

$$\pi(\sigma) = (\alpha_{\pi(0)}, \ldots, \alpha_{\pi(h)})$$

and ε_π is the sign of π, is a subcomplex of $\mathrm{C}_\bullet(A)$. Its elements are called *degenerate chains*. Set

$$\mathrm{L}_\bullet(A) = \mathrm{C}_\bullet(A)/\mathrm{D}_\bullet(A);$$

there is a natural homomorphism of complexes

$$p : \mathrm{C}_\bullet(A) \longrightarrow \mathrm{L}_\bullet(A).$$

Conversely, define a homomorphism of complexes

$$j : \mathrm{L}_\bullet(A) \longrightarrow \mathrm{C}_\bullet(A)$$

as follows. Choose a total ordering of A. To the class modulo $\mathrm{D}_\bullet(A)$ of a simplex $\sigma = (\alpha_0, \ldots, \alpha_h)$, associate 0 if two of the α_i are equal, and otherwise associate the sequence $(\beta_0, \ldots, \beta_h)$ obtained by arranging the α_i in increasing order. It is clear that $p \circ j$ is the identity of $\mathrm{L}_\bullet(A)$.

(11.8.2). Let B be a second finite set. If d' and d'' are the differentials of $\mathrm{C}_\bullet(A)$ and $\mathrm{C}_\bullet(B)$, the tensor-product complex

$$\mathrm{C}_\bullet(A) \otimes \mathrm{C}_\bullet(B)$$

may be regarded as the free abelian group generated by the elements of $\Sigma(A) \times \Sigma(B)$, with differential

$$d(\sigma, \tau) = (d'\sigma, \tau) + (-1)^{h+1}(\sigma, d''\tau) \qquad \text{if } \mathrm{Card}\,|\sigma| = h + 1.$$

The natural homomorphisms $\mathrm{C}_\bullet(A) \to \mathrm{L}_\bullet(A)$ and $\mathrm{C}_\bullet(B) \to \mathrm{L}_\bullet(B)$ define a homomorphism

$$p : \mathrm{C}_\bullet(A) \otimes \mathrm{C}_\bullet(B) \longrightarrow \mathrm{L}_\bullet(A) \otimes \mathrm{L}_\bullet(B),$$

the latter tensor product being isomorphic to

$$\frac{\mathrm{C}_\bullet(A) \otimes \mathrm{C}_\bullet(B)}{\mathrm{C}_\bullet(A) \otimes \mathrm{D}_\bullet(B) + \mathrm{D}_\bullet(A) \otimes \mathrm{C}_\bullet(B)}.$$

Likewise, using the homomorphisms $\mathrm{L}_\bullet(A) \to \mathrm{C}_\bullet(A)$ and $\mathrm{L}_\bullet(B) \to \mathrm{C}_\bullet(B)$ defined in (11.8.1), with total orderings on A and B, one obtains a homomorphism

$$j : \mathrm{L}_\bullet(A) \otimes \mathrm{L}_\bullet(B) \longrightarrow \mathrm{C}_\bullet(A) \otimes \mathrm{C}_\bullet(B)$$

such that $p \circ j$ is the identity.

With this notation: $\mathbf{0}_{\mathbf{III}}$ | 44

Proposition (11.8.3). — *There exists a homotopy*

$$h : \mathrm{C}_\bullet(A) \otimes \mathrm{C}_\bullet(B) \longrightarrow \mathrm{C}_\bullet(A) \otimes \mathrm{C}_\bullet(B)$$

such that $h(\sigma, \tau)$ is a linear combination of pairs of simplices (σ_i, τ_i) satisfying $|\sigma_i| \subset |\sigma|$ and $|\tau_i| \subset |\tau|$, and such that, if $f = j \circ p$, then

(11.8.3.1) $$f - 1 = h \circ d + d \circ h.$$

Proof. It suffices to define h on each pair (σ, τ) of simplices, by induction on the sum of the degrees of σ and τ; when that sum is 0, one may take $h = 0$. Set

$$\omega = f(\sigma, \tau) - (\sigma, \tau) - h\big(d(\sigma, \tau)\big).$$

By the induction hypothesis and the definition of d, one has

$$\omega \in \mathrm{C}_\bullet(|\sigma|) \otimes \mathrm{C}_\bullet(|\tau|).$$

Moreover,

$$d\omega = f\big(d(\sigma, \tau)\big) - d(\sigma, \tau) - d\big(h(d(\sigma, \tau))\big) = h\big(d(d(\sigma, \tau))\big) = 0$$

by (11.8.3.1) and the induction hypothesis. Now

$$\mathrm{H}_q\big(\mathrm{C}_\bullet(A)\big) = 0 \qquad (q > 0)$$

(G, I, 3.7.4), and consequently

$$\mathrm{H}_q\big(\mathrm{C}_\bullet(A) \otimes \mathrm{C}_\bullet(B)\big) = 0 \qquad (q > 0)$$

by the Künneth formula (G, I, 5.5.2). Applying this observation with A replaced by $|\sigma|$ and B by $|\tau|$, one finds

$$\omega' \in \mathrm{C}_\bullet(|\sigma|) \otimes \mathrm{C}_\bullet(|\tau|)$$

such that $\omega = d\omega'$. Taking $h(\sigma, \tau) = \omega'$ verifies (11.8.3.1) for the pair (σ, τ), and the induction continues. □

(11.8.4). With the notation of (11.8.2), write

$$(\sigma, \tau) \leqslant (\sigma', \tau')$$

if $|\sigma| \subset |\sigma'|$ and $|\tau| \subset |\tau'|$. A *coefficient system* $\mathscr{S}$ on $\Sigma(A) \times \Sigma(B)$ consists of a family $(\Gamma_{\sigma,\tau})$ of abelian groups, where $\Gamma_{\sigma,\tau}$ depends only on the sets $|\sigma|$ and $|\tau|$, together with homomorphisms

$$\Gamma_{\sigma,\tau} \longrightarrow \Gamma_{\sigma',\tau'} \qquad \big((\sigma, \tau) \leqslant (\sigma', \tau')\big)$$

forming an inductive system for this preorder.

Define a cochain complex $\mathrm{C}^\bullet(A, B; \mathscr{S})$ whose elements are the families

$$\lambda = \big(\lambda(\sigma, \tau)\big), \qquad \lambda(\sigma, \tau) \in \Gamma_{\sigma,\tau},$$

as (σ, τ) ranges over $\Sigma(A) \times \Sigma(B)$. Its differential is defined as follows. If

$$d(\sigma, \tau) = \sum_i \pm(\sigma_i, \tau_i),$$

then $|\sigma_i| \subset |\sigma|$ and $|\tau_i| \subset |\tau|$ for every i, and one sets

$$d\lambda(\sigma, \tau) = \sum_i \pm\lambda_i(\sigma_i, \tau_i),$$

where $\lambda_i(\sigma_i, \tau_i)$ denotes the canonical image of $\lambda(\sigma_i, \tau_i)$ in $\Gamma_{\sigma,\tau}$.

A cochain $\lambda \in \mathrm{C}^\bullet(A, B; \mathscr{S})$ is called *bi-alternating* if $\lambda(\sigma, \tau) = 0$ whenever either σ or τ has two equal terms, and if

$$\lambda(\pi(\sigma), \tau) = \varepsilon_\pi \lambda(\sigma, \tau), \qquad \lambda(\sigma, \pi'(\tau)) = \varepsilon_{\pi'} \lambda(\sigma, \tau)$$

for arbitrary permutations π and π' of the indices. These cochains plainly generate a subcomplex $\mathrm{L}^\bullet(A, B; \mathscr{S})$ of $\mathrm{C}^\bullet(A, B; \mathscr{S})$.

Proposition (11.8.5). — *The canonical injection*

$$\mathrm{L}^\bullet(A, B; \mathscr{S}) \longrightarrow \mathrm{C}^\bullet(A, B; \mathscr{S})$$

induces an isomorphism on cohomology.

Proof. If p and j have the meanings assigned in (11.8.2), then the maps

$$'p : \lambda \longmapsto \lambda \circ p, \qquad 'j : \lambda \longmapsto \lambda \circ j$$

are defined on $\mathrm{L}^\bullet(A, B; \mathscr{S})$ and $\mathrm{C}^\bullet(A, B; \mathscr{S})$, respectively; the first is precisely the canonical injection. Since $'j \circ 'p$ is the identity, it remains only to prove that $'p \circ 'j$ is homotopic to the identity. By (11.8.3), the map

$$'h : \lambda \longmapsto \lambda \circ h$$

is defined on $\mathrm{C}^\bullet(A, B; \mathscr{S})$, so transposing (11.8.3.1) gives the desired result. □

(11.8.6). Proposition (11.8.5) reduces the computation of the cohomology of $\mathrm{L}^\bullet(A, B; \mathscr{S})$ to that of $\mathrm{C}^\bullet(A, B; \mathscr{S})$. On the other hand, by the Eilenberg–Zilber theorem (G, I, 3.10.2), the latter cohomology is canonically isomorphic to the cohomology obtained from the chain complex $\mathrm{P}_\bullet(A, B)$ of linear combinations of pairs $(\sigma, \tau) \in \Sigma(A) \times \Sigma(B)$ for which σ and τ have the same degree. The differential of this complex is $\mathbf{0_{III}}$ | 45

$$d(\sigma, \tau) = \sum_{j,k} (-1)^{j+k} (\sigma_j, \tau_k)$$

when

$$d\sigma = \sum_j (-1)^j \sigma_j, \qquad d\tau = \sum_k (-1)^k \tau_k.$$

There are two canonical homomorphisms of complexes

$$f : \mathrm{P}_\bullet(A, B) \longrightarrow \mathrm{C}_\bullet(A) \otimes \mathrm{C}_\bullet(B), \qquad g : \mathrm{C}_\bullet(A) \otimes \mathrm{C}_\bullet(B) \longrightarrow \mathrm{P}_\bullet(A, B),$$

and it is proved there that homotopies h and h' exist such that

$$f \circ g - 1 = d \circ h + h \circ d, \qquad g \circ f - 1 = d \circ h' + h' \circ d.$$

Moreover,

$$f(\sigma, \tau) \in \mathrm{C}_\bullet(|\sigma|) \otimes \mathrm{C}_\bullet(|\tau|), \qquad g(\sigma, \tau) \in \mathrm{P}_\bullet(|\sigma|, |\tau|),$$

and the homotopies may be chosen so that

$$h(\sigma, \tau) \in \mathrm{C}_\bullet(|\sigma|) \otimes \mathrm{C}_\bullet(|\tau|), \qquad h'(\sigma, \tau) \in \mathrm{P}_\bullet(|\sigma|, |\tau|).$$

Indeed, $h(\sigma, \tau)$ and $h'(\sigma, \tau)$ may be defined by induction on the sum of the degrees of σ and τ, while

$$\mathrm{H}_q\big(\mathrm{C}_\bullet(|\sigma|) \otimes \mathrm{C}_\bullet(|\tau|)\big) = \mathrm{H}_q\big(\mathrm{P}_\bullet(|\sigma|, |\tau|)\big) = 0 \qquad (q > 0)$$

(*loc. cit.*); the argument is the same as in (11.8.3).

Now define $\mathrm{P}^\bullet(A, B; \mathscr{S})$ to be the set of families

$$\lambda = \big(\lambda(\sigma, \tau)\big), \qquad \lambda(\sigma, \tau) \in \Gamma_{\sigma,\tau},$$

where (σ, τ) ranges over pairs of simplices of the same degree. When

$$d\sigma = \sum_j (-1)^j \sigma_j, \qquad d\tau = \sum_k (-1)^k \tau_k,$$

the formula

$$d\lambda(\sigma, \tau) = \sum_{j,k} (-1)^{j+k} \lambda(\sigma_j, \tau_k)$$

is defined and gives the differential of $\mathrm{P}^\bullet(A, B; \mathscr{S})$. The maps

$$'f : \lambda \longmapsto \lambda \circ f, \quad 'g : \lambda \longmapsto \lambda \circ g, \quad 'h : \lambda \longmapsto \lambda \circ h, \quad 'h' : \lambda \longmapsto \lambda \circ h'$$

are all defined by the preceding support properties. Thus $'f \circ 'g$ and $'g \circ 'f$ are homotopic to the identity, giving the required isomorphism between the cohomology of $\mathrm{C}^\bullet(A, B; \mathscr{S})$ and that of $\mathrm{P}^\bullet(A, B; \mathscr{S})$.

(11.8.7). *Remark.* The argument of (11.8.3), applied to $\mathrm{C}_\bullet(A)$ and $\mathrm{L}_\bullet(A)$, shows that if j and p are defined as in (11.8.1), then $f = j \circ p$ again satisfies (11.8.3.1), with $|h(\sigma)| \subset |\sigma|$. As in (11.8.5), one obtains an isomorphism from the cohomology of $\mathrm{L}^\bullet(A; \mathscr{S})$ to that of $\mathrm{C}^\bullet(A; \mathscr{S})$, the two complexes being defined in the obvious way. This is the result whose proof is sketched in (G, I, 3.8.1).

(11.8.8). Return now to the notation and hypotheses of (11.8.2), and let

$$\mathscr{S}^\bullet = (\mathscr{S}^k)$$

be a complex of coefficient systems on $\Sigma(A) \times \Sigma(B)$. For each (σ, τ), the groups $\Gamma^k_{\sigma,\tau}$ therefore form a complex of abelian groups ($k \in \mathbf{Z}$), and for $(\sigma, \tau) \leqslant (\sigma', \tau')$ there are commutative diagrams

$$\begin{tikzcd} \Gamma^k_{\sigma,\tau} \arrow[r] \arrow[d] & \Gamma^{k+1}_{\sigma,\tau} \arrow[d] \\ \Gamma^k_{\sigma',\tau'} \arrow[r] & \Gamma^{k+1}_{\sigma',\tau'}. \end{tikzcd}$$

It follows immediately that **0**$_{\mathbf{III}}$ | 46

$$\mathrm{C}^\bullet(A, B; \mathscr{S}^\bullet) = \big(\mathrm{C}^h(A, B; \mathscr{S}^k)\big)_{(h,k)\in\mathbf{Z}\times\mathbf{Z}}$$

is a bicomplex of abelian groups, and that

$$\mathrm{L}^\bullet(A, B; \mathscr{S}^\bullet) = \big(\mathrm{L}^h(A, B; \mathscr{S}^k)\big)$$

is a sub-bicomplex.

Proposition (11.8.9). — *The canonical injection*

$$\mathrm{L}^\bullet(A, B; \mathscr{S}^\bullet) \longrightarrow \mathrm{C}^\bullet(A, B; \mathscr{S}^\bullet)$$

induces an isomorphism on the cohomology of these two bicomplexes.

Proof. For brevity set

$$\mathrm{C}^{\bullet\bullet} = \mathrm{C}^\bullet(A, B; \mathscr{S}^\bullet), \qquad \mathrm{L}^{\bullet\bullet} = \mathrm{L}^\bullet(A, B; \mathscr{S}^\bullet).$$

Since $\mathrm{C}^{hk} = \mathrm{L}^{hk} = 0$ for $h < 0$, the second spectral sequences of these bicomplexes are regular (11.3.3). The homomorphism $\mathrm{L}^{\bullet\bullet} \to \mathrm{C}^{\bullet\bullet}$ therefore gives a morphism of spectral sequences

$$''\mathrm{E}(\mathrm{L}^{\bullet\bullet}) \longrightarrow {}''\mathrm{E}(\mathrm{C}^{\bullet\bullet})$$

which, on the E_2 terms, is

$$\mathrm{H}^p_{\mathrm{II}}\big(\mathrm{H}^q_{\mathrm{I}}(\mathrm{L}^{\bullet\bullet})\big) \longrightarrow \mathrm{H}^p_{\mathrm{II}}\big(\mathrm{H}^q_{\mathrm{I}}(\mathrm{C}^{\bullet\bullet})\big). \tag{11.8.9.1}$$

For every $k \in \mathbf{Z}$, however, (11.8.5) shows that

$$\mathrm{H}^q_{\mathrm{I}}(\mathrm{L}^{\bullet,k}) \longrightarrow \mathrm{H}^q_{\mathrm{I}}(\mathrm{C}^{\bullet,k})$$

is bijective. The conclusion follows from (11.1.5). □

(11.8.10). Similarly, with the notation of (11.8.6), there is a canonical homomorphism of bicomplexes

$$\mathrm{C}^\bullet(A, B; \mathscr{S}^\bullet) \longrightarrow \mathrm{P}^\bullet(A, B; \mathscr{S}^\bullet),$$

with the evident notation. The argument of (11.8.9), now using (11.8.6), shows that this homomorphism likewise induces an isomorphism on cohomology.

11.9. A lemma on the complexes of finite type

Proposition (11.9.1). — *Let* $\mathtt{C}$ *be an abelian category, and let* K' *and* K'' *be subsets of the set of objects of* $\mathtt{C}$*, with* $K'' \subset K'$*, satisfying the following conditions:*

(i) For every $A' \in K'$ and every epimorphism $u : A \to A'$ in $\mathtt{C}$, there exist an object $B \in K''$ and a morphism $v : B \to A$ such that $u \circ v$ is an epimorphism.

(ii) For every pair $A, B \in K'$ and every epimorphism $u : A \to B$, the object $\operatorname{Ker}(u)$ belongs to K'.

(iii) The product of two objects of K'' belongs to K''.

Let $P_\bullet = (P_i)_{i\in\mathbf{Z}}$ be a complex in $\mathtt{C}$ such that $\mathrm{H}_i(P_\bullet) \in K'$ for every i, and suppose that there is an integer d for which $\mathrm{H}_i(P_\bullet) = 0$ when $i < d$. Then there exist a complex $Q_\bullet = (Q_i)_{i\in\mathbf{Z}}$ in $\mathtt{C}$ such that $Q_i \in K''$ for every i and $Q_i = 0$ for $i < d$, and a homomorphism of complexes

$$u : Q_\bullet \longrightarrow P_\bullet$$

whose induced morphism

$$\mathrm{H}_\bullet(Q_\bullet) \longrightarrow \mathrm{H}_\bullet(P_\bullet)$$

is an isomorphism.

Proof. We first prove the following consequence of condition (i).

(i bis) Let $u : C \to B$ *be an epimorphism in* $\mathtt{C}$*, let* A *be an object of* K'*, and let* $v : A \to B$ *be a morphism in* $\mathtt{C}$*. Then there exist an object* $D \in K''$*, an epimorphism* $u' : D \to A$*, and a morphism* $v' : D \to C$ *such that the diagram*

(11.9.1.1)
$$\begin{tikzcd} D \arrow[r, "u'"] \arrow[d, "v'"'] & A \arrow[d, "v"] \\ C \arrow[r, "u"'] & B \end{tikzcd}$$

is commutative.

Form the fibre product $C \times_B A$ in $\mathtt{C}$ and let

$$p : C \times_B A \longrightarrow C, \qquad q : C \times_B A \longrightarrow A$$

be the canonical projections, so that $\mathbf{0}_{\mathbf{III}}$ | 47

(11.9.1.2)
$$\begin{tikzcd} C \times_B A \arrow[r, "q"] \arrow[d, "p"'] & A \arrow[d, "v"] \\ C \arrow[r, "u"'] & B \end{tikzcd}$$

is commutative. The cokernel of q is the quotient of A by $v^{-1}(u(C))$ ([27, p. 1-12]). Since u is an epimorphism, $u(C) = B$ and $v^{-1}(u(C)) = A$; hence q is an epimorphism. Applying (i) to $q : C \times_B A \to A$, one obtains an object $D \in K''$ and a morphism $w : D \to C \times_B A$ such that $q \circ w$ is an epimorphism. It is enough to take $u' = q \circ w$ and $v' = p \circ w$.

We now prove the proposition by induction. Suppose, for some $i \geqslant d-1$, that for every $j \leqslant i$ we have constructed objects Q_j, differentials

$$d_j^Q : Q_j \longrightarrow Q_{j-1}$$

with $Q_j = 0$ for $j < d$ and $d_{j-1}^Q \circ d_j^Q = 0$, and morphisms

$$u_j : Q_j \longrightarrow P_j$$

such that

$$d_j^P \circ u_j = u_{j-1} \circ d_j^Q \qquad (j \leqslant i).$$

Assume moreover that the following conditions hold:

(I_i) $Q_j \in K''$ for $j \leqslant i$, and $\mathrm{B}_j(Q_\bullet) \in K'$ for $j < i$.

(II_i) For $j < i$, the homomorphism

$$\mathrm{H}_j(Q_\bullet) \longrightarrow \mathrm{H}_j(P_\bullet)$$

induced by $(u_k)_{k \leqslant i}$ is an isomorphism.

(III_i) The composite

$$v_i : \mathrm{Z}_i(Q_\bullet) \longrightarrow \mathrm{Z}_i(P_\bullet) \longrightarrow \mathrm{H}_i(P_\bullet),$$

where the first arrow is the restriction of u_i and the second is canonical, is an epimorphism.

By (ii), $\mathrm{Z}_i(Q_\bullet)$ belongs to K': it is the kernel of the epimorphism

$$Q_i \longrightarrow \mathrm{B}_{i-1}(Q_\bullet),$$

and this uses (I_i). Condition (ii) and (III_i) also show that

$$N_i = \mathrm{Ker}(v_i)$$

belongs to K'. By (i bis), there exist an object $Q'_{i+1} \in K''$, an epimorphism

$$d'_{i+1} : Q'_{i+1} \longrightarrow N_i,$$

and a morphism $u'_{i+1} : Q'_{i+1} \to P_{i+1}$ such that

(11.9.1.3)
$$\begin{tikzcd} Q'_{i+1} \arrow[r, "d'_{i+1}"] \arrow[d, "u'_{i+1}"'] & N_i \arrow[d, "u_i"] \\ P_{i+1} \arrow[r, "d^P_{i+1}"'] & \mathrm{B}_i(P_\bullet) \end{tikzcd}$$

is commutative.

The canonical morphism

$$\mathrm{Z}_{i+1}(P_\bullet) \longrightarrow \mathrm{H}_{i+1}(P_\bullet)$$

is an epimorphism, and $\mathrm{H}_{i+1}(P_\bullet) \in K'$. Condition (i) therefore supplies an object $Q''_{i+1} \in K''$ and a morphism

$$u''_{i+1} : Q''_{i+1} \longrightarrow \mathrm{Z}_{i+1}(P_\bullet)$$

such that the composite

$$Q''_{i+1} \longrightarrow \mathrm{Z}_{i+1}(P_\bullet) \longrightarrow \mathrm{H}_{i+1}(P_\bullet)$$

is an epimorphism. If $d''_{i+1} : Q''_{i+1} \to N_i$ is the zero morphism, then

(11.9.1.4)
$$\begin{tikzcd} Q''_{i+1} \arrow[r, "d''_{i+1}"] \arrow[d, "u''_{i+1}"'] & N_i \arrow[d, "u_i"] \\ \mathrm{Z}_{i+1}(P_\bullet) \arrow[r, "d^P_{i+1}"'] & P_i \end{tikzcd}$$

is commutative; the lower horizontal arrow is zero.

Set $\mathbf{0_{III}}$ | 48

$$Q_{i+1} = Q'_{i+1} \times Q''_{i+1}, \qquad d^Q_{i+1} = d'_{i+1} + d''_{i+1}, \qquad u_{i+1} = u'_{i+1} + u''_{i+1}.$$

By (iii), Q_{i+1} belongs to K''. Since

$$d^Q_{i+1}(Q_{i+1}) = d'_{i+1}(Q'_{i+1}) = N_i \subset \mathrm{Z}_i(Q_\bullet),$$

one has $d^Q_i \circ d^Q_{i+1} = 0$ and $\mathrm{B}_i(Q_\bullet) = N_i$; this proves ($\mathrm{I}_{i+1}$). The commutativity of (11.9.1.3) and (11.9.1.4) gives

$$d^P_{i+1} \circ u_{i+1} = u_i \circ d^Q_{i+1}.$$

By the definition of N_i, the morphism

$$\mathrm{H}_i(Q_\bullet) = \mathrm{Z}_i(Q_\bullet)/N_i \longrightarrow \mathrm{H}_i(P_\bullet)$$

induced by the u_k for $k \leqslant i+1$ is an isomorphism, since v_i is an epimorphism; hence (II_{i+1}) holds. Finally, the factor Q''_{i+1} lies in $\mathrm{Z}_{i+1}(Q_\bullet)$. The choice of u''_{i+1} shows that

$$v_{i+1} : \mathrm{Z}_{i+1}(Q_\bullet) \longrightarrow \mathrm{Z}_{i+1}(P_\bullet) \longrightarrow \mathrm{H}_{i+1}(P_\bullet)$$

is an epimorphism, because its restriction to Q''_{i+1} already is one. Thus (III_{i+1}) holds, the induction continues, and the proposition follows. □

Corollary (11.9.2). — *Let A be a Noetherian ring, not necessarily commutative, and let $P_\bullet = (P_i)_{i\in\mathbf{Z}}$ be a complex of right A-modules. Suppose that every $\mathrm{H}_i(P_\bullet)$ is a finitely generated A-module and that there is an integer d such that $\mathrm{H}_i(P_\bullet) = 0$ for $i < d$. Then there exist a complex $Q_\bullet = (Q_i)_{i\in\mathbf{Z}}$ of free A-modules of finite rank, with $Q_i = 0$ for $i < d$, and a homomorphism of complexes*

$$u : Q_\bullet \longrightarrow P_\bullet$$

whose induced morphism

$$\mathrm{H}_\bullet(Q_\bullet) \longrightarrow \mathrm{H}_\bullet(P_\bullet)$$

is an isomorphism.

Proof. Apply (11.9.1) with $\mathtt{C}$ the category of right A-modules, with K' the set of finitely generated A-modules, and with K'' the set of free A-modules of finite rank. Conditions (i), (ii), and (iii) of (11.9.1) follow immediately from the hypothesis that A is Noetherian. □

(11.9.3). *Remarks.*

(i) Under the hypotheses of (11.9.2), suppose in addition that the P_i are flat right A-modules. Then, for every left A-module M, the homomorphism of complexes

$$u \otimes 1 : Q_\bullet \otimes_A M \longrightarrow P_\bullet \otimes_A M$$

again induces an isomorphism

$$\mathrm{H}_\bullet(Q_\bullet \otimes_A M) \simeq \mathrm{H}_\bullet(P_\bullet \otimes_A M),$$

as will be seen in Chapter III.

(ii) The conclusion of (11.9.2) need not hold when A is not Noetherian. Indeed, applying it to a complex having only one nonzero term would imply that every finitely generated right A-module admits a resolution by finitely generated free modules, which is false in general (Bourbaki, *Algèbre commutative*, chap. I, §2, exerc. 6).

It is possible, however, to replace the hypothesis that A is Noetherian by the assumption that the $\mathrm{H}_i(P_\bullet)$ admit finite ∞-presentations (cf. Chapter IV).

11.10. Euler–Poincaré characteristic of a complex of finite length modules

(11.10.1). Let A be a ring, not necessarily commutative, and let

$$M^\bullet : 0 \longrightarrow M^0 \longrightarrow M^1 \longrightarrow \cdots \longrightarrow M^n \longrightarrow 0 \tag{11.10.1.1}$$

be a complex of left A-modules of finite length. The *Euler–Poincaré characteristic* of this complex is the integer $\mathbf{0}_{\mathrm{III}}$ | 49

$$\chi(M^\bullet) = \sum_{i=0}^{n} (-1)^i \operatorname{length}(M^i). \tag{11.10.1.2}$$

Proposition (11.10.2). — *For every finite complex $M^\bullet$ of left A-modules of finite length,*

$$\chi(M^\bullet) = \chi\big(\mathrm{H}^\bullet(M^\bullet)\big),$$

where $\mathrm{H}^\bullet(M^\bullet)$ is regarded as a complex with zero differential. In particular, if the sequence (11.10.1.1) is exact, then $\chi(M^\bullet) = 0$.

Proof. For brevity write

$$\mathrm{B}^i = \mathrm{B}^i(M^\bullet), \qquad \mathrm{Z}^i = \mathrm{Z}^i(M^\bullet), \qquad \mathrm{H}^i = \mathrm{H}^i(M^\bullet) = \mathrm{Z}^i/\mathrm{B}^i.$$

The modules B^i, Z^i, and H^i all have finite length. The exact sequences

$$0 \longrightarrow \mathrm{B}^i \longrightarrow \mathrm{Z}^i \longrightarrow \mathrm{H}^i \longrightarrow 0$$

and

$$0 \longrightarrow \mathrm{Z}^i \longrightarrow M^i \longrightarrow \mathrm{B}^{i+1} \longrightarrow 0$$

give

$$\operatorname{length}(\mathrm{Z}^i) = \operatorname{length}(\mathrm{H}^i) + \operatorname{length}(\mathrm{B}^i)$$

and

$$\mathrm{length}(M^i) = \mathrm{length}(\mathrm{Z}^i) + \mathrm{length}(\mathrm{B}^{i+1}).$$

Consequently,

$$\mathrm{length}(M^i) - \mathrm{length}(\mathrm{H}^i) = \mathrm{length}(\mathrm{B}^{i+1}) + \mathrm{length}(\mathrm{B}^i).$$

Multiply this equality by $(-1)^i$ and sum for $0 \leqslant i \leqslant n$. Since $\mathrm{B}^0 = \mathrm{B}^{n+1} = 0$, the desired equality follows. □

Corollary (11.10.3). — *Let* $\mathrm{E} = (\mathrm{E}_r^{pq})$ *be a spectral sequence in the category of modules over a ring* A*. Suppose that the* E_2^{pq} *are* A*-modules of finite length and that* $\mathrm{E}_2^{pq} \neq 0$ *for only finitely many pairs* (p,q)*. Then the Euler–Poincaré characteristics*

$$\chi(\mathrm{E}_r^{(\bullet)})$$

of all the complexes

$$\mathrm{E}_r^{(\bullet)} = (\mathrm{E}_r^{(n)})_{n\in\mathbf{Z}}$$

of (11.1.1) are equal. If, moreover, E *is weakly convergent and one sets*

$$\mathrm{E}_\infty^{(n)} = \bigoplus_{p+q=n} \mathrm{E}_\infty^{pq} \qquad (n \in \mathbf{Z}),$$

then

$$\chi(\mathrm{E}_\infty^{(\bullet)}) = \chi(\mathrm{E}_2^{(\bullet)}),$$

where

$$\mathrm{E}_\infty^{(\bullet)} = (\mathrm{E}_\infty^{(n)})_{n\in\mathbf{Z}}$$

is regarded as a complex with zero differential.

Proof. First note that if $\mathrm{E}_2^{pq} = 0$, then $\mathrm{E}_r^{pq} = 0$ for $2 \leqslant r \leqslant +\infty$. Thus every complex $\mathrm{E}_r^{(\bullet)}$ is finite and consists of A-modules of finite length. For every finite r, the equality

$$\chi(\mathrm{E}_r^{(\bullet)}) = \chi(\mathrm{E}_{r+1}^{(\bullet)})$$

therefore follows from (11.10.2) and the isomorphism

$$\mathrm{H}^\bullet(\mathrm{E}_r^{(\bullet)}) \simeq \mathrm{E}_{r+1}^{(\bullet)}$$

of complexes with zero differential.

Because the E_r^{pq} have finite length, for each pair (p,q) the sequences

$$(\mathrm{B}_k(\mathrm{E}_2^{pq}))_{k\geqslant 2}, \qquad (\mathrm{Z}_k(\mathrm{E}_2^{pq}))_{k\geqslant 2}$$

are stationary. Weak convergence, together with the fact that $\mathrm{E}_2^{pq} = 0$ for all but finitely many pairs (p,q), therefore implies that some integer $r \geqslant 2$ satisfies

$$\mathrm{E}_\infty^{pq} = \mathrm{E}_r^{pq}$$

for every pair (p,q). The assertion concerning $\chi(\mathrm{E}_\infty^{(\bullet)})$ follows. □

§12. Supplement on sheaf cohomology

12.1. Cohomology of sheaves of modules on ringed spaces

(12.1.1). Let $(X, \mathscr{O}_X)$ be a ringed space. Recall that, for every $\mathscr{O}_X$-Module $\mathscr{F}$, one defines the cohomology $\mathrm{H}^\bullet(X, \mathscr{F})$, which is a universal cohomological functor (T, 2.2) from the category $\mathtt{C}(X)$ of $\mathscr{O}_X$-Modules to the category of abelian groups; it is the derived functor of the left exact functor **0**$_{\mathbf{III}}$ | 49

$$\mathscr{F} \longmapsto \Gamma(X, \mathscr{F}).$$

The functor $\mathrm{H}^\bullet(X, \mathscr{F})$ is isomorphic to the restriction to the category $\mathtt{C}(X)$ of the cohomological functor defined in the same way on the category of sheaves of abelian groups on X (G, II, 7.2.1). **0**$_{\mathbf{III}}$ | 50

(12.1.2). Set $A = \Gamma(X, \mathscr{O}_X)$. Since every element of A defines an endomorphism of the abelian group $\Gamma(X, \mathscr{F})$, it defines by functoriality an endomorphism of the δ-functor $\mathrm{H}^\bullet(X, \mathscr{F})$. These endomorphisms endow each $\mathrm{H}^p(X, \mathscr{F})$ with an A-module structure, and the boundary operator ∂ is A-linear. Moreover, for any two nonnegative integers p, q and any two $\mathscr{O}_X$-Modules $\mathscr{F}, \mathscr{G}$, there is a homomorphism of A-modules, called the *cup product*,

$$\mathrm{H}^p(X, \mathscr{F}) \otimes_A \mathrm{H}^q(X, \mathscr{G}) \longrightarrow \mathrm{H}^{p+q}(X, \mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{G}) \tag{12.1.2.1}$$

(G, II, 6.6). These homomorphisms make the direct sum S of the $\mathrm{H}^p(X, \mathscr{O}_X)$, for $p \geqslant 0$, an anticommutative graded A-algebra, and the direct sum of the $\mathrm{H}^p(X, \mathscr{F})$ a graded S-module.

For every open covering $\mathfrak{U}$ of X, we shall always denote by $\check{\mathrm{C}}^\bullet(\mathfrak{U}, \mathscr{F})$ (contrary to (G, II, 5.1)) the complex of alternating cochains of the nerve of $\mathfrak{U}$ with values in the coefficient system $\Gamma(U_\alpha, \mathscr{F})$. It is clear that $\check{\mathrm{C}}^\bullet(\mathfrak{U}, \mathscr{F})$ is a graded A-module, so that the cohomology groups $\check{\mathrm{H}}^p(\mathfrak{U}, \mathscr{F})$ of this complex are endowed with an A-module structure. Moreover, the canonical maps

$$\check{\mathrm{H}}^p(\mathfrak{U}, \mathscr{F}) \longrightarrow \mathrm{H}^p(X, \mathscr{F})$$

(G, II, 5.4) are A-linear.

(12.1.3). Let $(X', \mathscr{O}_{X'})$ be a second ringed space, and let $f = (\psi, \theta)$ be a morphism from X' to X. Set $A' = \Gamma(X', \mathscr{O}_{X'})$; the ψ-morphism θ canonically defines a ring homomorphism $A \to A'$. Let $\mathscr{F}$ be an $\mathscr{O}_X$-Module and $\mathscr{F}'$ an $\mathscr{O}_{X'}$-Module. For every f-morphism $u : \mathscr{F} \to \mathscr{F}'$ ($\mathbf{0}_\mathbf{I}$, 4.4.1), we shall see that one can define, for every $p \geqslant 0$, a di-homomorphism

$$u_p : \mathrm{H}^p(X, \mathscr{F}) \longrightarrow \mathrm{H}^p(X', \mathscr{F}'). \tag{12.1.3.1}$$

Indeed, since ψ^* is exact in the category of sheaves of abelian groups on X, the functor

$$\mathscr{F} \longmapsto \mathrm{H}^\bullet(X', \psi^*(\mathscr{F}))$$

is a δ-functor on that category, and it is known that there is a canonical homomorphism of δ-functors

$$\mathrm{H}^\bullet(X, \mathscr{F}) \longrightarrow \mathrm{H}^\bullet(X', \psi^*(\mathscr{F})) \tag{12.1.3.2}$$

uniquely determined by the condition that, in degree 0, it reduces to the canonical homomorphism

$$\Gamma(X, \mathscr{F}) \longrightarrow \Gamma(X', \psi^*(\mathscr{F}))$$

(T, 3.2.2). Moreover, every element of A determines an endomorphism μ of $\Gamma(X, \mathscr{F})$ and an endomorphism μ' of $\Gamma(X', \psi^*(\mathscr{F}))$ such that the diagram

$$\begin{tikzcd} \Gamma(X, \mathscr{F}) \arrow[r] \arrow[d, "\mu"'] & \Gamma(X', \psi^*(\mathscr{F})) \arrow[d, "\mu'"] \\ \Gamma(X, \mathscr{F}) \arrow[r] & \Gamma(X', \psi^*(\mathscr{F})) \end{tikzcd} \tag{12.1.3.3}$$

is commutative. By the uniqueness property for extending morphisms of universal cohomological functors (T, 2.2), one obtains unique extensions of μ and μ' to cohomology which make the diagrams analogous to (12.1.3.3) commutative. Thus (12.1.3.2) is a homomorphism of A-modules. $\mathbf{0}_{\mathbf{III}}$ | 51

Now note that

$$f^*(\mathscr{F}) = \psi^*(\mathscr{F}) \otimes_{\psi^*(\mathscr{O}_X)} \mathscr{O}_{X'},$$

and hence that there is a canonical di-homomorphism

$$\psi^*(\mathscr{F}) \longrightarrow f^*(\mathscr{F})$$

from the $\psi^*(\mathscr{O}_X)$-Module $\psi^*(\mathscr{F})$ to the $\mathscr{O}_{X'}$-Module $f^*(\mathscr{F})$. By functoriality, one therefore obtains a functorial di-homomorphism

$$\mathrm{H}^p(X', \psi^*(\mathscr{F})) \longrightarrow \mathrm{H}^p(X', f^*(\mathscr{F})), \tag{12.1.3.4}$$

the corresponding rings being A and A'. Composing this di-homomorphism with (12.1.3.2), one obtains a canonical di-homomorphism, functorial in $\mathscr{F}$,

$$\theta_p : \mathrm{H}^p(X, \mathscr{F}) \longrightarrow \mathrm{H}^p(X', f^*(\mathscr{F})). \tag{12.1.3.5}$$

Finally, by functoriality, the homomorphism $u^\sharp : f^*(\mathscr{F}) \to \mathscr{F}'$ gives a homomorphism of A'-modules

$$\mathrm{H}^p(X', f^*(\mathscr{F})) \longrightarrow \mathrm{H}^p(X', \mathscr{F}'),$$

which, composed with (12.1.3.5), gives (12.1.3.1).

Let $f' = (\psi', \theta') : X'' \to X'$ be a second morphism of ringed spaces, and let $f'' = f \circ f'$ be the composite morphism. Taking account of the compatibility of the functor ψ'^* with tensor products ($\mathbf{0}_\mathbf{I}$, 4.3.3), one immediately checks that the composite of the di-homomorphism

$$\mathrm{H}^p(X', f^*(\mathscr{F})) \longrightarrow \mathrm{H}^p\big(X'', f'^*(f^*(\mathscr{F}))\big)$$

with (12.1.3.5) is the corresponding di-homomorphism

$$\mathrm{H}^p(X, \mathscr{F}) \longrightarrow \mathrm{H}^p(X'', f''^*(\mathscr{F})).$$

(12.1.4). A direct definition of the homomorphism (12.1.3.2) can be given as follows. Take an injective resolution $\mathscr{L}^\bullet = (\mathscr{L}^i)$ of $\mathscr{F}$ consisting of sheaves of abelian groups on X. Since the functor ψ^* is exact, $\psi^*(\mathscr{L}^\bullet)$ is a resolution of $\psi^*(\mathscr{F})$ consisting of sheaves on X'. If $\mathscr{L}'^\bullet = (\mathscr{L}'^i)$ is an injective resolution of $\psi^*(\mathscr{F})$ in the category of sheaves of abelian groups on X', there is a morphism

$$\psi^*(\mathscr{L}^\bullet) \longrightarrow \mathscr{L}'^\bullet$$

of complexes of sheaves of abelian groups, compatible with the augmentations (M, V, 1.1.a), and determined up to homotopy. One thereby obtains homomorphisms

$$\Gamma(X, \mathscr{L}^\bullet) \longrightarrow \Gamma(X', \psi^*(\mathscr{L}^\bullet)) \longrightarrow \Gamma(X', \mathscr{L}'^\bullet)$$

of complexes of abelian groups. Their composite, on passing to cohomology, gives a morphism of δ-functors

$$\mathrm{H}^\bullet(X, \mathscr{F}) \longrightarrow \mathrm{H}^\bullet(X', \psi^*(\mathscr{F}));$$

since it coincides with (12.1.3.2) in degree 0, it is identical to it (T, 2.2).

Now consider an open covering $\mathfrak{U} = (U_\alpha)$ of X, and let $\mathfrak{U}' = (f^{-1}(U_\alpha))$ be its inverse-image open covering of X'. For every open subset V of X, the canonical homomorphisms

$$\Gamma(V, \mathscr{F}) \longrightarrow \Gamma(f^{-1}(V), f^*(\mathscr{F}))$$

immediately define (cf. G, II, 5.1) a homomorphism of complexes

$$\check{\mathrm{C}}^\bullet(\mathfrak{U}, \mathscr{F}) \longrightarrow \check{\mathrm{C}}^\bullet(\mathfrak{U}', f^*(\mathscr{F})),$$

and hence canonical homomorphisms

$$\theta_p : \check{\mathrm{H}}^p(\mathfrak{U}, \mathscr{F}) \longrightarrow \check{\mathrm{H}}^p(\mathfrak{U}', f^*(\mathscr{F})). \tag{12.1.4.1}$$

Moreover, there are commutative diagrams $\mathbf{0}_{\mathbf{III}}$ | 52

$$\begin{tikzcd} \check{\mathrm{H}}^p(\mathfrak{U}, \mathscr{F}) \arrow[r, "\theta_p"] \arrow[d] & \check{\mathrm{H}}^p(\mathfrak{U}', f^*(\mathscr{F})) \arrow[d] \\ \mathrm{H}^p(X, \mathscr{F}) \arrow[r, "\theta_p"'] & \mathrm{H}^p(X', f^*(\mathscr{F})), \end{tikzcd} \tag{12.1.4.2}$$

where the vertical arrows are the canonical homomorphisms of (G, II, 5.2). To prove the commutativity of (12.1.4.2), consider the complex of sheaves of alternating cochains of $\mathscr{F}$ relative to $\mathfrak{U}$, $\mathscr{C}^\bullet(\mathfrak{U}, \mathscr{F})$, for which

$$\Gamma\big(X, \mathscr{C}^\bullet(\mathfrak{U}, \mathscr{F})\big) = \check{\mathrm{C}}^\bullet(\mathfrak{U}, \mathscr{F})$$

(G, II, 5.2). The canonical homomorphisms

$$\Gamma(V, \mathscr{F}) \longrightarrow \Gamma(f^{-1}(V), \psi^*(\mathscr{F}))$$

then define a ψ-morphism

$$\mathscr{C}^\bullet(\mathfrak{U}, \mathscr{F}) \longrightarrow \mathscr{C}^\bullet(\mathfrak{U}', \psi^*(\mathscr{F})),$$

and, with the notation above, there is a commutative diagram

$$\begin{tikzcd}
\Gamma\big(X, \mathscr{C}^\bullet(\mathfrak{U}, \mathscr{F})\big) \arrow[r] \arrow[d] & \Gamma\big(X', \mathscr{C}^\bullet(\mathfrak{U}', \psi^*(\mathscr{F}))\big) \arrow[d] & \\
\Gamma(X, \mathscr{L}^\bullet) \arrow[r] & \Gamma(X', \psi^*(\mathscr{L}^\bullet)) \arrow[r] & \Gamma(X', \mathscr{L}'^\bullet).
\end{tikzcd}$$

Passing to cohomology gives commutative diagrams

$$\begin{tikzcd}
\check{\mathrm{H}}^p(\mathfrak{U}, \mathscr{F}) \arrow[r] \arrow[d] & \check{\mathrm{H}}^p(\mathfrak{U}', \psi^*(\mathscr{F})) \arrow[d] \\
\mathrm{H}^p(X, \mathscr{F}) \arrow[r] & \mathrm{H}^p(X', \psi^*(\mathscr{F})),
\end{tikzcd}$$

where the vertical arrows are the canonical homomorphisms of (G, II, 5.2). It remains only to combine these diagrams with the commutative diagrams

$$\begin{tikzcd}
\check{\mathrm{H}}^p(\mathfrak{U}', \psi^*(\mathscr{F})) \arrow[r] \arrow[d] & \check{\mathrm{H}}^p(\mathfrak{U}', f^*(\mathscr{F})) \arrow[d] \\
\mathrm{H}^p(X', \psi^*(\mathscr{F})) \arrow[r] & \mathrm{H}^p(X', f^*(\mathscr{F})),
\end{tikzcd}$$

which arise from the homomorphism $\psi^*(\mathscr{F}) \to f^*(\mathscr{F})$ and the functoriality of the canonical homomorphisms of (G, II, 5.2), to obtain the commutativity of (12.1.4.2). $\mathbf{0}_{\mathbf{III}}$ | 53

Note that if $A = \Gamma(X, \mathscr{O}_X)$ and $A' = \Gamma(X', \mathscr{O}_{X'})$, then (12.1.4.1) is a di-homomorphism of modules corresponding to the rings A and A'. There is a transitivity property for (12.1.4.1) with respect to a composite of two morphisms, analogous to that of (12.1.3.5). Finally, in the preceding definitions, instead of an injective resolution $\mathscr{L}^\bullet$ of $\mathscr{F}$, one could equally well have started with a resolution such that

$$\mathrm{H}^p(X, \mathscr{L}^i) = 0 \qquad \text{for every } i \text{ and every } p > 0$$

(G, II, 4.7.1).

(12.1.5). Let $\mathscr{F}, \mathscr{G}, \mathscr{H}$ be three $\mathscr{O}_X$-Modules, and consider an $\mathscr{O}_X$-homomorphism

$$u : \mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{G} \longrightarrow \mathscr{H},$$

which gives, in cohomology, the homomorphisms

$$\mathrm{H}^p(X, \mathscr{F}) \otimes_A \mathrm{H}^q(X, \mathscr{G}) \longrightarrow \mathrm{H}^{p+q}(X, \mathscr{H}) \tag{12.1.5.1}$$

deduced from the cup product (12.1.2.1). We show that, under the hypotheses and with the notation of (12.1.3), the diagrams

$$\begin{tikzcd}
\mathrm{H}^p(X, \mathscr{F}) \otimes_A \mathrm{H}^q(X, \mathscr{G}) \arrow[r] \arrow[d] & \mathrm{H}^{p+q}(X, \mathscr{H}) \arrow[d] \\
\mathrm{H}^p(X', f^*(\mathscr{F})) \otimes_{A'} \mathrm{H}^q(X', f^*(\mathscr{G})) \arrow[r] & \mathrm{H}^{p+q}(X', f^*(\mathscr{H}))
\end{tikzcd} \tag{12.1.5.2}$$

are commutative, where the vertical arrows come from the canonical homomorphisms (12.1.3.5).

Recall for this purpose that (12.1.5.1) can be obtained from the canonical resolutions (G, II, 4.3) $\mathscr{L}^\bullet, \mathscr{M}^\bullet, \mathscr{N}^\bullet$ of $\mathscr{F}, \mathscr{G}, \mathscr{H}$ respectively, which consist of $\mathscr{O}_X$-Modules, and from the linear map

$$\mathscr{L}^\bullet \otimes_{\mathscr{O}_X} \mathscr{M}^\bullet \longrightarrow \mathscr{N}^\bullet$$

of complexes of $\mathscr{O}_X$-Modules corresponding to u. This map provides a homomorphism of complexes of A-modules

$$\Gamma(X, \mathscr{L}^\bullet) \otimes_A \Gamma(X, \mathscr{M}^\bullet) \longrightarrow \Gamma(X, \mathscr{N}^\bullet),$$

and hence, on passing to cohomology, homomorphisms

$$\mathrm{H}^p\big(\Gamma(X, \mathscr{L}^\bullet)\big) \otimes_A \mathrm{H}^q\big(\Gamma(X, \mathscr{M}^\bullet)\big) \longrightarrow \mathrm{H}^{p+q}\big(\Gamma(X, \mathscr{N}^\bullet)\big)$$

(G, II, 6.6). There is clearly a commutative diagram

(12.1.5.3)
$$\begin{tikzcd} \Gamma(X,\mathscr{L}^\bullet)\otimes_A\Gamma(X,\mathscr{M}^\bullet) \arrow[r] \arrow[d] & \Gamma(X,\mathscr{N}^\bullet) \arrow[d] \\ \Gamma(X',\psi^*(\mathscr{L}^\bullet))\otimes_{\Gamma(X',\psi^*(\mathscr{O}_X))}\Gamma(X',\psi^*(\mathscr{M}^\bullet)) \arrow[r] & \Gamma(X',\psi^*(\mathscr{N}^\bullet)). \end{tikzcd}$$

Passing to cohomology gives commutative diagrams **0**$_{\mathrm{III}}$ | 54

(12.1.5.4)
$$\begin{tikzcd} \mathrm{H}^p(X,\mathscr{F})\otimes_A\mathrm{H}^q(X,\mathscr{G}) \arrow[r] \arrow[d] & \mathrm{H}^{p+q}(X,\mathscr{H}) \arrow[d] \\ \mathrm{H}^p\big(\Gamma(X',\psi^*(\mathscr{L}^\bullet))\big)\otimes_{\Gamma(X',\psi^*(\mathscr{O}_X))}\mathrm{H}^q\big(\Gamma(X',\psi^*(\mathscr{M}^\bullet))\big) \arrow[r] & \mathrm{H}^{p+q}\big(\Gamma(X',\psi^*(\mathscr{N}^\bullet))\big). \end{tikzcd}$$

But since $\psi^*(\mathscr{L}^\bullet)$, $\psi^*(\mathscr{M}^\bullet)$, and $\psi^*(\mathscr{N}^\bullet)$ are resolutions of $\psi^*(\mathscr{F})$, $\psi^*(\mathscr{G})$, and $\psi^*(\mathscr{H})$ respectively, there is a commutative diagram (G, II, 6.6.1)

(12.1.5.5)
$$\begin{tikzcd} \mathrm{H}^p\big(\Gamma(X',\psi^*(\mathscr{L}^\bullet))\big)\otimes_{\Gamma(X',\psi^*(\mathscr{O}_X))}\mathrm{H}^q\big(\Gamma(X',\psi^*(\mathscr{M}^\bullet))\big) \arrow[r] \arrow[d] & \mathrm{H}^{p+q}\big(\Gamma(X',\psi^*(\mathscr{N}^\bullet))\big) \arrow[d] \\ \mathrm{H}^p(X',\psi^*(\mathscr{F}))\otimes_{\Gamma(X',\psi^*(\mathscr{O}_X))}\mathrm{H}^q(X',\psi^*(\mathscr{G})) \arrow[r] & \mathrm{H}^{p+q}(X',\psi^*(\mathscr{H})). \end{tikzcd}$$

Finally, by functoriality, there is a commutative diagram

(12.1.5.6)
$$\begin{tikzcd} \mathrm{H}^p(X',\psi^*(\mathscr{F}))\otimes_{\Gamma(X',\psi^*(\mathscr{O}_X))}\mathrm{H}^q(X',\psi^*(\mathscr{G})) \arrow[r] \arrow[d] & \mathrm{H}^{p+q}(X',\psi^*(\mathscr{H})) \arrow[d] \\ \mathrm{H}^p(X',f^*(\mathscr{F}))\otimes_{A'}\mathrm{H}^q(X',f^*(\mathscr{G})) \arrow[r] & \mathrm{H}^{p+q}(X',f^*(\mathscr{H})). \end{tikzcd}$$

Combining the three diagrams (12.1.5.4), (12.1.5.5), and (12.1.5.6) yields the desired commutative diagram (12.1.5.2).

Remark (12.1.6). — With the notation of (12.1.3), suppose that there is a commutative diagram **0**$_{\mathrm{III}}$ | 55

(12.1.6.1)
$$\begin{tikzcd} 0 \arrow[r] & \mathscr{F} \arrow[r, "r"] \arrow[d, "u"'] & \mathscr{G} \arrow[r, "s"] \arrow[d, "v"'] & \mathscr{H} \arrow[r] \arrow[d, "w"'] & 0 \\ 0 \arrow[r] & \mathscr{F}' \arrow[r, "r'"'] & \mathscr{G}' \arrow[r, "s'"'] & \mathscr{H}' \arrow[r] & 0, \end{tikzcd}$$

where r,s are homomorphisms of $\mathscr{O}_X$-Modules, r',s' are homomorphisms of $\mathscr{O}_{X'}$-Modules, u,v,w are f-morphisms, and the rows are exact. It follows that the diagram

(12.1.6.2)
$$\begin{tikzcd} \cdots \arrow[r] & \mathrm{H}^p(X,\mathscr{F}) \arrow[r] \arrow[d, "u_p"'] & \mathrm{H}^p(X,\mathscr{G}) \arrow[r] \arrow[d, "v_p"'] & \mathrm{H}^p(X,\mathscr{H}) \arrow[r, "\partial"] \arrow[d, "w_p"'] & \mathrm{H}^{p+1}(X,\mathscr{F}) \arrow[r] \arrow[d, "u_{p+1}"'] & \cdots \\ \cdots \arrow[r] & \mathrm{H}^p(X',\mathscr{F}') \arrow[r] & \mathrm{H}^p(X',\mathscr{G}') \arrow[r] & \mathrm{H}^p(X',\mathscr{H}') \arrow[r, "\partial"'] & \mathrm{H}^{p+1}(X',\mathscr{F}') \arrow[r] & \cdots \end{tikzcd}$$

is commutative. Indeed, (12.1.6.1) factors as

$$\begin{tikzcd} 0 \arrow[r] & \mathscr{F} \arrow[r] \arrow[d] & \mathscr{G} \arrow[r] \arrow[d] & \mathscr{H} \arrow[r] \arrow[d] & 0 \\ 0 \arrow[r] & \psi^*(\mathscr{F}) \arrow[r] \arrow[d] & \psi^*(\mathscr{G}) \arrow[r] \arrow[d] & \psi^*(\mathscr{H}) \arrow[r] \arrow[d] & 0 \\ 0 \arrow[r] & \mathscr{F}' \arrow[r] & \mathscr{G}' \arrow[r] & \mathscr{H}' \arrow[r] & 0, \end{tikzcd}$$

where the middle row is exact (**0**$_{\mathrm{I}}$, 3.7.2). It is then enough to use the fact that (12.1.3.2) is a homomorphism of δ-functors and that the $\mathrm{H}^p(X',\mathscr{F}')$ form a δ-functor in $\mathscr{F}'$.

(12.1.7). With the hypotheses and notation of (12.1.3), consider now the case

$$\mathscr{F} = f_*(\mathscr{F}') = \psi_*(\mathscr{F}').$$

We shall see that the di-homomorphism defined in (12.1.3),

$$\mathrm{H}^p(X, f_*(\mathscr{F}')) \longrightarrow \mathrm{H}^p(X', \mathscr{F}'), \tag{12.1.7.1}$$

can be obtained (up to an automorphism of $\mathrm{H}^p(X', \mathscr{F}')$) as an edge homomorphism of a spectral sequence for the composite functor

$$\mathscr{F}' \rightsquigarrow \Gamma(X, \psi_*(\mathscr{F}'))$$

(T, 2.4). The description of (12.1.7.1) given in (12.1.4) shows here that this homomorphism can be obtained as follows. Take injective resolutions $\mathscr{L}^\bullet$ and $\mathscr{L}'^\bullet$ of $\psi_*(\mathscr{F}')$ and $\mathscr{F}'$, respectively, and then a homomorphism of complexes

$$v : \psi^*(\mathscr{L}^\bullet) \longrightarrow \mathscr{L}'^\bullet$$

"above" the canonical homomorphism $\psi^*(\psi_*(\mathscr{F}')) \to \mathscr{F}'$. We next note that $\mathbf{0}_{\mathrm{III}}$ | 56

$$\Gamma(X', \mathscr{L}'^\bullet) = \Gamma(X, \psi_*(\mathscr{L}'^\bullet))$$

and that the composite homomorphism

$$\Gamma(X, \mathscr{L}^\bullet) \longrightarrow \Gamma(X', \psi^*(\mathscr{L}^\bullet)) \xrightarrow{\Gamma(v)} \Gamma(X', \mathscr{L}'^\bullet)$$

is none other than

$$\Gamma(v^\flat) : \Gamma(X, \mathscr{L}^\bullet) \longrightarrow \Gamma(X, \psi_*(\mathscr{L}'^\bullet)) \tag{12.1.7.2}$$

($\mathbf{0}_{\mathrm{I}}$, 3.7.1); and (12.1.7.1) is obtained by passing to cohomology in (12.1.7.2).

On the other hand, the spectral sequences for the composite functor

$$\mathscr{F}' \rightsquigarrow \Gamma(X, \psi_*(\mathscr{F}'))$$

are obtained by taking an injective Cartan–Eilenberg resolution

$$\mathscr{M}^{\bullet\bullet} = (\mathscr{M}^{ij})$$

of the complex $\psi_*(\mathscr{L}'^\bullet)$ in the category of sheaves of abelian groups on X. The spectral sequences in question are those of the bicomplex $\Gamma(X, \mathscr{M}^{\bullet\bullet})$; they are biregular, since $\mathscr{M}^{ij} = 0$ for $i < 0$ or $j < 0$. Now the first spectral sequence of this bicomplex degenerates, since the sheaves $\psi_*(\mathscr{L}'^i)$ are flasque (G, II, 3.1.1), and therefore

$$\mathrm{H}^q_{\mathrm{II}}(\Gamma(X, \mathscr{M}^{i,\bullet})) = \mathrm{H}^q(\psi_*(\mathscr{L}'^i)) = 0 \qquad (q > 0)$$

(G, II, 4.4.3). Consequently, there are bijective edge homomorphisms (11.1.6)

$${}'E_2^{i0} = \mathrm{H}^i\Big(\mathrm{H}^0_{\mathrm{II}}(\Gamma(X, \mathscr{M}^{\bullet\bullet}))\Big) \longrightarrow \mathrm{H}^i(\Gamma(X, \mathscr{M}^{\bullet\bullet})), \tag{12.1.7.3}$$

and we know (11.3.4) that this homomorphism comes, on passing to cohomology, from the augmentation

$$\Gamma(X, \psi_*(\mathscr{L}'^\bullet)) \longrightarrow \Gamma(X, \mathscr{M}^{\bullet\bullet}), \tag{12.1.7.4}$$

which itself comes from the augmentation

$$\eta : \psi_*(\mathscr{L}'^\bullet) \longrightarrow \mathscr{M}^{\bullet\bullet}.$$

For the second spectral sequence, on the other hand, there are edge homomorphisms

$${}''E_2^{i0} = \mathrm{H}^i\Big(\mathrm{H}^0_{\mathrm{I}}(\Gamma(X, \mathscr{M}^{\bullet\bullet}))\Big) \longrightarrow \mathrm{H}^i(\Gamma(X, \mathscr{M}^{\bullet\bullet})), \tag{12.1.7.5}$$

which come (11.3.4), on passing to cohomology, from the homomorphism of complexes

$$Z^0_{\mathrm{I}}(\Gamma(X, \mathscr{M}^{\bullet\bullet})) \longrightarrow \Gamma(X, \mathscr{M}^{\bullet\bullet}).$$

Since ψ_* is left exact, the sequence

$$0 \longrightarrow \psi_*(\mathscr{F}') \longrightarrow \psi_*(\mathscr{L}'^0) \longrightarrow \psi_*(\mathscr{L}'^1)$$

is exact. By the definition of a Cartan–Eilenberg resolution (11.4.2), we may therefore take

$$B_{\mathrm{I}}^0(\mathscr{M}^{\bullet\bullet}) = 0, \qquad Z_{\mathrm{I}}^0(\mathscr{M}^{\bullet\bullet}) = \mathscr{L}^\bullet.$$

Since the diagram

$$\begin{tikzcd} \mathscr{L}^0 \arrow[rr, "i^0"] & & \mathscr{M}^{00} \\ \psi_*(\mathscr{F}') \arrow[u, "\varepsilon"] \arrow[urr, "\varepsilon''"] \arrow[rr, "\varepsilon'"'] & & \psi_*(\mathscr{L}'^0) \arrow[u, "\eta^0"'] \end{tikzcd}$$

is commutative, the injection of complexes $i : \mathscr{L}^\bullet \to \mathscr{M}^{\bullet\bullet}$ is compatible with the augmentations ε and ε''. Thus there are two homomorphisms of complexes from $\mathscr{L}^\bullet$ to $\mathscr{M}^{\bullet\bullet}$,

$$\begin{tikzcd} \mathscr{L}^\bullet \arrow[r, "i"] \arrow[dr, "v^\flat"'] & \mathscr{M}^{\bullet\bullet} \\ & \psi_*(\mathscr{L}'^\bullet) \arrow[u, "\eta"'] \end{tikzcd}$$

compatible with the augmentations ε and ε''. Since $\mathscr{L}^\bullet$ is an injective resolution and $\mathscr{M}^{\bullet\bullet}$ consists of **0_{III}** | 57
injective sheaves, it follows from (M, V, 1.1(a)) that these two homomorphisms are homotopic. The same is therefore true of the two corresponding homomorphisms

$$\Gamma(X, \mathscr{L}^\bullet) \longrightarrow \Gamma(X, \mathscr{M}^{\bullet\bullet}),$$

and, on passing to cohomology, they consequently give the same homomorphism. In other words, we have shown that the edge homomorphism (12.1.7.5), written

$$\mathrm{H}^p(X, \psi_*(\mathscr{F}')) \longrightarrow \mathrm{H}^p\big(\Gamma(X, \mathscr{M}^{\bullet\bullet})\big),$$

is the composite of (12.1.7.1) and (12.1.7.3), the latter being written

$$\mathrm{H}^p(X', \mathscr{F}') \longrightarrow \mathrm{H}^p\big(\Gamma(X, \mathscr{M}^{\bullet\bullet})\big)$$

and having been seen to be an isomorphism. This proves the assertion.

12.2. Higher direct images

(12.2.1). Let $(X, \mathscr{O}_X)$ and $(Y, \mathscr{O}_Y)$ be two ringed spaces, and let $f = (\psi, \theta)$ be a morphism from X to Y. It defines the direct image functor

$$f_* : \mathtt{C}(X) \longrightarrow \mathtt{C}(Y),$$

which is moreover identical to the restriction to $\mathtt{C}(X)$ of the functor ψ_* defined on the category of sheaves of abelian groups on X. The latter functor is additive and left exact; and since every sheaf of abelian groups on X is isomorphic to a subsheaf of an injective sheaf of abelian groups, one defines the right derived functors

$$\mathscr{F} \longmapsto \mathrm{R}^p\psi_*(\mathscr{F})$$

of ψ_*. The $\mathrm{R}^p\psi_*(\mathscr{F})$ are sheaves of abelian groups on Y, and the $\mathrm{R}^p\psi_*$ form a universal cohomological functor (T, 2.3).

Moreover, $\mathrm{R}^p\psi_*(\mathscr{F})$ is the sheaf associated with the presheaf

$$V \longmapsto \mathrm{H}^p(f^{-1}(V), \mathscr{F})$$

(T, 3.7.2). Suppose now that $\mathscr{F}$ is an $\mathscr{O}_X$-module. Then $\mathrm{H}^p(f^{-1}(V), \mathscr{F})$ is naturally endowed with the structure of a $\Gamma(f^{-1}(V), \mathscr{O}_X)$-module, hence with that of a $\Gamma(V, \psi_*(\mathscr{O}_X))$-module; the homomorphism

$$\theta : \mathscr{O}_Y \longrightarrow \psi_*(\mathscr{O}_X)$$

then endows it with the structure of a $\Gamma(V, \mathscr{O}_Y)$-module. For the structures so defined, restriction from an open subset V to an open subset $V' \subset V$ defines a di-homomorphism. This therefore defines on every $\mathrm{R}^p\psi_*(\mathscr{F})$ the structure of an $\mathscr{O}_Y$-module. We denote this $\mathscr{O}_Y$-module by $\mathrm{R}^p f_*(\mathscr{F})$; thus $\mathrm{R}^p f_*$ is defined as an additive functor from $\mathtt{C}(X)$ to $\mathtt{C}(Y)$.

Moreover, the $\mathrm{R}^p f_*$ form a δ-functor. Indeed, if

$$0 \longrightarrow \mathscr{F}' \longrightarrow \mathscr{F} \longrightarrow \mathscr{F}'' \longrightarrow 0$$

is an exact sequence of $\mathscr{O}_X$-modules, the preceding description of the $\mathrm{R}^p\psi_*$ and of the $\mathscr{O}_Y$-module structure on $\mathrm{R}^p\psi_*(\mathscr{F})$ immediately shows that the boundary homomorphism

$$\partial : \mathrm{R}^p\psi_*(\mathscr{F}'') \longrightarrow \mathrm{R}^{p+1}\psi_*(\mathscr{F}')$$

is an $\mathscr{O}_Y$-module homomorphism. Finally, the $\mathrm{R}^p f_*$ are identified with the right derived functors of f_*. Every $\mathscr{O}_X$-module admits an injective resolution by $\mathscr{O}_X$-modules, and such a resolution consists of flasque sheaves of abelian groups (G, II, 7.1); it can therefore be used to compute the $\mathrm{R}^p\psi_*(\mathscr{F})$, since $\mathrm{R}^n\psi_*(\mathscr{G}) = 0$ for $n \geqslant 1$ and every flasque sheaf $\mathscr{G}$ (T, 2.4.1, Remark 3, and the corollary of Proposition 3.3.2). It follows that the $\mathrm{R}^p f_*$ form a universal cohomological functor from $\mathtt{C}(X)$ to $\mathtt{C}(Y)$ (T, 2.3).

(12.2.2). Let $\mathscr{F}$ and $\mathscr{G}$ be two $\mathscr{O}_X$-modules. With the notation of (12.2.1), for every open subset V of Y there is the cup-product homomorphism (12.1.2.1)

$$\begin{aligned} &\mathrm{H}^p(f^{-1}(V), \mathscr{F}) \otimes_{\Gamma(f^{-1}(V),\mathscr{O}_X)} \mathrm{H}^q(f^{-1}(V), \mathscr{G}) \\ &\qquad\qquad \longrightarrow \mathrm{H}^{p+q}\big(f^{-1}(V), \mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{G}\big). \end{aligned}$$

It follows immediately from the definition of the cup product (G, II, 6.6) that these homomorphisms commute with restriction from V to an open subspace V' of V. On the other hand, θ gives a ring homomorphism **0_{III}** | 58

$$\Gamma(V, \mathscr{O}_Y) \longrightarrow \Gamma(V, \psi_*(\mathscr{O}_X)) = \Gamma(f^{-1}(V), \mathscr{O}_X),$$

and hence a canonical homomorphism of tensor products

$$\begin{aligned} &\mathrm{H}^p(f^{-1}(V), \mathscr{F}) \otimes_{\Gamma(V,\mathscr{O}_Y)} \mathrm{H}^q(f^{-1}(V), \mathscr{G}) \\ &\quad \longrightarrow \mathrm{H}^p(f^{-1}(V), \mathscr{F}) \otimes_{\Gamma(f^{-1}(V),\mathscr{O}_X)} \mathrm{H}^q(f^{-1}(V), \mathscr{G}), \end{aligned}$$

which is likewise compatible with restriction from V to V'. By composition, one thus obtains a homomorphism of $\Gamma(V, \mathscr{O}_Y)$-modules. For the sheaves associated with the presheaves in question, it defines a canonical homomorphism, functorial in $\mathscr{F}$ and $\mathscr{G}$,

$$\mathrm{R}^p f_*(\mathscr{F}) \otimes_{\mathscr{O}_Y} \mathrm{R}^q f_*(\mathscr{G}) \longrightarrow \mathrm{R}^{p+q} f_*\big(\mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{G}\big). \tag{12.2.2.1}$$

For $p = q = 0$, this homomorphism reduces to ($\mathbf{0_I}$, 4.2.2.1).

Proposition (12.2.3). — *For every $\mathscr{O}_X$-module $\mathscr{F}$ and every locally free $\mathscr{O}_Y$-module $\mathscr{L}$ of finite rank, there are canonical functorial isomorphisms*

$$\mathrm{R}^p f_*(\mathscr{F}) \otimes_{\mathscr{O}_Y} \mathscr{L} \xrightarrow{\sim} \mathrm{R}^p f_*\big(\mathscr{F} \otimes_{\mathscr{O}_X} f^*(\mathscr{L})\big). \tag{12.2.3.1}$$

Proof. The homomorphism (12.2.3.1) is obtained by composing the following particular case of (12.2.2.1),

$$\mathrm{R}^p f_*(\mathscr{F}) \otimes_{\mathscr{O}_Y} f_*\big(f^*(\mathscr{L})\big) \longrightarrow \mathrm{R}^p f_*\big(\mathscr{F} \otimes_{\mathscr{O}_X} f^*(\mathscr{L})\big), \tag{12.2.3.2}$$

with the homomorphism from the first member of (12.2.3.1) to that of (12.2.3.2) induced by the canonical homomorphism ($\mathbf{0_I}$, 4.4.3.2). To verify that (12.2.3.1) is an isomorphism when $\mathscr{L}$ is locally free, one may immediately reduce to the case $\mathscr{L} = \mathscr{O}_Y$, since the question is local on Y and the functors in question are additive in $\mathscr{L}$. In that case, in view of the definition of (12.2.2.1), the proposition reduces to verifying that the corresponding homomorphism of presheaves is bijective; this follows immediately from $f^*(\mathscr{O}_Y) = \mathscr{O}_X$. □

(12.2.4). Let $(Z, \mathscr{O}_Z)$ be a third ringed space, and let $g : Y \to Z$ be a morphism of ringed spaces. We know (G, II, 7.1 and 3.1.1) that, for every injective $\mathscr{O}_X$-module $\mathscr{G}$, $f_*(\mathscr{G})$ is a flasque sheaf of abelian groups. Consequently, by (12.2.1),

$$\mathrm{R}^p g_*\big(f_*(\mathscr{G})\big) = 0 \qquad (p > 0).$$

It follows (T, 2.4.1) that the Leray spectral sequence for composite functors applies to the composite $g_* \circ f_*$. There is a biregular spectral sequence whose abutment is the functor $\mathrm{R}^\bullet h_*$, where $h = g \circ f$, and whose E_2-term is

$$E_2^{pq} = \mathrm{R}^p g_*\big(\mathrm{R}^q f_*(\mathscr{F})\big). \tag{12.2.4.1}$$

(12.2.5). Under the conditions of (12.2.4), we shall directly define canonical homomorphisms of $\mathscr{O}_Z$-modules

(12.2.5.1) $$\mathrm{R}^n g_*\big(f_*(\mathscr{F})\big) \longrightarrow \mathrm{R}^n h_*(\mathscr{F})$$

and

(12.2.5.2) $$\mathrm{R}^n h_*(\mathscr{F}) \longrightarrow g_*\big(\mathrm{R}^n f_*(\mathscr{F})\big),$$

which may be identified with the "edge homomorphisms" of the Leray spectral sequence (cf. (12.1.7)). $\mathbf{0}_{\mathrm{III}}$ | 59
It is enough to work with the presheaves with which the higher direct image sheaves are associated (12.2.1). For this purpose, let W be any open subset of Z, and consider its inverse image $g^{-1}(W)$ in Y. There is a canonical di-homomorphism

(12.2.5.3) $$\mathrm{H}^n\big(g^{-1}(W), f_*(\mathscr{F})\big) \longrightarrow \mathrm{H}^n\big(f^{-1}(g^{-1}(W)), f^*(f_*(\mathscr{F}))\big),$$

the corresponding rings being $\Gamma(g^{-1}(W), \mathscr{O}_Y)$ and $\Gamma(h^{-1}(W), \mathscr{O}_X)$. On the other hand, the canonical homomorphism ($\mathbf{0}_{\mathrm{I}}$, 4.4.3.3) gives, by functoriality, canonical homomorphisms

(12.2.5.4) $$\mathrm{H}^n\big(h^{-1}(W), f^*(f_*(\mathscr{F}))\big) \longrightarrow \mathrm{H}^n\big(h^{-1}(W), \mathscr{F}\big),$$

which are homomorphisms of $\Gamma(h^{-1}(W), \mathscr{O}_X)$-modules. Taking into account the ring homomorphism

$$\Gamma(W, \mathscr{O}_Z) \longrightarrow \Gamma(g^{-1}(W), \mathscr{O}_Y),$$

we see that composing (12.2.5.3) with (12.2.5.4) gives a homomorphism of presheaves and hence the homomorphism of sheaves (12.2.5.1).

The definition of (12.2.5.2) is still simpler. By definition, $\mathrm{R}^n h_*(\mathscr{F})$ is associated with the presheaf

$$W \longmapsto \mathrm{H}^n\big(f^{-1}(g^{-1}(W)), \mathscr{F}\big),$$

while $\mathrm{R}^n f_*(\mathscr{F})$ is associated with the presheaf

$$V \longmapsto \mathrm{H}^n(f^{-1}(V), \mathscr{F}).$$

There is therefore a canonical homomorphism

$$\mathrm{H}^n\big(f^{-1}(g^{-1}(W)), \mathscr{F}\big) \longrightarrow \Gamma\big(g^{-1}(W), \mathrm{R}^n f_*(\mathscr{F})\big),$$

and it is immediate that these homomorphisms define a homomorphism of presheaves, which in turn defines (12.2.5.2).

(12.2.6). Under the hypotheses of (12.2.4), let $\mathscr{F}$, $\mathscr{G}$, and $\mathscr{K}$ be three $\mathscr{O}_X$-modules, and let

$$u : \mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{G} \longrightarrow \mathscr{K}$$

be an $\mathscr{O}_X$-homomorphism. Then the following diagrams are commutative:

(12.2.6.1)
$$\begin{CD}
\mathrm{R}^p g_*(f_*(\mathscr{F})) \otimes_{\mathscr{O}_Z} \mathrm{R}^q g_*(f_*(\mathscr{G})) @>>> \mathrm{R}^{p+q} g_*(f_*(\mathscr{K})) \\
@VVV @VVV \\
\mathrm{R}^p h_*(\mathscr{F}) \otimes_{\mathscr{O}_Z} \mathrm{R}^q h_*(\mathscr{G}) @>>> \mathrm{R}^{p+q} h_*(\mathscr{K}),
\end{CD}$$

and

(12.2.6.2)
$$\begin{CD}
\mathrm{R}^p h_*(\mathscr{F}) \otimes_{\mathscr{O}_Z} \mathrm{R}^q h_*(\mathscr{G}) @>>> \mathrm{R}^{p+q} h_*(\mathscr{K}) \\
@VVV @VVV \\
g_*(\mathrm{R}^p f_*(\mathscr{F})) \otimes_{\mathscr{O}_Z} g_*(\mathrm{R}^q f_*(\mathscr{G})) @>>> g_*(\mathrm{R}^{p+q} f_*(\mathscr{K})).
\end{CD}$$

Here the horizontal arrows come from (12.2.2.1) (the last one combined with ($\mathbf{0}_{\mathrm{I}}$, 4.2.2.1)), and the $\mathbf{0}_{\mathrm{III}}$ | 60
vertical arrows from (12.2.5.1) and (12.2.5.2), respectively.

Indeed, it is enough to verify the assertion for the corresponding homomorphisms of presheaves. Returning to the definitions in (12.2.2) and (12.2.5), one is immediately reduced, for (12.2.6.1), to the commutative diagrams (12.1.5.2); the verification is still simpler for (12.2.6.2).

12.3. Supplements on the Ext functors of sheaves

(12.3.1). Let $(X, \mathscr{O}_X)$ be a ringed space. We shall not recall the definition and principal properties of the bifunctors

$$\mathrm{Ext}^p_{\mathscr{O}_X}(X; \mathscr{F}, \mathscr{G}), \qquad \mathscr{E}xt^p_{\mathscr{O}_X}(\mathscr{F}, \mathscr{G}),$$

the first taking values in the category of $\Gamma(X, \mathscr{O}_X)$-modules and the second in the category of $\mathscr{O}_X$-modules, nor the biregular spectral sequence $E(\mathscr{F}, \mathscr{G})$ relating them (T, 4.2 and G, II, 7.3).

(12.3.2). Just as in (M, XIV, 1), one defines the notion of an *extension* of an $\mathscr{O}_X$-module $\mathscr{F}$ by an $\mathscr{O}_X$-module $\mathscr{G}$ and the composition law on classes of equivalent extensions: the arguments used for modules plainly carry over to an arbitrary abelian category. The second proof of (M, XIV, 1.1), which uses only the existence of embeddings into injective objects, is therefore still valid in the category of $\mathscr{O}_X$-modules. It shows that

$$\mathrm{Ext}^1_{\mathscr{O}_X}(X; \mathscr{F}, \mathscr{G})$$

is canonically identified with the abelian group of classes of extensions of $\mathscr{F}$ by $\mathscr{G}$.

Proposition (12.3.3). — *Let $(X, \mathscr{O}_X)$ be a ringed space whose sheaf of rings $\mathscr{O}_X$ is coherent. Then, for every pair of coherent $\mathscr{O}_X$-modules $\mathscr{F}$ and $\mathscr{G}$ and every $p \geqslant 0$,*

$$\mathscr{E}xt^p_{\mathscr{O}_X}(\mathscr{F}, \mathscr{G})$$

is a coherent $\mathscr{O}_X$-module.

Proof. The $\mathscr{E}xt^p_{\mathscr{O}_X}(\mathscr{F}, \mathscr{G})$ form a contravariant cohomological functor in $\mathscr{F}$. Since $\mathscr{F}$ is coherent, for every p and every point $x \in X$ there are an open neighbourhood U of x in X and an exact sequence of $(\mathscr{O}_X|U)$-modules

$$0 \longrightarrow \mathscr{R} \longrightarrow \mathscr{L}_{p-1} \longrightarrow \cdots \longrightarrow \mathscr{L}_0 \longrightarrow \mathscr{F}|U \longrightarrow 0,$$

where each $\mathscr{L}_i$ $(0 \leqslant i \leqslant p-1)$ is isomorphic to $\mathscr{O}_X^{n_i}|U$, and $\mathscr{R}$ is coherent. This follows by induction on p from ($\mathbf{0_I}$, 5.3.2) and ($\mathbf{0_I}$, 5.3.4), since $\mathscr{O}_X$ is coherent.

For $p \geqslant 1$, moreover,

$$\mathscr{E}xt^p_{\mathscr{O}_X|U}(\mathscr{L}|U, \mathscr{G}|U) = 0$$

for every $\mathscr{O}_X$-module $\mathscr{L}$ for which $\mathscr{L}|U$ is isomorphic to $\mathscr{O}_X^n|U$ (T, 4.2.3). The argument of (M, V, 7.2) therefore applies to the contravariant cohomological functor

$$\mathscr{F} \longmapsto \mathscr{H}om_{\mathscr{O}_X|U}(\mathscr{F}|U, \mathscr{G}|U)$$

and gives an exact sequence

$$\begin{aligned}\mathscr{H}om_{\mathscr{O}_X|U}(\mathscr{L}_{p-1}, \mathscr{G}|U) &\longrightarrow \mathscr{H}om_{\mathscr{O}_X|U}(\mathscr{R}, \mathscr{G}|U)\\ &\longrightarrow \mathscr{E}xt^p_{\mathscr{O}_X|U}(\mathscr{F}|U, \mathscr{G}|U) \longrightarrow 0.\end{aligned}$$

The first two terms are coherent $(\mathscr{O}_X|U)$-modules ($\mathbf{0_I}$, 5.3.5); hence so is the third ($\mathbf{0_I}$, 5.3.4). □

$\mathbf{0_{III}}$ | 61

Proposition (12.3.4). — *Let $f : X \to Y$ be a flat morphism of ringed spaces, and let $\mathscr{F}$ and $\mathscr{G}$ be two $\mathscr{O}_Y$-modules.*

(i) *There is a homomorphism of cohomological bifunctors*

$$f^*\big(\mathscr{E}xt^\bullet_{\mathscr{O}_Y}(\mathscr{F}, \mathscr{G})\big) \longrightarrow \mathscr{E}xt^\bullet_{\mathscr{O}_X}\big(f^*(\mathscr{F}), f^*(\mathscr{G})\big), \tag{12.3.4.1}$$

which in degree 0 reduces to the canonical homomorphism ($\mathbf{0_I}$, 4.4.6).

(ii) *There is a canonical morphism of spectral sequences*

$$E(\mathscr{F}, \mathscr{G}) \longrightarrow E\big(f^*(\mathscr{F}), f^*(\mathscr{G})\big), \tag{12.3.4.2}$$

whose map on E_2-terms is given by the homomorphisms

$$\mathrm{H}^p\big(Y, \mathscr{E}xt^q_{\mathscr{O}_Y}(\mathscr{F}, \mathscr{G})\big) \longrightarrow \mathrm{H}^p\big(X, \mathscr{E}xt^q_{\mathscr{O}_X}(f^*(\mathscr{F}), f^*(\mathscr{G}))\big), \tag{12.3.4.3}$$

deduced from (12.3.4.1) and (12.1.3.1).

Proof. (i) Since f^* is exact on the category of $\mathscr{O}_Y$-modules ($\mathbf{0_I}$, 6.7.2), the functors

$$\mathscr{G} \longmapsto f^*\big(\mathscr{H}om_{\mathscr{O}_Y}(\mathscr{F},\mathscr{G})\big), \qquad \mathscr{G} \longmapsto \mathscr{H}om_{\mathscr{O}_X}\big(f^*(\mathscr{F}), f^*(\mathscr{G})\big)$$

are left exact. The canonical homomorphism ($\mathbf{0_I}$, 4.4.6) therefore canonically induces a homomorphism between their derived functors.

To compute these derived functors, take an injective resolution $\mathscr{L}^\bullet = (\mathscr{L}^i)$ of $\mathscr{G}$. One then has homomorphisms

$$\mathscr{H}^p\big(f^*\big(\mathscr{H}om_{\mathscr{O}_Y}(\mathscr{F},\mathscr{L}^\bullet)\big)\big) \longrightarrow \mathscr{H}^p\big(\mathscr{H}om_{\mathscr{O}_X}(f^*(\mathscr{F}), f^*(\mathscr{L}^\bullet))\big)$$

between the cohomology sheaves of complexes. By the exactness of f^*, the first member is

$$f^*\big(\mathscr{E}xt^p_{\mathscr{O}_Y}(\mathscr{F},\mathscr{G})\big).$$

The exactness of f^* also implies that $f^*(\mathscr{L}^\bullet)$ is a resolution of $f^*(\mathscr{G})$. If $\mathscr{L}'^\bullet = (\mathscr{L}'^i)$ is an injective resolution of $f^*(\mathscr{G})$ in the category of $\mathscr{O}_X$-modules, there is a homomorphism of complexes

$$f^*(\mathscr{L}^\bullet) \longrightarrow \mathscr{L}'^\bullet,$$

determined up to homotopy, and hence a well-defined homomorphism on cohomology. Its composite with the preceding homomorphism is (12.3.4.1).

(ii) With the preceding notation, there is a homomorphism of complexes of $\mathscr{O}_X$-modules

$$f^*\big(\mathscr{H}om_{\mathscr{O}_Y}(\mathscr{F},\mathscr{L}^\bullet)\big) \longrightarrow \mathscr{H}om_{\mathscr{O}_X}\big(f^*(\mathscr{F}),\mathscr{L}'^\bullet\big).$$

Let $\mathscr{M}^{\bullet\bullet}$ be a Cartan–Eilenberg injective resolution of $\mathscr{H}om_{\mathscr{O}_Y}(\mathscr{F},\mathscr{L}^\bullet)$ in the category of $\mathscr{O}_Y$-modules. Since f^* is exact, $f^*(\mathscr{M}^{\bullet\bullet})$ is a Cartan–Eilenberg resolution of $f^*(\mathscr{H}om_{\mathscr{O}_Y}(\mathscr{F},\mathscr{L}^\bullet))$. If $\mathscr{M}'^{\bullet\bullet}$ is a Cartan–Eilenberg injective resolution of $\mathscr{H}om_{\mathscr{O}_X}(f^*(\mathscr{F}),\mathscr{L}'^\bullet)$, there is (11.4.2) a homomorphism, determined up to homotopy,

$$f^*(\mathscr{M}^{\bullet\bullet}) \longrightarrow \mathscr{M}'^{\bullet\bullet},$$

compatible with the preceding homomorphism; in other words, there is an f-morphism $\mathscr{M}^{\bullet\bullet} \to \mathscr{M}'^{\bullet\bullet}$ of bicomplexes of sheaves. It induces a di-homomorphism

$$\Gamma(Y,\mathscr{M}^{\bullet\bullet}) \longrightarrow \Gamma(X,\mathscr{M}'^{\bullet\bullet})$$

of bicomplexes of modules, determined up to homotopy, and therefore a well-defined morphism of spectral sequences (11.3.2). This is precisely the desired morphism (12.3.4.2), and the description (12.3.4.3) follows immediately from the definitions.

□

Proposition (12.3.5). — *Under the hypotheses of* (12.3.4), *suppose in addition that the sheaf of rings $\mathscr{O}_Y$ is coherent. Then, for every coherent $\mathscr{O}_Y$-module $\mathscr{F}$, the canonical homomorphisms* (12.3.4.1) *are bijective.*

Proof. Since the question is local on Y, we may suppose that there is an exact sequence $\mathbf{0_{III}}$ | 62

$$0 \longrightarrow \mathscr{R} \longrightarrow \mathscr{O}_Y^n \longrightarrow \mathscr{F} \longrightarrow 0.$$

Then $\mathscr{R}$ is also a coherent $\mathscr{O}_Y$-module ($\mathbf{0_I}$, 5.3.4). To prove that the homomorphisms

$$f^*\big(\mathscr{E}xt^p_{\mathscr{O}_Y}(\mathscr{F},\mathscr{G})\big) \longrightarrow \mathscr{E}xt^p_{\mathscr{O}_X}\big(f^*(\mathscr{F}), f^*(\mathscr{G})\big)$$

are bijective, we argue by induction on p. For $p = 0$, the assertion is ($\mathbf{0_I}$, 6.7.6.1). There is a commutative diagram with exact rows

$$\begin{tikzcd}
f^*\big(\mathscr{E}xt^{p-1}_{\mathscr{O}_Y}(\mathscr{O}_Y^n,\mathscr{G})\big) \arrow[r] \arrow[d] & f^*\big(\mathscr{E}xt^{p-1}_{\mathscr{O}_Y}(\mathscr{R},\mathscr{G})\big) \arrow[r, "\partial"] \arrow[d] & f^*\big(\mathscr{E}xt^{p}_{\mathscr{O}_Y}(\mathscr{F},\mathscr{G})\big) \arrow[r] \arrow[d] & f^*\big(\mathscr{E}xt^{p}_{\mathscr{O}_Y}(\mathscr{O}_Y^n,\mathscr{G})\big) \arrow[d] \\
\mathscr{E}xt^{p-1}_{\mathscr{O}_X}(\mathscr{O}_X^n, f^*(\mathscr{G})) \arrow[r] & \mathscr{E}xt^{p-1}_{\mathscr{O}_X}(f^*(\mathscr{R}), f^*(\mathscr{G})) \arrow[r, "\partial"] & \mathscr{E}xt^{p}_{\mathscr{O}_X}(f^*(\mathscr{F}), f^*(\mathscr{G})) \arrow[r] & \mathscr{E}xt^{p}_{\mathscr{O}_X}(\mathscr{O}_X^n, f^*(\mathscr{G})).
\end{tikzcd}$$

Here we have used $f^*(\mathscr{O}_Y) = \mathscr{O}_X$; since f^* is exact, both rows are exact. Moreover,

$$\mathscr{E}xt^p_{\mathscr{O}_Y}(\mathscr{O}_Y^n,\mathscr{G}) = 0, \qquad \mathscr{E}xt^p_{\mathscr{O}_X}(\mathscr{O}_X^n, f^*(\mathscr{G})) = 0 \qquad (p > 0)$$

(T, 4.2.3). By the induction hypothesis, the first two vertical arrows in the preceding diagram are isomorphisms, while the right-hand terms are zero. It follows that

$$f^*\big(\mathscr{E}xt^p_{\mathscr{O}_Y}(\mathscr{F},\mathscr{G})\big) \longrightarrow \mathscr{E}xt^p_{\mathscr{O}_X}\big(f^*(\mathscr{F}),f^*(\mathscr{G})\big)$$

is an isomorphism. □

12.4. Hypercohomology of the direct image functor

(12.4.1). Let $(X,\mathscr{O}_X)$ and $(Y,\mathscr{O}_Y)$ be two ringed spaces, and let $f : X \longrightarrow Y$ be a morphism of ringed spaces. One can form the hypercohomology of f_* with respect to an arbitrary complex of $\mathscr{O}_X$-modules $\mathscr{K}^\bullet = (\mathscr{K}^i)_{i\in\mathbf{Z}}$ (11.4.4), since filtered inductive limits exist and are exact in the abelian category of $\mathscr{O}_Y$-modules (T, 3.1.1). The $\mathscr{O}_Y$-modules of hypercohomology $\mathrm{R}^p f_*(\mathscr{K}^\bullet)$ will also be denoted $\mathscr{H}^p(f,\mathscr{K}^\bullet)$, or simply $\mathscr{H}^p_f(\mathscr{K}^\bullet)$. Recall that $\mathscr{H}^\bullet(f,\mathscr{K}^\bullet)$ is the cohomology of the bicomplex of $\mathscr{O}_Y$-modules $f_*(\mathscr{L}^{\bullet\bullet})$, where $\mathscr{L}^{\bullet\bullet}$ is a Cartan–Eilenberg injective resolution of $\mathscr{K}^\bullet$ in the category of $\mathscr{O}_X$-modules. It is the abutment of two spectral sequences whose E_2-terms are given by

$$'E_2^{pq} = \mathscr{H}^p\big(\mathscr{H}^q(f,\mathscr{K}^\bullet)\big) \tag{12.4.1.1}$$

and

$$''E_2^{pq} = \mathscr{H}^p\big(f,\mathscr{H}^q(\mathscr{K}^\bullet)\big) \quad \big(= \mathrm{R}^p f_*(\mathscr{H}^q(\mathscr{K}^\bullet))\big). \tag{12.4.1.2}$$

In these formulas we have adopted the general notation $T(A^\bullet)$ for the transform of a complex by a functor (11.2.1), and, for an $\mathscr{O}_X$-module $\mathscr{F}$, we write $\mathscr{H}^p(f,\mathscr{F})$ in place of $\mathrm{R}^p f_*(\mathscr{F})$. Recall also that the first spectral sequence is always regular. Both spectral sequences are biregular when $\mathscr{K}^\bullet$ is bounded below, or when there is an integer m such that every $\mathscr{O}_X$-module admits a flasque resolution of length $\leqslant m$ (11.4.4). $\mathbf{0}_{\mathbf{III}}$ | 63

(12.4.2). We shall similarly denote by $\mathbf{H}^\bullet(X,\mathscr{K}^\bullet)$ the hypercohomology of the functor Γ with respect to a complex $\mathscr{K}^\bullet$ of $\mathscr{O}_X$-modules. Thus the $\mathbf{H}^p(X,\mathscr{K}^\bullet)$ are $\Gamma(X,\mathscr{O}_X)$-modules. Moreover, $\mathbf{H}^\bullet(X,\mathscr{K}^\bullet)$ may be regarded as a special case of $\mathscr{H}^\bullet(f,\mathscr{K}^\bullet)$, where f is a morphism from $(X,\mathscr{O}_X)$ to a ringed space consisting of one point equipped with the ring $\Gamma(X,\mathscr{O}_X)$.

For every open subset V of X, we shall write $\mathbf{H}^\bullet(V,\mathscr{K}^\bullet)$ in place of $\mathbf{H}^\bullet(V,\mathscr{K}^\bullet|V)$.

Proposition (12.4.3). — *For every integer $p\in\mathbf{Z}$, the $\mathscr{O}_Y$-module $\mathscr{H}^p(f,\mathscr{K}^\bullet)$ is canonically isomorphic to the sheaf associated with the presheaf*

$$U \longmapsto \mathbf{H}^p\big(f^{-1}(U),\mathscr{K}^\bullet\big)$$

on Y.

Proof. With the notation of (12.4.1), the cohomology sheaf $\mathscr{H}^p(f_*(\mathscr{L}^{\bullet\bullet}))$ is associated with the presheaf

$$U \longmapsto \mathrm{H}^p\big(\Gamma(U,f_*(\mathscr{L}^{\bullet\bullet}))\big) = \mathrm{H}^p\big(\Gamma(f^{-1}(U),\mathscr{L}^{\bullet\bullet})\big).$$

But it is clear that $\mathscr{L}^{\bullet\bullet}|f^{-1}(U)$ is a Cartan–Eilenberg injective resolution of $\mathscr{K}^\bullet|f^{-1}(U)$ (T, 3.1.3). Consequently,

$$\mathrm{H}^p\big(\Gamma(f^{-1}(U),\mathscr{L}^{\bullet\bullet})\big) = \mathbf{H}^p\big(f^{-1}(U),\mathscr{K}^\bullet\big)$$

by definition. □

Proposition (12.4.4). — *The hypercohomology $\mathscr{H}^\bullet(f,\mathscr{K}^\bullet)$ is a cohomological functor of $\mathscr{K}^\bullet$ in each of the following cases:*

a) *$\mathscr{K}^\bullet$ varies in the category of bounded below complexes;*
b) *there is an integer m such that every $\mathscr{O}_X$-module admits a flasque resolution of length $\leqslant m$;*
c) *X is a Noetherian space.*

Proof. Cases a) and b) are special cases of (11.5.4). Case c), on the other hand, follows from (11.5.2), since in this case the functor f_* commutes with inductive limits (G, II, 3.10.1). □

(12.4.5). Let $\mathfrak{U} = (U_\alpha)$ now be an open covering of X. For every complex of *presheaves* $\mathscr{K}^\bullet = (\mathscr{K}^j)$ on X, consider the bicomplex $\check{C}^\bullet(\mathfrak{U}, \mathscr{K}^\bullet)$ whose component of bidegree (i,j) is $\check{C}^i(\mathfrak{U}, \mathscr{K}^j)$, the group of alternating i-cochains of the nerve of $\mathfrak{U}$ with values in $\mathscr{K}^j$ (G, II, 5.1). We call the cohomology of this bicomplex the *hypercohomology of the covering* $\mathfrak{U}$ *with coefficients in* $\mathscr{K}^\bullet$, and denote it by

$$\mathbf{H}^\bullet(\mathfrak{U}, \mathscr{K}^\bullet) = \mathrm{H}^\bullet(\check{C}^\bullet(\mathfrak{U}, \mathscr{K}^\bullet)).$$

The Leray spectral sequence of a covering (T, 3.8.1 and G, II, 5.9.1) generalizes to hypercohomology as follows.

Proposition (12.4.6). — *Let $\mathscr{K}^\bullet = (\mathscr{K}^i)$ be a complex of $\mathscr{O}_X$-modules. There is a regular spectral functor of $\mathscr{K}^\bullet$ with abutment $\mathbf{H}^\bullet(X, \mathscr{K}^\bullet)$ and E_2-term*

$$E_2^{pq} = \check{\mathrm{H}}^p(\mathfrak{U}, h^q(\mathscr{K}^\bullet)), \tag{12.4.6.1}$$

where $h^q(\mathscr{K}^\bullet)$ denotes the presheaf complex

$$V \longmapsto \mathrm{H}^q(V, \mathscr{K}^\bullet)$$

on X. This spectral sequence is biregular if $\mathscr{K}^\bullet$ is bounded below.

Proof. Let $\mathscr{L}^{\bullet\bullet}$ be a Cartan–Eilenberg injective resolution of $\mathscr{K}^\bullet$, and consider the tricomplex

$$\check{C}^\bullet(\mathfrak{U}, \mathscr{L}^{\bullet\bullet}) = (\check{C}^i(\mathfrak{U}, \mathscr{L}^{jk})).$$

First regard this tricomplex as a bicomplex in the degrees i and $j+k$. Since i takes only nonnegative values, the second spectral sequence of this bicomplex is regular (11.3.3) and degenerate, because

$$\check{\mathrm{H}}^q(\mathfrak{U}, \mathscr{L}^{jk}) = 0 \qquad (q > 0),$$

the $\mathscr{O}_X$-modules $\mathscr{L}^{jk}$ being flasque sheaves (G, II, 5.2.3). It follows that there is a canonical isomorphism **0**$_{\mathbf{III}}$ | 64

$$\mathrm{H}^n(\check{C}^\bullet(\mathfrak{U}, \mathscr{L}^{\bullet\bullet})) \simeq \mathrm{H}^n(\Gamma(X, \mathscr{L}^{\bullet\bullet}))$$

(11.1.6), by virtue of (G, II, 5.2.2), and therefore, by definition (12.4.2), an isomorphism

$$\mathrm{H}^n(\check{C}^\bullet(\mathfrak{U}, \mathscr{L}^{\bullet\bullet})) \simeq \mathbf{H}^n(X, \mathscr{K}^\bullet).$$

Now regard $\check{C}^\bullet(\mathfrak{U}, \mathscr{L}^{\bullet\bullet})$ as a bicomplex in the degrees $i+j$ and k. Since k takes only nonnegative values, the first spectral sequence of this bicomplex is always regular. It is biregular if $\mathscr{L}^{jk} = 0$ for $j < j_0$, that is, when $\mathscr{K}^\bullet$ is bounded below (11.3.3). This is the desired spectral sequence. Indeed, for every j, $\mathscr{L}^{j,\bullet}$ is an injective resolution of $\mathscr{K}^j$; consequently, as i varies,

$$\mathrm{H}^q(\check{C}^i(\mathfrak{U}, \mathscr{L}^{j,\bullet}))$$

is precisely the cochain complex $\check{C}^i(\mathfrak{U}, h^q(\mathscr{K}^j))$. This proves the proposition. □

Corollary (12.4.7). — *If, for every simplex σ of the nerve of $\mathfrak{U}$ and every integer i, one has*

$$\mathrm{H}^q(U_\sigma, \mathscr{K}^i) = 0 \qquad (q > 0),$$

then there is a canonical isomorphism

$$\mathbf{H}^\bullet(\mathfrak{U}, \mathscr{K}^\bullet) \simeq \mathbf{H}^\bullet(X, \mathscr{K}^\bullet). \tag{12.4.7.1}$$

Proof. The hypothesis implies that $\check{C}^\bullet(\mathfrak{U}, h^q(\mathscr{K}^j)) = 0$ for $q > 0$, and hence that $E_2^{pq} = 0$ for $q > 0$. Since the spectral sequence (12.4.6.1) is degenerate and regular, the conclusion follows from the definition (12.4.5) of $\mathbf{H}^\bullet(\mathfrak{U}, \mathscr{K}^\bullet)$ and from (11.1.6). □

(12.4.8). Let $(X', \mathscr{O}_{X'})$ be a second ringed space, and let $f = (\psi, \theta)$ be a morphism from X' to X. By the same method as in (12.1.3) and (12.1.4), one defines a di-homomorphism for the hypercohomology of a complex $\mathscr{K}^\bullet$ of $\mathscr{O}_X$-modules:

$$\mathbf{H}^p(X, \mathscr{K}^\bullet) \longrightarrow \mathbf{H}^p(X', f^*(\mathscr{K}^\bullet)). \tag{12.4.8.1}$$

Starting with a Cartan–Eilenberg injective resolution $\mathscr{L}^{\bullet\bullet}$ of $\mathscr{K}^\bullet$, observe that, since ψ^* is exact, $\psi^*(\mathscr{L}^{\bullet\bullet})$ is a Cartan–Eilenberg resolution of $\psi^*(\mathscr{K}^\bullet)$ in the category of $\psi^*(\mathscr{O}_X)$-modules. There is therefore a morphism

$$\psi^*(\mathscr{L}^{\bullet\bullet}) \longrightarrow \mathscr{L}'^{\bullet\bullet},$$

where $\mathscr{L}'^{\bullet\bullet}$ is a Cartan–Eilenberg injective resolution of $\psi^*(\mathscr{K}^\bullet)$. It induces a morphism in cohomology

$$\mathbf{H}^\bullet(X, \mathscr{K}^\bullet) \longrightarrow \mathbf{H}^\bullet(X', \psi^*(\mathscr{K}^\bullet)).$$

Composing it with the morphism induced by functoriality from $\psi^*(\mathscr{K}^\bullet) \longrightarrow f^*(\mathscr{K}^\bullet)$ gives the desired morphism (12.4.8.1).

Starting with (12.4.8.1) and (12.4.3), and arguing as in (12.2.5), one can then define, for two morphisms of ringed spaces

$$f : X \longrightarrow Y, \qquad g : Y \longrightarrow Z,$$

with $h = g \circ f$, homomorphisms for the hypercohomology of a complex $\mathscr{K}^\bullet$ of $\mathscr{O}_X$-modules:

(12.4.8.2) $$\mathscr{H}^n(g, f_*(\mathscr{K}^\bullet)) \longrightarrow \mathscr{H}^n(h, \mathscr{K}^\bullet),$$

and

(12.4.8.3) $$\mathscr{H}^n(h, \mathscr{K}^\bullet) \longrightarrow g_*\big(\mathscr{H}^n(f, \mathscr{K}^\bullet)\big).$$

We leave the details of the definitions to the reader.

§13. Projective limits in homological algebra

13.1. The Mittag-Leffler condition

(13.1.1). Let $\mathtt{C}$ be an abelian category in which infinite products exist (axiom AB 3* of T, 1.5). Then the infimum of a family of subobjects of an object of $\mathtt{C}$ exists, and every projective system of objects of $\mathtt{C}$ has a projective limit; the latter is a left exact functor of the projective system in question (T, 1.8). Let $(A_\alpha, f_{\alpha\beta})$ be a projective system of objects of $\mathtt{C}$ whose index set I is filtered to the right. Put **0**$_{\mathbf{III}}$ | 65

$$A = \varprojlim A_\alpha,$$

and, for each $\alpha \in$ I, let $f_\alpha : A \longrightarrow A_\alpha$ be the canonical morphism. For every $\alpha \in$ I, the subobjects $f_{\alpha\beta}(A_\beta)$, for $\alpha \leqslant \beta$, form a decreasing filtered family of subobjects of A_α. The subobject

$$A'_\alpha = \inf_{\beta \geqslant \alpha} f_{\alpha\beta}(A_\beta)$$

is called the subobject of *universal images* in A_α. It is clear that

$$f_\alpha(A) \subset A'_\alpha, \qquad f_{\alpha\beta}(A'_\beta) \subset A'_\alpha \quad (\alpha \leqslant \beta).$$

Thus $(A'_\alpha, f_{\alpha\beta}|A'_\beta)$ is a projective system and

$$A = \varprojlim A'_\alpha.$$

(13.1.2). For a projective system $(A_\alpha, f_{\alpha\beta})$ in $\mathtt{C}$, the following is called the *Mittag-Leffler condition*:

(ML) *For every index α, there is a $\beta \geqslant \alpha$ such that, for every $\gamma \geqslant \beta$,*

$$f_{\alpha\gamma}(A_\gamma) = f_{\alpha\beta}(A_\beta).$$

It is clear that condition (ML) holds if all the $f_{\alpha\beta}$ are epimorphisms. Conversely, suppose that (ML) holds, and for each $\alpha \in$ I let A'_α be the subobject of universal images in A_α. Then, for $\alpha \leqslant \beta$, the restriction of $f_{\alpha\beta}$ to A'_β is an *epimorphism*

$$A'_\beta \longrightarrow A'_\alpha.$$

Indeed, choose $\gamma \geqslant \beta$ such that

$$f_{\beta\delta}(A_\delta) = f_{\beta\gamma}(A_\gamma) \qquad (\delta \geqslant \gamma).$$

Then $A'_\beta = f_{\beta\gamma}(A_\gamma)$, and therefore

$$f_{\alpha\beta}(A'_\beta) = f_{\alpha\gamma}(A_\gamma), \qquad A'_\alpha = f_{\alpha\gamma}(A_\gamma) = f_{\alpha\beta}(A'_\beta).$$

Condition (ML) also holds when the objects A_α are *Artinian* in $\mathtt{C}$, that is, when every family of subobjects of A_α has a minimal member. Indeed, a minimal member of the decreasing filtered family $\big(f_{\alpha\beta}(A_\beta)\big)$ of subobjects of A_α is necessarily the smallest of those subobjects.

(13.1.3). *Remark* (13.1.3). Condition (ML) can also be formulated when $\mathtt{C}$ is, for example, the category of sets. One can again define the subset of universal images in A_α, and the observations made in (13.1.1) and (13.1.2) remain valid.

13.2. The Mittag-Leffler condition for abelian groups

Proposition (13.2.1). — *Let*

$$0 \longrightarrow A_\alpha \xrightarrow{u_\alpha} B_\alpha \xrightarrow{v_\alpha} C_\alpha \longrightarrow 0$$

be an exact sequence of projective systems of abelian groups, relative to the same filtered index set I.

(i) *If* (B_α) *satisfies* (ML), *then so does* (C_α).
(ii) *If* (A_α) *and* (C_α) *satisfy* (ML), *then so does* (B_α).

Proof. Let $(f_{\alpha\beta})$, $(g_{\alpha\beta})$, and $(h_{\alpha\beta})$ be the systems of homomorphisms defining (A_α), (B_α), and (C_α), respectively.

(i) Suppose that

$$g_{\alpha\beta}(B_\beta) = g_{\alpha\lambda}(B_\lambda) \qquad (\lambda \geqslant \beta).$$

Since v_β and v_λ are surjective,

$$h_{\alpha\beta}(C_\beta) = v_\alpha\big(g_{\alpha\beta}(B_\beta)\big) = v_\alpha\big(g_{\alpha\lambda}(B_\lambda)\big) = h_{\alpha\lambda}(C_\lambda)$$

for $\lambda \geqslant \beta$.

(ii) Let $\alpha \in \mathrm{I}$. Choose $\beta \geqslant \alpha$ such that

$$f_{\alpha\beta}(A_\beta) = f_{\alpha\lambda}(A_\lambda) \qquad (\lambda \geqslant \beta),$$

and then choose $\gamma \geqslant \beta$ such that

$$h_{\beta\gamma}(C_\gamma) = h_{\beta\lambda}(C_\lambda) \qquad (\lambda \geqslant \gamma).$$

Let $y_\alpha \in g_{\alpha\gamma}(B_\gamma)$, write $y_\alpha = g_{\alpha\gamma}(y_\gamma)$ with $y_\gamma \in B_\gamma$, and put $y_\beta = g_{\beta\gamma}(y_\gamma)$. Then

$$v_\beta(y_\beta) = h_{\beta\gamma}\big(v_\gamma(y_\gamma)\big).$$

For every $\lambda \geqslant \gamma$, there is, by hypothesis, a $y_\lambda \in B_\lambda$ such that

$$h_{\beta\gamma}\big(v_\gamma(y_\gamma)\big) = h_{\beta\lambda}\big(v_\lambda(y_\lambda)\big).$$

Hence $v_\beta(y_\beta - g_{\beta\lambda}(y_\lambda)) = 0$, and therefore there is an $x_\beta \in A_\beta$ such that $\mathbf{0}_{\mathrm{III}}$ | 66

$$y_\beta = g_{\beta\lambda}(y_\lambda) + u_\beta(x_\beta).$$

It follows that

$$y_\alpha = g_{\alpha\lambda}(y_\lambda) + u_\alpha\big(f_{\alpha\beta}(x_\beta)\big).$$

Since $\lambda \geqslant \beta$, there is an $x_\lambda \in A_\lambda$ such that

$$f_{\alpha\beta}(x_\beta) = f_{\alpha\lambda}(x_\lambda).$$

Consequently,

$$y_\alpha = g_{\alpha\lambda}\big(y_\lambda + u_\lambda(x_\lambda)\big) \in g_{\alpha\lambda}(B_\lambda),$$

which proves the assertion. □

Proposition (13.2.2). — *Let* I *be a filtered ordered set having a countable cofinal subset, and let*

$$0 \longrightarrow A_\alpha \xrightarrow{u_\alpha} B_\alpha \xrightarrow{v_\alpha} C_\alpha \longrightarrow 0$$

be an exact sequence of projective systems of abelian groups indexed by I. *If* (A_α) *satisfies* (ML), *then the sequence*

$$0 \longrightarrow \varprojlim A_\alpha \longrightarrow \varprojlim B_\alpha \longrightarrow \varprojlim C_\alpha \longrightarrow 0$$

is exact.

Proof. It remains only to prove that the homomorphism

$$v = \varprojlim v_\alpha : \varprojlim B_\alpha \longrightarrow \varprojlim C_\alpha$$

is surjective. Let $z = (z_\alpha) \in \varprojlim C_\alpha$, and put

$$E_\alpha = v_\alpha^{-1}(z_\alpha).$$

The E_α plainly form a projective system of nonempty sets under the restrictions of the homomorphisms $g_{\alpha\beta} : B_\beta \longrightarrow B_\alpha$.

We show that this projective system satisfies (ML). Identifying A_α with a subgroup of B_α by means of u_α, choose, for every $\alpha \in \mathrm{I}$, an index $\beta \geqslant \alpha$ such that

$$g_{\alpha\beta}(A_\beta) = g_{\alpha\lambda}(A_\lambda) \qquad (\lambda \geqslant \beta).$$

We claim that also

$$g_{\alpha\beta}(E_\beta) = g_{\alpha\lambda}(E_\lambda) \qquad (\lambda \geqslant \beta).$$

Indeed, take $y_\lambda \in E_\lambda$ and set

$$y_\beta = g_{\beta\lambda}(y_\lambda), \qquad y_\alpha = g_{\alpha\lambda}(y_\lambda).$$

Let $y'_\alpha = g_{\alpha\beta}(y'_\beta)$ for some $y'_\beta \in E_\beta$. Then $y'_\beta - y_\beta = x_\beta \in A_\beta$, and by hypothesis there is an $x_\lambda \in A_\lambda$ such that

$$g_{\alpha\beta}(x_\beta) = g_{\alpha\lambda}(x_\lambda).$$

Thus

$$y'_\alpha = g_{\alpha\beta}(y_\beta) + g_{\alpha\beta}(x_\beta) = g_{\alpha\lambda}(y_\lambda + x_\lambda) \in g_{\alpha\lambda}(E_\lambda),$$

which proves the claim.

It is known (Bourbaki, *Top. gén.*, chap. II, §3, th. 1) that, under the hypotheses imposed on I, a projective system of nonempty sets satisfying (ML) has a nonempty projective limit. There is therefore a point $y = (y_\alpha) \in \varprojlim E_\alpha$. Since $v_\alpha(y_\alpha) = z_\alpha$ for every α, one has $z = v(y)$. □

Proposition (13.2.3). — *Under the hypotheses on* I *of (13.2.2), let* $(\mathrm{K}^\bullet_\alpha)_{\alpha\in\mathrm{I}}$ *be a projective system of complexes of abelian groups*

$$\mathrm{K}^\bullet_\alpha = (\mathrm{K}^n_\alpha)_{n\in\mathbf{Z}},$$

whose differentials have degree $+1$. *For every* n, *there is a canonical functorial homomorphism*

$$h_n : \mathrm{H}^n\big(\varprojlim \mathrm{K}^\bullet_\alpha\big) \longrightarrow \varprojlim \mathrm{H}^n(\mathrm{K}^\bullet_\alpha). \tag{13.2.3.1}$$

If, for every degree n, *the projective system of abelian groups* $(\mathrm{K}^n_\alpha)_{\alpha\in\mathrm{I}}$ *satisfies* (ML), *then every* h_n *is surjective. If, in addition, the projective system* $(\mathrm{H}^{n-1}(\mathrm{K}^\bullet_\alpha))_{\alpha\in\mathrm{I}}$ *satisfies* (ML), *then* h_n *is bijective.*

Proof. Put

$$\mathrm{K}^n = \varprojlim \mathrm{K}^n_\alpha \qquad (n \in \mathbf{Z}).$$

The homomorphisms h_n are defined by the commutative diagrams

$$\begin{array}{ccccccccc}
\cdots & \longrightarrow & \mathrm{K}^{n-1} & \longrightarrow & \mathrm{K}^n & \longrightarrow & \mathrm{K}^{n+1} & \longrightarrow & \cdots \\
 & & \downarrow & & \downarrow & & \downarrow & & \\
\cdots & \longrightarrow & \mathrm{K}^{n-1}_\alpha & \longrightarrow & \mathrm{K}^n_\alpha & \longrightarrow & \mathrm{K}^{n+1}_\alpha & \longrightarrow & \cdots,
\end{array}$$

the differentials in $\mathrm{K}^\bullet$ being the projective limits of the corresponding differentials in the $\mathrm{K}^\bullet_\alpha$. Consider the exact sequences **0_{III} | 67**

$$(*_n) \qquad 0 \longrightarrow \mathrm{B}^n(\mathrm{K}^\bullet_\alpha) \longrightarrow \mathrm{Z}^n(\mathrm{K}^\bullet_\alpha) \longrightarrow \mathrm{H}^n(\mathrm{K}^\bullet_\alpha) \longrightarrow 0$$

and

$$(**_n) \qquad 0 \longrightarrow \mathrm{Z}^{n-1}(\mathrm{K}^\bullet_\alpha) \longrightarrow \mathrm{K}^{n-1}_\alpha \longrightarrow \mathrm{B}^n(\mathrm{K}^\bullet_\alpha) \longrightarrow 0.$$

The hypothesis and Proposition (13.2.1) (i) show that the projective system $(\mathrm{B}^n(\mathrm{K}^\bullet_\alpha))_{\alpha\in\mathrm{I}}$ satisfies (ML) for every n. It follows from (13.2.2) that

$$(***_n) \qquad 0 \longrightarrow \varprojlim_\alpha \mathrm{B}^n(\mathrm{K}^\bullet_\alpha) \longrightarrow \varprojlim_\alpha \mathrm{Z}^n(\mathrm{K}^\bullet_\alpha) \longrightarrow \varprojlim_\alpha \mathrm{H}^n(\mathrm{K}^\bullet_\alpha) \longrightarrow 0$$

is exact. Now $\varprojlim_\alpha \mathrm{B}^n(\mathrm{K}^\bullet_\alpha)$ identifies with a subgroup of K^{n+1} containing $\mathrm{B}^n(\mathrm{K}^\bullet)$, while $\varprojlim_\alpha \mathrm{Z}^n(\mathrm{K}^\bullet_\alpha)$ identifies with a subgroup of $\mathrm{Z}^n(\mathrm{K}^\bullet)$. Consequently, h_n is surjective.

Suppose now, in addition, that $(\mathrm{H}^{n-1}(\mathrm{K}^\bullet_\alpha))_{\alpha\in\mathrm{I}}$ satisfies (ML). The exact sequences $(*_{n-1})$ and Proposition (13.2.1) (ii) show that $(\mathrm{Z}^{n-1}(\mathrm{K}^\bullet_\alpha))_{\alpha\in\mathrm{I}}$ satisfies (ML). Applying (13.2.2) to the exact sequences $(**_n)$ gives an exact sequence

$$0 \longrightarrow \varprojlim_\alpha \mathrm{Z}^{n-1}(\mathrm{K}^\bullet_\alpha) \longrightarrow \mathrm{K}^{n-1} \xrightarrow{u} \varprojlim_\alpha \mathrm{B}^n(\mathrm{K}^\bullet_\alpha) \longrightarrow 0.$$

Since $\varprojlim_\alpha \mathrm{B}^n(\mathrm{K}^\bullet_\alpha) \supset \mathrm{B}^n(\mathrm{K}^\bullet)$ and the composite of u with the injection

$$\varprojlim_\alpha \mathrm{B}^n(\mathrm{K}^\bullet_\alpha) \longrightarrow \mathrm{K}^n$$

is the differential $\mathrm{K}^{n-1} \longrightarrow \mathrm{K}^n$, the surjectivity of u implies

$$\varprojlim_\alpha \mathrm{B}^n(\mathrm{K}^\bullet_\alpha) = \mathrm{B}^n(\mathrm{K}^\bullet).$$

Thus h_n is injective. □

(13.2.4). *Remarks* (13.2.4).

(i) The argument of (13.2.2) (cf. Bourbaki, *loc. cit.*) shows that the conclusion of that proposition remains valid if one assumes only that the A_α can be equipped with structures of complete metrizable spaces in which translations are homeomorphisms, that the maps $f_{\alpha\beta} : A_\beta \longrightarrow A_\alpha$ defining the projective system are uniformly continuous for the metrics in question, and that (A_α) satisfies the condition

(ML′) *For every index α, there is a $\beta \geqslant \alpha$ such that, for every $\gamma \geqslant \beta$, $f_{\alpha\gamma}(A_\gamma)$ is dense in $f_{\alpha\beta}(A_\beta)$.*

This gives an analogous supplement to (13.2.3). Suppose that $\mathrm{K}^n_\alpha = 0$ for $n < 0$ and every α; that $(\mathrm{K}^n_\alpha)_{\alpha\in\mathrm{I}}$ satisfies (ML) for $n \geqslant 0$; and that $A_\alpha = \mathrm{H}^0(\mathrm{K}^\bullet_\alpha)$ can be equipped with metric-space structures having the properties just stated. Then the conclusions of (13.2.3) are unchanged for $n \geqslant 2$, and h_1 is moreover *bijective*. Indeed, the argument of (13.2.2) also shows that $(\mathrm{B}^1(\mathrm{K}^\bullet_\alpha))_{\alpha\in\mathrm{I}}$ satisfies (ML), that the sequence $(***_1)$ is exact, and finally that

$$\varprojlim_\alpha \mathrm{B}^1(\mathrm{K}^\bullet_\alpha) = \mathrm{B}^1(\mathrm{K}^\bullet).$$

This proves, among other things, the assertions of (T, 3.10.2).

(ii) One can introduce the right derived functors $\varprojlim^{(n)}$ of the functor $\varprojlim$, and obtain more complete statements than those above [Roo61].

13.3. Application: cohomology of a projective limit of sheaves

Proposition (13.3.1). — *Let X be a topological space, let $(\mathscr{F}_k)_{k\in\mathbf{N}}$ be a projective system of sheaves of abelian groups on X, and put $\mathscr{F} = \varprojlim_k \mathscr{F}_k$. Suppose that the following conditions hold:* $\mathbf{0_{III}}$ | 68

(i) *There is a basis $\mathfrak{B}$ for the topology of X such that, for every $U \in \mathfrak{B}$ and every $i \geqslant 0$, the projective system $(\mathrm{H}^i(U,\mathscr{F}_k))_{k\in\mathbf{N}}$ satisfies (ML).*

(ii) *For every $x \in X$ and every $i > 0$, one has*

$$\varinjlim_U\big(\varprojlim_k \mathrm{H}^i(U,\mathscr{F}_k)\big) = 0,$$

where U ranges over the neighbourhoods of x belonging to $\mathfrak{B}$.

(iii) *The homomorphisms $u_{hk} : \mathscr{F}_k \longrightarrow \mathscr{F}_h$ $(h \leqslant k)$ defining the projective system $(\mathscr{F}_k)$ are surjective.*

Under these conditions, for every $i > 0$, the canonical homomorphism

$$h_i : \mathrm{H}^i(X,\mathscr{F}) \longrightarrow \varprojlim_k \mathrm{H}^i(X,\mathscr{F}_k)$$

is surjective. If, moreover, for a given value of i the projective system $(\mathrm{H}^{i-1}(X,\mathscr{F}_k))_{k\in\mathbf{N}}$ satisfies (ML), then h_i is bijective.

Proof. a) We first suppose that the $\mathscr{F}_k$, as well as the kernels $\mathscr{N}_{hk}$ of the u_{hk}, are flasque; we shall then show that condition (iii) in the statement implies $\mathrm{H}^i(X, \mathscr{F}) = 0$ for $i > 0$. It suffices to prove that, for every open subset U of X and every covering $\mathfrak{U}$ of U by open subsets of U, one has

$$\check{\mathrm{H}}^i(\mathfrak{U}, \mathscr{F}) = 0 \qquad (i > 0).$$

Indeed, it then follows first that, for Čech cohomology, $\check{\mathrm{H}}^i(U, \mathscr{F}) = 0$ for every $i > 0$, and hence, by (G, II, 5.9.2) applied to the set of all open subsets of X, that $\mathrm{H}^i(X, \mathscr{F}) = 0$ for every $i > 0$.

Since the $\mathscr{F}_k$ are flasque, one has $\check{\mathrm{H}}^i(\mathfrak{U}, \mathscr{F}_k) = 0$ for every $i > 0$ (G, II, 5.2.3). For each k, consider the complex $\check{\mathrm{C}}^\bullet(\mathfrak{U}, \mathscr{F}_k)$ of alternating cochains on the nerve of the covering $\mathfrak{U}$ (G, II, 5.1); these complexes plainly form a projective system of complexes of abelian groups. Let us show that all the maps

$$\check{\mathrm{C}}^\bullet(\mathfrak{U}, \mathscr{F}_k) \longrightarrow \check{\mathrm{C}}^\bullet(\mathfrak{U}, \mathscr{F}_h) \qquad (h \leqslant k)$$

are surjective. By definition, it is enough to show that, for every open subset V of X, the map $\Gamma(V, \mathscr{F}_k) \longrightarrow \Gamma(V, \mathscr{F}_h)$ is surjective. But the sequence

$$0 \longrightarrow \mathscr{N}_{hk} \longrightarrow \mathscr{F}_k \longrightarrow \mathscr{F}_h \longrightarrow 0$$

is exact by hypothesis and therefore gives the exact cohomology sequence

$$\Gamma(V, \mathscr{F}_k) \longrightarrow \Gamma(V, \mathscr{F}_h) \longrightarrow \mathrm{H}^1(V, \mathscr{N}_{hk}) = 0,$$

since $\mathscr{N}_{hk}$ is flasque.

The projective system $(\check{\mathrm{C}}^\bullet(\mathfrak{U}, \mathscr{F}_k))_{k \in \mathbf{N}}$ therefore satisfies (ML), and the same is true of $(\check{\mathrm{H}}^i(\mathfrak{U}, \mathscr{F}_k))_{k \in \mathbf{N}}$ for every $i \geqslant 0$: for $i > 0$ this is trivial, while for $i = 0$ it follows from what precedes, since $\check{\mathrm{H}}^0(\mathfrak{U}, \mathscr{F}_k) = \Gamma(U, \mathscr{F}_k)$ (G, II, 5.2.2). We may therefore apply (13.2.3), which gives

$$\check{\mathrm{H}}^i(\mathfrak{U}, \mathscr{F}) = \varprojlim_k \check{\mathrm{H}}^i(\mathfrak{U}, \mathscr{F}_k) = 0 \qquad (i > 0).$$

b) We now pass to the general case. For each $k \in \mathbf{N}$, consider the *canonical resolution*

$$\mathscr{C}^\bullet(X, \mathscr{F}_k) = \big(\mathscr{C}^i(X, \mathscr{F}_k)\big)_{i \geqslant 0}$$

of $\mathscr{F}_k$ by flasque sheaves (G, II, 4.3). For every $i \geqslant 0$, it is clear that $(\mathscr{C}^i(X, \mathscr{F}_k))_{k \in \mathbf{N}}$ is a projective system of flasque sheaves; let us show that it satisfies the conditions of part *a)*. Indeed, if $\mathscr{N}_{hk}$ denotes **0_{III}** | 69
the kernel of u_{hk} for $h \leqslant k$, then the sequence

$$0 \longrightarrow \mathscr{N}_{hk} \longrightarrow \mathscr{F}_k \longrightarrow \mathscr{F}_h \longrightarrow 0$$

is exact by (iii), and our assertion follows from the exactness of the functor $\mathscr{A} \longmapsto \mathscr{C}^i(X, \mathscr{A})$ (G, II, 4.3).

Put

$$\mathscr{G}^i = \varprojlim_k \mathscr{C}^i(X, \mathscr{F}_k).$$

By part *a)*, one has $\mathrm{H}^j(X, \mathscr{G}^i) = 0$ for $j > 0$ and $i \geqslant 0$. We shall show that $\mathscr{G}^\bullet = (\mathscr{G}^i)_{i \geqslant 0}$ is a resolution of the sheaf $\mathscr{F}$. Since $\mathrm{H}^j(X, \mathscr{G}^i) = 0$ for $j > 0$, the cohomology $\mathrm{H}^\bullet(X, \mathscr{F})$ will then be equal to $\mathrm{H}^\bullet(\Gamma(X, \mathscr{G}^\bullet))$ (G, II, 4.7.1).

Taking the projective limit of the exact sequences

$$0 \longrightarrow \mathscr{F}_k \longrightarrow \mathscr{C}^0(X, \mathscr{F}_k) \longrightarrow \mathscr{C}^1(X, \mathscr{F}_k) \longrightarrow \cdots$$

plainly gives a complex of sheaves of abelian groups

$$0 \longrightarrow \mathscr{F} \longrightarrow \mathscr{G}^0 \longrightarrow \mathscr{G}^1 \longrightarrow \cdots.$$

To prove our assertion, it remains to establish that $\mathscr{H}^i(\mathscr{G}^\bullet) = 0$ for $i > 0$. This sheaf is generated by the presheaf

$$U \longmapsto \mathrm{H}^i\big(\Gamma(U, \mathscr{G}^\bullet)\big)$$

(G, II, 4.1). Now the complex $\Gamma(U, \mathscr{G}^\bullet)$ is the projective limit of the projective system of complexes of abelian groups

$$\big(\Gamma(U, \mathscr{C}^\bullet(X, \mathscr{F}_k))\big)_{k \in \mathbf{N}}$$

(0_{I}, 3.2.6). We saw in part *a)* that, for every $i \geqslant 0$, the maps

$$\Gamma(U, \mathscr{C}^i(X, \mathscr{F}_k)) \longrightarrow \Gamma(U, \mathscr{C}^i(X, \mathscr{F}_h)) \qquad (h \leqslant k)$$

are surjective. On the other hand,

$$\mathrm{H}^i(U, \mathscr{F}_k) = \mathrm{H}^i\big(\Gamma(U, \mathscr{C}^\bullet(X, \mathscr{F}_k))\big),$$

since the canonical resolution $\mathscr{C}^\bullet(U, \mathscr{F}_k|U)$ is induced on U by $\mathscr{C}^\bullet(X, \mathscr{F}_k)$. By hypothesis (i), for every $U \in \mathfrak{B}$ we may apply (13.2.3) to this projective system of complexes, and hence

$$\mathrm{H}^i\big(\Gamma(U, \mathscr{G}^\bullet)\big) = \varprojlim_k \mathrm{H}^i(U, \mathscr{F}_k) \qquad (i \geqslant 0).$$

Hypothesis (ii) then shows, by definition, that the sheaves $\mathscr{H}^i(\mathscr{G}^\bullet)$ vanish for $i > 0$.

Thus, for every $i \geqslant 0$,

$$\mathrm{H}^i(X, \mathscr{F}) = \mathrm{H}^i\big(\Gamma(X, \mathscr{G}^\bullet)\big), \qquad \Gamma(X, \mathscr{G}^\bullet) = \varprojlim_k \Gamma(X, \mathscr{C}^\bullet(X, \mathscr{F}_k)).$$

We have just observed that all the maps

$$\Gamma(X, \mathscr{C}^i(X, \mathscr{F}_k)) \longrightarrow \Gamma(X, \mathscr{C}^i(X, \mathscr{F}_h)) \qquad (h \leqslant k)$$

are surjective; the conclusion therefore follows once more from (13.2.3). □

(13.3.2). *Remarks* (13.3.2).

(i) The statement of (13.3.1) is of interest only for $i > 0$, since, for $i = 0$, h_i is always an isomorphism without any hypothesis (0_{I}, 3.2.6).

(ii) Conditions (i) and (ii) of (13.3.1) are satisfied, in particular, if $\mathrm{H}^i(U, \mathscr{F}_k) = 0$ for every k, every $i > 0$, and every $U \in \mathfrak{B}$, and if, for $U \in \mathfrak{B}$, the maps

$$\Gamma(U, \mathscr{F}_k) \longrightarrow \Gamma(U, \mathscr{F}_h)$$

are surjective. This is the most frequent case in which (13.3.1) is applied.

13.4. Mittag-Leffler condition and graded objects associated with projective systems

(13.4.1). Let $\mathbf{A} = (A_k, u_{kh})_{k \in \mathbf{Z}}$ be a projective system in an abelian category $\mathtt{C}$. We say that it is *bounded below* if there is a k_0 such that $A_k = 0$ for $k < k_0$. On each A_k we define a *filtration* $(\mathrm{F}^p(A_k))_{p \in \mathbf{Z}}$ by

$$\mathrm{F}^p(A_k) = \begin{cases} \mathrm{Ker}(A_k \longrightarrow A_{p-1}) & \text{for } p \leqslant k+1, \\ 0 & \text{for } p \geqslant k+1. \end{cases} \tag{13.4.1.1}$$

By hypothesis, $\mathrm{F}^{k_0}(A_k) = A_k$ and $\mathrm{F}^{k+1}(A_k) = 0$; in other words, the filtration under consideration is finite ((11.1.3)). The graded objects associated with this filtration are therefore **0**

$$\mathrm{gr}^p(A_k) = \mathrm{Ker}(A_k \longrightarrow A_{p-1}) / \mathrm{Ker}(A_k \longrightarrow A_p).$$

Consequently, $\mathrm{gr}^p(A_k)$ is isomorphic to the image under $A_k \longrightarrow A_p$ of $\mathrm{Ker}(A_k \longrightarrow A_{p-1})$. By the transitivity of the morphisms defining a projective system, one therefore has

$$\mathrm{gr}^p(A_k) = \mathrm{Ker}(A_p \longrightarrow A_{p-1}) \cap \mathrm{Im}(A_k \longrightarrow A_p). \tag{13.4.1.2}$$

But (13.4.1.1) gives $\mathrm{Ker}(A_p \longrightarrow A_{p-1}) = \mathrm{gr}^p(A_p)$, and hence

$$\mathrm{gr}^p(A_k) = \mathrm{gr}^p(A_p) \cap \mathrm{Im}(A_k \longrightarrow A_p). \tag{13.4.1.3}$$

The preceding definitions also show that, for $k \leqslant h$,

$$u_{kh}\big(\mathrm{F}^p(A_h)\big) \subset \mathrm{F}^p(A_k),$$

and consequently, for every $p \in \mathbf{Z}$, the $\mathrm{gr}^p(u_{kh})$ define a projective system $(\mathrm{gr}^p(A_k))_{k \in \mathbf{Z}}$.

(13.4.2). We say that the projective system $\mathbf{A}$ is *essentially constant* if the morphisms $A_{k+1} \longrightarrow A_k$ are isomorphisms for all sufficiently large k. We say that $\mathbf{A}$ is *strict* if the morphisms $A_i \longrightarrow A_j$ $(j \leqslant i)$ are epimorphisms.

When $\mathbf{A}$ is strict, it follows from (13.4.1.3) that, for $p \leqslant k \leqslant h$, the canonical morphism

$$\mathrm{gr}^p(A_h) \longrightarrow \mathrm{gr}^p(A_k)$$

is an isomorphism; in other words, the projective system $(\mathrm{gr}^p(A_k))_{k\in\mathbf{Z}}$ is essentially constant. The sequence of objects $\mathrm{gr}^p(A_p)$, identified for every p with $\varprojlim_k \mathrm{gr}^p(A_k)$, is then denoted $\mathrm{gr}^\bullet(\mathbf{A})$ and is called the *graded object associated with the strict projective system* $\mathbf{A} = (A_k)$.

Suppose now that the bounded-below projective system $\mathbf{A}$ satisfies (ML). By (13.1.2), the projective system $\mathbf{A}' = (A'_k)$ of "universal image" objects is strict; it is also bounded below. The graded object $\mathrm{gr}^\bullet(\mathbf{A}')$ associated with $\mathbf{A}'$ is then likewise called the graded object *associated with* $\mathbf{A}$ and is denoted $\mathrm{gr}^\bullet(\mathbf{A})$.

Proposition (13.4.3). — *Let $\mathbf{A} = (A_k)_{k\in\mathbf{Z}}$ be a bounded-below projective system in an abelian category $\mathtt{C}$. The following conditions are equivalent:*

a) $\mathbf{A}$ *satisfies (ML).*
b) *For every $p \in \mathbf{Z}$, the projective system $(\mathrm{gr}^p(A_k))_{k\in\mathbf{Z}}$ is essentially constant.*

Moreover, when these conditions hold, there is, for every $p \in \mathbf{Z}$, a canonical isomorphism

(13.4.3.1)
$$\mathrm{gr}^p(\mathbf{A}) \simeq \varprojlim_k \mathrm{gr}^p(A_k).$$

Proof. It follows at once from (13.4.1.2) that *a)* implies *b)*. The same formula, applied to the projective system $\mathbf{A}'$ in the notation of (13.4.2), gives (13.4.3.1) by definition.

For $k \leqslant h$, put
$$A_{kh} = \mathrm{Im}(A_h \longrightarrow A_k).$$
If $k \leqslant h \leqslant j$, then $A_{kj} \subset A_{kh} \subset A_k$. Equip A_{kh} with the filtration induced by $(\mathrm{F}^p(A_k))$. The transitivity of the morphisms defining $\mathbf{A}$ shows immediately that this is also the quotient filtration of $(\mathrm{F}^p(A_h))$; consequently,

(13.4.3.2)
$$\mathrm{gr}^p(A_{kh}) = \mathrm{Im}\big(\mathrm{gr}^p(A_h) \longrightarrow \mathrm{gr}^p(A_k)\big).$$

Suppose now that *b)* holds. For every $p \in \mathbf{Z}$ and every $k \geqslant p$, there is an integer $\mathrm{L}(p,k)$ such that the right-hand side of (13.4.3.2) is constant for $h \geqslant \mathrm{L}(p,k)$. Since $\mathrm{gr}^p(A_k) = 0$ for $p < k_0$, for fixed k only finitely many of the integers $\mathrm{L}(p,k)$ need be nonzero as p ranges over the integers $\leqslant k$. Let $\mathrm{L}(k) = m$ be the largest of these integers. For every $h \geqslant m$, one has $A_{kh} \subset A_{km}$, and, by the definition of m, the canonical injection $A_{kh} \longrightarrow A_{km}$ induces an isomorphism $\mathbf{0}_{\mathrm{III}}$ | 71
$$\mathrm{gr}^\bullet(A_{kh}) \xrightarrow{\sim} \mathrm{gr}^\bullet(A_{km}).$$
Since the filtrations are finite, this injection is itself bijective (Bourbaki, *Alg. comm.*, chap. III, §2, nº 8, th. 1). This proves that $\mathbf{A}$ satisfies (ML). □

(13.4.4). Suppose that the projective limit $A = \varprojlim_k A_k$ exists in $\mathtt{C}$. In the definitions of (13.4.1), one may then replace A_k by A, and the filtration thereby defined on A still satisfies

(13.4.4.1)
$$\mathrm{gr}^p(A) = \mathrm{gr}^p(A_p) \cap \mathrm{Im}(A \longrightarrow A_p).$$

Corollary (13.4.5). — *Suppose that $\mathtt{C}$ is the category of abelian groups. If the projective system $\mathbf{A}$ satisfies (ML) and $A = \varprojlim_k A_k$, then for every $p \in \mathbf{Z}$ there is a canonical isomorphism*

(13.4.5.1)
$$\mathrm{gr}^p(A) \simeq \varprojlim_k \mathrm{gr}^p(A_k).$$

Proof. Indeed,
$$\mathrm{Im}(A_k \longrightarrow A_p) = \mathrm{Im}(A \longrightarrow A_p)$$
for all sufficiently large k (Bourbaki, *Top. gén.*, chap. II, 3ᵉ éd., §3, nº 5, th. 1), and the conclusion follows from (13.4.1.3) and (13.4.4.1). □

13.5. Projective limits of spectral sequences of filtered complexes

(13.5.1). Let $\mathtt{C}$ be an abelian category and let $X^\bullet$ be a complex of objects of $\mathtt{C}$ equipped with a filtration $(\mathrm{F}^p(X^\bullet))_{p\in\mathbf{Z}}$ such that $\mathrm{F}^{p_0}(X^\bullet) = X^\bullet$ for some index p_0. For every $k \in \mathbf{Z}$, consider the complex

$$\mathrm{X}^\bullet_k = \mathrm{X}^\bullet/\mathrm{F}^{k+1}(\mathrm{X}^\bullet);$$

it is canonically equipped with the filtration consisting of

$$\mathrm{F}^p(\mathrm{X}^\bullet_k) = \mathrm{F}^p(\mathrm{X}^\bullet)/\mathrm{F}^{k+1}(\mathrm{X}^\bullet) \quad \text{for } p \leqslant k,$$

and $\mathrm{F}^p(X^\bullet_k) = 0$ for $p \geqslant k+1$. Moreover, there are canonical morphisms $X^\bullet_{k+1} \longrightarrow X^\bullet_k$, which make $\mathbf{X}^\bullet = (X^\bullet_k)_{k\in\mathbf{Z}}$ a *projective system of filtered complexes of objects of* $\mathtt{C}$. We note that this projective system is *strict* and that $X^\bullet_k = 0$ for $k < p_0$.

(13.5.2). More generally, consider a bounded-below strict projective system $\mathbf{X}^\bullet = (X^\bullet_k)_{k\in\mathbf{Z}}$ of complexes of objects of $\mathtt{C}$, and equip each $X^\bullet_k$ with the filtration defined in (13.4.1) (applied in the abelian category of bounded-below complexes of objects of $\mathtt{C}$). The morphisms $X^\bullet_k \longrightarrow X^\bullet_p$ ($p \leqslant k$) then become morphisms of *filtered* complexes with finite filtrations. The functoriality of the spectral sequences of filtered complexes ((11.2.3)) shows that the transition morphisms of $\mathbf{X}^\bullet$ induce morphisms making

$$\mathrm{E}(\mathbf{X}^\bullet) = \big(\mathrm{E}(\mathrm{X}^\bullet_k)\big)_{k\in\mathbf{Z}}$$

a *projective system of spectral sequences*.

Lemma (13.5.3). — *Suppose that the projective system $\mathbf{X}^\bullet = (X^\bullet_k)_{k\in\mathbf{Z}}$ of filtered complexes is obtained as in (13.5.2). Then:*

a) *For $r \geqslant p - p_0$, one has*
$$\mathrm{B}^{pq}_r(\mathrm{X}^\bullet_k) = \mathrm{B}^{pq}_\infty(\mathrm{X}^\bullet_k)$$
for every $k \in \mathbf{Z}$.

b) *For $k+1 \leqslant p+r$, one has*
$$\mathrm{Z}^{pq}_r(\mathrm{X}^\bullet_k) = \mathrm{Z}^{pq}_\infty(\mathrm{X}^\bullet_k).$$

c) *For $k+1 \geqslant p+r$, the morphisms*
$$\mathrm{Z}^{pq}_r(\mathrm{X}^\bullet_h) \longrightarrow \mathrm{Z}^{pq}_r(\mathrm{X}^\bullet_k) \quad \textit{and} \quad \mathrm{B}^{pq}_r(\mathrm{X}^\bullet_h) \longrightarrow \mathrm{B}^{pq}_r(\mathrm{X}^\bullet_k)$$
are isomorphisms for every $h \geqslant k$.

These three properties follow immediately from the definitions in (11.2.2), taking into account **0_{III} | 72**
that $\mathrm{F}^{p-r+1}(X^\bullet_k) = X^\bullet_k$ when $p - r < p_0$.

(13.5.4). Suppose that the hypotheses of (13.5.3) hold. Then, for fixed p, q, and r (with r finite), the projective systems

$$\big(\mathrm{Z}^{pq}_r(\mathrm{X}^\bullet_k)\big)_{k\in\mathbf{Z}'} \qquad \big(\mathrm{B}^{pq}_r(\mathrm{X}^\bullet_k)\big)_{k\in\mathbf{Z}'} \qquad \big(\mathrm{E}^{pq}_r(\mathrm{X}^\bullet_k)\big)_{k\in\mathbf{Z}}$$

are *essentially constant*; their respective projective limits will be denoted by $\mathrm{Z}^{pq}_r(\mathbf{X}^\bullet)$, $\mathrm{B}^{pq}_r(\mathbf{X}^\bullet)$, and

$$\mathrm{E}^{pq}_r(\mathbf{X}^\bullet) = \mathrm{Z}^{pq}_r(\mathbf{X}^\bullet)/\mathrm{B}^{pq}_r(\mathbf{X}^\bullet).$$

The objects $\mathrm{Z}^{pq}_r(\mathbf{X}^\bullet)$ and $\mathrm{B}^{pq}_r(\mathbf{X}^\bullet)$ identify canonically with subobjects of $\mathrm{E}^{pq}_1(\mathbf{X}^\bullet)$. The definition of the d^{pq}_r (M, XV, 1) shows that these morphisms, taken relative to the $X^\bullet_k$, are also essentially constant, and hence define morphisms

$$d^{pq}_r : \mathrm{E}^{pq}_r(\mathbf{X}^\bullet) \longrightarrow \mathrm{E}^{p+r,q-r+1}_r(\mathbf{X}^\bullet) \tag{13.5.4.1}$$

such that $d^{p+r,q-r+1}_r \circ d^{pq}_r = 0$. Moreover, there are canonical isomorphisms from $\mathrm{Ker}(d^{pq}_r)$ onto

$$\mathrm{Z}^{pq}_{r+1}(\mathbf{X}^\bullet)/\mathrm{B}^{pq}_r(\mathbf{X}^\bullet)$$

and from $\mathrm{Im}(d^{pq}_r)$ onto

$$\mathrm{B}^{p+r,q-r+1}_{r+1}(\mathbf{X}^\bullet)/\mathrm{B}^{p+r,q-r+1}_r(\mathbf{X}^\bullet).$$

Lemma (13.5.5). — *Under the hypotheses of (13.5.3), for $s \geqslant r > p - p_0$ there is a canonical monomorphism*

(13.5.5.1) $$i : \mathrm{E}_s^{pq}(\mathbf{X}^\bullet) \longrightarrow \mathrm{E}_r^{pq}(\mathbf{X}^\bullet)$$

and a canonical isomorphism

(13.5.5.2) $$j_r : \mathrm{E}_r^{pq}(\mathbf{X}^\bullet) \xrightarrow{\sim} \mathrm{E}_\infty^{pq}(X_{p+r-1}^\bullet)$$

such that the diagram

(13.5.5.3) $$\begin{tikzcd} \mathrm{E}_s^{pq}(\mathbf{X}^\bullet) \arrow[r, "j_s"] \arrow[d, "i"'] & \mathrm{E}_\infty^{pq}(X_{p+s-1}^\bullet) \arrow[d] \\ \mathrm{E}_r^{pq}(\mathbf{X}^\bullet) \arrow[r, "j_r"] & \mathrm{E}_\infty^{pq}(X_{p+r-1}^\bullet) \end{tikzcd}$$

is commutative, where the right vertical arrow is induced by the morphism $X_{p+s-1}^\bullet \longrightarrow X_{p+r-1}^\bullet$.

Proof. The existence of i follows from

$$\mathrm{B}_r^{pq}(X_k^\bullet) = \mathrm{B}_\infty^{pq}(X_k^\bullet) \qquad (r > p - p_0)$$

((13.5.3), a)). For $k + 1 \leqslant p + r$, one has

$$\mathrm{Z}_r^{pq}(X_k^\bullet) = \mathrm{Z}_\infty^{pq}(X_k^\bullet)$$

((13.5.3), b)); in particular,

$$\mathrm{Z}_r^{pq}(X_{p+r-1}^\bullet) = \mathrm{Z}_\infty^{pq}(X_{p+r-1}^\bullet).$$

On the other hand, $\mathrm{Z}_r^{pq}(X_{p+r-1}^\bullet)$ and $\mathrm{B}_r^{pq}(X_{p+r-1}^\bullet)$ identify canonically with $\mathrm{Z}_r^{pq}(\mathbf{X}^\bullet)$ and $\mathrm{B}_r^{pq}(\mathbf{X}^\bullet)$ by (13.5.3), c). This proves the existence of j_r and the commutativity of (13.5.5.3). □

Corollary (13.5.6). — *Under the hypotheses of (13.5.3), if one of the projective limits*

$$\varprojlim_r \mathrm{E}_r^{pq}(\mathbf{X}^\bullet), \qquad \varprojlim_k \mathrm{E}_\infty^{pq}(X_k^\bullet)$$

exists, then so does the other, and there is a canonical isomorphism

(13.5.6.1) $$j_\infty : \varprojlim_r \mathrm{E}_r^{pq}(\mathbf{X}^\bullet) \xrightarrow{\sim} \varprojlim_k \mathrm{E}_\infty^{pq}(X_k^\bullet).$$

Moreover, the projective system $(\mathrm{E}_r^{pq}(\mathbf{X}^\bullet))_{r\in\mathbf{Z}}$ is essentially constant ((13.4.2)) if and only if the projective system $(\mathrm{E}_\infty^{pq}(X_k^\bullet))_{k\in\mathbf{Z}}$ is essentially constant.

(13.5.7). We denote by $\mathrm{B}_\infty^{pq}(\mathbf{X}^\bullet)$ and $\mathrm{Z}_\infty^{pq}(\mathbf{X}^\bullet)$ the subobjects of $\mathrm{E}_1^{pq}(\mathbf{X}^\bullet)$ equal respectively to $\mathrm{B}_r^{pq}(\mathbf{X}^\bullet)$ for $r > p - p_0$ and to $\inf_r \mathrm{Z}_r^{pq}(\mathbf{X}^\bullet)$, when the latter exists. Thus

$$\varprojlim_r \mathrm{E}_r^{pq}(\mathbf{X}^\bullet)$$

identifies canonically with **0_{III} | 73**

$$\mathrm{E}_\infty^{pq}(\mathbf{X}^\bullet) = \mathrm{Z}_\infty^{pq}(\mathbf{X}^\bullet)/\mathrm{B}_\infty^{pq}(\mathbf{X}^\bullet).$$

We note that the objects $\mathrm{Z}_r^{pq}(\mathbf{X}^\bullet)$, $\mathrm{B}_r^{pq}(\mathbf{X}^\bullet)$, $\mathrm{E}_r^{pq}(\mathbf{X}^\bullet)$ $(1 \leqslant r \leqslant +\infty)$, and the morphisms d_r^{pq} depend *functorially* on the projective system $\mathbf{X}^\bullet$, subject to the restrictions in (13.5.5), and the morphisms defined in (13.5.5) and (13.5.6) are functorial.

13.6. Spectral sequence of a functor relative to an object equipped with a finite filtration

(13.6.1). Let $\mathtt{C}$ and $\mathtt{C}'$ be two abelian categories, and let $\mathrm{T} : \mathtt{C} \longrightarrow \mathtt{C}'$ be an additive covariant functor. Suppose that every object of $\mathtt{C}$ is isomorphic to a subobject of an injective object, so that the right derived functors $\mathrm{R}^p\mathrm{T}$ ($p \geqslant 0$) exist.

Lemma (13.6.2). — *Let A be an object of $\mathtt{C}$ equipped with a finite filtration $(\mathrm{F}^i(A))_{i\in\mathbf{Z}}$. There exists an injective resolution $X^\bullet = (X^j)_{j\geqslant 0}$ of A, equipped with a finite filtration $(\mathrm{F}^i(X^\bullet))_{i\in\mathbf{Z}}$, such that*

$$\mathrm{F}^i(A) = A \quad (\textit{respectively, } \mathrm{F}^i(A) = 0)$$

implies

$$\mathrm{F}^i(X^\bullet) = X^\bullet \quad (\textit{respectively, } \mathrm{F}^i(X^\bullet) = 0),$$

and such that, for every $i \in \mathbf{Z}$, $\mathrm{F}^i(X^\bullet)$ is an injective resolution of $\mathrm{F}^i(A)$.

Proof. Let p (respectively, $q > p$) be the largest index such that $\mathrm{F}^p(A) = A$ (respectively, the smallest index such that $\mathrm{F}^q(A) = 0$). We argue by induction on $q - p$, the lemma being immediate when $q - p = 1$. Suppose that an injective resolution $X''^\bullet$ of $A/\mathrm{F}^{q-1}(A)$ having the required properties has been constructed. Consider the exact sequence

$$0 \longrightarrow \mathrm{F}^{q-1}(A) \longrightarrow A \longrightarrow A/\mathrm{F}^{q-1}(A) \longrightarrow 0,$$

take an injective resolution $X'^\bullet$ of $\mathrm{F}^{q-1}(A)$, and then choose an injective resolution $X^\bullet$ of A so as to obtain an exact sequence

$$0 \longrightarrow X'^\bullet \longrightarrow X^\bullet \longrightarrow X''^\bullet \longrightarrow 0$$

compatible with the preceding sequence (M, V, 2.2). It is clear that $X^\bullet$ has the required properties. □

Corollary (13.6.3). — *Let B be a second object of $\mathtt{C}$, equipped with a finite filtration $(\mathrm{F}^i(B))_{i\in\mathbf{Z}}$, let s be an integer, and let $u : A \longrightarrow B$ be a morphism such that*

$$u(\mathrm{F}^i(A)) \subset \mathrm{F}^{i+s}(B)$$

for every $i \in \mathbf{Z}$. If $Y^\bullet = (Y^j)_{j\geqslant 0}$ is an injective resolution of B equipped with a filtration $(\mathrm{F}^i(Y^\bullet))_{i\in\mathbf{Z}}$ having the properties stated in (13.6.2), then there exists a morphism $v : X^\bullet \longrightarrow Y^\bullet$, compatible with u, such that

$$v(\mathrm{F}^i(X^\bullet)) \subset \mathrm{F}^{i+s}(Y^\bullet)$$

for every $i \in \mathbf{Z}$. Moreover, any two such morphisms v and v' are homotopic.

This follows immediately, by induction on $q - p$, from the preceding construction and from (M, V, 2.3).

(13.6.4). Under the hypotheses of (13.6.2), consider the complex $\mathrm{T}(X^\bullet)$ in $\mathtt{C}'$. It is filtered by the complexes $\mathrm{T}(\mathrm{F}^i(X^\bullet))$, since $\mathrm{F}^i(X^\bullet)$ is a direct summand of $X^\bullet$. It follows from (13.6.3) that the *spectral sequence* of this filtered complex depends, up to isomorphism, only on the filtered object A. Its abutment is the cohomology $\mathrm{R}^\bullet\mathrm{T}(A)$, equipped with the filtration

$$\begin{aligned} \mathrm{F}^p(\mathrm{R}^n\mathrm{T}(A)) &= \mathrm{Im}\big(\mathrm{R}^n\mathrm{T}(\mathrm{F}^p(A)) \longrightarrow \mathrm{R}^n\mathrm{T}(A)\big) \\ &= \mathrm{Ker}\big(\mathrm{R}^n\mathrm{T}(A) \longrightarrow \mathrm{R}^n\mathrm{T}(A/\mathrm{F}^p(A))\big), \end{aligned} \tag{13.6.4.1}$$

by (11.2.2), and its E_1-term is

$$\mathrm{E}_1^{pq} = \mathrm{R}^{p+q}\mathrm{T}(\mathrm{gr}^p(A)), \tag{13.6.4.2}$$

where, as usual, $\mathrm{gr}^p(A) = \mathrm{F}^p(A)/\mathrm{F}^{p+1}(A)$. It is clear from (11.2.2) that the filtration of the abutment is finite and that, for fixed p and q, the sequences $\mathbf{0_{III}}$ | 74

$$\mathrm{B}_r^{pq}(A) = \mathrm{B}_r^{pq}(\mathrm{T}(X^\bullet)) \quad \text{and} \quad \mathrm{Z}_r^{pq}(A) = \mathrm{Z}_r^{pq}(\mathrm{T}(X^\bullet))$$

are stationary. The preceding spectral sequence is therefore *biregular* ((11.1.3)). We denote it by $\mathrm{E}(A) = (\mathrm{E}_r^{pq}(A))$ and call it the *spectral sequence of the functor* T *relative to the filtered object* A.

(13.6.5). Now suppose that the hypotheses of (13.6.3) hold, and retain its notation. Since $\mathrm{F}^i(X^\bullet)$ (respectively, $\mathrm{F}^i(Y^\bullet)$) is a direct summand of $X^\bullet$ (respectively, $Y^\bullet$), one has

$$(\mathrm{T}v)\big(\mathrm{T}(\mathrm{F}^i(X^\bullet))\big) \subset \mathrm{T}(\mathrm{F}^{i+s}(Y^\bullet))$$

for every $i \in \mathbf{Z}$. The definitions in (11.2.2) then show that, for $1 \leqslant r \leqslant +\infty$, $\mathrm{T}v$ defines morphisms

$$\mathrm{B}_r^{pq}(\mathrm{T}(X^\bullet)) \longrightarrow \mathrm{B}_r^{p+s,q-s}(\mathrm{T}(Y^\bullet))$$

and

$$\mathrm{Z}_r^{pq}(\mathrm{T}(X^\bullet)) \longrightarrow \mathrm{Z}_r^{p+s,q-s}(\mathrm{T}(Y^\bullet)),$$

and hence a morphism

$$w_r : \mathrm{E}_r^{pq}(A) \longrightarrow \mathrm{E}_r^{p+s,q-s}(B).$$

Similarly, on the abutments one has morphisms

$$u_n : \mathrm{R}^n\mathrm{T}(A) \longrightarrow \mathrm{R}^n\mathrm{T}(B)$$

such that

$$u_n\big(\mathrm{F}^p(\mathrm{R}^n\mathrm{T}(A))\big) \subset \mathrm{F}^{p+s}(\mathrm{R}^n\mathrm{T}(B)).$$

The definition of the d_r^{pq} (M, XV, 1) also shows that the diagrams

$$\begin{tikzcd}
\mathrm{E}_r^{pq}(A) \arrow[r, "d_r^{pq}"] \arrow[d, "w_r"'] & \mathrm{E}_r^{p+r,q-r+1}(A) \arrow[d, "w_r"] \\
\mathrm{E}_r^{p+s,q-s}(B) \arrow[r, "d_r^{p+s,q-s}"'] & \mathrm{E}_r^{p+r+s,q-r-s+1}(B)
\end{tikzcd}$$

are commutative. It follows that there is an analogous commutative diagram for the isomorphisms α_r^{pq}, which we leave to the reader to make explicit. Finally (*loc. cit.*), one also has commutative diagrams on the abutments:

$$\begin{tikzcd}
\mathrm{E}_\infty^{pq}(A) \arrow[r, "\beta^{pq}"] \arrow[d, "w_\infty"'] & \mathrm{gr}^p(\mathrm{R}^{p+q}\mathrm{T}(A)) \arrow[d, "u_{p+q}"] \\
\mathrm{E}_\infty^{p+s,q-s}(B) \arrow[r, "\beta^{p+s,q-s}"'] & \mathrm{gr}^{p+s}(\mathrm{R}^{p+q}\mathrm{T}(B)).
\end{tikzcd}$$

(13.6.6). Suppose in particular that there is a ring S, equipped with a *filtration* $(\mathrm{F}^i(S))_{i\in\mathbf{Z}}$, and a ring homomorphism

(13.6.6.1) $$h : S \longrightarrow \mathrm{Hom}_{\mathtt{C}}(A, A)$$

such that, for every $t \in \mathrm{F}^i(S)$, **0**$_{\mathbf{III}}$ | 75

$$h_t(\mathrm{F}^j(A)) \subset \mathrm{F}^{i+j}(A)$$

for every pair i, j. For brevity, we then say that A is equipped with the structure of a *filtered S–$\mathtt{C}$-module* over the filtered ring S.

Passing to the associated graded objects, every h_t, for $t \in \mathrm{F}^i(S)$, defines a graded endomorphism $\overline{h}_t$ of $\mathrm{gr}^\bullet(A)$, homogeneous of degree i. Moreover, this endomorphism depends only on the class of t in $\mathrm{gr}^i(S)$, and one thereby obtains a homomorphism of *graded rings*

$$\overline{h} : \mathrm{gr}^\bullet(S) \longrightarrow \mathrm{Hom}_{\mathtt{C}}^\bullet(\mathrm{gr}^\bullet(A), \mathrm{gr}^\bullet(A)),$$

where the right-hand side is the ring of graded endomorphisms of $\mathrm{gr}^\bullet(A)$. We say that $\mathrm{gr}^\bullet(A)$ is equipped with the structure of a *graded* $\mathrm{gr}^\bullet(S)$–$\mathtt{C}$*-module*.

It follows from (13.6.5) that, for $1 \leqslant r \leqslant +\infty$, every $\overline{t} \in \mathrm{gr}^i(S)$ canonically defines, on the bigraded objects

$$\big(\mathrm{B}_r^{pq}(A)\big)_{(p,q)\in\mathbf{Z}\times\mathbf{Z}'} \qquad \big(\mathrm{Z}_r^{pq}(A)\big)_{(p,q)\in\mathbf{Z}\times\mathbf{Z}'}$$

and

$$\mathrm{E}_r(A) = \big(\mathrm{E}_r^{pq}(A)\big)_{(p,q)\in\mathbf{Z}\times\mathbf{Z}'}$$

bigraded endomorphisms of degree $(i, -i)$. On $\mathrm{E}_r(A)$, for finite r, this endomorphism commutes with the bigraded endomorphism defined by the d_r^{pq}. These endomorphisms satisfy the usual associativity and distributivity conditions with respect to addition in $\mathrm{gr}^\bullet(S)$ and in the bigraded objects in question. For brevity, we say that the latter are *bigraded* $\mathrm{gr}^\bullet(S)$*–*$\mathtt{C}'$*-modules*; it is immediate that the α_r^{pq} define an isomorphism for this type of structure.

For every integer n, let $\mathrm{B}_r^{(n)}(A)$ (respectively, $\mathrm{Z}_r^{(n)}(A)$ and $\mathrm{E}_r^{(n)}(A)$) denote the graded subobject of $\mathrm{B}_r^{\bullet,\bullet}(A)$ (respectively, $\mathrm{Z}_r^{\bullet,\bullet}(A)$ and $\mathrm{E}_r^{\bullet,\bullet}(A)$) consisting of the terms for which $p+q=n$ ($1 \leqslant r \leqslant +\infty$). It is immediate that these are *graded* $\mathrm{gr}^\bullet(S)$*–*$\mathtt{C}'$*-modules*.

Finally, every $\bar{t} \in \mathrm{gr}^i(S)$ defines, for every n, a graded endomorphism of degree i on the graded object $\mathrm{gr}^\bullet(\mathrm{R}^n\mathrm{T}(A))$, which thereby acquires the structure of a graded $\mathrm{gr}^\bullet(S)$–$\mathtt{C}'$-module. For $p+q=n$, the β^{pq} define an isomorphism

$$\mathrm{E}^{(n)}(A) \simeq \mathrm{gr}^\bullet(\mathrm{R}^n\mathrm{T}(A))$$

for this type of structure.

We note that, when $\mathtt{C}'$ is the category of abelian groups, the structures of an S–$\mathtt{C}'$-module (respectively, of a graded or bigraded $\mathrm{gr}^\bullet(S)$–$\mathtt{C}'$-module) are simply the usual structures of an S-module (respectively, a graded or bigraded $\mathrm{gr}^\bullet(S)$-module).

13.7. Derived functors of a projective limit of arguments

(13.7.1). Let $\mathtt{C}$ and $\mathtt{C}'$ be two abelian categories, and suppose that every object of $\mathtt{C}$ is isomorphic to a subobject of an injective object. Let

$$\mathrm{T} : \mathtt{C} \longrightarrow \mathtt{C}'$$

be an additive covariant functor. Consider a strict projective system $\mathbf{A} = (A_k)_{k\in\mathbf{Z}}$ in $\mathtt{C}$, bounded below; more precisely, suppose that $A_k = 0$ for $k < k_0$. To this system we canonically associate, on each A_k, the filtration $(\mathrm{F}^p(A_k))_{p\in\mathbf{Z}}$ given by (13.4.1.1). Since the projective system is strict, the canonical morphisms

$$\mathrm{F}^i(A_h)/\mathrm{F}^j(A_h) \longrightarrow \mathrm{F}^i(A_k)/\mathrm{F}^j(A_k) \qquad (h \geqslant k) \tag{13.7.1.1}$$

are isomorphisms for $i \leqslant j \leqslant k+1$. Recall also that $\mathrm{F}^{k_0}(A_k) = A_k$ and $\mathrm{F}^{k+1}(A_k) = 0$ for every k.

(13.7.2). For each k, construct an injective resolution $\mathrm{X}_k^\bullet = (\mathrm{X}_k^j)_{j\geqslant 0}$ of A_k having the properties of (13.6.2). The canonical morphisms $A_{k+1} \longrightarrow A_k$ allow us, by (13.6.3), to define for each k a morphism of complexes

$$\mathrm{X}_{k+1}^\bullet \longrightarrow \mathrm{X}_k^\bullet$$

compatible with the filtrations and making $\mathbf{X}^\bullet = (\mathrm{X}_k^\bullet)_{k\in\mathbf{Z}}$ a projective system of complexes. We may moreover suppose that this projective system is strict. Indeed, by (13.7.1.1), **0**$_{\mathbf{III}}$ | 76

$$A_k \simeq A_{k+1}/\mathrm{F}^{k+1}(A_{k+1}).$$

Thus, in constructing $\mathrm{X}_{k+1}^\bullet$, we may take the injective resolution of $A_{k+1}/\mathrm{F}^{k+1}(A_{k+1})$ to be *equal* to $\mathrm{X}_k^\bullet$. It then follows from (M, V, 2.3) that the morphism of complexes $\mathrm{X}_{k+1}^\bullet \longrightarrow \mathrm{X}_k^\bullet$ may be constructed so that, on passing to quotients, it induces an isomorphism

$$\mathrm{X}_{k+1}^\bullet/\mathrm{F}^{k+1}(\mathrm{X}_{k+1}^\bullet) \xrightarrow{\sim} \mathrm{X}_k^\bullet$$

respecting the filtrations; this is precisely the condition of (13.5.1).

(13.7.3). By construction, the projective system $\mathrm{T}(\mathbf{X}^\bullet)$ of complexes $\mathrm{T}(\mathrm{X}_k^\bullet)$ satisfies the hypotheses of (13.5.3). The results of (13.5.4), (13.5.5), and (13.5.6) therefore apply to the spectral sequences

$$\mathrm{E}\big(\mathrm{T}(\mathrm{X}_k^\bullet)\big) = \mathrm{E}(A_k).$$

For $1 \leqslant r \leqslant +\infty$, we write $\mathrm{E}_r^{pq}(\mathbf{A})$ in place of $\mathrm{E}_r^{pq}(\mathrm{T}(\mathbf{X}^\bullet))$ (cf. (13.5.7) when $r = +\infty$), and use the same convention for the analogous notation. In particular,

$$\mathrm{E}_1^{pq}(\mathbf{A}) = \mathrm{R}^{p+q}\mathrm{T}\big(\mathrm{gr}^p(\mathbf{A})\big), \tag{13.7.3.1}$$

by (13.6.4.2) and the fact that the projective system $(\mathrm{gr}^p(A_k))_{k\in\mathbf{Z}}$ is essentially constant. These results, together with (13.4.3), give the following proposition, first proved by Shih Weishu by a different method (unpublished).

Proposition (13.7.4). — (Shih). *Let n be an integer. The following two conditions are equivalent:*

a) *For every pair (p,q) such that $p+q=n$, the projective system $(\mathrm{E}_r^{pq}(\mathbf{A}))_{r\geqslant 2}$ is essentially constant.*
b) *The projective system*

$$\mathrm{R}^n\mathrm{T}(\mathbf{A}) = \big(\mathrm{R}^n\mathrm{T}(A_k)\big)_{k\in\mathbf{Z}}$$

satisfies (ML).

Moreover, when these conditions hold, there is a canonical isomorphism

$$\mathrm{gr}^p\big(\mathrm{R}^n\mathrm{T}(\mathbf{A})\big) \simeq \mathrm{E}_\infty^{p,n-p}(\mathbf{A}) \qquad (p\in\mathbf{Z}). \tag{13.7.4.1}$$

Proof. By (13.5.6), condition a) says precisely that, for $p+q=n$, the projective system $(\mathrm{E}_\infty^{pq}(A_k))_{k\in\mathbf{Z}}$ is essentially constant. On the other hand, $\mathrm{gr}^p(\mathrm{R}^n\mathrm{T}(A_k))$ is canonically isomorphic to $\mathrm{E}_\infty^{p,n-p}(A_k)$. It follows from (13.4.3) that a) and b) are equivalent, and (13.7.4.1) is just (13.5.6.1) in the case under consideration. □

Corollary (13.7.5). — *Let $\mathscr{F}=(\mathscr{F}_k)_{k\in\mathbf{N}}$ be a projective system of sheaves of abelian groups satisfying conditions* (i), (ii), *and* (iii) *of* (13.3.1), *and put $\mathscr{F}=\varprojlim_k \mathscr{F}_k$. Suppose that, for the functor $\mathscr{G}\longmapsto\Gamma(X,\mathscr{G})$, the projective system $(\mathrm{E}_r^{pq}(\mathscr{F}))_r$ is essentially constant whenever $p+q=n$ or $p+q=n+1$. On $\mathrm{H}^{n+1}(X,\mathscr{F})$, consider the filtration*

$$\mathrm{F}^p\big(\mathrm{H}^{n+1}(X,\mathscr{F})\big) = \mathrm{Ker}\big(\mathrm{H}^{n+1}(X,\mathscr{F}) \longrightarrow \mathrm{H}^{n+1}(X,\mathscr{F}_{p-1})\big).$$

Then there is a canonical isomorphism

$$\mathrm{gr}^p\big(\mathrm{H}^{n+1}(X,\mathscr{F})\big) \simeq \mathrm{E}_\infty^{p,n-p+1}(\mathscr{F}) \qquad (p\in\mathbf{Z}). \tag{13.7.5.1}$$

Proof. Apply (13.7.4) with $\mathtt{C}$ the category of sheaves of abelian groups on X, $\mathtt{C}'$ the category of abelian groups, and $\mathrm{T}=\Gamma$. It gives, for every $p\in\mathbf{Z}$, a canonical isomorphism **0**$_{\mathbf{III}}$ | 77

$$\mathrm{gr}^p\big(\mathrm{R}^{n+1}\Gamma(\mathscr{F})\big) \simeq \mathrm{E}_\infty^{p,n-p+1}(\mathscr{F}).$$

Moreover, by (13.7.4), the projective system $(\mathrm{H}^n(X,\mathscr{F}_k))_{k\in\mathbf{Z}}$ satisfies (ML); hence (13.3.1) gives a canonical isomorphism

$$\mathrm{H}^{n+1}(X,\mathscr{F}) \simeq \varprojlim_k \mathrm{H}^{n+1}(X,\mathscr{F}_k).$$

Since the projective system $\mathrm{R}^{n+1}\Gamma(\mathscr{F})$ satisfies (ML) by (13.7.4), there is a canonical isomorphism

$$\mathrm{gr}^p\big(\mathrm{R}^{n+1}\Gamma(\mathscr{F})\big) \simeq \varprojlim_k \mathrm{gr}^p\big(\mathrm{H}^{n+1}(X,\mathscr{F}_k)\big)$$

by (13.4.3), and a canonical isomorphism

$$\varprojlim_k \mathrm{gr}^p\big(\mathrm{H}^{n+1}(X,\mathscr{F}_k)\big) \simeq \mathrm{gr}^p\left(\varprojlim_k \mathrm{H}^{n+1}(X,\mathscr{F}_k)\right)$$

by (13.4.5). It remains only to check that the preceding isomorphism is compatible with the filtrations on its two sides. This follows immediately from the definitions and, for every p, from the commutativity of

$$\begin{tikzcd} \mathrm{H}^{n+1}(X,\mathscr{F}) \arrow[r, "\sim"] \arrow[dr] & \varprojlim_k \mathrm{H}^{n+1}(X,\mathscr{F}_k) \arrow[d] \\ & \mathrm{H}^{n+1}(X,\mathscr{F}_{p-1}). \end{tikzcd}$$

□

(13.7.6). Let S be a ring equipped with a filtration $(\mathrm{F}^i(S))_{i\in\mathbf{Z}}$ such that $\mathrm{F}^0(S)=S$ (and hence $\mathrm{gr}^i(S)=0$ for $i<0$). Suppose that each A_k, with the filtration defined in (13.7.1), is a filtered S–$\mathtt{C}$-module in the sense of (13.6.6), and that the morphisms $A_h\longrightarrow A_k$ for $k\leqslant h$ are morphisms of filtered S–$\mathtt{C}$-modules. For brevity, we then say that $\mathbf{A}$ is a *projective system of filtered S–$\mathtt{C}$-modules*.

It is immediate that, for $k\leqslant h$ and $1\leqslant r\leqslant+\infty$, the morphisms

$$\mathrm{B}_r^{pq}(A_h)\longrightarrow \mathrm{B}_r^{pq}(A_k), \qquad \mathrm{Z}_r^{pq}(A_h)\longrightarrow \mathrm{Z}_r^{pq}(A_k)$$

are morphisms of bigraded $\mathrm{gr}^\bullet(S)$–$\mathtt{C}'$-modules ((13.6.5)), and that, for finite r, the families

$$(\mathrm{Z}_r^{pq}(\mathbf{A})), \qquad (\mathrm{B}_r^{pq}(\mathbf{A})), \qquad (\mathrm{E}_r^{pq}(\mathbf{A}))$$

are bigraded $\mathrm{gr}^\bullet(S)$–$\mathtt{C}'$-modules, the first two being submodules of $(\mathrm{E}_1^{pq}(\mathbf{A}))$. We again write $\mathrm{Z}_r^{(n)}(\mathbf{A})$, $\mathrm{B}_r^{(n)}(\mathbf{A})$, and $\mathrm{E}_r^{(n)}(\mathbf{A})$ for the respective graded subobjects obtained by retaining only the terms with $p+q=n$; these are graded $\mathrm{gr}^\bullet(S)$–$\mathtt{C}'$-modules.

When the projective system $(\mathrm{E}_r^{pq}(\mathbf{A}))_r$ is essentially constant, $\mathrm{E}_\infty^{pq}(\mathbf{A})$ is likewise a bigraded $\mathrm{gr}^\bullet(S)$–$\mathtt{C}'$-module, and each $\mathrm{E}_\infty^{(n)}(\mathbf{A})$ is a graded $\mathrm{gr}^\bullet(S)$–$\mathtt{C}'$-module. Moreover, for each k, the isomorphisms

$$\beta^{p,n-p} : \mathrm{E}_\infty^{p,n-p}(A_k) \simeq \mathrm{gr}^p(\mathrm{R}^n\mathrm{T}(A_k))$$

form an isomorphism of graded $\mathrm{gr}^\bullet(S)$–$\mathtt{C}'$-modules from $\mathrm{E}_\infty^{(n)}(A_k)$ onto $\mathrm{gr}^\bullet(\mathrm{R}^n\mathrm{T}(A_k))$. Under the preceding hypotheses, the isomorphism

$$\beta^{p,n-p} : \mathrm{E}_\infty^{(n)}(\mathbf{A}) \simeq \varprojlim_k \mathrm{gr}^\bullet(\mathrm{R}^n\mathrm{T}(A_k))$$

therefore also respects these structures. The same is plainly true of the canonical isomorphism

$$\mathrm{gr}^\bullet(\mathrm{R}^n\mathrm{T}(\mathbf{A})) \simeq \varprojlim_k \mathrm{gr}^\bullet(\mathrm{R}^n\mathrm{T}(A_k));$$

consequently, the isomorphisms (13.7.4.1) form an isomorphism of graded $\mathrm{gr}^\bullet(S)$–$\mathtt{C}'$-modules.

Proposition (13.7.7). — *Let S be a Noetherian $\mathfrak{J}$-adic ring. Suppose that $\mathtt{C}$ is an abelian category in which every object is isomorphic to a subobject of an injective object, and let T be an additive covariant functor from $\mathtt{C}$ to the category of abelian groups. Let $\mathbf{A} = (A_k)_{k\in\mathbf{Z}}$ be a strict projective system of filtered S–$\mathtt{C}$-modules, for the $\mathfrak{J}$-adic filtration on S, bounded below. For a fixed integer n, suppose that the following condition holds:* $\mathbf{0_{III}}$ | 78

(F_n) The graded $\mathrm{gr}^\bullet(S)$-module

$$\mathrm{E}_1^{(m)}(\mathbf{A}) = (\mathrm{R}^m\mathrm{T}(\mathrm{gr}^p(\mathbf{A})))_{p\in\mathbf{Z}}$$

of (13.7.3.1) is of finite type for $m=n$ and $m=n+1$.

Then:

(i) *The projective systems $(\mathrm{R}^n\mathrm{T}(A_k))_{k\in\mathbf{Z}}$ and $(\mathrm{R}^{n+1}\mathrm{T}(A_k))_{k\in\mathbf{Z}}$ satisfy* (ML).

(ii) *If*

$$\mathrm{R}'^n\mathrm{T}(\mathbf{A}) = \varprojlim_k \mathrm{R}^n\mathrm{T}(A_k),$$

then $\mathrm{R}'^n\mathrm{T}(\mathbf{A})$ is an S-module of finite type.

(iii) *The filtration on $\mathrm{R}'^n\mathrm{T}(\mathbf{A})$ defined by*

$$\mathrm{F}^p(\mathrm{R}'^n\mathrm{T}(\mathbf{A})) = \mathrm{Ker}(\mathrm{R}'^n\mathrm{T}(\mathbf{A}) \longrightarrow \mathrm{R}^n\mathrm{T}(A_{p-1})) \qquad (p\in\mathbf{Z})$$

is $\mathfrak{J}$-good; that is,

$$\mathfrak{J}\,\mathrm{F}^p(\mathrm{R}'^n\mathrm{T}(\mathbf{A})) \subset \mathrm{F}^{p+1}(\mathrm{R}'^n\mathrm{T}(\mathbf{A}))$$

for every p, with equality for all sufficiently large p. In particular, the topology on $\mathrm{R}'^n\mathrm{T}(\mathbf{A})$ defined by this filtration is the $\mathfrak{J}$-adic topology.

(iv) *The projective system $(\mathrm{E}_r^{pq}(\mathbf{A}))_r$ is essentially constant whenever $p+q=n$ or $p+q=n+1$. Thus $\mathrm{E}_\infty^{pq}(\mathbf{A})$ is defined ((13.5.7)), and the isomorphisms*

$$\mathrm{gr}^p(\mathrm{R}'^n\mathrm{T}(\mathbf{A})) \simeq \mathrm{E}_\infty^{p,n-p}(\mathbf{A}) \qquad (p\in\mathbf{Z}) \tag{13.7.7.1}$$

form an isomorphism of graded $\mathrm{gr}^\bullet(S)$-modules.

Proof. In view of (13.7.7.1), and taking account of the isomorphisms (13.7.4.1), we shall by abuse of notation also write $\mathrm{R}^n\mathrm{T}(\mathbf{A})$ for the projective limit $\mathrm{R}'^n\mathrm{T}(\mathbf{A})$ of the projective system $(\mathrm{R}^n\mathrm{T}(A_k))$.

The graded ring $\mathrm{gr}^\bullet(S)$ is Noetherian (Bourbaki, *Alg. comm.*, chap. III, §2, nº 9, cor. 5 of th. 2). Hence the increasing sequence of graded $\mathrm{gr}^\bullet(S)$-submodules $\mathrm{B}_r^{(m)}(\mathbf{A})$ of $\mathrm{E}_1^{(m)}(\mathbf{A})$ is stationary for $m=n$ and $m=n+1$. Condition (b) of (11.1.10) is therefore satisfied. It follows that condition (a) of (13.7.4) holds for n and for $n+1$, proving (i).

Furthermore, the isomorphisms (13.7.4.1), together with the remarks of (13.7.6), show that $\mathrm{gr}^\bullet(\mathrm{R}^n\mathrm{T}(\mathbf{A}))$ is a graded $\mathrm{gr}^\bullet(S)$-module isomorphic to

$$\mathrm{E}_\infty^{(n)}(\mathbf{A}) = \mathrm{Z}_\infty^{(n)}(\mathbf{A})/\mathrm{B}_\infty^{(n)}(\mathbf{A}).$$

Since $\mathrm{Z}_\infty^{(n)}(\mathbf{A})$ is a submodule of $\mathrm{E}_1^{(n)}(\mathbf{A})$, it is of finite type, and so is $\mathrm{E}_\infty^{(n)}(\mathbf{A})$. Finally, for the filtration $(\mathrm{F}^p(\mathrm{R}'^n\mathrm{T}(\mathbf{A})))$, it follows from (13.4.5) that

$$\mathrm{gr}^\bullet(\mathrm{R}^n\mathrm{T}(\mathbf{A})) \quad \text{and} \quad \mathrm{gr}^\bullet(\mathrm{R}'^n\mathrm{T}(\mathbf{A}))$$

are isomorphic graded $\mathrm{gr}^\bullet(S)$-modules. This proves (iv). Assertions (ii) and (iii) will follow from these results and the following lemma. ☐

Lemma (13.7.7.2). — *Let S be a Noetherian $\mathfrak{J}$-adic ring, and let M be an S-module equipped with a codiscrete filtration $(\mathrm{F}^p(M))_{p\in\mathbf{Z}}$ such that*

$$\mathfrak{J}\mathrm{F}^p(M) \subset \mathrm{F}^{p+1}(M).$$

Thus M is a filtered module over S endowed with its $\mathfrak{J}$-adic filtration. Suppose moreover that M is separated for the topology defined by $(\mathrm{F}^p(M))$. Then the following conditions are equivalent:

a) *M is an S-module of finite type and $(\mathrm{F}^p(M))$ is a $\mathfrak{J}$-good filtration.*
b) *$\mathrm{gr}^\bullet(M)$ is a $\mathrm{gr}^\bullet(S)$-module of finite type.*
c) *The $\mathrm{gr}^p(M)$ are S-modules of finite type and, for all sufficiently large p, the canonical homomorphisms*

(13.7.7.3) $$\mathfrak{J}\otimes_S \mathrm{gr}^p(M) \longrightarrow \mathrm{gr}^{p+1}(M)$$

are surjective. They are induced by $\mathfrak{J}\otimes_S \mathrm{F}^p(M) \longrightarrow \mathrm{F}^{p+1}(M)$, taking account of the fact that the image of the composite homomorphism $\mathbf{0_{III}}$ | 79

$$\mathfrak{J}\otimes_S \mathrm{F}^{p+1}(M) \longrightarrow \mathfrak{J}\otimes_S \mathrm{F}^p(M) \longrightarrow \mathrm{F}^{p+1}(M)$$

is $\mathfrak{J}\mathrm{F}^{p+1}(M) \subset \mathrm{F}^{p+2}(M)$.

For the proof, see Bourbaki, Alg. comm., *chap. III, §3, n° 1, prop. 3.*

(13.7.7.4). To apply the lemma (13.7.7.2), it remains to observe that the topology on $\mathrm{R}'^n\mathrm{T}(\mathbf{A})$ defined by the filtration under consideration makes it a separated and complete S-module: this is the projective-limit topology of the discrete groups $\mathrm{R}^n\mathrm{T}(A_k)$. On the other hand, if $A_k = 0$ for $k < k_0$, then also $\mathrm{R}^n\mathrm{T}(A_k) = 0$ for $k < k_0$; hence

$$\mathrm{F}^{k_0}(\mathrm{R}'^n\mathrm{T}(\mathbf{A})) = \mathrm{R}'^n\mathrm{T}(\mathbf{A}).$$

Thus all the hypotheses of the lemma are indeed satisfied.

Corollary (13.7.8). — *If hypothesis (F_n) holds, then for every $f \in S$ there is a canonical isomorphism*

(13.7.8.1) $$\varprojlim_k (\mathrm{R}^n\mathrm{T}(A_k))_f \simeq \mathrm{R}^n\mathrm{T}(\mathbf{A}) \otimes_S S_{\{f\}}.$$

Proof. Indeed, $\mathrm{R}^n\mathrm{T}(\mathbf{A})$ is an S-module of finite type, and $S_{\{f\}}$ is a Noetherian adic S-algebra (($\mathbf{0_I}$, 7.6.11)), namely the separated completion of S_f for the $\mathfrak{J}$-preadic topology (($\mathbf{0_I}$, 7.6.2)). It follows from ($\mathbf{0_I}$, 7.7.8) and ($\mathbf{0_I}$, 7.7.1) that

$$\mathrm{R}^n\mathrm{T}(\mathbf{A}) \otimes_S S_{\{f\}}$$

is isomorphic to the separated completion of $\mathrm{R}^n\mathrm{T}(\mathbf{A}) \otimes_S S_f$ for the $\mathfrak{J}$-preadic topology. A fundamental system of neighbourhoods of zero for this topology is

$$(\mathfrak{J}^p\mathrm{R}^n\mathrm{T}(\mathbf{A})) \otimes_S S_f;$$

the groups

$$\mathrm{F}^p(\mathrm{R}^n\mathrm{T}(\mathbf{A})) \otimes_S S_f$$

therefore also form such a system. The latter group is the kernel of the canonical map

$$(\mathrm{R}^n\mathrm{T}(\mathbf{A}))_f \longrightarrow (\mathrm{R}^n\mathrm{T}(A_{p-1}))_f.$$

Consequently, the separated group associated with $\mathrm{R}^n\mathrm{T}(\mathbf{A}) \otimes_S S_f$ identifies with a subgroup G of

$$\varprojlim_k (\mathrm{R}^n\mathrm{T}(A_k))_f.$$

But the projective system $((\mathrm{R}^n\mathrm{T}(A_k))_f)_k$ plainly satisfies (ML), and the image of $(\mathrm{R}^n\mathrm{T}(\mathbf{A}))_f$ in each $(\mathrm{R}^n\mathrm{T}(A_k))_f$ equals the common image of the $(\mathrm{R}^n\mathrm{T}(A_h))_f$ for all sufficiently large $h \geqslant k$. It follows at once that G is *everywhere dense* in $\varprojlim_k (\mathrm{R}^n\mathrm{T}(A_k))_f$. Since the latter group is separated and complete, the corollary is proved. □

§14. Combinatorial dimension of a topological space

Summary

Almost all of the preceding sections have been focused on the exposition of ideas of commutative algebra that will be used throughout Chapter IV. Even though a large amount of these ideas already appear in multiple works ([CC], [Sam53a], [SZ60], [Ser55b], [Nag62]), we thought that it would be more practical for the reader to have a coherent, vaguely independent exposition. Together with §§5, 6, and 7 of Chapter IV (where we use the language of schemes), these sections constitute, in the middle of our treatise, a miniature special treatise, somewhat independent of Chapters I to III, and one that aims to present, in a coherent manner, the properties of rings that "behave well" with respect to operations such as completion, or integral closure, by systematically associating these properties to more general ideas.[13]

14.1. Combinatorial dimension of a topological space $\mathbf{0}_{\text{IV-1}}$ | 6

(14.1.1). Let I be an ordered set; a *chain* of elements of I is, by definition, a strictly-increasing finite sequence $i_0 < i_1 < \cdots < i_n$ of elements of I ($n \geqslant 0$); by definition, the *length* of this chain is n. If X is a topological space, the set of its *irreducible closed* subsets is ordered by inclusion, and so we have the notion of a *chain* of irreducible closed subsets of X.

Definition (14.1.2). — Let X be a topological space. We define the combinatorial dimension of X (or simply the dimension of X, if there is no risk of confusion), denoted by $\dim c(X)$ (or simply $\dim(X)$), to be the upper bound of lengths of chains of irreducible closed subsets of X. For all $x \in X$, we define the combinatorial dimension of X at x (or simply the dimension of X at x), denoted by $\dim_x(X)$, to be the number $\inf_U(\dim(U))$, where U varies over the open neighbourhoods of x in X.

It follows from this definition that we have

$$\dim(\varnothing) = -\infty$$

(the upper bound in $\overline{\mathbf{R}}$ of the empty set being $-\infty$). If (X_α) is the family of irreducible components of X, then we have

$$\dim(X) = \sup_\alpha \dim(X_\alpha), \tag{14.1.2.1}$$

because every chain of irreducible closed subsets of X is, by definition, contained in some irreducible component of X, and, conversely, the irreducible components are closed in X, so every irreducible closed subset of an X_α is an irreducible closed subset of X.

[13] The majority of properties which we discuss were discovered by Chevalley, Zariski, Nagata, and Serre. The method used here was first developed in the autumn of 1961, in a course taught at Harvard University by A. Grothendieck.

Definition (14.1.3). — We say that a topological space X is equidimensional if all its irreducible components have the same dimension (which is thus equal to $\dim(X)$, by (14.1.2.1)).

Proposition (14.1.4). —

(i) *For every subset Y of a topological space X, we have* $\dim(Y) \leqslant \dim(X)$.
(ii) *If a topological space X is a finite union of closed subsets X_i, then we have* $\dim(X) = \sup_i \dim(X_i)$.

Proof. For every irreducible closed subset Z of Y, the closure $\overline{Z}$ of Z in X is irreducible ($\mathbf{0_I}$, 2.1.2), and $\overline{Z} \cap Y = Z$, whence (i). Now, if $X = \bigcup_{i=1}^{n} X_i$, where the X_i are closed, then every irreducible closed subset of X is contained in one of the X_i ($\mathbf{0_I}$, 2.1.1), and so every chain of irreducible closed subsets of X is contained in one of the X_i, whence (ii). □

From (14.1.4, i), we see that, for all $x \in X$, we can also write

(14.1.4.1) $$\dim_x(X) = \lim_{U} \dim(U),$$

where the limit is taken over the downward-directed set of open neighbourhoods of x in X.

$\mathbf{0_{IV\text{-}1}}$ | 7

Corollary (14.1.5). — *Let X be a topological space, x a point of X, U a neighbourhood of x, and Y_i $(1 \leqslant i \leqslant n)$ closed subsets of U such that, for all i, $x \in Y_i$, and such that U is the union of the Y_i. Then we have*

(14.1.5.1) $$\dim_x(X) = \sup_i(\dim_x(Y_i)).$$

Proof. It follows from (14.1.4, ii) that we have $\dim_x(X) = \inf_V(\sup_i(\dim(Y_i \cap V)))$, where V ranges over the set of open neighbourhoods of x that are contained in U; similarly, we have $\dim_x(Y_i) = \inf_V(\dim(Y_i \cap V))$ for all i. The corollary is thus evident if

$$\sup_i(\dim_x(Y_i)) = +\infty;$$

if this were not the case, then there would be an open neighbourhood $V_0 \subset U$ of x such that $\dim(Y_i \cap V) = \dim_x(Y_i)$ for $1 \leqslant i \leqslant n$ and for all $V \subset V_0$, whence the conclusion. □

Proposition (14.1.6). — *For every topological space X, we have* $\dim(X) = \sup_{x \in X} \dim_x(X)$.

Proof. It follows from Definition (14.1.2) and Proposition (14.1.4) that $\dim_x(X) \leqslant \dim(X)$ for all $x \in X$. Now, let $Z_0 \subset Z_1 \subset \ldots \subset Z_n$ be a chain of irreducible closed subsets of X, and let $x \in Z_0$; for every open subset $U \subset X$ that contains x, $U \cap Z_i$ is irreducible ($\mathbf{0_I}$, 2.1.6) and closed in U, and since we have $\overline{U \cap Z_i} = Z_i$ in X, the $U \cap Z_i$ are pairwise distinct; thus $\dim(U) \geqslant n$, which finishes the proof. □

Corollary (14.1.7). — *If (X_α) is an open, or closed and locally finite, cover of X, then* $\dim(X) = \sup_\alpha(\dim(X_\alpha))$.

Proof. If X_α is a neighbourhood of $x \in X$, then $\dim_x(X) \leqslant \dim(X_\alpha)$, whence the claim for open covers. On the other hand, if the X_α are closed, and U is a neighbourhood of $x \in X$ which meets only finitely many of the X_α, then

$$\dim_x(X) \leqslant \dim(U) = \sup_\alpha(\dim(U \cap X_\alpha)) \leqslant \sup_\alpha(\dim(X_\alpha))$$

by (14.1.4), whence the other claim. □

Corollary (14.1.8). — *Let X be a Noetherian Kolmogoroff space* ($\mathbf{0_I}$, 2.1.3), *and F the set of closed points of X. Then* $\dim(X) = \sup_{x \in F} \dim_x(X)$.

Proof. With the notation from the proof of (14.1.6), it suffices to note that there exists a closed point in Z_0 ($\mathbf{0_I}$, 2.1.3). □

Proposition (14.1.9). — *Let X be a nonempty Noetherian Kolmogoroff space. To have* $\dim(X) = 0$, *it is necessary and sufficient for X to be finite and discrete.*

Proof. If a space X is separated (and *a fortiori* if X is a discrete space), then all the irreducible closed subsets of X are single points, and so $\dim(X) = 0$. Conversely, suppose that X is a Noetherian Kolmogoroff space such that $\dim(X) = 0$; since every irreducible component of X contains a closed point $(\mathbf{0}_\mathbf{I}, 2.1.3)$, it must be exactly this single point. Since X has only a finite number of irreducible components, it is thus finite and discrete. □

Corollary (14.1.10). — *Let X be a Noetherian Kolmogoroff space. For a point $x \in X$ to be isolated, it is necessary and sufficient to have* $\dim_x(X) = 0$.

Proof. The condition is clearly necessary (without any hypotheses on X). It is also sufficient, because it implies that $\dim(U) = 0$ for any open neighbourhood U of x, and since U is a Noetherian Kolmogoroff space, U is finite and discrete. □ $\mathbf{0}_{\mathbf{IV\text{-}1}}$ | 8

Proposition (14.1.11). — *The function $x \mapsto \dim_x(X)$ is upper semi-continuous on X.*

Proof. It is clear that this function is upper semi-continuous at every point where its value is $+\infty$. So suppose that $\dim_x(X) = n < +\infty$; then Equation (14.1.4.1) shows that there exists an open neighbourhood U_0 of x such that $\dim(U) = n$ for every open neighbourhood $U \subset U_0$ of x. So, for all $y \in U_0$ and every open neighbourhood $V \subset U_0$ of y, we have $\dim(V) \leqslant \dim(U_0) = n$ (14.1.4); we thus deduce from (14.1.4.1) that $\dim_y(X) \leqslant n$. □

Remark (14.1.12). — If X and Y are topological spaces, and $f : X \to Y$ a continuous map, then it can be the case that $\dim(f(X)) > \dim(X)$; we obtain such an example by taking X to be a discrete space with 2 points, a and b, and Y to be the set $\{a, b\}$ endowed with the topology for which[14] the closed sets are $\varnothing$, $\{a\}$, and $\{a, b\}$; if $f : X \to Y$ is the identity map, then $\dim(Y) = 1$ and $\dim(X) = 0$. We note that Y is the spectrum of a discrete valuation ring A, of which a is the unique closed point, and b the generic point; if K and k are the field of fractions and the residue field of A (respectively), then X is the spectrum of the ring $k \times K$, and f is the continuous map corresponding to the homomorphism $(\phi, \psi) : A \to k \times K$, where $\phi : A \to k$ and $\psi : A \to K$ are the canonical homomorphism (cf. (**IV**, 5.4.3)).

14.2. Codimension of a closed subset

Definition (14.2.1). — Given an irreducible closed subset Y of a topological space X, we define the combinatorial codimension (or simply codimension) of Y in X, denoted by $\operatorname{codim}(Y, X)$, to be the upper bound of the lengths of chains of irreducible closed subsets of X of which Y is the smallest element. If Y is an arbitrary closed subset of X, then we define the codimension of Y in X, again denoted by $\operatorname{codim}(Y, X)$, to be the lower bound of the codimensions in X of the irreducible components of Y. We say that X is equicodimensional if all the minimal irreducible closed subsets of X have the same codimension in X.

It follows from this definition that $\operatorname{codim}(\varnothing, X) = +\infty$, since the lower bound of the empty set of $\overline{\mathbf{R}}$ is $+\infty$. If Y is closed in X, and if (X_α) (resp. (Y_α)) is the family of irreducible components of X (resp. Y), then every Y_β is contained in some X_α, and, more generally, every chain of irreducible closed subsets of X of which Y_β is the smallest element is formed of subsets of some X_α; we thus have

(14.2.1.1) $$\operatorname{codim}(Y, X) = \inf_\beta(\sup_\alpha(\operatorname{codim}(Y_\beta, X_\alpha))),$$

where, for every β, α ranges over the set of indices such that $Y_\beta \subset X_\alpha$.

Proposition (14.2.2). — *Let X be a topological space.*

(i) *If Φ is the set of irreducible closed subsets of X, then*

(14.2.2.1) $$\dim(X) = \sup_{Y \in \Phi}(\operatorname{codim}(Y, X)).$$

$\mathbf{0}_{\mathbf{IV\text{-}1}}$ | 9

(ii) *For every nonempty closed subset Y of X, we have*

(14.2.2.2) $$\dim(Y) + \operatorname{codim}(Y, X) \leqslant \dim(X).$$

[14] *[Trans.] This is now often referred to as the* Sierpiński space, *or the* connected two-point set.

(iii) *If Y, Z, and T are closed subsets of X such that $Y \subset Z \subset T$, then*

(14.2.2.3) $$\operatorname{codim}(Y,Z) + \operatorname{codim}(Z,T) \leqslant \operatorname{codim}(Y,T).$$

(iv) *For a closed subset Y of X to be such that $\operatorname{codim}(Y,X) = 0$, it is necessary and sufficient for Y to contain an irreducible component of X.*

Proof. Claims (i) and (iv) are immediate consequences of Definition (14.2.1). To show (ii), we can restrict to the case where Y is irreducible, and then the equation follows from Definitions (14.1.1) and (14.2.1). Finally, to show (iii), we can, by Definition (14.2.1), first restrict to the case where Y is irreducible; then $\operatorname{codim}(Y,Z) = \sup_\alpha(\operatorname{codim}(Y,Z_\alpha))$ for the irreducible components Z_α of Z that contain Y; it is clear that $\operatorname{codim}(Y,T) \geqslant \operatorname{codim}(Y,Z)$, so the inequality is true if $\operatorname{codim}(Y,Z) = +\infty$; but if this were not the case, then there would exist some α such that $\operatorname{codim}(Y,Z) = \operatorname{codim}(Y,Z_\alpha)$, and by (14.2.1), we can restrict to the case where Z itself is irreducible; but then the inequality in (14.2.2.3) is an evident consequence of Definition (14.2.1). □

Proposition (14.2.3). — *Let X be a topological space, and Y a closed subset of X. For every open subset U of X, we have*

(14.2.3.1) $$\operatorname{codim}(Y \cap U, U) \geqslant \operatorname{codim}(Y,X).$$

Furthermore, for this inequality (14.2.3.1) to be an equality, it is necessary and sufficient to have $\operatorname{codim}(Y,X) = \inf_\alpha(\operatorname{codim}(Y_\alpha,X))$, where (Y_α) is the family of irreducible components of Y that meet U.

Proof. We know ($\mathbf{0}_{\mathbf{I}}$, 2.1.6) that $Z \mapsto \overline{Z}$ is a bijection from the set of irreducible closed subsets of U to the set of irreducible closed subsets of X that meet U, and, in particular, induces a correspondence between the irreducible components of $Y \cap U$ and the irreducible components of Y that meet U; if Y_α is one of the latter such components, then we have $\operatorname{codim}(Y_\alpha,X) = \operatorname{codim}(Y_\alpha \cap U, U)$, and the proposition then follows from Definition (14.2.1). □

Definition (14.2.4). — Let X be a topological space, Y a closed subset of X, and x a point of X. We define the codimension of Y in X at the point x, denoted by $\operatorname{codim}_x(Y,X)$, to be the number $\sup_U(\operatorname{codim}(Y \cap U, U))$, where U ranges over the set of open neighbourhoods of x in X.

By (14.2.3), we can also write

(14.2.4.1) $$\operatorname{codim}_x(Y,X) = \lim_U(\operatorname{codim}(Y \cap U, U)),$$

where the limit is taken over the downward-directed set of open neighbourhoods of x in X. We note that we have

$$\operatorname{codim}_x(Y,X) = +\infty \text{ if } x \in X - Y.$$

$\mathbf{0}_{\mathbf{IV\text{-}1}}$ | 10

Proposition (14.2.5). — *If $(Y_i)_{1 \leqslant i \leqslant n}$ is a finite family of closed subsets of a topological space X, and Y is the union of this family, then*

(14.2.5.1) $$\operatorname{codim}(Y,X) = \inf_i(\operatorname{codim}(Y_i,X)).$$

Proof. Every irreducible component of one of the Y_i is contained in an irreducible component of Y, and, conversely, every irreducible component of Y is also an irreducible component of one of the Y_i ($\mathbf{0}_{\mathbf{I}}$, 2.1.1); the conclusion then follows from Definition (14.2.1) and the inequality in (14.2.2.3). □

Corollary (14.2.6). — *Let X be a topological space, and Y a locally-Noetherian closed subspace of X.*

(i) *For all $x \in X$, there exists only a finite number of irreducible components Y_i ($1 \leqslant i \leqslant n$) of Y that contain x, and we have $\operatorname{codim}_x(Y,X) = \inf_i(\operatorname{codim}(Y_i,X))$.*

(ii) *The function $x \mapsto \operatorname{codim}_x(Y,X)$ is lower semi-continuous on X.*

Proof. By hypothesis, there exists an open neighbourhood U_0 of x in X such that $Y \cap U_0$ is Noetherian, and so U_0 has only a finite number of irreducible components, which are the intersections of U_0 with the irreducible components of Y; *a fortiori* there are only a finite number of irreducible components Y_i ($1 \leqslant i \leqslant n$) of Y that contain x, and we can, by replacing U_0 with an open neighbourhood $U \subset U_0$ of x that doesn't meet any of the Y_j that do not contain x, assume that the $Y_i \cap U$ are the irreducible components of $Y \cap U$; for every open neighbourhood $V \subset U$ of x in X, the $Y_i \cap V$ are thus the irreducible components of $Y \cap V$, and (14.2.3) then shows that $\operatorname{codim}(Y_i, X) = \operatorname{codim}(Y_i \cap V, V)$, which proves (i). Further, for every $x' \in U$, the irreducible components of Y that contain x' are certain Y_i, and so $\operatorname{codim}_{x'}(Y, X) \geqslant \operatorname{codim}_x(Y, X)$, which proves (ii). □

14.3. The chain condition

(14.3.1). In a topological space X, we say that a chain $Z_0 \subset Z_1 \subset \cdots \subset Z_n$ of irreducible closed subsets is *saturated* if there does not exist an irreducible closed subset Z', distinct from each of the Z_i, such that $Z_k \subset Z' \subset Z_{k+1}$ for any k.

Proposition (14.3.2). — *Let X be a topological space such that, for any two irreducible closed subsets Y and Z of X with $Y \subset Z$, we have $\operatorname{codim}(Y, Z) < +\infty$. The following two conditions are equivalent.*

(a) *Any two saturated chains of closed irreducible subsets of X that have the same first and last elements as one another have the same length.*
(b) *If Y, Z, and T are irreducible closed subsets of X such that $Y \subset Z \subset T$, then*

(14.3.2.1) $$\operatorname{codim}(Y, T) = \operatorname{codim}(Y, Z) + \operatorname{codim}(Z, T).$$

Proof. It is immediate that (a) implies (b). Conversely, suppose that (b) is satisfied, and we will show that if we have two saturated chains with the same first and last elements as one another, of lengths m and $n \leqslant m$ (respectively), then $m = n$. We proceed by induction on n, with the proposition being clear for $n = 1$. So suppose that $1 < n < m$, and let $Z_0 \subset Z_1 \subset \cdots \subset Z_n$ be a saturated chain such that there exists another saturated chain, with first element Z_0 and last element $\mathbf{0}_{\mathbf{IV}\text{-}\mathbf{1}}$ | 11
Z_n, of length m. Since $\operatorname{codim}(Z_0, Z_n) \geqslant m > n$, and $\operatorname{codim}(Z_0, Z_1) = 1$, it follows from *(b)* that $\operatorname{codim}(Z_1, Z_n) = \operatorname{codim}(Z_0, Z_n) - 1 > n - 1$, which contradicts our induction hypothesis. □

When the conditions of (14.3.2) are satisfied, we say that X satisfies the *chain condition*, or that it is a *catenary space*. It is clear that every closed subspace of a catenary space is catenary.

Proposition (14.3.3). — *Let X be a Noetherian Kolmogoroff space of finite dimension. The following conditions are equivalent.*

(a) *Any two maximal chains of irreducible closed subsets of X have the same length.*
(b) *X is equidimensional, equicodimensional, and catenary.*
(c) *X is equidimensional, and, for any irreducible closed subsets Y and Z of X with $Y \subset Z$, we have*

(14.3.3.1) $$\dim(Z) = \dim(Y) + \operatorname{codim}(Y, Z).$$

(d) *X is equicodimensional, and, for any irreducible closed subsets Y and Z of X with $Y \subset Z$, we have*

(14.3.3.2) $$\operatorname{codim}(Y, X) = \operatorname{codim}(Y, Z) + \operatorname{codim}(Z, X).$$

Proof. The hypotheses on X imply that the first and last elements of a maximal chain of irreducible closed subsets of X are necessarily a closed point and an irreducible component of X (respectively) ($\mathbf{0}_{\mathbf{I}}$, 2.1.3); further, every saturated chain with first element Y and last element Z (thus $Y \subset Z$) is contained in a maximal chain whose elements differ from those of the given chain, or are contained in Y, or contain Z. These remarks immediately establish the equivalence between (a) and (b), and also show that if (a) is satisfied, then we have, for every irreducible closed subset Y of X,

(14.3.3.3) $$\dim(Y) + \operatorname{codim}(Y, X) = \dim(X);$$

from (14.3.2.1), we immediately deduce (14.3.3.1) and (14.3.3.2) from (14.3.3.3). Conversely, (14.3.3.1) implies (14.3.2.1), and so (14.3.3.1) implies the chain condition, by (14.3.2); further, by applying (14.3.3.1) to the case where Y is a single closed point x of X, and Z is an irreducible component of X, we get that $\operatorname{codim}(\{x\}, X) = \dim(Z)$; we thus conclude that (c) implies (b). Similarly, (14.3.3.2) implies (14.3.2.1), and thus the chain condition; further, with the same choice of Y and Z as above, (14.3.3.2) again implies that $\operatorname{codim}(\{x\}, X) = \dim(Z)$, and so (since every irreducible component of X contains a closed point, by ($\mathbf{0}_{\mathbf{I}}$, 2.1.3)), (d) implies (b). □

We say that a Noetherian Kolmogoroff space is *biequidimensional* if it is of *finite dimension* and if it verifies any of the (equivalent) conditions of (14.3.3).

Corollary (14.3.4). — *Let X be a biequidimensional Noetherian Kolmogoroff space; then, for every closed point x of X, and every irreducible component Z of X, we have*

(14.3.4.1) $$\dim(X) = \dim(Z) = \operatorname{codim}(\{x\}, X) = \dim_x(X).$$

$\mathbf{0_{IV\text{-}1}}$ | 12

Proof. The last equality follows from the fact that, if $Y_0 = \{x\} \subset Y_1 \subset \cdots \subset Y_m$ is a maximal chain of irreducible closed subsets of X, and U an open neighbourhood of x, then the $U \cap Y_i$ are pairwise distinct irreducible closed subsets of U (because $\overline{U \cap Y_i} = Y_i$), whence $\dim(U) = \dim(X)$, by (14.1.4). □

Corollary (14.3.5). — *Let X be a Noetherian Kolmogoroff space; if X is biequidimensional, then so is every union of irreducible components of X, and every irreducible closed subset of X. In addition, for every closed subset Y of X, we have*

(14.3.5.1) $$\dim(Y) + \operatorname{codim}(Y, X) = \dim(X).$$

Proof. Every chain of irreducible closed subsets of X is contained in an irreducible component of X, and so the first claim follows immediately from (14.3.3). Further, if X' is an irreducible closed subset of X, then X' trivially satisfies the conditions of (14.3.3, c), whence the second claim.

Finally, to show (14.3.5.1), note that we have seen, in the proof of (14.3.3), that this equation is true whenever Y is irreducible; if Y_i ($1 \leqslant i \leqslant m$) are the irreducible components of Y, then the Y_i for which $\dim(Y_i)$ is the largest are also those for which $\operatorname{codim}(Y_i, X)$ is the smallest; so (14.3.5.1) follows from the definitions of $\dim(Y)$ and $\operatorname{codim}(Y, X)$. □

Remark (14.3.6). — The reader will note that the proof of (14.3.2) applies to any ordered set, and the fact that we are working with the example of a set of irreducible closed subsets of a topological space is not used at all in the proof. It is the same in the proof of (14.3.3), which holds, more generally, for any ordered set E such that, for all $x \in E$, there exists some $z \leqslant x$ which is *minimal* in E, and such that the length of chains of elements of E is bounded.

§15. M-REGULAR SEQUENCES AND $\mathscr{F}$-REGULAR SEQUENCES

15.1. M-regular sequences and M-quasi-regular sequences

(15.1.1). Let A be a ring, N an A-module; in what follows, we will write $N[T_1, \ldots, T_n]$, for short, $\mathbf{0_{IV\text{-}1}}$ | 12
for the graded A-module $N \otimes_A A[T_1, \ldots, T_n]$ (T_i indeterminates), where N is graded by the trivial graduation and $A[T_1, \ldots, T_n]$ by the total degree.

Let M be an A-module, f_i ($1 \leqslant i \leqslant n$) elements of A, $\mathfrak{J} = \sum_{i=1}^n f_i A$ the ideal of A generated by the f_i, and let us equip M with the $\mathfrak{J}$-preadic filtration; we then define a *surjective graded homomorphism of graded A-modules*, of degree 0,

(15.1.1.1) $$\varphi : (\operatorname{gr}_0(M))[T_1, \ldots, T_n] \longrightarrow \operatorname{gr}_\bullet(M)$$

in the following way: if $\xi \in \operatorname{gr}_0(M)$ is the class mod $\mathfrak{J}M$ of an element $x \in M$, to the pair formed $\mathbf{0_{IV\text{-}1}}$ | 13
by ξ and a homogeneous polynomial $P[T_1, \ldots, T_n]$ of degree k, we associate the class mod $\mathfrak{J}^{k+1}M$ of $P(f_1, \ldots, f_n)x$; it is immediate that this class depends only on ξ and on P, and if S_k is the set of homogeneous polynomials of degree k in $A[T_1, \ldots, T_n]$, we have thus defined an A-linear map

$$\varphi_k : \operatorname{gr}_0(M) \otimes_A S_k \longrightarrow \operatorname{gr}_k(M),$$

which is surjective by definition of $\mathfrak{J}^k M$.

We will say in what follows that an element $f \in A$ is *not a zero divisor in an A-module M* if the homothety $f_M : x \mapsto fx$ of M is injective.

Lemma (15.1.2). — *Let M be an A-module, f an element of A, and let us equip M with the (fA)-preadic filtration. If f is not a zero divisor in M, the canonical homomorphism defined in (15.1.1):*

(15.1.2.1) $$\varphi : (M/fM)[T] \longrightarrow \operatorname{gr}_\bullet(M)$$

is bijective. The converse is true if M is separated for the (fA)-preadic topology.

Proof. We have here $\mathrm{gr}_k(M) = f^k M/f^{k+1}M$; to say that φ is injective means that for all $x \in M$ and all k, the relation $f^k x \in f^{k+1}M$ implies $x \in fM$; it is clear that this is indeed the case if f is not a zero divisor in M. Conversely, note that the homothety $f_M : x \mapsto fx$ defines, by passing to quotients, homomorphisms $\mathrm{gr}_k(M) \to \mathrm{gr}_{k+1}(M)$, hence a graded homomorphism g of degree 1 of $\mathrm{gr}_\bullet(M)$ into itself; and to say that φ is injective also means that g is injective. If we further suppose the filtration of M separated, it follows that f_M is injective (Bourbaki, *Alg. comm.*, chap. III, § 2, no. 8, cor. 1 of th. 1). ☐

Corollary (15.1.3). — *Let A be a Noetherian ring, M a finitely generated A-module. For f to be not a zero divisor in M, it is necessary and sufficient that φ be bijective.*

Proof. We need only show that the condition is sufficient; to prove that f_M is injective, it suffices to show that for every prime ideal $\mathfrak{p}$ of A, the homothety of ratio $f' = f/1 \in A' = A_\mathfrak{p}$ in the $A_\mathfrak{p}$-module $M_\mathfrak{p} = M'$ is injective (Bourbaki, *Alg. comm.*, chap. II, § 3, no. 4, th. 1). Now $f'^k M'/f'^{k+1}M' = (f^k M/f^{k+1}M) \otimes_A A'$, and it is immediate that the canonical homomorphism $\varphi' : (M'/f'M')[T] \to \mathrm{gr}_\bullet(M')$ is equal to $\varphi \otimes 1_{A'}$; if φ is injective, so is φ' ($\mathbf{0_I}$, 1.3.2). We are thus reduced to the case where A is a Noetherian *local* ring, whose maximal ideal we denote by $\mathfrak{m}$. If $f \notin \mathfrak{m}$, then f is invertible and there is nothing to prove. If $f \in \mathfrak{m}$, we know that M is separated for the (fA)-preadic topology ($\mathbf{0_I}$, 7.3.5), and it suffices therefore to apply (15.1.2). ☐

Definition (15.1.4). — Let A be a ring, M an A-module. We say that an element $f \in A$ is *M-regular* (resp. *M-quasi-regular*) if f is not a zero divisor in M (resp. if the homomorphism (15.1.2.1) is bijective).

We have thus just shown that every M-regular element is M-quasi-regular, and that the converse is true if A is Noetherian and M a finitely generated A-module. When M is no longer assumed to be finitely generated, the converse can fail: for example, if A is a principal ideal domain that is not a field, K its field of fractions, and M the A-module K/A, we have $fM = M$ for all $f \neq 0$ in A, hence both sides of (15.1.2.1) reduce to 0, but f is then a zero divisor in M.

(15.1.5). Suppose now that M is equipped with a *filtration* (M_k) such that $M_0 = M$, and denote by $\mathrm{gr}_\bullet(M) = \bigoplus_{k \geqslant 0} M_k/M_{k+1}$ the associated graded A-module. The notations being those of (15.1.1), set, for all $k \geqslant 0$, $\mathbf{0_{IV\text{-}1}}$ | 14

(15.1.5.1)
$$M'_k = M_k + \mathfrak{J}M_{k-1} + \cdots + \mathfrak{J}^{k-1}M_1 + \mathfrak{J}^k M_0.$$

It is clear that (M'_k) is a filtration on M. When $M_k = \mathfrak{Q}^k M$, where $\mathfrak{Q}$ is an ideal of A, the filtration (M'_k) is none other than the $(\mathfrak{J} + \mathfrak{Q})$-preadic filtration. We will again write $(\mathrm{gr}_\bullet(M) \otimes_A (A/\mathfrak{J}))[T_1, \ldots, T_n]$ for the graded tensor product of graded A-modules (**II**, 2.1.2) $(\mathrm{gr}_\bullet(M) \otimes_A (A/\mathfrak{J})) \otimes_A A[T_1, \ldots, T_n]$. We define a *surjective graded homomorphism of graded A-modules*, of degree 0,

(15.1.5.2)
$$\psi : (\mathrm{gr}_\bullet(M) \otimes_A (A/\mathfrak{J}))[T_1, \ldots, T_n] \longrightarrow \mathrm{gr}'_\bullet(M)$$

in the following way: if $\alpha \in A/\mathfrak{J}$ is the class of an element $a \in A$, $\xi \in M_k/M_{k+1}$ the class of an element $x \in M_k$, and $P[T_1, \ldots, T_n]$ a homogeneous polynomial of degree h, we associate to the triplet (α, ξ, P) the class mod M'_{k+h+1} of $P(f_1, \ldots, f_n)ax$; one verifies immediately that this element depends only on ξ, α, and P, and this defines the surjective graded homomorphism (15.1.5.2), by virtue of the definition (15.1.5.1). One recovers the homomorphism (15.1.1.1) by considering the filtration on M such that $M_1 = 0$.

Lemma (15.1.6). — *We keep the notations of (15.1.5) and suppose $n = 1$, setting $f = f_1$. If f is $\mathrm{gr}_\bullet(M)$-regular, the homomorphism (15.1.5.2) is bijective.*

Proof. Let Q_k (resp. Q'_k) be the sub-A-module of elements of degree k in the first (resp. second) member of (15.1.5.2). We equip Q_k with the filtration

(15.1.6.1)
$$(Q_k)_i = \sum_{j \leqslant k-i} (\mathrm{gr}_{k-j}(M) \otimes_A (A/fA))T^j$$

so that $(Q_k)_0 = Q_k$ and $(Q_k)_{k+1} = 0$, and for this filtration, one has

$$\mathrm{gr}_i(Q_k) = (\mathrm{gr}_i(M) \otimes_A (A/fA))T^{k-i}.$$

We equip Q'_k with the filtration formed by $\psi((Q_k)_i) = (Q'_k)_i$. As these filtrations are *finite*, it suffices to prove that the homomorphisms $\psi_{ki} : \mathrm{gr}_i(Q_k) \to \mathrm{gr}_i(Q'_k)$ induced by ψ_k are injective (Bourbaki, *Alg. comm.*, chap. III, § 3, no. 8, cor. 1 of th. 1). Now $\mathrm{gr}_i(Q_k) = ((M_i/M_{i+1}) \otimes_A (A/fA))T^{k-i}$; on the other hand, $(Q'_k)_{i+1}$ is the image of

$$M_k + fM_{k-1} + \cdots + f^{k-i-1}M_{i+1}$$

in M'_k/M'_{k+1}. We are thus led to write that, for $x \in M_i$, the relation $\mathbf{0}_{\textbf{IV-1}}$ | 15

$$f^{k-i}x \in M_k + fM_{k-1} + \cdots + f^{k-i-1}M_{i+1} + M'_{k+1} \tag{15.1.6.2}$$

implies $x \in fM_i + M_{i+1}$. Now, the second member of (15.1.6.2) is contained in $M_{i+1} + M'_{k+1}$, and by virtue of (15.1.5.1), M'_{k+1} is contained in $M_{i+1} + f^{k+1-i}M$. The hypothesis on f implies that f is not a zero divisor in M/M_h for all h (Bourbaki, *loc. cit.*). The relation $f^{k-i}x \in f^{k+1-i}M + M_{i+1}$ thus implies (reasoning by induction) $x \in fM_i + M_{i+1}$. □

Definition (15.1.7). — Let $(f_i)_{1\leqslant i\leqslant n}$ be a sequence of elements of A. We say that it is *M-regular* if, for $1 \leqslant i \leqslant n$, f_i is $(M/(\sum_{1\leqslant j\leqslant i-1} f_jM))$-regular. We say that the sequence (f_i) is *M-quasi-regular* if the canonical homomorphism φ defined in (15.1.1.1) is bijective.

When $M = A$, we say simply "regular sequence" and "quasi-regular sequence".

Proposition (15.1.8). — *The notations being those of* (15.1.5), *suppose that the sequence $(f_i)_{1\leqslant i\leqslant n}$ is $\mathrm{gr}_\bullet(M)$-regular. Then the canonical homomorphism* (15.1.5.2) *is bijective.*

Proof. The proposition is none other than (15.1.6) for $n = 1$; let us reason by induction on n. Set $\mathfrak{J}'' = \sum_{i=1}^{n-1} f_iA$, so that $\mathfrak{J} = \mathfrak{J}'' + f_nA$, and let

$$M''_k = M_k + \mathfrak{J}''M_{k-1} + \cdots + \mathfrak{J}''^{k-1}M_1 + \mathfrak{J}''^kM_0;$$

one can then write

$$M'_k = M''_k + f_nM''_{k-1} + \cdots + f_n^{k-1}M''_1 + f_n^kM''_0.$$

Let us write $\mathrm{gr}''_\bullet(M)$ for the graded A-module associated to M filtered by the filtration (M''_k). One can write, up to canonical isomorphisms,

$$(\mathrm{gr}_\bullet(M) \otimes (A/\mathfrak{J})) \otimes_A A[T_1, \ldots, T_n] = (\mathrm{gr}_\bullet(M) \otimes (A/\mathfrak{J}''))[T_1, \ldots, T_{n-1}] \otimes (A/f_nA) \otimes_A A[T_n]$$

and by (15.1.5.2), ψ factorizes as

$$(\mathrm{gr}''_\bullet(M) \otimes_A (A/f_nA))[T_n] \longrightarrow \mathrm{gr}'_\bullet(M) \tag{15.1.8.1}$$

and

$$((\mathrm{gr}_\bullet(M) \otimes (A/\mathfrak{J}''))[T_1, \ldots, T_{n-1}]) \otimes (A/f_nA) \otimes_A A[T_n] \xrightarrow{\psi'\otimes 1} \mathrm{gr}''_\bullet(M) \otimes (A/f_nA) \otimes_A A[T_n]$$

where ψ' is the map (15.1.5.2) in which one replaces n by $n-1$, $\mathfrak{J}$ by $\mathfrak{J}''$, and $\mathrm{gr}'_\bullet(M)$ by $\mathrm{gr}''_\bullet(M)$. The induction hypothesis implies that ψ' is bijective, and it remains to see, by applying (15.1.6), that it suffices to show that f_n is $\mathrm{gr}''_\bullet(M)$-regular. But $\mathrm{gr}''_\bullet(M)$ identifies with $(\mathrm{gr}_\bullet(M) \otimes (A/\mathfrak{J}''))[T_1, \ldots, T_{n-1}]$; by hypothesis, the homothety of ratio f_n in $\mathrm{gr}_\bullet(M) \otimes (A/\mathfrak{J}'')$ is bijective; since $A[T_1, \ldots, T_{n-1}]$ is a free A-module, it follows that f_n is $\mathrm{gr}''_\bullet(M)$-regular. □

Proposition (15.1.9). — *Let M be an A-module, $(f_i)_{1\leqslant i\leqslant n}$ a sequence of elements of A. If the sequence (f_i) is M-regular, it is M-quasi-regular. The converse is true when one supposes in addition that the A-modules M, $M/f_1M, \ldots, M/(\sum_{1\leqslant i\leqslant n-1} f_iM)$ are separated for the $\mathfrak{J}$-preadic topology.*

Proof. The first assertion follows from (15.1.8), taking $M_1 = 0$, and then the homomorphism (15.1.5.2) reduces to (15.1.1.1). Conversely, suppose that the homomorphism φ of (15.1.1.1) is bijective. Note that if we set

$$\mathfrak{J}'' = \sum_{i=1}^{n-1} f_iA,$$

and denote by $\mathrm{gr}''_\bullet(M)$ the graded A-module associated to M filtered by the $\mathfrak{J}''$-preadic filtration, φ factorizes as $\mathbf{0}_{\textbf{IV-1}}$ | 16

$$(\mathrm{gr}''_\bullet(M) \otimes (A/f_nA))[T_n] \longrightarrow \mathrm{gr}_\bullet(M) \tag{15.1.9.1}$$

and $\varphi' \otimes 1$, where φ' is the canonical homomorphism

$$(\mathrm{gr}''_0(M))[T_1, \dots, T_{n-1}] \longrightarrow \mathrm{gr}''_\bullet(M).$$

As these two homomorphisms are surjective, they are both bijective if φ is supposed bijective, hence φ' is necessarily injective, and thus bijective since it is surjective. One can then reason by induction on n (the case $n = 1$ follows from (15.1.2)), since on M, $M/f_1M, \dots, M/(\sum_{j=1}^{n-2} f_jM)$ the $\mathfrak{J}''$-preadic topology is finer than the $\mathfrak{J}$-preadic topology, and is thus separated. One sees therefore that the sequence $(f_i)_{1\leqslant i\leqslant n-1}$ is M-regular. On the other hand, let us show that if $y \in M/\mathfrak{J}''M$ is such that $f_n^k y \in f_n^{k+1}(M/\mathfrak{J}''M)$, then $y \in f_n(M/\mathfrak{J}''M)$. Indeed, if x is a representative of y, let us show that $f_n^k x \in \mathfrak{J}^{k+1}M$; our assertion will then follow from the fact that (15.1.9.1) is injective. The hypothesis implies $f_n^k x \in f_n^{k+1}M + \mathfrak{J}''M \subset \mathfrak{J}M$, whence, since φ is injective, $f_n^{k-1}x \in \mathfrak{J}^k M$; by induction, one thus obtains $x \in \mathfrak{J}M$, and finally $f_n^k x \in \mathfrak{J}^{k+1}M$. We finish the reasoning as in (15.1.2): on $M/\mathfrak{J}''M$, the $\mathfrak{J}$-preadic filtration is identical to the (f_nA)-preadic filtration, which is separated by hypothesis, and one concludes that the homothety of ratio f_n in $M/\mathfrak{J}''M$ is injective, which finishes showing that the sequence $(f_i)_{1\leqslant i\leqslant n}$ is M-regular. ☐

Corollary (15.1.10). — *With the notations of (15.1.9), suppose that for every finitely generated A-module N, $M \otimes_A N$ is separated for the $\mathfrak{J}$-preadic topology. Then, for the sequence (f_i) to be M-regular, it is necessary and sufficient that it be M-quasi-regular.*

One will note that the hypothesis of (15.1.10) implies that, if the sequence $(f_i)_{1\leqslant i\leqslant n}$ is M-regular, so is the sequence $(f_{\sigma(i)})$ for every permutation σ of the interval $[1, n]$.

Corollary (15.1.11). — *Let A be a Noetherian ring, M a finitely generated A-module, $(f_i)_{1\leqslant i\leqslant n}$ a finite sequence of elements contained in the radical of A. Then, for the sequence (f_i) to be M-regular, it is necessary and sufficient that it be M-quasi-regular.*

Proof. This is a particular case of (15.1.10), since every finitely generated A-module is then separated for the $\mathfrak{J}$-preadic topology ($\mathbf{0_I}$, 7.3.5). ☐

Remarks (15.1.12). —

(i) When A is a Noetherian local ring, M a finitely generated A-module, and when the f_i are contained in the maximal ideal of A, the notion of M-regular sequence was introduced by J.-P. Serre under the name of *M-suite* [Ser55b].

(ii) Even if A is Noetherian and $M = A$, a sequence (f, g) of two elements of A that is quasi-regular is not necessarily regular. For example, the sequence $(0, 1)$ is quasi-regular, since then $\mathfrak{J} = fA + gA = A$, hence $\mathrm{gr}_\bullet(A) = 0$; but if $A \neq 0$ it is not regular, since 0 is not A-regular. One will note however that in this case the sequence $(1, 0)$ is regular, since 1 is not a zero divisor in A, and since $A/A = 0$, 0 is not a zero divisor in this module (cf. (15.1.1)).

(iii) In (15.1.6), one cannot in general replace the hypothesis that f is $\mathrm{gr}_\bullet(M)$-regular by the hypothesis that it is $\mathrm{gr}_\bullet(M)$-quasi-regular. To see this, let us take the example (15.1.4) where A is a principal ideal domain with field of fractions $K \neq A$, and let us take $M = K$, the filtration (M_k) of M being defined by $M_0 = M = K$, $M_1 = A$, $M_k = 0$ for $k \geqslant 2$, whence $\mathrm{gr}_0(M) = K/A$, $\mathrm{gr}_1(M) = A$, $\mathrm{gr}_k(M) = 0$ for $k \geqslant 2$. If $f \neq 0$ in A, one sees that f is not $\mathrm{gr}_\bullet(M)$-regular, but since $f^k\,\mathrm{gr}_\bullet(M)/f^{k+1}\,\mathrm{gr}_\bullet(M) = f^kA/f^{k+1}A$, it is immediate that the homomorphism (15.1.2.1) (where M is replaced by $\mathrm{gr}_\bullet(M)$) is injective, hence f is $\mathrm{gr}_\bullet(M)$-quasi-regular. But with the notations of (15.1.6), one then has $M'_k = K$ for all $k \geqslant 0$, hence $\mathrm{gr}'_\bullet(M) = 0$, while the first member of (15.1.5.2) is not reduced to 0. $\mathbf{0_{IV\text{-}1}}$ | 17

Proposition (15.1.13). — *Let A be a ring, M, N two A-modules, $(f_i)_{1\leqslant i\leqslant n}$ a sequence of elements of A. If the sequence (f_i) is M-regular and if N is a flat A-module, then the sequence (f_i) is $(M \otimes_A N)$-regular. The converse is true if N is a faithfully flat A-module.*

Proof. Indeed (without any hypothesis on N), $(M \otimes_A N)/(\sum_{j=1}^{i-1} f_j(M \otimes_A N))$ is isomorphic to $(M/(\sum_{j=1}^{i-1} f_jM)) \otimes_A N$; it suffices then to apply ($\mathbf{0_I}$, 6.1.1) and ($\mathbf{0_I}$, 6.4.1) to the homothety of ratio f_i in $M/(\sum_{j=1}^{i-1} f_jM)$. ☐

Corollary (15.1.14). — *Let A be a ring, M an A-module, $(f_i)_{1\leqslant i\leqslant n}$ a finite sequence of elements of A. Let $\rho : A \to B$ be a ring homomorphism, $M' = M_{(B)} = M \otimes_A B$, $f'_i = \rho(f_i)$ for $1 \leqslant i \leqslant n$. If B is a flat A-module and if the sequence (f_i) is M-regular, then the sequence (f'_i) is M'-regular; the converse is true if B is a faithfully flat A-module.*

Proof. Indeed, $M'/(\sum_{j=1}^{i-1} f'_j M')$ identifies with $(M/(\sum_{j=1}^{i-1} f_j M)) \otimes_A B$, and the homothety of ratio f'_i in the B-module $M'/(\sum_{j=1}^{i-1} f'_j M')$ with the homothety of ratio f_i in the A-module $(M/(\sum_{j=1}^{i-1} f_j M)) \otimes_A B$; the assertion thus follows from (15.1.13). □

Proposition (15.1.15). — *Let A be a ring, B a commutative A-algebra, $(f_i)_{1\leqslant i\leqslant n}$ a finite sequence of elements of B, M a B-module. Suppose that the sequence (f_i) is M-regular and that each of the A-modules $M/(\sum_{j=1}^{i-1} f_j M)$ $(1 \leqslant i \leqslant n)$ is flat. Then, for every ring homomorphism $\rho : A \to A'$, setting $B' = B \otimes_A A'$, $M' = M \otimes_A A'$, and $f'_i = f_i \otimes 1$ $(1 \leqslant i \leqslant n)$, the sequence (f'_i) is M'-regular and the A'-modules $M'/(\sum_{j=1}^{i-1} f'_j M')$ $(1 \leqslant i \leqslant n)$ are flat.*

Proof. Consider the exact sequence (by hypothesis)

$$0 \longrightarrow M \xrightarrow{f_1} M \longrightarrow M/f_1 M \longrightarrow 0$$

(the arrow $M \xrightarrow{f_1} M$ being the homothety of ratio f_1 in M). The hypothesis that M/f_1M is A-flat implies that the sequence

$$0 \longrightarrow M \otimes_A A' \xrightarrow{f_1 \otimes 1} M \otimes_A A' \longrightarrow (M/f_1 M) \otimes_A A' \longrightarrow 0$$

is exact ($\mathbf{0_I}$, 6.1.2). This shows that the homothety of ratio f'_1 in M' is injective. $\mathbf{0_{IV\text{-}1}}$ | 18

Set then, for $1 \leqslant i \leqslant n-1$, $M_i = M/(\sum_{j=1}^{i} f_j M)$, $M'_i = M'/(\sum_{j=1}^{i} f'_j M')$; we have $M'_i = M_i \otimes_A A'$, $M_i/f_{i+1}M_i = M_{i+1}$, $M'_i/f'_{i+1}M'_i = M'_{i+1}$; it suffices to replace M and f_1 by M_i and f_{i+1} to conclude that the homothety of ratio f'_{i+1} in M'_i is injective, by reason of the flatness of $M_i/f_{i+1}M_i$. The last assertion follows from ($\mathbf{0_I}$, 6.2.1). □

Proposition (15.1.16). — *Let A, B be two Noetherian local rings, k the residue field of A, $\varphi : A \to B$ a local homomorphism, M a finitely generated B-module. Let $(f_i)_{1\leqslant i\leqslant n}$ be a sequence of elements of the maximal ideal of B, and for each i, let g_i be the image of f_i in $B \otimes_A k$. The following conditions are equivalent:*

- *a) The sequence (f_i) is M-regular and the quotients $M_i = M/(\sum_{j=1}^{i} f_j M)$ are flat A-modules for $1 \leqslant i \leqslant n$.*
- *b) The sequence (f_i) is M-regular and the A-module M_n is flat.*
- *c) The A-module M is flat and the sequence $(g_i)_{1\leqslant i\leqslant n}$ is $(M \otimes_A k)$-regular.*
- *d) The A-module M is flat, and for every ring homomorphism $\rho : A \to A'$, if we set $B' = B \otimes_A A'$, $M' = M \otimes_A A'$, $f'_i = f_i \otimes 1$ $(1 \leqslant i \leqslant n)$, the sequence (f'_i) is M'-regular.*

Proof. It is clear that a) implies b); to show that b) implies d), it suffices, by virtue of (15.1.15), to show that b) implies that the M_i are flat A-modules for $0 \leqslant i \leqslant n-1$ (setting $M_0 = M$). As $M_{i+1} = M_i/f_{i+1}M_i$, we are reduced, by descending induction, to proving that if h is an element of the maximal ideal of B such that the homothety of ratio h in M is injective and M/hM is a flat A-module, then M is a flat A-module; but this is none other than ($\mathbf{0_{III}}$, 10.2.7). It is clear that c) is a particular case of d) obtained by taking $A' = k$. It thus remains to prove that c) implies a). As M is a flat A-module and a finitely generated B-module, it follows from c) and from ($\mathbf{0_{III}}$, 10.2.4) that the homothety of ratio f_1 in M is injective and that its cokernel $M/f_1M = M_1$ is a flat A-module. Let us reason by induction on i and suppose shown that M_i is a flat A-module; as the homothety of ratio g_{i+1} in $M_i \otimes_A k$ is injective by hypothesis, it follows again from ($\mathbf{0_{III}}$, 10.2.4) that the homothety of ratio f_{i+1} in M_i is injective and that $M_i/f_{i+1}M_i = M_{i+1}$ is a flat A-module, which finishes the proof. One will note that the proof that c) implies a) does not use the fact that the f_i belong to the maximal ideal of B. □

Corollary (15.1.17). — *The hypotheses on A and B being those of (15.1.16), let M be a finitely generated B-module, flat over A, R a sub-B-module of M such that $N = M/R$ is a flat A-module. Let $(f_i)_{1\leqslant i\leqslant n}$ be a sequence of elements of the maximal ideal of B having the following properties:*

(i) *$f_i M \subset R$ for $1 \leqslant i \leqslant n$.*
(ii) *If g_i is the image of f_i in $B \otimes_A k$, the sequence $(g_i)_{1\leqslant i\leqslant n}$ is $(M \otimes_A k)$-regular.*
(iii) *The sum of the sub-$(B \otimes_A k)$-modules $g_i(M \otimes_A k)$ of $M \otimes_A k$ is the image of $R \otimes_A k$ in $M \otimes_A k$ (equal to the kernel of the canonical homomorphism $M \otimes_A k \to N \otimes_A k$).*

Then the sequence (f_i) is M-regular and $R = \sum_{i=1}^{n} f_i M$.

Proof. As N is a flat A-module, it follows from the exactness of the sequence $0 \to R \to M \to N \to 0$ that the sequence $0 \to R \otimes_A k \to M \otimes_A k \to N \otimes_A k \to 0$ is exact ($\mathbf{0_I}$, 6.1.2); we thus have $R \otimes_A k = \sum g_i(M \otimes_A k)$. As M is a finitely generated B-module and B is Noetherian, R is also a finitely generated B-module, whence $R = \sum f_i M$ by Nakayama's lemma, since the f_i belong to the maximal ideal of B. □ $\mathbf{0_{IV\text{-}1}}$ | 19

Lemma (15.1.18). — *Let A be a ring, M an A-module equipped with a separated and exhaustive filtration $(M_k)_{k\geqslant 0}$, and let $f \in A$ be a $\mathrm{gr}_\bullet(M)$-regular element. Then:*

(i) *f is M-regular.*
(ii) *For all k, one has $M_k \cap fM = fM_k$, and the canonical image M'_k of M_k in $M' = M/fM$ is thus canonically isomorphic to M_k/fM_k.*
(iii) *The sequence*

$$0 \longrightarrow M_{k+1}/fM_{k+1} \longrightarrow M_k/fM_k \longrightarrow \mathrm{gr}_k(M)/f\cdot \mathrm{gr}_k(M) \longrightarrow 0$$

is exact, and if one equips M' with the quotient filtration (M'_k), $\mathrm{gr}_\bullet(M')$ is thus canonically isomorphic to $\mathrm{gr}_\bullet(M)/f\cdot\mathrm{gr}_\bullet(M)$.

Proof. Assertion (i) follows from the hypothesis on f and from Bourbaki, *Alg. comm.*, chap. III, § 2, no. 8, cor. 1 of th. 1. As $\mathrm{gr}_\bullet(M/M_k)$ is a direct factor of $\mathrm{gr}_\bullet(M)$, f is $\mathrm{gr}_\bullet(M/M_k)$-regular by (i), which establishes (ii). To prove (iii), it suffices to see that the map $M_{k+1}/fM_{k+1} \to M_k/fM_k$ is injective: now, if $x \in M_{k+1}$ is such that $x \in fM_k$, it follows from (ii) that $x \in fM_{k+1}$, which finishes proving the lemma. □

Proposition (15.1.19). — *Let A be a ring, M an A-module equipped with a filtration $(M_k)_{k\geqslant 0}$ such that $M_0 = M$, $(f_i)_{1\leqslant i\leqslant n}$ a $\mathrm{gr}_\bullet(M)$-regular sequence of elements of A. Suppose in addition that, for $0 \leqslant i \leqslant n-1$, the quotient filtration of (M_k) on $M/(\sum_{j\leqslant i} f_j M)$ is separated. Then the sequence (f_i) is M-regular, and if one sets $M' = M/(\sum_{i\leqslant n} f_i M)$ and equips M' with the quotient filtration of (M_k), $\mathrm{gr}_\bullet(M')$ is canonically isomorphic to $\mathrm{gr}_\bullet(M)/(\sum_{i\leqslant n} f_i\,\mathrm{gr}_\bullet(M))$.*

Proof. For $n = 1$, the proposition follows from the lemma (15.1.18). Let us reason by induction on n, setting $N = M/(\sum_{i\leqslant n-1} f_i M)$ and denoting by (N_k) the quotient filtration of (M_k) on N, which is separated by hypothesis; moreover, $\mathrm{gr}_\bullet(N)$ is isomorphic to

$$\mathrm{gr}_\bullet(M)/\Big(\sum_{i\leqslant n-1} f_i\,\mathrm{gr}_\bullet(M)\Big).$$

By hypothesis, f_n is thus $\mathrm{gr}_\bullet(N)$-regular, and it follows from the lemma (15.1.18) applied to N that f_n is N-regular and $\mathrm{gr}_\bullet(M')$ is isomorphic to $\mathrm{gr}_\bullet(N)/f_n\,\mathrm{gr}_\bullet(N)$, which proves the proposition. □

The proposition (15.1.19) will apply in particular for filtrations satisfying one or the other of the following hypotheses:

1° The filtration (M_k) is finite and separated (since this implies $M_k = 0$ for k large enough);
2° A is a Noetherian ring, $\mathfrak{J}$ an ideal contained in the radical of A, M a finitely generated A-module, and (M_k) the $\mathfrak{J}$-preadic filtration ($\mathbf{0_I}$, 7.3.5).

Corollary (15.1.20). — *Let A be a ring, M an A-module, $(f_i)_{1\leqslant i\leqslant n}$ an M-regular sequence of elements of A. Then, for any integers $\nu_i \geqslant 1$, the sequence $(f_i^{\nu_i})$ is M-regular, and $M/(\sum_{i\leqslant n} f_i^{\nu_i} M)$ has a composition series whose quotients are isomorphic to $M/(\sum_{i\leqslant n} f_i M)$.* $\mathbf{0_{IV\text{-}1}}$ | 20

Proof. Let us reason by induction on n; for $n = 1$ the assertions are immediate since $f^j M/f^{j+1}M$ is isomorphic to M/fM, the homothety of ratio f in M being injective by hypothesis. Set then $N = M/(\sum_{i\leqslant n-1} f_i^{\nu_i} M)$; by the induction hypothesis, N admits a finite filtration (N_k) for which $\mathrm{gr}_k(N)$ are isomorphic to $M/(\sum_{i\leqslant n-1} f_i M)$; by hypothesis f_n is thus $\mathrm{gr}_\bullet(N)$-regular; it follows by

(15.1.19) that f_n is N-regular. Applying the case $n = 1$ proved at the start, one concludes that $f_n^{\nu_n}$ is N-regular and that $N/f_n^{\nu_n}N$ admits a composition series whose quotients are isomorphic to N/f_nN; but for the filtration of N/f_nN given by the quotient filtration of (N_k), $\mathrm{gr}_k(N/f_nN)$ is isomorphic to $\mathrm{gr}_k(N)/f_n\,\mathrm{gr}_k(N)$ by (15.1.19) for all k, hence to $M/(\sum_{i\leqslant n} f_iM)$, which proves the corollary. □

Proposition (15.1.21). — *Let A, B be two Noetherian local rings, $\varphi : A \to B$ a local homomorphism, M a finitely generated B-module, $(f_i)_{1\leqslant i\leqslant n}$ an A-regular sequence of elements of the maximal ideal of A. The following properties are equivalent:*

a) M is a flat A-module.

b) If $\mathfrak{J}$ is the ideal $\sum_{i\leqslant n} f_iA$, $M/\mathfrak{J}M$ is a flat $A/\mathfrak{J}$-module and the sequence (f_i) is M-regular.

Proof. The fact that a) implies b) follows from (15.1.13) and from ($\mathbf{0_{III}}$, 10.2.2). Conversely, if the sequence (f_i) is M-regular, it is M-quasi-regular (15.1.9), hence the homomorphism (15.1.1.1) is bijective. But as the sequence $(f_i)_{1\leqslant i\leqslant n}$ is also supposed A-regular, it is A-quasi-regular, and the corresponding canonical homomorphism $(A/\mathfrak{J})[T_1,\dots,T_n] \to \mathrm{gr}_\bullet(A)$ is bijective. One concludes that the canonical morphism ($\mathbf{0_{III}}$, 10.1.1.2)

$$\mathrm{gr}_0(M) \otimes_{A/\mathfrak{J}} \mathrm{gr}_\bullet(A) \longrightarrow \mathrm{gr}_\bullet(M)$$

is bijective. The conclusion then follows from ($\mathbf{0_{III}}$, 10.2.2), the f_i being in the maximal ideal of A and the homomorphism φ being local. □

15.2. $\mathscr{F}$-regular sequences

(15.2.1). Let X be a ringed space, $\mathscr{F}$ an $\mathscr{O}_X$-Module, f_i $(1 \leqslant i \leqslant n)$ a sequence of sections of $\mathscr{O}_X$ over X, $\mathscr{J}$ the Ideal of $\mathscr{O}_X$ generated by the f_i (image of $\mathscr{O}_X^n$ by the homomorphism $\mathscr{O}_X^n \to \mathscr{O}_X$ defined canonically by the f_i ($\mathbf{0_I}$, 5.1.1)). The sub-$\mathscr{O}_X$-Modules $\mathscr{J}^k\mathscr{F}$ define a *filtration* on $\mathscr{F}$, and one sets further $\mathrm{gr}_k(\mathscr{F}) = \mathscr{J}^k\mathscr{F}/\mathscr{J}^{k+1}\mathscr{F}$; if S_k is the set of homogeneous polynomials of total degree k in the ring $\mathbf{Z}[T_1,\dots,T_n]$, S_k can be considered as a simple sheaf on X, and one defines as in (15.1.1) a canonical homomorphism

$$\varphi_k : \mathrm{gr}_0(\mathscr{F}) \otimes_{\mathbf{Z}} S_k \longrightarrow \mathrm{gr}_k(\mathscr{F}) \tag{15.2.1.1}$$

in the following way: for every open set U of X (or of a base of the topology of X), one considers the homomorphism (15.1.1.1) $\mathbf{0_{IV\text{-}1}}$ | 21

$$\varphi_{k,U} : (\mathrm{gr}_0(\Gamma(U,\mathscr{F}))) \otimes_{\mathbf{Z}} S_k \longrightarrow \mathrm{gr}_k(\Gamma(U,\mathscr{F}))$$

defined by the n sections $f_i|U \in \Gamma(U,\mathscr{O}_X)$, the $\Gamma(U,\mathscr{O}_X)$-module $\Gamma(U,\mathscr{F})$ being filtered by the submodules $(\Gamma(U,\mathscr{J}))^k\Gamma(U,\mathscr{F})$. The $\mathscr{O}_X$-Module $\mathrm{gr}_k(\mathscr{F})$ being associated to the presheaf $U \mapsto \mathrm{gr}_k(\Gamma(U,\mathscr{F}))$ for all k, the $\varphi_{k,U}$ define a homomorphism of (15.2.1.1). By virtue of the exactness properties of inductive limits of modules and their commutation with tensor products, it follows from the above that for all $x \in X$, the homomorphism of the stalks of the two members of (15.2.1.1) at the point x identifies with the homomorphism of (15.1.1)

$$\mathrm{gr}_0(\mathscr{F}_x) \otimes_{\mathbf{Z}} S_k \longrightarrow \mathrm{gr}_k(\mathscr{F}_x) \tag{15.2.1.2}$$

defined by the sequence $((f_i)_x)_{1\leqslant i\leqslant n}$ of elements of $\mathscr{O}_x$.

(15.2.2). The notations being those of (15.2.1), we say that the sequence $(f_i)_{1\leqslant i\leqslant n}$ is *$\mathscr{F}$-regular* if, denoting by $f_j\mathscr{F}$ the sub-$\mathscr{O}_X$-Module of $\mathscr{F}$, the image of the endomorphism of $\mathscr{F}$ defined by f_j, the endomorphism of $\mathscr{F}/(\sum_{j=1}^{i-1} f_j\mathscr{F})$ defined by f_i is *injective* for $1 \leqslant i \leqslant n$; we say that the sequence (f_i) is *$\mathscr{F}$-quasi-regular* if the homomorphisms (15.2.1.1) are injective. It follows from these definitions and the remarks of (15.2.1) that for the sequence (f_i) to be $\mathscr{F}$-regular (resp. $\mathscr{F}$-quasi-regular), it is necessary and sufficient that, for all $x \in X$, the sequence $((f_i)_x)_{1\leqslant i\leqslant n}$ be $\mathscr{F}_x$-regular (resp. $\mathscr{F}_x$-quasi-regular). Every $\mathscr{F}$-regular sequence is thus $\mathscr{F}$-quasi-regular (15.1.9); the converse is true if $\mathscr{F}$ is an $\mathscr{O}_X$-Module *of finite type*, if the $\mathscr{O}_x$ are *Noetherian* rings for all $x \in X$, and if moreover the $(f_i)_x$ belong to the *radical* of $\mathscr{O}_x$ for all $x \in X$ (15.1.11).

If $X = \mathrm{Spec}(A)$ is an affine scheme, and $\mathscr{F} = \widetilde{M}$, it follows from (**I**, 1.3) that for the sequence (f_i) to be $\mathscr{F}$-regular (resp. $\mathscr{F}$-quasi-regular), it is necessary and sufficient that it be M-regular (resp. M-quasi-regular).

When $\mathscr{F} = \mathscr{O}_X$, one omits the mention of $\mathscr{F}$ in the preceding definitions.

Remark (15.2.3). — When $X = \mathrm{Spec}(A)$ and $\mathfrak{J} = \sum_{i=1}^{n} f_i A$, the sequence (f_j) is quasi-regular for *every* A-module M in every open set U not meeting $V(\mathfrak{J})$, since for every point $x \in U$, $\mathfrak{J}_x = \mathscr{O}_x$ and the two members of (15.2.1.2) are zero. The notion of $\widetilde{M}$-regular sequence is thus of interest only in a neighbourhood of the points of $V(\mathfrak{J})$.

Proposition (15.2.4). — *Let X be a ringed space, $\mathscr{F}$ a coherent $\mathscr{O}_X$-Module, x a point of X, $(f_i)_{1\leqslant i\leqslant n}$ a sequence of elements of $\Gamma(X, \mathscr{O}_X)$. If the sequence $((f_i)_x)_{1\leqslant i\leqslant n}$ is $\mathscr{F}_x$-regular, there exists an open neighbourhood U of x such that the sequence $(f_i|U)_{1\leqslant i\leqslant n}$ is $(\mathscr{F}|U)$-regular.*

Proof. Indeed, for $1 \leqslant i \leqslant n$, the $\mathscr{O}_X$-Module $\mathscr{F}/(\sum_{j=1}^{i-1} f_j\mathscr{F})$ is coherent ($\mathbf{0_I}$, 5.3.4), hence so is the kernel of the endomorphism of this $\mathscr{O}_X$-Module defined by f_i ($\mathbf{0_I}$, 5.3.4); as the stalk of this kernel at the point x is zero, the same holds for its restriction to a neighbourhood of x ($\mathbf{0_I}$, 5.2.2). □

Proposition (15.2.5). — *Let $u = (\psi, \theta) : X \to Y$ be a flat morphism of ringed spaces ($\mathbf{0_I}$, 6.7.1); let $\mathscr{F}$ be an $\mathscr{O}_Y$-Module, $\mathscr{G} = u^*(\mathscr{F})$, $(f_i)_{1\leqslant i\leqslant n}$ a sequence of elements of $\Gamma(Y, \mathscr{O}_Y)$, $(g_i)_{1\leqslant i\leqslant n}$ the sequence of their images $g_i = \theta(f_i) \in \Gamma(Y, u_*(\mathscr{O}_X)) = \Gamma(X, \mathscr{O}_X)$. If the sequence (f_i) is $\mathscr{F}$-regular, the sequence (g_i) is $\mathscr{G}$-regular. The converse is true if u is a faithfully flat morphism ($\mathbf{0_I}$, 6.7.8).* $\mathbf{0_{IV\text{-}1}}$ | 22

Proof. Let x be a point of X, $y = u(x) = \psi(x)$; we have

$$\mathscr{G}_x = \psi_x^*(\mathscr{F}_y) \otimes_{\psi_x^*(\mathscr{O}_y)} \mathscr{O}_x, \qquad \text{and} \qquad (g_i)_x = \theta_x^*(\psi_x^*((f_i)_y));$$

as $\theta_x^* : \psi_x^*(\mathscr{O}_y) \to \mathscr{O}_x$ makes $\mathscr{O}_x$ a flat $\psi_x^*(\mathscr{O}_y)$-module, and since the functor ψ^* is exact, the first assertion follows from the corresponding assertion of (15.1.14); the same holds for the second, taking into account the fact that u being faithfully flat means that ψ is surjective and that θ_x^* makes $\mathscr{O}_x$ a faithfully flat $\psi_x^*(\mathscr{O}_y)$-module. □

§16. Dimension and depth of Noetherian local rings

16.1. Dimension of a ring

(16.1.1). We call the *dimension* (or *Krull dimension*) of a ring A and denote by dim A the (combinatorial) dimension of its spectrum Spec(A) (14.2.1); as the irreducible closed subsets of Spec(A) are the $\mathrm{V}(\mathfrak{p})$, where $\mathfrak{p}$ is a prime ideal of A (Bourbaki, *Alg. comm.*, chap. II, § 4, nº 3, cor. 1 of prop. 14), it amounts to saying that dim(A) is *the upper bound of the lengths of chains* (14.1.1)

$$\mathfrak{p}_0 \subset \mathfrak{p}_1 \subset \ldots \subset \mathfrak{p}_n$$

of *prime ideals* of A. If $\mathrm{A} \neq 0$, we have $\dim \mathrm{A} \geqslant 0$. A nonzero Artinian ring (in particular a field) is of dimension 0 (Bourbaki, *Alg. comm.*, chap. IV, § 2, nº 5, prop. 7); a Dedekind ring that is not a field (in particular **Z** or a polynomial ring $k[\mathrm{T}]$ over a field k) is of dimension 1 (Bourbaki, *Alg. comm.*, chap. VII, § 2). A Noetherian ring is not necessarily of finite dimension [30]. If $(\mathfrak{p}_\alpha)$ is the family of minimal prime ideals of A, we have (14.1.2.1)

(16.1.1.1) $$\dim(\mathrm{A}) = \sup_\alpha(\dim(\mathrm{A}/\mathfrak{p}_\alpha)).$$

(16.1.2). For every ideal $\mathfrak{a}$ of A, the prime ideals of $\mathrm{A}/\mathfrak{a}$ correspond bijectively to the prime ideals of A containing $\mathfrak{a}$, hence

(16.1.2.1) $$\dim(\mathrm{A}/\mathfrak{a}) \leqslant \dim(\mathrm{A}).$$

If in addition $\mathfrak{a}$ *is not contained in any minimal prime ideal* $\mathfrak{p}_\alpha$ of A, every chain of prime ideals of A containing $\mathfrak{a}$ can be completed by one of the $\mathfrak{p}_\alpha$, hence

(16.1.2.2) $$1 + \dim(\mathrm{A}/\mathfrak{a}) \leqslant \dim(\mathrm{A}).$$

(16.1.3). If S is a multiplicative subset of A, the prime ideals of $\mathrm{S}^{-1}\mathrm{A}$ correspond bijectively to the prime ideals of A not meeting S, hence $\mathbf{0_{IV\text{-}1}}$ | 23

(16.1.3.1) $$\dim(\mathrm{S}^{-1}\mathrm{A}) \leqslant \dim(\mathrm{A}).$$

For every prime ideal $\mathfrak{p}$ of A, we have, by definition (14.2.1)

(16.1.3.2) $$\dim(\mathrm{A}_\mathfrak{p}) = \mathrm{codim}(\mathrm{V}(\mathfrak{p}), \mathrm{Spec}(\mathrm{A})).$$

This number is also called the *height* of the prime ideal $\mathfrak{p}$ and denoted $\mathrm{ht}(\mathfrak{p})$. More generally, for every ideal $\mathfrak{a}$ of A, we call the *height* of $\mathfrak{a}$ the number

(16.1.3.3) $$\mathrm{ht}(\mathfrak{a}) = \mathrm{codim}(\mathrm{V}(\mathfrak{a}), \mathrm{Spec}(\mathrm{A})).$$

If $(\mathfrak{p}_\lambda)$ is the family of minimal prime ideals among those containing $\mathfrak{a}$, we have then (14.2.1)

(16.1.3.4) $$\mathrm{ht}(\mathfrak{a}) = \inf_\lambda(\mathrm{ht}(\mathfrak{p}_\lambda)).$$

We evidently have

(16.1.3.5) $$\dim(\mathrm{A}) = \sup_{\mathfrak{m}}(\dim(\mathrm{A}_{\mathfrak{m}}))$$

where $\mathfrak{m}$ ranges over the set of maximal ideals of A.

(16.1.4). For every prime ideal $\mathfrak{p}$ of A, we have (14.2.2.2)

(16.1.4.1) $$\dim(\mathrm{A}_{\mathfrak{p}}) + \dim(\mathrm{A}/\mathfrak{p}) \leqslant \dim \mathrm{A}.$$

We say that A is *catenary* (resp. *equidimensional*, *equicodimensional*, *biequidimensional*) when Spec(A) is catenary (resp. equidimensional, equicodimensional, biequidimensional). When A is Noetherian and biequidimensional, the two members of (16.1.4.1) are equal for every prime ideal $\mathfrak{p}$ of A (14.3.5).

For every ideal $\mathfrak{a}$ of A, the prime ideals of $\mathrm{A}/\mathfrak{a}$ correspond bijectively to the prime ideals of A containing $\mathfrak{a}$, hence, *if* A *is catenary, so is* $\mathrm{A}/\mathfrak{a}$. Similarly, for every multiplicative subset S of A, the prime ideals of $\mathrm{S}^{-1}\mathrm{A}$ correspond bijectively to the prime ideals of A not meeting S, hence *if* A *is catenary, so is* $\mathrm{S}^{-1}\mathrm{A}$.

Furthermore, as the prime ideals of A contained in a prime ideal $\mathfrak{p}$ correspond bijectively to the prime ideals of $\mathrm{A}_{\mathfrak{p}}$, for A to be catenary it suffices that $\mathrm{A}_{\mathfrak{p}}$ be so for every $\mathfrak{p}$. To say that A is catenary means ((14.3.2) and (16.1.3.2)) that for every pair of prime ideals $\mathfrak{p}$, $\mathfrak{q}$ of A such that $\mathfrak{q} \subset \mathfrak{p}$, we have

(16.1.4.2) $$\dim(\mathrm{A}_{\mathfrak{q}}) + \dim(\mathrm{A}_{\mathfrak{p}}/\mathfrak{q}\mathrm{A}_{\mathfrak{p}}) = \dim(\mathrm{A}_{\mathfrak{p}}).$$

If A is biequidimensional, it is the same for $\mathrm{A}_{\mathfrak{p}}$ for every prime ideal $\mathfrak{p}$ of A.

Proposition (16.1.5). — *Let* $\rho : \mathrm{A} \to \mathrm{B}$ *be a ring homomorphism making* B *an integral* A*-algebra. Then* $\dim(\mathrm{B}) \leqslant \dim(\mathrm{A})$*; if in addition* ρ *is injective, we have* $\dim(\mathrm{B}) = \dim(\mathrm{A})$.

Proof. If $\mathfrak{n}$ is the kernel of ρ, $\rho(\mathrm{A})$ is isomorphic to $\mathrm{A}/\mathfrak{n}$, hence $\dim \rho(\mathrm{A}) \leqslant \dim(\mathrm{A})$ by (16.1.2.1), and since B is integral over $\rho(\mathrm{A})$, one can reduce to proving the second assertion. If $\mathfrak{p}'_0 \subset \mathfrak{p}'_1 \subset \ldots \subset \mathfrak{p}'_n$ is a chain of prime ideals of B, the $\mathfrak{p}'_i \cap \mathrm{A}$ are then distinct prime ideals in A (Bourbaki, *Alg. comm.*, chap. V, § 2, n° 1, cor. 1 of prop. 1), hence they form a chain of prime ideals. Conversely, for every chain $\mathfrak{p}_0 \subset \mathfrak{p}_1 \subset \ldots \subset \mathfrak{p}_m$ of prime ideals of A, we know that for each i there exists a prime ideal $\mathfrak{p}'_i$ of B such that $\mathfrak{p}'_i \cap \mathrm{A} = \mathfrak{p}_i$ and $\mathfrak{p}'_i \subset \mathfrak{p}'_{i+1}$ for $0 \leqslant i \leqslant m-1$ (*loc. cit.*, cor. 2 of th. 1). Hence the conclusion. $\square$ $\mathbf{0}_{\textbf{IV-1}}$ | 24

Proposition (16.1.6). — *Let* B *be an integral ring,* A *a local subring of* B*,* $\mathfrak{m}$ *its maximal ideal. Suppose that* A *is integrally closed and that* B *is integral over* A*; then, for every maximal ideal* $\mathfrak{n}$ *of* B*, we have* $\dim(\mathrm{B}_{\mathfrak{n}}) = \dim(\mathrm{A})$.

Proof. The first part of the reasoning of (16.1.5) shows that $\dim(\mathrm{B}_{\mathfrak{n}}) \leqslant \dim(\mathrm{A})$. Conversely, consider a chain of prime ideals $\mathfrak{p}_0 \subset \mathfrak{p}_1 \subset \ldots \subset \mathfrak{p}_k = \mathfrak{m}$ of A; we know that $\mathfrak{n} \cap \mathrm{A} = \mathfrak{m}$ (Bourbaki, *Alg. comm.*, chap. V, § 2, n° 1, prop. 1) and by virtue of the hypotheses made, one can apply the second theorem of Cohen-Seidenberg (Bourbaki, *Alg. comm.*, chap. V, § 2, n° 4, th. 3), which proves the existence of a chain of prime ideals $\mathfrak{p}'_0 \subset \mathfrak{p}'_1 \subset \ldots \subset \mathfrak{p}'_k = \mathfrak{n}$ of B such that $\mathfrak{p}'_i \cap \mathrm{A} = \mathfrak{p}_i$ for each i; from this one deduces immediately $\dim(\mathrm{B}_{\mathfrak{n}}) \geqslant \dim(\mathrm{A})$, whence the proposition. $\square$

(16.1.7). Let M be an A-module; we call the *dimension* of M and denote by $\dim_{\mathrm{A}}(\mathrm{M})$ or $\dim(\mathrm{M})$ the dimension of the ring $\mathrm{A}/\mathrm{Ann}(\mathrm{M})$ (isomorphic to the ring of homotheties A_{M} of M). We thus have $\dim(\mathrm{M}^k) = \dim(\mathrm{M})$ for every $k > 0$. If M is *of finite type*, the prime ideals of A containing Ann(M) are exactly those belonging to Supp(M) ($\mathbf{0}_{\mathrm{I}}$, 1.7.4) and the latter is closed in Spec(A), hence we then have

(16.1.7.1) $$\dim(\mathrm{M}) = \dim(\mathrm{Supp}(\mathrm{M})) \leqslant \dim(\mathrm{A}).$$

If M, N are two A-modules such that $N \subset M$, we have

(16.1.7.2) $$\dim(N) \leqslant \dim(M), \qquad \dim(M/N) \leqslant \dim(M).$$

If S is a multiplicative subset of A and if M is of finite type, we have

(16.1.7.3) $$\dim_{S^{-1}A}(S^{-1}M) \leqslant \dim_A(M).$$

Furthermore, every maximal chain of prime ideals containing $\mathrm{Ann}(M)$ terminates at a maximal ideal $\mathfrak{m}$, hence its length is equal to the length of the chain of corresponding prime ideals of $A_{\mathfrak{m}}$ (which contain $(\mathrm{Ann}(M))_{\mathfrak{m}}$); from this remark and from (16.1.7.3), one obtains

(16.1.7.4) $$\dim_A(M) = \sup_{\mathfrak{m}}(\dim_{A_{\mathfrak{m}}}(M_{\mathfrak{m}}))$$

where $\mathfrak{m}$ ranges over the set of maximal ideals of A. We say that M is *catenary* (resp. *equidimensional*, *equicodimensional*, *biequidimensional*) when $A/\mathrm{Ann}(M)$ is.

Proposition (16.1.8). — *Let* A *be a ring,* M *an* A*-module of finite type,* $\mathfrak{p}$ *a prime ideal of* A*. We have*

(16.1.8.1) $$\dim_{A_{\mathfrak{p}}}(M_{\mathfrak{p}}) + \dim_A(M/\mathfrak{p}M) \leqslant \dim_A(M).$$

Proof. We have $\mathrm{Ann}(M_{\mathfrak{p}}) = (\mathrm{Ann}(M))_{\mathfrak{p}}$, hence the prime ideals of $A_{\mathfrak{p}}$ containing $\mathrm{Ann}(M_{\mathfrak{p}})$ correspond bijectively to the prime ideals of A containing $\mathrm{Ann}(M)$ and contained in $\mathfrak{p}$. On the other hand, if $\mathrm{Ann}(M) = \mathfrak{n}$, $V(\mathrm{Ann}(M/\mathfrak{p}M)) = V(\mathfrak{p}+\mathfrak{n})$ ($\mathbf{0}_{\mathrm{I}}$, 1.7.5), hence the prime ideals of A containing $\mathrm{Ann}(M/\mathfrak{p}M)$ contain $\mathfrak{p}+\mathfrak{n}$; whence the conclusion. We note in addition that $\mathbf{0}_{\textbf{IV-1}}$ | 25

(16.1.8.2) $$\dim_{A/\mathfrak{p}}(M/\mathfrak{p}M) = \dim_A(M/\mathfrak{p}M).$$

□

Proposition (16.1.9). — *Let* A *be a Noetherian ring,* $\rho : A \to B$ *a ring homomorphism,* M *a* B*-module such that* $M_{[\rho]}$ *is an* A*-module of finite type. Then*

(16.1.9.1) $$\dim_A(M_{[\rho]}) = \dim_B(M).$$

Proof. Indeed, the ring B_M of homotheties of the B-module M is a subring of the A-module $C = \mathrm{End}_A(M_{[\rho]})$, and C is an A-module of finite type (Bourbaki, *Alg. comm.*, chap. III, § 3, nº 1, lemma 2), hence it is the same for B_M; moreover the ring A_M of homotheties of the A-module $M_{[\rho]}$ is a subring of B_M, canonical image of A in C, hence B_M is finite over A_M; the conclusion then follows from (16.1.5). □

(16.1.10). Let A be a Noetherian ring; if M is an A-module of *finite length*, we know (Bourbaki, *Alg. comm.*, chap. IV, § 2, nº 5, prop. 7 and cor. 1 of prop. 7) that $\mathrm{Supp}(M)$ is a finite discrete set, hence $\dim(M) = 0$ if $M \neq 0$; conversely, if M is an A-module of finite type such that $\dim(M) = 0$, every point of $\mathrm{Supp}(M)$ is closed, in other words it is a maximal ideal of A, hence (*loc. cit.*, prop. 7) M is of finite length.

16.2. Dimension of a semi-local Noetherian ring[15]

(16.2.1). Let A be a *semi-local Noetherian* ring, $\mathfrak{r}$ its radical; recall that an *ideal of definition* $\mathfrak{q}$ of A is an ideal such that $\mathfrak{q} \subset \mathfrak{r}$ and $\mathfrak{q}$ contains a power of $\mathfrak{r}$, or equivalently, that the only prime ideals containing $\mathfrak{q}$ are *maximal*, or that $A/\mathfrak{q}$ is an Artinian ring. Let M be an A-module of finite type; for every integer $n > 0$, $M/\mathfrak{q}^n M$ is an A-module of *finite length*, equal to $\sum_{i=0}^{n-1} \mathrm{long}(\mathrm{gr}_i(M))$, where $\mathrm{gr}_\bullet(M)$ is the $(A/\mathfrak{q})$-graded module associated to M equipped with the $\mathfrak{q}$-preadic filtration. Recall that there exists a *polynomial* $Q(n)$ with rational coefficients such that $\mathrm{long}(\mathrm{gr}_n(M)) = Q(n)$ for n sufficiently large (**III**, 2.5.4); from this one deduces immediately that there exists a polynomial $P_{\mathfrak{q}}(M, n)$ in n, with rational coefficients, such that $\mathrm{long}(M/\mathfrak{q}^n M) = P_{\mathfrak{q}}(M, n)$ *for n sufficiently large*; it is clear that this polynomial is unique and that its leading coefficient is > 0 if $M \neq 0$; we call it the *Hilbert–Samuel polynomial* of M for the $\mathfrak{q}$-preadic filtration.

$\mathbf{0}_{\textbf{IV-1}}$ | 26

[15] This section reproduces the lecture given by Serre in a course at the Collège de France in 1958.

Lemma (16.2.2.1). — *Let* (M_n) *be a* $\mathfrak{q}$*-good filtration of* M *(Bourbaki,* Alg. comm.*, chap. III, § 3, n° 1); then* $\log(\mathrm{M}/\mathrm{M}_n)$ *is equal, for n sufficiently large, to a polynomial in n whose degree and leading coefficient are the same as those of* $\mathrm{P}_{\mathfrak{q}}(\mathrm{M}, n)$*.*

Proof. Indeed, there exists n_0 such that $\mathrm{M}_{n+1} = \mathfrak{q}\mathrm{M}_n$ for $n \geqslant n_0$, whence the inclusions $\mathfrak{q}^{n+n_0}\mathrm{M} \subset \mathrm{M}_{n+n_0} = \mathfrak{q}^n\mathrm{M}_{n_0} \subset \mathfrak{q}^n\mathrm{M} \subset \mathrm{M}_n$ for n sufficiently large, which implies

$$\mathrm{P}_{\mathfrak{q}}(\mathrm{M}, n+n_0) \geqslant \operatorname{long}(\mathrm{M}/\mathrm{M}_{n+n_0}) \geqslant \mathrm{P}_{\mathfrak{q}}(\mathrm{M}, n) \geqslant \operatorname{long}(\mathrm{M}/\mathrm{M}_n)$$

hence the conclusion. □

If $\mathfrak{q}'$ is a second ideal of definition, one has $\mathfrak{q}' \supset \mathfrak{q}^m$ for some integer m, hence $\mathrm{P}_{\mathfrak{q}'}(\mathrm{M}, n) \leqslant \mathrm{P}_{\mathfrak{q}}(\mathrm{M}, mn)$; the *degree* of $\mathrm{P}_{\mathfrak{q}}(\mathrm{M}, n)$ therefore *does not depend on the ideal of definition* $\mathfrak{q}$; we denote it $d(\mathrm{M})$.

Lemma (16.2.2.2). — *Let* $0 \to \mathrm{M}' \to \mathrm{M} \to \mathrm{M}'' \to 0$ *be a short exact sequence of* A*-modules of finite type. Then the polynomial* $\mathrm{P}_{\mathfrak{q}}(\mathrm{M}, n) - \mathrm{P}_{\mathfrak{q}}(\mathrm{M}', n) - \mathrm{P}_{\mathfrak{q}}(\mathrm{M}'', n)$ *has degree* $\leqslant d(\mathrm{M}') - 1 \leqslant d(\mathrm{M}) - 1$*.*

Proof. Indeed, the filtration of the $\mathrm{M}'_n = \mathrm{M}' \cap \mathfrak{q}^n\mathrm{M}$ is $\mathfrak{q}$-good (Bourbaki, *Alg. comm.*, chap. III, § 3, n° 1, prop. 1); as $\operatorname{long}(\mathrm{M}/\mathfrak{q}^n\mathrm{M}) = \operatorname{long}(\mathrm{M}''/\mathfrak{q}^n\mathrm{M}'') + \operatorname{long}(\mathrm{M}'/\mathrm{M}'_n)$, the lemma follows immediately from (16.2.2.1) applied to M'. □

Theorem (16.2.3). — (Krull-Chevalley-Samuel). *Let* A *be a semi-local Noetherian ring,* $\mathfrak{r}$ *its radical,* $\mathrm{M} \neq 0$ *an* A*-module of finite type,* $d(\mathrm{M})$ *the degree of the Hilbert–Samuel polynomial of* M *(for any ideal of definition of* A*); let* $s(\mathrm{M})$ *denote the lower bound of the number of elements* $x_1, \ldots, x_n$ *of* $\mathfrak{r}$ *such that* $\mathrm{M}/(x_1\mathrm{M} + \ldots + x_n\mathrm{M})$ *is of finite length. Then*

$$d(\mathrm{M}) = s(\mathrm{M}) = \dim(\mathrm{M}).$$

Lemma (16.2.3.1). — *For every* $x \in \mathfrak{r}$*, let* ${}_x\mathrm{M}$ *be the submodule of* M *of elements annihilated by x. Then:*

(i) $s(\mathrm{M}) \leqslant s(\mathrm{M}/x\mathrm{M}) + 1$.

(ii) *Let* $\mathfrak{p}_i$ *be the prime ideals belonging to* $\operatorname{Supp}(\mathrm{M})$ *and such that*

$$\dim(\mathrm{A}/\mathfrak{p}_i) = \dim(\mathrm{M}) \quad (1 \leqslant i \leqslant m).$$

If $x \notin \mathfrak{p}_i$ *for every i, we have* $\dim(\mathrm{M}/x\mathrm{M}) \leqslant \dim(\mathrm{M}) - 1$.

(iii) *If* $\mathfrak{q}$ *is an ideal of definition of* A*, the polynomial*

$$\mathrm{P}_{\mathfrak{q}}({}_x\mathrm{M}, n) - \mathrm{P}_{\mathfrak{q}}(\mathrm{M}/x\mathrm{M}, n)$$

has degree $\leqslant d(\mathrm{M}) - 1$.

Proof. The assertion (i) is trivial, since if $(x_i)_{1 \leqslant i \leqslant m}$ is such that for the module $\mathrm{N} = \mathrm{M}/x\mathrm{M}$, $\mathrm{N}/(x_1\mathrm{N} + \ldots + x_m\mathrm{N})$ is of finite length, this amounts to saying that $\mathrm{M}/(x\mathrm{M} + x_1\mathrm{M} + \ldots + x_m\mathrm{M})$ is isomorphic to this module.

For (ii), note that, if $\mathfrak{a}$ denotes the annihilator of M, the prime ideals containing the annihilator of $\mathrm{M}/x\mathrm{M}$ are those containing $\mathfrak{a} + \mathrm{A}x$ ($\mathbf{0}_{\mathrm{I}}$, 1.7.5); none of the $\mathfrak{p}_i$ can therefore contain $\mathfrak{a} + \mathrm{A}x$ and by definition of $\dim(\mathrm{M})$ (16.1.7) every chain of prime ideals containing $\mathfrak{a} + \mathrm{A}x$ has therefore length $\leqslant \dim(\mathrm{M}) - 1$.

Finally, to prove (iii), note that one has two short exact sequences **$\mathbf{0}_{\mathbf{IV}\text{-}\mathbf{1}}$** | 27

$$0 \longrightarrow {}_x\mathrm{M} \longrightarrow \mathrm{M} \xrightarrow{x} x\mathrm{M} \longrightarrow 0, \qquad 0 \longrightarrow x\mathrm{M} \longrightarrow \mathrm{M} \longrightarrow \mathrm{M}/x\mathrm{M} \longrightarrow 0$$

and the assertion follows immediately from the lemma (16.2.2.2). □

The proof of (16.2.3) proceeds in three steps:

(16.2.3.2). $\dim(\mathrm{M}) \leqslant d(\mathrm{M})$.

We argue by induction on $d(\mathrm{M})$, the case $d(\mathrm{M}) = 0$ being trivial. Suppose thus $d(\mathrm{M}) \geqslant 1$, and let $\mathfrak{p}_0 \in \operatorname{Supp}(\mathrm{M})$ such that $\dim(\mathrm{A}/\mathfrak{p}_0) = \dim(\mathrm{M})$. This implies that $\mathfrak{p}_0$ is a *minimal* element of $\operatorname{Supp}(\mathrm{M})$, hence is associated to M (Bourbaki, *Alg. comm.*, chap. IV, § 1, n° 4, th. 2) and M therefore contains a submodule N isomorphic to $\mathrm{A}/\mathfrak{p}_0$ (*loc. cit.*, § 1, n° 1); as $d(\mathrm{M}) \geqslant d(\mathrm{N})$ by (16.2.2.2), it suffices to prove that $\dim(\mathrm{N}) \leqslant d(\mathrm{N})$. Let then $\mathfrak{p}_0 \subset \mathfrak{p}_1 \subset \ldots \subset \mathfrak{p}_n$ be a chain of distinct prime ideals in A, and let us show that $n \leqslant d(\mathrm{N})$. This is evident if $n = 0$. Otherwise, there exists

$x \in \mathfrak{p}_1 \cap \mathfrak{r}$ such that $x \notin \mathfrak{p}_0$, for the relation $\mathfrak{p}_0 \supset \mathfrak{p}_1 \cap \mathfrak{r}$ would imply $\mathfrak{p}_0 \supset \mathfrak{r}$ since $\mathfrak{p}_0$ does not contain $\mathfrak{p}_1$, hence $\mathfrak{p}_0$ would be maximal, which is absurd. We have $\mathfrak{p}_i \in \mathrm{Supp}(\mathrm{N}/x\mathrm{N})$, for $i \geqslant 1$, hence $n-1 \leqslant \dim(\mathrm{N}/x\mathrm{N})$ (16.1.7). As ${}_x\mathrm{N} = 0$ by the choice of x, we have $d(\mathrm{N}/x\mathrm{N}) \leqslant d(\mathrm{N}) - 1$ by (16.2.3.1), (iii). The induction hypothesis then implies $d(\mathrm{N}/x\mathrm{N}) = \dim(\mathrm{N}/x\mathrm{N}) \geqslant n-1$, hence $n - 1 \leqslant d(\mathrm{N}) - 1$.

(16.2.3.3). $d(\mathrm{M}) \leqslant s(\mathrm{M})$.

Let indeed $(x_i)_{1 \leqslant i \leqslant n}$ be a family of elements of $\mathfrak{r}$ such that, if we set $\mathfrak{a} = x_1\mathrm{A} + \ldots + x_n\mathrm{A}$, $\mathrm{M}/\mathfrak{a}\mathrm{M}$ is of finite length. The ideals associated to $\mathrm{M}/\mathfrak{a}\mathrm{M}$ are then maximal (Bourbaki, *Alg. comm.*, chap. IV, § 2, n° 5, prop. 7) and since these are the only prime ideals containing $\mathfrak{q} = \mathfrak{a} + (\mathfrak{r} \cap \mathrm{Ann}(\mathrm{M}))$, $\mathrm{A}/\mathfrak{q}$ is Artinian (*loc. cit.*, prop. 9) and $\mathfrak{q}$ is an ideal of definition of A. But as $\mathfrak{q}^m\mathrm{M}/\mathfrak{q}^{m+1}\mathrm{M} = \mathfrak{a}^m\mathrm{M}/\mathfrak{a}^{m+1}\mathrm{M}$, and if M is generated by r elements z_j, $\mathfrak{a}^m\mathrm{M}/\mathfrak{a}^{m+1}\mathrm{M}$ is an $(\mathrm{A}/\mathfrak{q})$-module generated by the canonical images of $x_1^{\nu_1}x_2^{\nu_2}\cdots x_n^{\nu_n}z_j$ where $\sum_i \nu_i = m$, hence by $r\binom{m+n-1}{n-1}$ elements; its length is therefore $\leqslant ar\binom{m+n-1}{n-1}$, where a is a constant, and one deduces immediately that the degree of $\mathrm{P}_{\mathfrak{q}}(\mathrm{M}, n)$ is $\leqslant n$; whence $d(\mathrm{M}) \leqslant s(\mathrm{M})$.

(16.2.3.4). $s(\mathrm{M}) \leqslant \dim(\mathrm{M})$.

Let us note first that $n = \dim(\mathrm{M})$ is finite by (16.2.3.2). We argue by induction on n; the proposition is evident for $n = 0$, since M is then of finite length (16.1.10). Suppose $n \geqslant 1$, and let $\mathfrak{p}_i$ $(1 \leqslant i \leqslant m)$ be the prime ideals of $\mathrm{Supp}(\mathrm{M})$ such that $\dim(\mathrm{A}/\mathfrak{p}_i) = n$; the definition of the $\mathfrak{p}_i$ shows that they are minimal elements of $\mathrm{Supp}(\mathrm{M})$, hence finite in number (Bourbaki, *Alg. comm.*, chap. IV, § 1, n° 4, th. 2). As $n \geqslant 1$, the $\mathfrak{p}_i$ are not maximal, and there therefore exists $x \in \mathfrak{r}$ such that $x \notin \mathfrak{p}_i$ for every i (Bourbaki, *Alg. comm.*, chap. II, § 1, n° 1, prop. 2). By virtue of (16.2.3.1), we have $s(\mathrm{M}) \leqslant s(\mathrm{M}/x\mathrm{M}) + 1$ and $\dim(\mathrm{M}) \geqslant \dim(\mathrm{M}/x\mathrm{M}) + 1$; the induction hypothesis gives the conclusion.

Corollary (16.2.4). — *Under the hypotheses of (16.2.3), we have*

(16.2.4.1) $$\dim_{\widehat{\mathrm{A}}}(\widehat{\mathrm{M}}) = \dim_{\mathrm{A}}(\mathrm{M}).$$

$\mathbf{0}_{\mathbf{IV}\text{-}\mathbf{1}}$ | 28

Proof. Indeed, $\mathrm{M}/\mathfrak{r}^n\mathrm{M}$ and $\widehat{\mathrm{M}}/\mathfrak{r}^n\widehat{\mathrm{M}}$ are isomorphic, hence $d(\widehat{\mathrm{M}}) = d(\mathrm{M})$. □

Corollary (16.2.5). — *The dimension of a semi-local Noetherian ring* A *is finite and equal to the minimum number of elements of the radical of* A *generating an ideal of definition.*

Proof. This is the equality $s(\mathrm{M}) = \dim(\mathrm{M})$ for $\mathrm{M} = \mathrm{A}$. □

In particular:

Corollary (16.2.6). — *Let* A *be a local Noetherian ring,* $\mathfrak{m}$ *its maximal ideal,* $k = \mathrm{A}/\mathfrak{m}$ *its residue field; we have*

(16.2.6.1) $$\dim(\mathrm{A}) \leqslant \mathrm{rg}_k(\mathfrak{m}/\mathfrak{m}^2).$$

Proof. Indeed, we know that if the x_i $(1 \leqslant i \leqslant n)$ are elements of $\mathfrak{m}$ whose classes mod. $\mathfrak{m}^2$ form a basis of the k-vector space $\mathfrak{m}/\mathfrak{m}^2$, the x_i generate $\mathfrak{m}$ (Bourbaki, *Alg. comm.*, chap. II, § 3, n° 2, cor. 2 of prop. 4). □

Proposition (16.2.7). — *Let k be a field,* B *a graded k-algebra of finite type generated by its elements of degree* 1 *and such that* $\mathrm{B}_0 = k$*; let* E *be a graded* B*-module of finite type, such that* (**III**, 2.5.4) *for n sufficiently large,* $\mathrm{rg}_k(\mathrm{E}_n) = r(n)$ *is of the form* $\Phi(n) - \Phi(n-1)$*, where* Φ *is a polynomial in n of degree d. Then there exist d homogeneous elements of degree* $\geqslant 1$ *in* B, $t_1, \ldots, t_d$*, forming a family* $(t_i)_{1 \leqslant i \leqslant d}$ *such that* $\mathrm{E}/(\sum_i t_i\mathrm{E})$ *is of finite rank over k.*

Proof. Let $\mathfrak{q}$ be the maximal ideal $\bigoplus_{n \geqslant 1} \mathrm{B}_n$ of B, and, for every n, let E'_n be the sub-B-module $\bigoplus_{h \geqslant n+1} \mathrm{E}_h$ of E. Every element of $\mathrm{B} - \mathfrak{q}$ determines an injective homothety in the Artinian B-module E/E'_n, and this homothety is thus bijective (Bourbaki, *Alg.*, chap. VIII, § 2, n° 2, lemma 3), which implies that $(\mathrm{E}/\mathrm{E}'_n)_{\mathfrak{q}}$ identifies with E/E'_n; as the residue field of $\mathrm{B}_{\mathfrak{q}}$ is k, one deduces from the hypothesis that $\mathrm{long}_{\mathrm{B}_{\mathfrak{q}}}((\mathrm{E}/\mathrm{E}'_n)_{\mathfrak{q}})$ is a polynomial in n of degree d. Moreover, E is a B-module of finite type and B is generated over k by its homogeneous elements of degree 1, hence the filtration (E'_n) is $\mathfrak{q}$-good (Bourbaki, *Alg. comm.*, chap. III, § 1, n° 3, lemma 1), hence the filtration $((\mathrm{E}'_n)_{\mathfrak{q}})$ on $\mathrm{E}_{\mathfrak{q}}$ is $\mathfrak{q}\mathrm{B}_{\mathfrak{q}}$-good. Since $\mathrm{B}_{\mathfrak{q}}$ is a local Noetherian ring, one concludes from (16.2.3) and (16.2.2.1) that $\dim(\mathrm{E}_{\mathfrak{q}}) = d$. We argue by induction on d, the assertion being evident if $d = 0$. Suppose $d \geqslant 1$, and observe that the minimal prime ideals $\mathfrak{p}_i$ $(1 \leqslant i \leqslant r)$ in $\mathrm{Ass}(\mathrm{E})$ are *graded* (Bourbaki, *Alg. comm.*, chap. IV, § 3, n° 1, prop. 1), and that $\mathfrak{q}$ is distinct from the union of the $\mathfrak{p}_i$ since $d \geqslant 1$; there is therefore a *homogeneous* element $t_1 \in \mathfrak{q}$ not belonging to any of the $\mathfrak{p}_i$ (Bourbaki, *Alg. comm.*, chap. III, § 1, n° 4, prop. 8). As the prime ideals $(\mathfrak{p}_i)_{\mathfrak{q}}$ are the minimal elements of $\mathrm{Ass}(\mathrm{E}_{\mathfrak{q}})$ (Bourbaki, *Alg. comm.*, chap. IV, § 1, n° 2, prop. 5), we have $\dim(\mathrm{E}_{\mathfrak{q}}/t_1\mathrm{E}_{\mathfrak{q}}) = d - 1$ (16.3.4). It suffices then to apply the induction hypothesis to the graded B-module $\mathrm{E}/t_1\mathrm{E}$ to obtain the conclusion. □

16.3. Systems of parameters in a Noetherian local ring

Proposition (16.3.1). — *Let* A *be a Noetherian ring,* $\mathfrak{p}$ *a prime ideal of* A*, and* n *an integer. The following conditions are equivalent:*

a) $\mathrm{ht}(\mathfrak{p}) = \dim(\mathrm{A}_{\mathfrak{p}}) \leqslant n$*;*

b) There exist n *elements* x_i *of* A $(1 \leqslant i \leqslant n)$ *such that* $\mathfrak{p}$ *is minimal in the set of prime ideals containing the ideal* $\mathfrak{a}$ *generated by the* x_i *(in other words,* $\mathrm{V}(\mathfrak{p})$ *is an irreducible component of* $\mathrm{V}(\mathfrak{a})$*).*

Proof. Condition b) implies that $\mathfrak{a}\mathrm{A}_{\mathfrak{p}}$ is an ideal of definition of $\mathrm{A}_{\mathfrak{p}}$, whence a) by virtue of (16.2.5). Conversely, if a) holds, there exists an ideal of definition $\mathfrak{b}$ of $\mathrm{A}_{\mathfrak{p}}$ generated by n elements x_i/s, with $s \in \mathrm{A} - \mathfrak{p}$. By virtue of the one-to-one correspondence between prime ideals of $\mathrm{A}_{\mathfrak{p}}$ and prime ideals of A contained in $\mathfrak{p}$, the ideal $\mathfrak{a}$ of A generated by the x_i satisfies b). □

For $n = 1$, one obtains the special case: $\mathbf{0}_{\mathbf{IV\text{-}1}}$ | 29

Corollary (16.3.2). — ("Hauptidealsatz"). *For a prime ideal in a Noetherian ring to be of height* $\leqslant 1$*, it is necessary and sufficient that it be minimal in the set of prime ideals containing a suitable principal ideal.*

Corollary (16.3.3). — (Artin-Tate). *Let* A *be an integral Noetherian ring. The following conditions are equivalent:*

a) A *is a semi-local ring of dimension* $\leqslant 1$.

b) There exists $f \neq 0$ *in* A *such that* A_f *is a field.*

Proof. The condition *a*) is equivalent to saying that A has only finitely many prime ideals $\mathfrak{m}_i \neq 0$, and that these ideals are all maximal (0 being a prime ideal). As the product of the $\mathfrak{m}_i$ is not zero, since A is integral, an element $f \neq 0$ of this product belongs to every maximal ideal, hence (0) is the only prime ideal of the integral ring A_f, in other words A_f is a field. (One notes that this part of the argument does not use the fact that A is Noetherian.) Let us now prove that *b*) implies *a*); the hypothesis *b*) means that every prime ideal $\mathfrak{p} \neq 0$ of A contains f. Let $\mathfrak{p}_i$ $(1 \leqslant i \leqslant n)$ be the minimal prime ideals among those containing f (which are finite in number since $\mathrm{A}/f\mathrm{A}$ is Noetherian); it suffices to prove that the $\mathfrak{p}_i$ are *maximal* ideals, for then every nonzero prime ideal necessarily contains one of the $\mathfrak{p}_i$ and is therefore equal to it. Suppose then that there exists a maximal ideal $\mathfrak{m}$ containing one of the $\mathfrak{p}_i$ and distinct from the $\mathfrak{p}_i$; $\mathfrak{m}$ is therefore not contained in the union of the $\mathfrak{p}_i$ (Bourbaki, *Alg. comm.*, chap. II, § 1, n° 1, prop. 2), in other words there exists $g \in \mathfrak{m}$ not belonging to any of the $\mathfrak{p}_i$. Let $\mathfrak{q}$ be a minimal prime ideal among those containing g; it follows from the "Hauptidealsatz" (16.3.2) that $\mathfrak{q}$ is of height 1, hence $\neq 0$; it therefore contains by assumption f, hence also one of the $\mathfrak{p}_i$, and as g does not belong to any of the $\mathfrak{p}_i$, $\mathfrak{q}$ is distinct from the $\mathfrak{p}_i$; it would thus be of height $\geqslant 2$, which is a contradiction. □

Proposition (16.3.4). — *Let* A *be a semi-local Noetherian ring,* $\mathfrak{r}$ *its radical,* M *an* A*-module of finite type,* $\mathfrak{p}_i$ *the elements of* $\mathrm{Supp}(\mathrm{M})$ *such that* $\dim(\mathrm{A}/\mathfrak{p}_i) = \dim(\mathrm{M})$*. Then the* $\mathfrak{p}_i$ *are minimal elements of* $\mathrm{Ass}(\mathrm{M})$*, and* $\dim(\mathrm{M}/\mathfrak{p}_i\mathrm{M}) = \dim(\mathrm{M})$*. For every* $x \in \mathfrak{r}$*, we have*

$$\dim(\mathrm{M}/x\mathrm{M}) \geqslant \dim(\mathrm{M}) - 1. \tag{16.3.4.1}$$

Furthermore, for the two members of (16.3.4.1) *to be equal, it is necessary and sufficient that* x *not belong to any of the* $\mathfrak{p}_i$.

Proof. The first assertion is immediate, since the $\mathfrak{p}_i$ are by definition the minimal elements of $\mathrm{Supp}(\mathrm{M})$ (16.1.6), and they are also the minimal elements of $\mathrm{Ass}(\mathrm{M})$ (Bourbaki, *Alg. comm.*, chap. IV, § 1, n° 4, th. 2). Furthermore, $\mathrm{Supp}(\mathrm{M}/\mathfrak{p}_i\mathrm{M})$ is the set of prime ideals of A containing $\mathfrak{p}_i$ ($\mathbf{0}_\mathrm{I}$, 1.7.5), hence $\dim(\mathrm{M}/\mathfrak{p}_i\mathrm{M}) = \dim(\mathrm{A}/\mathfrak{p}_i) = \dim(\mathrm{M})$.

Set $\mathrm{N} = \mathrm{M}/x\mathrm{M}$. If $x_1, \ldots, x_n$ are elements of $\mathfrak{r}$ such that $\mathrm{M}/(x\mathrm{M} + x_1\mathrm{M} + \ldots + x_n\mathrm{M})$ is of finite length, we have $s(\mathrm{M}) \leqslant n+1$, hence $\dim(\mathrm{M}) \leqslant n+1$ by (16.2.3), and as one can choose them so that $n = s(\mathrm{N}) = \dim(\mathrm{N})$, we get (16.3.4.1).

The fact that the two members of (16.3.4.1) are equal when x does not belong to any of the $\mathfrak{p}_i$ follows from (16.3.4.1) and (16.2.3.1). Conversely, if $\dim(\mathrm{M}/x\mathrm{M}) = \dim(\mathrm{M}) - 1$, none of the $\mathfrak{p}_i$ can belong to $\mathrm{Supp}(\mathrm{M}/x\mathrm{M})$, and the prime ideals in the support of the latter are those containing $\mathrm{Ann}(\mathrm{M}) + \mathrm{A}x$; since the $\mathfrak{p}_i$ contain $\mathrm{Ann}(\mathrm{M})$, they cannot contain x. ☐ $\mathbf{0}_{\mathbf{IV\text{-}1}}$ | 30

Corollary (16.3.5). — *With the notations of* (16.3.4), *for every ideal* $\mathfrak{a} \subset \mathfrak{p}_i$, *we have* $\dim(\mathrm{M}/\mathfrak{a}\mathrm{M}) = \dim(\mathrm{M})$ *and if one sets* $\mathrm{N} = \mathrm{M}/\mathfrak{a}\mathrm{M}$, *the relation* $\dim(\mathrm{M}/x\mathrm{M}) = \dim(\mathrm{M}) - 1$ *implies* $\dim(\mathrm{N}/x\mathrm{N}) = \dim(\mathrm{N}) - 1$.

Proof. Indeed, $\mathrm{Supp}(\mathrm{N})$ is the set of prime ideals containing $\mathfrak{a} + \mathrm{Ann}(\mathrm{M})$, hence $\mathfrak{p}_i$ belongs to $\mathrm{Supp}(\mathrm{N})$ and $\dim(\mathrm{N}) \leqslant \dim(\mathrm{M}) = \dim(\mathrm{A}/\mathfrak{p}_i)$, hence $\dim(\mathrm{A}/\mathfrak{p}_i) = \dim(\mathrm{N})$; furthermore the prime ideals $\mathfrak{q} \in \mathrm{Supp}(\mathrm{N})$ such that $\dim(\mathrm{A}/\mathfrak{q}) = \dim(\mathrm{N})$ are certain of the $\mathfrak{p}_j$; if x does not belong to any of the $\mathfrak{p}_j$, we have then $\dim(\mathrm{N}/x\mathrm{N}) = \dim(\mathrm{N}) - 1$ by virtue of (16.3.4). ☐

Definition (16.3.6). — Let A be a semi-local Noetherian ring, $\mathfrak{r}$ its radical, M an A-module of finite type, and set $n = \dim(\mathrm{M})$. A *system of parameters* for M is any family $(x_i)_{1 \leqslant i \leqslant n}$ of n elements of $\mathfrak{r}$ such that $\mathrm{M}/(x_1\mathrm{M} + \ldots + x_n\mathrm{M})$ is of *finite length*.

We have seen (16.2.3) that such systems always exist. We have seen in the course of the proof of (16.2.3.3) that if $\mathfrak{J} = \sum_{i=1}^n x_i\mathrm{A}$ is such that $\mathrm{M}/\mathfrak{J}\mathrm{M}$ is of finite length, $\mathfrak{q} = \mathfrak{J} + \mathrm{Ann}(\mathrm{M})$ is an *ideal of definition* of A, and conversely, if this is so, $\mathrm{M}/\mathfrak{J}\mathrm{M}$ is a module of finite type over the Artinian ring $\mathrm{A}/\mathfrak{q}$, hence is of finite length. It amounts to the same to say that $(x_i)_{1 \leqslant i \leqslant n}$ is a system of parameters *for* M or *for* $\mathrm{A}/\mathrm{Ann}(\mathrm{M})$ (or equivalently that their images in $\mathrm{A}/\mathrm{Ann}(\mathrm{M})$ form a system of parameters for this ring). If $(x_i)_{1 \leqslant i \leqslant n}$ is a system of parameters for M, so is (x_i^k) for every integer $k \geqslant 1$, since one can reduce, by the preceding, to the case $\mathrm{M} = \mathrm{A}$, and if $\mathfrak{J}$ is an ideal of definition of A, $\sum_i x_i^k\mathrm{A}$ contains $\mathfrak{J}^{kn}$, hence is also an ideal of definition.

Proposition (16.3.7). — *Let* A *be a semi-local Noetherian ring,* $\mathfrak{r}$ *its radical,* $x_1, \ldots, x_k$ *elements of* $\mathfrak{r}$, M *an* A-*module of finite type. Then*

(16.3.7.1) $$\dim(\mathrm{M}/(x_1\mathrm{M} + \ldots + x_k\mathrm{M})) \geqslant \dim(\mathrm{M}) - k.$$

Furthermore, for the two members of (16.3.7.1) *to be equal, it is necessary and sufficient that there exist elements* x_i $(k+1 \leqslant i \leqslant n = \dim(\mathrm{M}))$ *of* $\mathfrak{r}$ *such that* $(x_i)_{1 \leqslant i \leqslant n}$ *is a system of parameters for* M.

Proof. The inequality (16.3.7.1) follows from (16.3.4.1) by induction on k. If the two members of (16.3.7.1) are equal, and if $x_{k+1}, \ldots, x_n$ is a system of parameters for $\mathrm{M}/(x_1\mathrm{M} + \ldots + x_k\mathrm{M})$, it is clear that $\mathrm{M}/(x_1\mathrm{M} + \ldots + x_k\mathrm{M} + x_{k+1}\mathrm{M} + \ldots + x_n\mathrm{M})$ is of finite length, hence $(x_i)_{1 \leqslant i \leqslant n}$ is a system of parameters for M; conversely, if there exist x_i $(k+1 \leqslant i \leqslant n)$ having this property and if one sets $\mathrm{N} = \mathrm{M}/(x_1\mathrm{M} + \ldots + x_k\mathrm{M})$, it is clear that $\mathrm{N}/(x_{k+1}\mathrm{N} + \ldots + x_n\mathrm{N})$ is of finite length, hence $\dim(\mathrm{N}) \leqslant n - k$, and the two members are equal by virtue of (16.3.7.1). ☐

$\mathbf{0}_{\mathbf{IV\text{-}1}}$ | 31

Proposition (16.3.8). — *Let* A *be a semi-local Noetherian ring,* $\mathrm{X} = \mathrm{Spec}(\mathrm{A})$ *its spectrum,* $\mathfrak{a}$ *an ideal of* A *distinct from* A *such that* $\mathrm{codim}(\mathrm{V}(\mathfrak{a}), \mathrm{X}) = r > 0$. *Then there exist r elements* $x_1, \ldots, x_r$ *of* $\mathfrak{a}$, *forming part of a system of parameters of* A, *such that*

$$\mathrm{codim}(\mathrm{V}(\mathfrak{a}), \mathrm{V}(\mathrm{A}x_1 + \ldots + \mathrm{A}x_r)) = 0.$$

Proof. Let $\mathfrak{p}_i$ $(1 \leqslant i \leqslant m)$ be the minimal prime ideals of the ring A, $\mathfrak{q}_j$ $(1 \leqslant j \leqslant n)$ the minimal prime ideals among those containing $\mathfrak{a}$; we have (14.2.1) $\mathrm{codim}(\mathrm{V}(\mathfrak{a}), \mathrm{X}) = \inf_j(\dim(\mathrm{A}_{\mathfrak{q}_j}))$ (16.1.3.2). The hypothesis $r > 0$ implies that $\mathfrak{a}$ is not contained in any of the $\mathfrak{p}_i$; hence there exists $x \in \mathfrak{a}$ not belonging to any of the $\mathfrak{p}_i$ (Bourbaki, *Alg. comm.*, chap. II, § 1, n° 1, prop. 2). One has as above $\mathrm{codim}(\mathrm{V}(\mathfrak{a}), \mathrm{V}(\mathrm{A}x)) = \inf_j(\dim((\mathrm{A}/\mathrm{A}x)_{\mathfrak{q}_j/\mathrm{A}x})) = \inf_j(\dim(\mathrm{A}_{\mathfrak{q}_j}/\mathrm{A}_{\mathfrak{q}_j}x))$; but as $x/1$ is not in any of the minimal prime ideals of $\mathrm{A}_{\mathfrak{q}_j}$, $\dim(\mathrm{A}_{\mathfrak{q}_j}/\mathrm{A}_{\mathfrak{q}_j}x) = \dim(\mathrm{A}_{\mathfrak{q}_j}) - 1$ (16.3.4), whence $\mathrm{codim}(\mathrm{V}(\mathfrak{a}), \mathrm{V}(\mathrm{A}x)) = r - 1$. For the same reason, $\dim(\mathrm{A}/\mathrm{A}x) = \dim(\mathrm{A}) - 1$. We argue by induction on r; if $r > 1$, there exist $r - 1$ elements x'_i $(2 \leqslant i \leqslant r)$ of $\mathrm{A}' = \mathrm{A}/\mathrm{A}x$, forming part of a system of parameters of A' and such that $\mathrm{codim}(\mathrm{V}(\mathfrak{a}/\mathrm{A}x), \mathrm{V}(\mathrm{A}'x'_2 + \ldots + \mathrm{A}'x'_r)) = 0$. Let $(x'_i)_{r+1 \leqslant i \leqslant s}$ be a family of elements of A' such that $(x'_i)_{2 \leqslant i \leqslant s}$ is a system of parameters of A'; for every i such that $2 \leqslant i \leqslant s$, let x_i be a representative of the class x'_i in A, with $x_i \in \mathfrak{a}$ for $2 \leqslant i \leqslant r$. It is immediate that $\mathrm{A}/(\mathrm{A}x + \mathrm{A}x_2 + \ldots + \mathrm{A}x_s)$ is of finite length, and as $\dim(\mathrm{A}) = s$, we see that $x_1 = x$ and the x_i for $i \geqslant 2$ satisfy the conditions of the statement. □

Proposition (16.3.9). — *Let* A, B *be two local Noetherian rings,* $\mathfrak{m}$ *the maximal ideal of* A, k *its residue field,* $\varphi : \mathrm{A} \to \mathrm{B}$ *a local homomorphism.*

(i) *We have*

$$\dim(\mathrm{B}) \leqslant \dim(\mathrm{A}) + \dim(\mathrm{B} \otimes_{\mathrm{A}} k). \tag{16.3.9.1}$$

(ii) *Let* $\mathrm{M} \neq 0$ *be an* A*-module of finite type,* $\mathrm{N} \neq 0$ *a* B*-module of finite type. We have*

$$\dim_{\mathrm{B}}(\mathrm{M} \otimes_{\mathrm{A}} \mathrm{N}) \leqslant \dim_{\mathrm{A}}(\mathrm{M}) + \dim_{\mathrm{B} \otimes_{\mathrm{A}} k}(\mathrm{N} \otimes_{\mathrm{A}} k). \tag{16.3.9.2}$$

Proof. Let m be the dimension of A, $(s_i)_{1 \leqslant i \leqslant m}$ a system of parameters of A (16.3.6), so that $\mathfrak{a} = \sum_i s_i \mathrm{A}$, $\mathrm{A}/\mathfrak{a}$ is an A-module of finite length. Then the Artinian ring $\mathrm{A}/\mathfrak{a}$ has nilpotent maximal ideal $\mathfrak{m}/\mathfrak{a}$; the ideal $\mathfrak{m}\mathrm{B}/\mathfrak{a}\mathrm{B}$ of $\mathrm{B}/\mathfrak{a}\mathrm{B}$, image of $(\mathfrak{m}/\mathfrak{a}) \otimes_{\mathrm{A}} \mathrm{B}$, is therefore also nilpotent, and hence $\dim(\mathrm{B}/\mathfrak{a}\mathrm{B}) = \dim(\mathrm{B}/\mathfrak{m}\mathrm{B})$ (the spectra of these two rings having the same underlying space). On the other hand $\mathrm{B}/\mathfrak{a}\mathrm{B} = \mathrm{B}/(s_1\mathrm{B} + \ldots + s_m\mathrm{B})$, and the images of the s_i in B belong to the maximal ideal of B. Hence by (16.3.7), we have

$$\dim(\mathrm{B}) \leqslant m + \dim(\mathrm{B} \otimes_{\mathrm{A}} k)$$

which is (16.3.9.1).

To prove (16.3.9.2), note that if $\mathfrak{r}$ (resp. $\mathfrak{s}$) is the annihilator of M (resp. N) in A (resp. B), we have $\dim_{\mathrm{A}}(\mathrm{M}) = \dim(\mathrm{A}/\mathfrak{r})$, $\dim_{\mathrm{B}}(\mathrm{N}) = \dim(\mathrm{B}/\mathfrak{s})$ by definition (16.1.7); on the other hand, $\mathrm{Supp}(\mathrm{M} \otimes_{\mathrm{A}} \mathrm{N})$ is a closed subset of $\mathrm{Spec}(\mathrm{B})$ that identifies (**I**, 9.1.13) to $\mathrm{Supp}(\mathrm{M}) \times_{\mathrm{Spec}(\mathrm{A})} \mathrm{Supp}(\mathrm{N}) = \mathrm{Spec}((\mathrm{B}/\mathfrak{s}) \otimes_{\mathrm{A}} (\mathrm{A}/\mathfrak{r})) = \mathrm{Spec}(\mathrm{B}/(\mathfrak{s} + \mathfrak{r}\mathrm{B}))$. As $\mathrm{N} \otimes_{\mathrm{A}} k$ is a B-module of finite type, we have $\dim_{\mathrm{B} \otimes_{\mathrm{A}} k}(\mathrm{N} \otimes_{\mathrm{A}} k) = \dim_{\mathrm{B}}(\mathrm{N} \otimes_{\mathrm{A}} k)$ (16.1.9), and $\mathrm{Supp}(\mathrm{N} \otimes_{\mathrm{A}} k)$ is equal to $\mathrm{Spec}(\mathrm{B}/(\mathfrak{s} + \mathfrak{m}\mathrm{B}))$ by the same reasoning as above. Applying (16.3.9.1) to $\mathrm{A}/\mathfrak{r}$ and to $\mathrm{B}/(\mathfrak{s} + \mathfrak{r}\mathrm{B})$, we get $\mathbf{0_{IV\text{-}1}}$ | 32

$$\dim(\mathrm{B}/(\mathfrak{s} + \mathfrak{r}\mathrm{B})) \leqslant \dim(\mathrm{A}/\mathfrak{r}) + \dim(\mathrm{B}/(\mathfrak{s} + \mathfrak{m}\mathrm{B}))$$

which is nothing other than (16.3.9.2). □

Corollary (16.3.10). — *Under the hypotheses of* (16.3.9), *if* $\mathfrak{m}\mathrm{B}$ *is an ideal of definition of* B, *we have* $\dim(\mathrm{B}) \leqslant \dim(\mathrm{A})$; *if in addition* A *is integral and* $\dim(\mathrm{A}) = \dim(\mathrm{B})$, φ *is injective.*

Proof. The first assertion follows from (16.3.9) since then $\dim(\mathrm{B}/\mathfrak{m}\mathrm{B}) = 0$. One can moreover replace A by $\varphi(\mathrm{A})$, hence $\dim(\mathrm{B}) \leqslant \dim(\varphi(\mathrm{A}))$; if $\mathfrak{a} = \mathrm{Ker}(\varphi) \neq 0$, and if A is integral, we have $\dim(\varphi(\mathrm{A})) = \dim(\mathrm{A}/\mathfrak{a}) < \dim(\mathrm{A})$ (16.1.2.2), hence one can have $\dim(\mathrm{A}) = \dim(\mathrm{B})$ only if $\mathfrak{a} = 0$. □

16.4. Depth and codepth[16]

Proposition (16.4.1). — *Let* A *be a local Noetherian ring,* $\mathfrak{m}$ *its maximal ideal,* M *an* A*-module of finite type. Then every* M*-regular sequence* $(x_i)_{1 \leqslant i \leqslant r}$ (15.1.7) *formed of elements of* $\mathfrak{m}$*, is part of a system of parameters for* M*.*

Proof. We argue by induction on r; consider the A-module

$$\mathrm{N} = \mathrm{M}/(x_1\mathrm{M} + \ldots + x_{r-1}\mathrm{M});$$

by the induction hypothesis $x_1, \ldots, x_{r-1}$ form part of a system of parameters for M, hence $\dim(\mathrm{N}) = \dim(\mathrm{M}) - (r-1)$ (16.3.7). As by hypothesis the homothety of ratio x_r in N is injective, x_r does not belong to any of the prime ideals associated to N, hence (16.3.4) $\dim(\mathrm{N}/x_r\mathrm{N}) = \dim(\mathrm{N}) - 1$, which can also be written

$$\dim(\mathrm{M}/(x_1\mathrm{M} + \ldots + x_r\mathrm{M})) = \dim(\mathrm{M}) - r;$$

the conclusion then follows from (16.3.7). □

For an M-regular sequence formed of elements of $\mathfrak{m}$, $\mathrm{M} \neq 0$, there are at most $\dim(\mathrm{M})$ elements.

Lemma (16.4.2). — *Let* A *be a local Noetherian ring,* $\mathfrak{m}$ *its maximal ideal,* $k = \mathrm{A}/\mathfrak{m}$ *its residue field,* M *an* A*-module. For an* M*-regular sequence* $(x_i)_{1 \leqslant i \leqslant n}$ *of elements of* $\mathfrak{m}$ *to be maximal, it is necessary and sufficient that* $\mathrm{Hom}_{\mathrm{A}}(k, \mathrm{M}/(x_1\mathrm{M} + \ldots + x_n\mathrm{M})) \neq 0$.

Proof. To say that (x_i) is maximal means that, for no $x \in \mathfrak{m}$, the homothety of ratio x in $\mathrm{N} = \mathrm{M}/(x_1\mathrm{M} + \ldots + x_n\mathrm{M})$ is injective, or equivalently that $\mathfrak{m}$ is contained in the union of the prime ideals associated to N (Bourbaki, *Alg. comm.*, chap. IV, § 1, n° 1, cor. 2 of prop. 2), hence equal to one of them, since it is a maximal ideal (Bourbaki, *Alg. comm.*, chap. II, § 1, n° 1, prop. 2); in other words, $\mathbf{0_{IV\text{-}1}}$ | 33
there is an element $z \in \mathrm{N}$ whose annihilator is $\mathfrak{m}$, and hence the submodule $\mathrm{A}z$ of N is isomorphic to $\mathrm{A}/\mathfrak{m} = k$; whence the lemma. □

Lemma (16.4.3). — *Let* A *be a local Noetherian ring,* $\mathfrak{m}$ *its maximal ideal,* $k = \mathrm{A}/\mathfrak{m}$ *its residue field,* M *an* A*-module,* $(x_i)_{1 \leqslant i \leqslant n}$ *an* M*-regular sequence of elements of* $\mathfrak{m}$*. Then the* A*-modules* $\mathrm{Hom}_{\mathrm{A}}(k, \mathrm{M}/(x_1\mathrm{M} + \ldots + x_n\mathrm{M}))$ *and* $\mathrm{Ext}^n_{\mathrm{A}}(k, \mathrm{M})$ *are isomorphic, and for* $n \geqslant 1$*, they are also isomorphic to* $\mathrm{Ext}^{n-1}_{\mathrm{A}}(k, \mathrm{M}/x_1\mathrm{M})$*.*

Proof. We argue by induction on n, the proposition being evident for $n = 0$. Set $\mathrm{N} = \mathrm{M}/x_1\mathrm{M}$; the sequence $(x_i)_{2 \leqslant i \leqslant n}$ is N-regular, hence

$$\mathrm{Hom}_{\mathrm{A}}(k, \mathrm{M}/(x_1\mathrm{M} + \ldots + x_n\mathrm{M})) = \mathrm{Hom}_{\mathrm{A}}(k, \mathrm{N}/(x_2\mathrm{N} + \ldots + x_n\mathrm{N}))$$

is isomorphic to $\mathrm{Ext}^{n-1}_{\mathrm{A}}(k, \mathrm{N})$ by the induction hypothesis. Consider then the short exact sequence $0 \to \mathrm{M} \xrightarrow{x_1} \mathrm{M} \to \mathrm{M}/x_1\mathrm{M} = \mathrm{N} \to 0$; one deduces the exact sequence of Ext

$$\mathrm{Ext}^{n-1}_{\mathrm{A}}(k, \mathrm{M}) \longrightarrow \mathrm{Ext}^{n-1}_{\mathrm{A}}(k, \mathrm{N}) \longrightarrow \mathrm{Ext}^{n}_{\mathrm{A}}(k, \mathrm{M}) \xrightarrow{x_1} \mathrm{Ext}^{n}_{\mathrm{A}}(k, \mathrm{M}). \tag{16.4.3.1}$$

By the induction hypothesis, $\mathrm{Ext}^{n-1}_{\mathrm{A}}(k, \mathrm{M})$ is isomorphic to $\mathrm{Hom}_{\mathrm{A}}(k, \mathrm{M}/(x_1\mathrm{M} + \ldots + x_{n-1}\mathrm{M}))$, which is zero since $(x_i)_{1 \leqslant i \leqslant n-1}$ is not a maximal M-regular sequence (16.4.2). On the other hand, as $x_1 \in \mathfrak{m}$, the homothety of ratio x_1 in the A-module $\mathrm{Hom}_{\mathrm{A}}(k, \mathrm{T})$ is zero for every A-module T, hence it is the same for every A-module $\mathrm{Ext}^n_{\mathrm{A}}(k, \mathrm{T})$; the assertions of the lemma then follow immediately from the exact sequence (16.4.3.1). □

Corollary (16.4.4). — *Let* A *be a local Noetherian ring,* $\mathfrak{m}$ *its maximal ideal,* $k = \mathrm{A}/\mathfrak{m}$ *its residue field,* M *an* A*-module of finite type* $\neq 0$*. All maximal* M*-regular sequences of elements of* $\mathfrak{m}$ *have the same number of elements, which is the smallest integer* n *such that* $\mathrm{Ext}^n_{\mathrm{A}}(k, \mathrm{M}) \neq 0$*.*

Definition (16.4.5). — Let A be a local Noetherian ring, $\mathfrak{m}$ its maximal ideal, M an A-module of finite type. We call the upper bound of the numbers of elements in M-regular sequences formed of elements of $\mathfrak{m}$ the *depth* of M, and denote it $\mathrm{prof}_{\mathrm{A}}\,\mathrm{M}$ or $\mathrm{prof}(\mathrm{M})$. We thus have $\mathrm{prof}(\mathrm{M}) = +\infty$ if and only if $\mathrm{M} = 0$, and, by (16.4.1),

$$\mathrm{prof}(\mathrm{M}) \leqslant \dim(\mathrm{M}) \quad \text{if} \quad \mathrm{M} \neq 0. \tag{16.4.5.1}$$

We evidently have $\mathrm{prof}(\mathrm{M}^k) = \mathrm{prof}(\mathrm{M})$ for every $k > 0$.

[16] In the third part of Chapter III, we develop the notion of depth from the cohomological point of view and in a more general framework.

Proposition (16.4.6). — *Let* A *be a local Noetherian ring,* $\mathfrak{m}$ *its maximal ideal,* M *an* A*-module of finite type.*

(i) *For* $\operatorname{prof}(M) = 0$*, it is necessary and sufficient that* $\mathfrak{m} \in \operatorname{Ass}(M)$ *(or equivalently that there exists a submodule of* M *isomorphic to the residue field* $k = A/\mathfrak{m}$ *of* A*).*

(ii) *For every* M*-regular element* x *belonging to the maximal ideal of* A*, we have*

$$\operatorname{prof}(M/xM) = \operatorname{prof}(M) - 1. \tag{16.4.6.1}$$

(iii) *If* $M \neq 0$*, we have*

$$\operatorname{prof}(M) \leqslant \inf_{\mathfrak{p}\in\operatorname{Ass}(M)} \dim(A/\mathfrak{p}) \leqslant \dim(M). \tag{16.4.6.2}$$

$\mathbf{0}_{\mathbf{IV\text{-}1}}$ | 34

(iv) *We have* $\operatorname{prof}_A(M) = \operatorname{prof}_{\widehat{A}}(\widehat{M})$*.*

Proof. (i) To say $\operatorname{prof}(M) = 0$ means that there is no $x \in \mathfrak{m}$ such that the homothety of ratio x in M is injective, that is, every $x \in \mathfrak{m}$ belongs to a prime ideal associated to M (Bourbaki, *Alg. comm.*, chap. IV, § 1, n° 1, cor. 2 of prop. 2); but $\mathfrak{m}$ cannot be the union of prime ideals associated to M unless it is equal to one of them (Bourbaki, *Alg. comm.*, chap. II, § 1, n° 1, prop. 2).

(ii) If $(x_i)_{1\leqslant i\leqslant m}$ is a (M/xM)-regular maximal sequence of elements of $\mathfrak{m}$, the sequence formed of x and the x_i is M-regular, and it follows from the definition that it is maximal when the first sequence is; whence the conclusion.

(iii) We argue by induction on $n = \operatorname{prof}(M)$, the assertion being evident for $n = 0$. We use the following lemma: □

Lemma (16.4.6.3). — *Let* A *be a Noetherian ring,* M *an* A*-module of finite type,* $t \in A$ *an* M*-regular element. Then, for every* $\mathfrak{p} \in \operatorname{Ass}(M)$*, every* minimal *prime ideal among those containing* $\mathfrak{p} + At$ *belongs to* $\operatorname{Ass}(M/tM)$*.*

Proof of the lemma. We know that there exists a short exact sequence

$$0 \longrightarrow M' \longrightarrow M \longrightarrow M'' \longrightarrow 0$$

such that $\operatorname{Ass}(M') = \{\mathfrak{p}\}$, $\operatorname{Ass}(M'') = \operatorname{Ass}(M) - \{\mathfrak{p}\}$ (Bourbaki, *Alg. comm.*, chap. IV, § 1, n° 1, prop. 4); as t is M-regular, it is also M′-regular and M″-regular (*loc. cit.*, § 1, n° 1, cor. 2 of prop. 2). One deduces that the sequence

$$0 \longrightarrow M'/tM' \longrightarrow M/tM \longrightarrow M''/tM'' \longrightarrow 0$$

is exact (15.1.18). Consequently, $\operatorname{Ass}(M'/tM') \subset \operatorname{Ass}(M/tM)$. But the prime ideals of A containing $\mathfrak{p}$ are the points of $\operatorname{Supp}(M')$ (*loc. cit.*, § 1, n° 3, prop. 7), hence the prime ideals containing $\mathfrak{p} + At$ are the points of the support of $M'/tM' = M' \otimes_A (A/tA)$ ($\mathbf{0}_{\mathrm{I}}$, 1.7.5); a minimal element of the set of these prime ideals belongs then to $\operatorname{Ass}(M'/tM')$ (Bourbaki, *loc. cit.*, § 1, n° 3, cor. 1 of prop. 7), and *a fortiori* to $\operatorname{Ass}(M/tM)$. □

Continuation of the proof of (16.4.6). This lemma established, we return to the proof of (iii). Let $x \in \mathfrak{m}$ be an M-regular element, so that $\operatorname{prof}(M/xM) = n - 1$ by (ii); for every $\mathfrak{p} \in \operatorname{Ass}(M)$, it follows from the lemma that there is a prime ideal $\mathfrak{p}'$ associated to M/xM and containing $\mathfrak{p} + xA$; but as x is M-regular, we have $x \notin \mathfrak{p}$, whence $\mathfrak{p}' \neq \mathfrak{p}$ and hence $\dim(A/\mathfrak{p}') \leqslant \dim(A/\mathfrak{p}) - 1$. The induction hypothesis shows that $n - 1 \leqslant \dim(A/\mathfrak{p}')$; one concludes that $n \leqslant \dim(A/\mathfrak{p})$ for every $\mathfrak{p} \in \operatorname{Ass}(M)$.

(iv) One can restrict to the case $M \neq 0$. Recall that $\widehat{M} = M \otimes_A \widehat{A}$ up to canonical isomorphism ($\mathbf{0}_{\mathrm{I}}$, 7.3.3); as $\widehat{A}$ is a flat A-module, there are canonical isomorphisms $\operatorname{Ext}^i_A(k, M) \otimes_A \widehat{A} \xrightarrow{\sim} \operatorname{Ext}^i_{\widehat{A}}(k, M \otimes_A \widehat{A})$ since $k = k \otimes_A \widehat{A}$ up to canonical isomorphism ($\mathbf{0}_{\mathrm{III}}$, 12.3.5). The assertion (iv) then follows from (16.4.4) and the fact that $\widehat{A}$ is a faithfully flat A-module ($\mathbf{0}_{\mathrm{I}}$, 7.3.5). □

(16.4.6.4). One notes that if $\mathfrak{p}$ is a prime ideal of A, one can *also* have $\operatorname{prof}_{A_\mathfrak{p}}(M_\mathfrak{p}) < \operatorname{prof}_A(M)$ and $\operatorname{prof}_{A_\mathfrak{p}}(M_\mathfrak{p}) > \operatorname{prof}_A(M)$; for an example of the first case, it suffices to take A a local integral ring of dimension $\geqslant 1$; we have $\operatorname{prof}(A) \geqslant 1$ but $\operatorname{prof}(K) = 0$ for the field of fractions K of A. For an example of the second case, consider a Noetherian integral local ring A_0 of dimension $\geqslant 2$, with maximal ideal $\mathfrak{m}_0$ and residue field $k = A_0/\mathfrak{m}_0$; let $A = A_0 \oplus \mathfrak{J}$ be the trivial extension of A_0 by the $\mathbf{0}_{\mathbf{IV\text{-}1}}$ | 35

A_0-module k (so that the multiplication in A is given by $(x,z)(x',z') = (xx', xz' + x'z)$). It is clear that $\mathfrak{J}$ is the nilradical of A and $A/\mathfrak{J}$ is isomorphic to A_0, so that every prime ideal $\mathfrak{p}$ of A is of the form $\mathfrak{p}_0 \oplus \mathfrak{J}$, where $\mathfrak{p}_0$ is a prime ideal of A_0; in particular $\mathfrak{m} = \mathfrak{m}_0 \oplus \mathfrak{J}$ is the only maximal ideal of A. As every element of $\mathfrak{m}_0$ annihilates $\mathfrak{J}$, we have $\operatorname{prof}(A) = \operatorname{prof}(A_{\mathfrak{m}}) = 0$; on the contrary, if $\mathfrak{p}_0 \neq \mathfrak{m}_0$, the elements of $\mathfrak{J}$ are annihilated by those of $\mathfrak{m}_0 - \mathfrak{p}_0$, hence $A_{\mathfrak{p}}$ is canonically isomorphic to $(A_0)_{\mathfrak{p}_0}$, and as A_0 is integral, $\operatorname{prof}((A_0)_{\mathfrak{p}_0}) \geqslant 1$ if $\mathfrak{p}_0 \neq 0$.

Corollary (16.4.7). — *For a local Noetherian reduced ring* A *to be of depth* 0, *it is necessary and sufficient that* A *be a field.*

Proof. Indeed, as the intersection of the minimal prime ideals of A is 0, A has no embedded associated prime ideals; by (16.4.6), (i), if $\operatorname{prof}(A) = 0$, the maximal ideal $\mathfrak{m}$ of A is also a minimal prime ideal, hence it is the only prime ideal of A, and as A is reduced, $\mathfrak{m} = 0$. □

Proposition (16.4.8). — *Let* A, B *be two local Noetherian rings,* $\rho : A \to B$ *a local homomorphism,* M *a* B*-module such that* $M_{[\rho]}$ *is an* A*-module of finite type. Then*

(16.4.8.1) $$\operatorname{prof}_A(M_{[\rho]}) = \operatorname{prof}_B(M).$$

Proof. One can restrict to the case $M \neq 0$; suppose $\operatorname{prof}_A(M_{[\rho]}) = n$. If $(x_i)_{1 \leqslant i \leqslant n}$ is a $(M_{[\rho]})$-regular maximal sequence formed of elements of the maximal ideal of A, the $\rho(x_i)$ constitute an M-regular sequence formed of elements of the maximal ideal of B, and we have then, setting $N = M/(\rho(x_1)M + \ldots + \rho(x_n)M)$, $\operatorname{prof}_B(N) = \operatorname{prof}_B(M) - n$ (16.4.6), (ii); similarly $N_{[\rho]} = M_{[\rho]}/(x_1 M_{[\rho]} + \ldots + x_n M_{[\rho]})$ and $\operatorname{prof}_A(N_{[\rho]}) = 0$; one is thus reduced to proving the proposition when $n = 0$. Let k be the residue field of A; since k is a quotient of A, the A-module $P = \operatorname{Hom}_A(k, M_{[\rho]})$ is a submodule of $\operatorname{Hom}_A(A, M_{[\rho]}) = M_{[\rho]}$, and the hypothesis implies that $P \neq 0$ (16.4.6), (i); furthermore, P is an A-module of finite type (since $M_{[\rho]}$ is an A-module of finite type), hence a finite-dimensional k-vector space, annihilated by the maximal ideal of A, and finally an A-module of *finite length*. Moreover, P is also a submodule of the B-module M, and since it is of finite length as an A-module, it is *a fortiori* of finite length as a B-module. As it is $\neq 0$, it contains a simple sub-B-module, that is to say one isomorphic to the residue field of B; one concludes then by (16.4.6), (i) that $\operatorname{prof}_B(M) = 0$. □

Definition (16.4.9). — Let A be a local Noetherian ring, M an A-module of finite type. If $M \neq 0$, we call the *codepth* of M and denote $\operatorname{coprof}_A(M)$ or $\operatorname{coprof}(M)$, the finite integer $\dim_A(M) - \operatorname{prof}_A(M) \geqslant 0$ (16.4.5.1). If $M = 0$, we set $\operatorname{coprof}(M) = 0$. We evidently have $\operatorname{coprof}(M^k) = \operatorname{coprof}(M)$ for every $k > 0$.

Proposition (16.4.10). — *Let* A *be a local Noetherian ring,* M *an* A*-module of finite type.* $\mathbf{0_{IV\text{-}1}}$ | 36

(i) *For every* M*-regular element* x *belonging to the maximal ideal of* A, *we have* $\operatorname{coprof}(M/xM) = \operatorname{coprof}(M)$.
(ii) *We have* $\operatorname{coprof}_A(M) = \operatorname{coprof}_{\widehat{A}}(\widehat{M})$.

Proof. Indeed, (i) follows from (16.3.4) and (16.4.6), (ii), and (ii) from (16.2.4) and (16.4.6), (iv). □

We shall show later (**IV**, 6.11.5) that for every prime ideal $\mathfrak{p}$ of A, we have $\operatorname{coprof}_{A_{\mathfrak{p}}}(M_{\mathfrak{p}}) \leqslant \operatorname{coprof}_A(M)$.

Proposition (16.4.11). — *Under the hypotheses of* (16.4.8), *we have*

(16.4.11.1) $$\operatorname{coprof}_A(M_{[\rho]}) = \operatorname{coprof}_B(M).$$

Proof. This follows from (16.1.9) and (16.4.8). □

16.5. Cohen-Macaulay modules

Definition (16.5.1). — Let A be a local Noetherian ring. An A-module of finite type M is called a *Cohen-Macaulay module* if $\mathrm{coprof}(\mathrm{M}) = 0$, that is, if $\mathrm{M} = 0$ or $\dim(\mathrm{M}) = \mathrm{prof}(\mathrm{M})$. We say that A is a *Cohen-Macaulay ring* if the A-module A is a Cohen-Macaulay module.

An A-module of finite length is a Cohen-Macaulay module since it is of dimension 0 (16.1.10). A local reduced ring of dimension 1 is a Cohen-Macaulay ring, since then its maximal ideal $\mathfrak{m}$ cannot be associated to A (Bourbaki, *Alg. comm.*, chap. IV, § 2, n° 5, prop. 10), hence $\mathrm{prof}(\mathrm{A}) = 1$ by virtue of (16.4.6), (i). If A is an *integral local integrally closed* ring of dimension $\geqslant 2$, we have $\mathrm{prof}(\mathrm{A}) \geqslant 2$: indeed, if $x \neq 0$ is an element of $\mathfrak{m}$, we know (Bourbaki, *Alg. comm.*, chap. VII, § 1, n° 4, prop. 8) that the prime ideals associated to $\mathrm{A}/x\mathrm{A}$ are of height 1, hence distinct from $\mathfrak{m}$ and their union is therefore distinct from $\mathfrak{m}$ (Bourbaki, *Alg. comm.*, chap. II, § 1, n° 1, prop. 2); there thus exist (x, y) sequences that are A-regular and formed of elements of $\mathfrak{m}$, whence our assertion. One concludes that an integral local integrally closed ring of dimension 2 is a Cohen-Macaulay ring.

Proposition (16.5.2). — *Let* A *be a local Noetherian ring,* M *an* A*-module of finite type. For* M *to be a Cohen-Macaulay module, it is necessary and sufficient that* $\widehat{\mathrm{M}}$ *be a* $\widehat{\mathrm{A}}$*-module of Cohen-Macaulay.*

Proof. This follows immediately from (16.4.10), (ii). □

Proposition (16.5.3). — *Under the hypotheses of* (16.4.8)*, for* M *to be a Cohen-Macaulay* B*-module, it is necessary and sufficient that* $\mathrm{M}_{[\rho]}$ *be a Cohen-Macaulay* A*-module.*

Proof. This follows from (16.4.11). □

Proposition (16.5.4). — *Let* A *be a local Noetherian ring,* M *an* A*-module of finite type* $\neq 0$*. If* M *is a Cohen-Macaulay module, we have* $\dim(\mathrm{A}/\mathfrak{p}) = \dim(\mathrm{M})$ *for every prime ideal* $\mathfrak{p} \in \mathrm{Ass}(\mathrm{M})$*; in particular no prime ideal associated to* M *is embedded.*

Proof. This follows immediately from the inequalities (16.4.6.2). □

One can also say that M (or $\mathrm{Supp}(\mathrm{M})$) is *equidimensional* (16.1.7).

$\mathbf{0_{IV\text{-}1}}$ | 37

Proposition (16.5.5). — *Let* A *be a local Noetherian ring,* $\mathfrak{m}$ *its maximal ideal,* M *an* A*-module of finite type* $\neq 0$*,* x *an element of* $\mathfrak{m}$*. Suppose that* M *is a Cohen-Macaulay module; then the following conditions are equivalent:*

- *a)* x *is* M*-regular;*
- *b)* $\dim(\mathrm{M}/x\mathrm{M}) = \dim(\mathrm{M}) - 1$*;*
- *c)* x *does not belong to any* minimal *element of* $\mathrm{Supp}(\mathrm{M})$*.*

Furthermore, $\mathrm{M}/x\mathrm{M}$ *is then a Cohen-Macaulay module.*

Proof. We have seen (16.5.4) that all the $\mathfrak{p}$ in $\mathrm{Ass}(\mathrm{M})$ are minimal in $\mathrm{Supp}(\mathrm{M})$ and such that $\dim(\mathrm{A}/\mathfrak{p}) = \dim(\mathrm{M})$; the equivalence of a) and c) then follows from Bourbaki, *Alg. comm.*, chap. IV, § 1, n° 1, cor. 2 of prop. 2; the equivalence of b) and c) follows from (16.3.4). The fact that $\mathrm{M}/x\mathrm{M}$ is a Cohen-Macaulay module follows finally from (16.4.10), (i). □

Corollary (16.5.6). — *Under the hypotheses of* (16.5.5)*, let* $(x_i)_{1 \leqslant i \leqslant r}$ *be a sequence of elements of* $\mathfrak{m}$*. The following conditions are equivalent:*

- *a) The sequence* (x_i) *is* M*-regular.*
- *b)* $\dim(\mathrm{M}/(x_1\mathrm{M} + \ldots + x_r\mathrm{M})) = \dim(\mathrm{M}) - r$*.*
- *c) The* x_i *form part of a system of parameters for* M*.*

Furthermore, when these conditions are satisfied, $\mathrm{N} = \mathrm{M}/(x_1\mathrm{M} + \ldots + x_r\mathrm{M})$ *is a Cohen-Macaulay module, hence for every prime ideal* $\mathfrak{p} \in \mathrm{Ass}(\mathrm{N})$*, we have* $\dim(\mathrm{A}/\mathfrak{p}) = \dim(\mathrm{M}) - r$*.*

Proof. We already know that b) and c) are equivalent (16.3.6) and that a) implies c) (16.4.1) without any hypothesis on M. To see that c) implies a), and to prove the last assertion of the statement, we argue by induction on r, the assertion being trivial for $r = 0$. Since x_1 forms part of a system of parameters, $\dim(\mathrm{M}/x_1\mathrm{M}) = \dim(\mathrm{M}) - 1$ (16.3.6), hence x_1 is M-regular and $\mathrm{M}/x_1\mathrm{M}$ is Cohen-Macaulay by (16.5.5). Since the sequence $(x_i)_{2 \leqslant i \leqslant r}$ forms part of a system of parameters for P =

M/x_1M, the induction hypothesis shows that $(x_i)_{2\leqslant i\leqslant r}$ is a P-regular sequence and that $P/(x_2P + \ldots + x_rP) = N$ is a Cohen-Macaulay module; furthermore $(x_i)_{1\leqslant i\leqslant r}$ is M-regular. □

Remark (16.5.7). — It follows from (16.5.6) that there is an identity between *systems of parameters* for M and the maximal M-regular sequences of elements of $\mathfrak{m}$ when M is a Cohen-Macaulay module. Conversely, it follows from (16.4.1) that if there is any M-regular sequence that is a system of parameters for M, then M is a Cohen-Macaulay module. The last property stated in (16.5.6) also *characterizes* Cohen-Macaulay modules:

Proposition (16.5.8). — *Let* A *be a local Noetherian ring,* M *an* A*-module of finite type. Suppose that for every sequence $(x_i)_{1\leqslant i\leqslant r}$ of elements of* A *forming part of a system of parameters for* M*, and for every prime ideal $\mathfrak{p}$ associated to* $N = M/(x_1M + \ldots + x_rM)$*, we have* $\dim(A/\mathfrak{p}) = \dim(N)$*. Then* M *is a Cohen-Macaulay module.*

Proof. Let $(y_i)_{1\leqslant i\leqslant n}$ be a system of parameters for M; it suffices to show that the sequence (y_i) is M-regular. We argue by induction on $n = \dim(M)$, the proposition being trivial for $n = 0$. By hypothesis (applied with $r = 0$) the prime ideals $\mathfrak{p}_j$ associated to M are all such that $\dim(A/\mathfrak{p}_j) = \dim(M)$; as y_1 forms part of a system of parameters for M, it follows from (16.3.7) and (16.3.4) that $\mathbf{0}_{\textbf{IV-1}}$ | 38
y_1 does not belong to any of the $\mathfrak{p}_j$, hence is M-regular. If we set $P = M/y_1M$, then $(y_i)_{2\leqslant i\leqslant n}$ is a system of parameters for P, and it is immediate that P satisfies the hypothesis of the statement; applying the induction hypothesis, one sees that $(y_i)_{2\leqslant i\leqslant n}$ is a P-regular sequence, which proves the proposition. □

Proposition (16.5.9). — *Let* A *be a local Noetherian ring,* M *an* A*-module of finite type. Suppose that* M *is a Cohen-Macaulay module. Let* $\mathfrak{p} \in \operatorname{Supp}(M)$*, and set* $r = \dim(M) - \dim(M/\mathfrak{p}M)$*. Then there exists an* M*-regular sequence* $(x_i)_{1\leqslant i\leqslant r}$*, formed of elements of* $\mathfrak{p}$*; for every such sequence, we have*

$$\dim(M/(x_1M + \ldots + x_rM)) = \dim(M/\mathfrak{p}M) = \dim(A/\mathfrak{p}),$$

and $\mathfrak{p}$ *is a* minimal *element of* $\operatorname{Ass}(M/(x_1M + \ldots + x_rM))$.

Proof. Let us first prove the existence of the x_i; there is nothing to prove for $r = 0$. For $r > 0$, we proceed by induction. As for every prime ideal $\mathfrak{q}_i$ associated to M we have $\dim(A/\mathfrak{q}_i) = \dim(M)$ (16.5.4), the hypothesis $\dim(M/\mathfrak{p}M) < \dim(M)$ implies that $\mathfrak{p}$ cannot be contained in any of the $\mathfrak{q}_i$, the latter being the minimal prime ideals among those containing Ann(M) (16.1.2.2) and (16.1.7); one concludes that $\mathfrak{p}$ is not contained in the union of the $\mathfrak{q}_i$ (Bourbaki, *Alg. comm.*, chap. II, § 1, n° 1, prop. 2), and hence there exists $x_1 \in \mathfrak{p}$ that is M-regular (Bourbaki, *Alg. comm.*, chap. IV, § 1, n° 1, cor. 2 of prop. 2). It follows from (16.5.5) that $N = M/x_1M$ is a Cohen-Macaulay module, of dimension $\dim(M) - 1$; as $x_1 \in \mathfrak{p}$, moreover $N/\mathfrak{p}N = M/\mathfrak{p}M$, whence $\dim(N) - \dim(N/\mathfrak{p}N) = r - 1$; one can therefore apply the induction hypothesis to N, and if $(x_i)_{2\leqslant i\leqslant r}$ is an N-regular sequence formed of elements of $\mathfrak{p}$, it is clear that $(x_i)_{1\leqslant i\leqslant r}$ is an M-regular sequence formed of elements of $\mathfrak{p}$.

Now if one sets $P = M/(x_1M + \ldots + x_rM)$, we have $P/\mathfrak{p}P = M/\mathfrak{p}M$ since the x_i are in $\mathfrak{p}$, and $\dim(P) = \dim(P/\mathfrak{p}P)$ by (16.5.6). But since P is a Cohen-Macaulay module, we also have $\dim(P) = \dim(A/\mathfrak{p}')$ for every $\mathfrak{p}' \in \operatorname{Ass}(P)$ (16.5.4). As $\mathfrak{p} \in \operatorname{Supp}(P)$ ($\mathbf{0}_{\mathrm{I}}$, 1.7.5), $\mathfrak{p}$ contains some $\mathfrak{p}' \in \operatorname{Ass}(P)$ (Bourbaki, *Alg. comm.*, chap. IV, § 1, n° 4, th. 2), and as $\dim(P) = \dim(P/\mathfrak{p}P) \leqslant \dim(A/\mathfrak{p}) \leqslant \dim(A/\mathfrak{p}') = \dim(P)$, one necessarily has $\mathfrak{p} = \mathfrak{p}'$ (16.1.2.2), which completes the proof. □

Corollary (16.5.10). — *Under the same hypotheses as in (16.5.9):*

(i) $M_{\mathfrak{p}}$ *is an* $A_{\mathfrak{p}}$*-module of Cohen-Macaulay.*
(ii) *We have*

(16.5.10.1) $$\dim(M) = \dim_A(M/\mathfrak{p}M) + \dim_{A_{\mathfrak{p}}}(M_{\mathfrak{p}}).$$

Proof. With the notations of (16.5.9), let x_i' be the canonical images of the x_i in $A_{\mathfrak{p}}$ $(1 \leqslant i \leqslant r)$; as the x_i' belong to the maximal ideal of $A_{\mathfrak{p}}$ and form a $M_{\mathfrak{p}}$-regular sequence by flatness (15.1.14), we have

$$\operatorname{prof}_{A_{\mathfrak{p}}}(M_{\mathfrak{p}}) \geqslant r = \dim(M) - \dim(M/\mathfrak{p}M) \geqslant \dim_{A_{\mathfrak{p}}}(M_{\mathfrak{p}})$$

(by virtue of (16.1.8.1)). But taking into account (16.4.5.1), the three terms of this inequality are necessarily equal, whence the corollary. □

$\mathbf{0}_{\mathbf{IV\text{-}1}}$ | 39

Corollary (16.5.11). — *Let* A *be a local Noetherian ring; suppose that there exists a Cohen-Macaulay* A*-module of finite type* M *with support* Spec(A)*. Then, for every prime ideal* $\mathfrak{p}$ *of* A*, we have*

(16.5.11.1) $$\dim(A) = \dim(A/\mathfrak{p}) + \dim(A_\mathfrak{p}).$$

Proof. Indeed, $\mathrm{Supp}(M/\mathfrak{p}M) = \mathrm{Spec}(A/\mathfrak{p})$ ($\mathbf{0}_\mathrm{I}$, 1.7.5) and $\mathrm{Supp}(M_\mathfrak{p}) = \mathrm{Spec}(A_\mathfrak{p})$; the relation (16.5.11.1) is thus a special case of (16.5.10.1). ☐

Corollary (16.5.12). — *Every quotient ring of a local Noetherian ring* A *satisfying the conditions of* (16.5.11) *(in particular every quotient ring of a local Cohen-Macaulay ring) is* catenary.

Proof. It suffices evidently to prove that A itself is catenary, that is to say for two prime ideals $\mathfrak{p} \subset \mathfrak{q}$ of A, we have (16.1.4.2)

$$\dim(A_\mathfrak{q}) = \dim(A_\mathfrak{q}/\mathfrak{p}A_\mathfrak{q}) + \dim(A_\mathfrak{p}).$$

But, by virtue of (16.5.10), (i) $A_\mathfrak{q}$ satisfies the same hypotheses as A, and the preceding relation is then none other than (16.5.11.1) applied to $A_\mathfrak{q}$ and to the prime ideal $\mathfrak{p}A_\mathfrak{q}$ of $A_\mathfrak{q}$. ☐

(16.5.13). Let A be a Noetherian ring, M an A-module of finite type. We say that M is a *Cohen-Macaulay* A*-module* if, for every prime ideal $\mathfrak{p}$ of A, $M_\mathfrak{p}$ is an $A_\mathfrak{p}$-module of Cohen-Macaulay; by virtue of (16.5.10) this definition coincides with (16.5.1) when A is *local*. We say that A is a *Cohen-Macaulay ring* if all the $A_\mathfrak{p}$ are. It is clear that if M (resp. A) is a Cohen-Macaulay A-module (resp. a Cohen-Macaulay ring), $S^{-1}M$ is a Cohen-Macaulay $S^{-1}A$-module (resp. $S^{-1}A$ is a Cohen-Macaulay ring) for every multiplicative subset S of A.

§17. Regular rings

17.1. Definition of regular rings $\mathbf{0}_{\mathbf{IV\text{-}1}}$ | 39

Proposition (17.1.1). — *Let A be a Noetherian local ring of dimension n, $\mathfrak{m}$ its maximal ideal, $k = A/\mathfrak{m}$ its residue field. The following conditions are equivalent:*

a) *The canonical surjective homomorphism of graded k-modules* (15.1.1)
$$\varphi : \mathbf{S}^*_k(\mathfrak{m}/\mathfrak{m}^2) \longrightarrow \mathrm{gr}^*_\mathfrak{m}(A)$$
(where the second term is the graded k-module associated to A equipped with the $\mathfrak{m}$-preadic filtration) is bijective.

b) *We have* $\mathrm{rg}_k(\mathfrak{m}/\mathfrak{m}^2) = n$.

c) *The ideal $\mathfrak{m}$ admits a system of generators of n elements.*

d) *The ideal $\mathfrak{m}$ admits a system of generators that is an A-regular sequence.*

Proof. By Nakayama's lemma, $\mathrm{rg}_k(\mathfrak{m}/\mathfrak{m}^2)$ is the smallest number of elements of a system of generators of $\mathfrak{m}$, so b) and c) are equivalent. On the other hand, if $(x_i)_{1\leqslant i\leqslant r}$ is a system of generators of $\mathfrak{m}$ whose classes $\overline{x}_i$ mod. $\mathfrak{m}^2$ form a basis of the k-vector space $\mathfrak{m}/\mathfrak{m}^2$, $\mathbf{S}^*(\mathfrak{m}/\mathfrak{m}^2)$ is isomorphic to the polynomial ring $k[T_1, \ldots, T_r]$; taking into account that every A-module of finite type is separated for $\mathbf{0}_{\mathbf{IV\text{-}1}}$ | 40
the $\mathfrak{m}$-preadic filtration ($\mathbf{0}_\mathbf{I}$, 7.3.5), it follows from (15.1.9) that conditions a) and d) are equivalent; moreover, since every A-regular sequence of elements of $\mathfrak{m}$ has at most n elements (16.4.1), we see that d) implies c). It remains to prove that c) implies a).

Let us set, for brevity, $S = \mathbf{S}^*(\mathfrak{m}/\mathfrak{m}^2) = k[T_1, \ldots, T_n]$, $G = \mathrm{gr}^*_\mathfrak{m}(A)$, and consider the exact sequence $0 \to \mathfrak{J} \to S \xrightarrow{\varphi} G \to 0$, where the kernel $\mathfrak{J}$ of φ is thus a graded ideal of S. For every integer $s > 0$, we thus have

(17.1.1.1) $$\binom{s+n-1}{n-1} = \mathrm{long}(S_s) = \mathrm{long}(G_s) + \mathrm{long}(\mathfrak{J}_s).$$

Suppose $\mathfrak{J} \neq 0$, so that there exists a homogeneous element $u \in \mathfrak{J}$ of degree $h > 0$; $\mathfrak{J}_s$ contains uS_{s-h} for $s \geqslant h$, and since $u \neq 0$ and S is integral, uS_{s-h} is isomorphic to S_{s-h} as a k-vector space; we would thus have $\mathrm{long}(\mathfrak{J}_s) \geqslant \mathrm{long}(S_{s-h}) = \binom{s-h+n-1}{n-1}$, whence for $s \geqslant h$,

(17.1.1.2) $$\mathrm{long}(G_s) \leqslant \binom{s+n-1}{n-1} - \binom{s-h+n-1}{n-1}.$$

But the second term of (17.1.1.2) is a polynomial in s of degree $\leqslant n-2$; since $G_s = \mathfrak{m}^s/\mathfrak{m}^{s+1}$, and for s sufficiently large, $\mathrm{long}(G_s)$ is a polynomial in s of degree exactly equal to $n-1$ whose leading coefficient is >0 (16.2.1), which contradicts the inequality (17.1.1.2). □

Definition (17.1.2). — We say that a Noetherian local ring that satisfies the equivalent conditions of (17.1.1) is *regular*.

Corollary (17.1.3). — *A regular local ring is integral, integrally closed, and a Cohen-Macaulay ring.*

Proof. The last assertion follows from (17.1.1, d)); on the other hand, if A is regular, $\mathrm{gr}^*_{\mathfrak{m}}(A)$ is integral and completely integrally closed, being isomorphic to $k[T_1, \ldots, T_n]$; we conclude that A also possesses these two properties (Bourbaki, *Alg. comm.*, chap. III, §2, n° 3, cor. of prop. 1 and chap. V, §1, n° 5, prop. 15). □

Example (17.1.4). — (i) A regular local ring of dimension 0, being integral by (17.1.3), is necessarily a *field*, and conversely.

(ii) For a Noetherian local ring of dimension 1 to be regular, it is necessary and sufficient that it be a *discrete valuation ring*: indeed, to say that a Noetherian local ring of dimension 1 is regular means that its maximal ideal is *principal*, and the conclusion follows from Bourbaki, *Alg. comm.*, chap. VI, §3, n° 6, prop. 9.

(iii) Let k be a field; the formal power series ring $A = k[[T_1, \ldots, T_n]]$ is a *regular ring of dimension* n; indeed, it is clear that the T_i ($1 \leqslant i \leqslant n$) generate the maximal ideal $\mathfrak{m}$ of A and form an A-regular sequence, since $A/(T_1A + \cdots + T_iA)$ is isomorphic to $k[[T_{i+1}, \ldots, T_n]]$.

Proposition (17.1.5). — *For a Noetherian local ring A to be regular, it is necessary and sufficient that its completion $\widehat{A}$ be regular.*

Proof. Indeed, the maximal ideal of $\widehat{A}$ is $\mathfrak{m}\widehat{A}$ and we know that $\mathfrak{m}^h/\mathfrak{m}^{h+1}$ and $(\mathfrak{m}\widehat{A})^h/(\mathfrak{m}\widehat{A})^{h+1}$ are isomorphic k-vector spaces; condition a) of (17.1.1) is thus the same for A and $\widehat{A}$. □ **$\mathbf{0_{IV\text{-}1}}$ | 41**

Definition (17.1.6). — Given a Noetherian local ring A, with maximal ideal $\mathfrak{m}$, we call a *regular system of parameters* of A a system of parameters for A (16.3.5) that generates $\mathfrak{m}$.

The existence of such a system is equivalent to the fact that A is regular (17.1.1); if $(x_i)_{1\leqslant i\leqslant n}$ is a regular system of parameters, it is a minimal system of generators of $\mathfrak{m}$, whose classes mod. $\mathfrak{m}^2$ form a basis of $\mathfrak{m}/\mathfrak{m}^2$ over k; by virtue of (17.1.1, a)) and (15.1.9), (x_i) is a maximal A-regular sequence (whence the terminology).

One should note however that, in a regular ring, a system of parameters for A that is also an A-regular sequence is *not* necessarily a regular system of parameters, as shown by the example of k-th powers of a regular system of parameters (15.1.20).

Proposition (17.1.7). — *Let A be a Noetherian local ring, $\mathfrak{m}$ its maximal ideal, $k = A/\mathfrak{m}$ its residue field, $(x_i)_{1\leqslant i\leqslant r}$ a sequence of elements of $\mathfrak{m}$, $\mathfrak{J}$ the ideal $x_1A + \cdots + x_rA$. The following conditions are equivalent:*

a) *A is regular and the x_i are part of a regular system of parameters of A.*

a') *A is regular and the classes $\overline{x}_i$ of the x_i mod. $\mathfrak{m}^2$ are linearly independent over k.*

b) *The x_i are part of a system of parameters for A and $A/\mathfrak{J}$ is a regular ring.*

Moreover, when these conditions are satisfied, $\mathfrak{J}$ is a prime ideal.

Proof. The last assertion follows trivially from the fact that $A/\mathfrak{J}$, being regular, is integral (17.1.3). Set $n = \dim(A)$. The equivalence of a) and a') is immediate; indeed, the classes mod. $\mathfrak{m}^2$ of the elements of a regular system of parameters form a basis of $\mathfrak{m}/\mathfrak{m}^2$ over k, and conversely, if the $\overline{x}_i$ ($1 \leqslant i \leqslant r$) are linearly independent over k, one can find $n-r$ elements $x_i \in \mathfrak{m}$ ($r+1 \leqslant i \leqslant n$) such that the $\overline{x}_i$ ($1 \leqslant i \leqslant n$) form a basis of $\mathfrak{m}/\mathfrak{m}^2$, so $(x_i)_{1\leqslant i\leqslant n}$ is a regular system of parameters. To see that a) implies b), note that since the x_i are part of a system of parameters of A, we have $\dim(A/\mathfrak{J}) = n-r$ (16.3.6); let $\mathfrak{n} = \mathfrak{m}/\mathfrak{J}$ be the ideal of $A/\mathfrak{J}$. We have an exact sequence

$$0 \longrightarrow (\mathfrak{m}^2 + \mathfrak{J})/\mathfrak{m}^2 \longrightarrow \mathfrak{m}/\mathfrak{m}^2 \longrightarrow \mathfrak{n}/\mathfrak{n}^2 \longrightarrow 0 \tag{17.1.7.1}$$

since $\mathfrak{n}^2 = (\mathfrak{m}^2 + \mathfrak{J})/\mathfrak{J}$; hypothesis a) implies that $\mathrm{rg}_k((\mathfrak{m}^2 + \mathfrak{J})/\mathfrak{m}^2) = r$, so $\mathrm{rg}_k(\mathfrak{n}/\mathfrak{n}^2) = n - r = \dim(A/\mathfrak{J})$, which proves b) by virtue of (17.1.1, b)).

Conversely, to prove that b) implies a), note that the fact that the x_i are part of a system of parameters implies $\dim(A/\mathfrak{J}) = n - r$ (16.3.6); the hypothesis that $A/\mathfrak{J}$ is regular implies on the other hand $\mathrm{rg}_k(\mathfrak{n}/\mathfrak{n}^2) = n - r$ (17.1.1); moreover we evidently have $\mathrm{rg}_k((\mathfrak{m}^2 + \mathfrak{J})/\mathfrak{m}^2) \leqslant r$, so from (17.1.7.1) we obtain $\mathrm{rg}_k(\mathfrak{m}/\mathfrak{m}^2) \leqslant r + (n - r) = n$; thus A is regular by (16.2.6) and (17.1.1). Furthermore the relation $\mathrm{rg}_k(\mathfrak{m}/\mathfrak{m}^2) = n$ then implies $\mathrm{rg}_k((\mathfrak{m}^2 + \mathfrak{J})/\mathfrak{m}^2) = r$, and consequently the $\overline{x}_i$ are linearly independent over k. □

$\mathbf{0_{IV\text{-}1}}$ | 42

Corollary (17.1.8). — *Let A be a Noetherian local ring, $\mathfrak{m}$ its maximal ideal, t an element of $\mathfrak{m}$. The following conditions are equivalent:*

a) *A/tA is regular and t is a non-zero-divisor in A.*
b) *A is regular and $t \notin \mathfrak{m}^2$.*

Proof. This is the special case $r = 1$ of (17.1.7) (taking into account that an element of $\mathfrak{m}$ that is a non-zero-divisor is part of a system of parameters (16.4.1)). □

Corollary (17.1.9). — *Let A be a regular local ring, $\mathfrak{m}$ its maximal ideal, $\mathfrak{J}$ an ideal of A contained in $\mathfrak{m}$. The following conditions are equivalent:*

a) *The ring $A/\mathfrak{J}$ is regular.*
b) *$\mathfrak{J}$ is generated by a sequence $(x_i)_{1 \leqslant i \leqslant r}$ forming part of a regular system of parameters of A.*

Proof. We have already seen (17.1.7) that b) implies a). Conversely, suppose that $A/\mathfrak{J}$ is regular (which implies that $\mathfrak{J}$ is prime) and let $n = \dim(A)$, $n - r = \dim(A/\mathfrak{J})$; with the notation of (17.1.7), the exact sequence (17.1.7.1) gives $\mathrm{rg}_k((\mathfrak{m}^2 + \mathfrak{J})/\mathfrak{m}^2) = r$, so there exists a sequence $(x_i)_{1 \leqslant i \leqslant r}$ of elements of $\mathfrak{J}$ forming part of a regular system of parameters of A. Set $\mathfrak{J}' = x_1 A + \cdots + x_r A$; it follows from (17.1.7) that $\mathfrak{J}'$ is a prime ideal of A and that $A/\mathfrak{J}'$ is regular and of dimension $n - r$; but since $A/\mathfrak{J} = (A/\mathfrak{J}')/(\mathfrak{J}/\mathfrak{J}')$ and $\mathfrak{J}/\mathfrak{J}'$ is prime in the integral ring $A/\mathfrak{J}'$, the dimensions of $A/\mathfrak{J}$ and $A/\mathfrak{J}'$ can only be equal if $\mathfrak{J} = \mathfrak{J}'$ (16.1.2.2). □

17.2. Reminders on projective and injective dimension of modules

(17.2.1). Let A be a ring, M an A-module. Recall (M, VI, 2) that we call *projective dimension* (resp. *injective dimension*) of M and denote $\dim.\mathrm{proj}(M)$ or $\dim.\mathrm{proj}_A(M)$ (resp. $\dim.\mathrm{inj}(M)$ or $\dim.\mathrm{inj}_A(M)$) the smallest n (integer or equal to $+\infty$) such that there exists a left projective resolution (resp. a right injective resolution) of M of length n. It is equivalent (loc. cit.) to say that n is the smallest number such that for every A-module N, we have $\mathrm{Ext}^i_A(M, N) = 0$ (resp. $\mathrm{Ext}^i_A(N, M) = 0$) for all $i > n$, or only for $i = n + 1$. For every direct factor M' of M, we thus have $\dim.\mathrm{proj}(M') \leqslant \dim.\mathrm{proj}(M)$ since $\mathrm{Ext}^i_A(M', N)$ is a direct factor of $\mathrm{Ext}^i_A(M, N)$; similarly $\dim.\mathrm{inj}(M') \leqslant \dim.\mathrm{inj}(M)$. A condition equivalent to $\dim.\mathrm{proj}(M) = n$ (resp. $\dim.\mathrm{inj}(M) = n$) is that n is the smallest number such that, for every exact sequence

$$0 \longrightarrow \mathrm{R} \longrightarrow \mathrm{P}_{n-1} \longrightarrow \cdots \longrightarrow \mathrm{P}_0 \longrightarrow M \longrightarrow 0$$

(resp. $0 \to M \to \mathrm{Q}_0 \to \cdots \to \mathrm{Q}_{n-1} \to \mathrm{C} \to 0$), where all the P_i for $0 \leqslant i < n$ are projective (resp. all the Q_i for $0 \leqslant i < n$ are injective), R is projective (resp. C is injective).

Remark (17.2.2). — (i) To say that M is a projective (resp. injective) A-module is therefore equivalent to saying that $\dim.\mathrm{proj}(M) = 0$ (resp. $\dim.\mathrm{inj}(M) = 0$).

(ii) Let T be a covariant additive functor from the category of A-modules to an abelian category. It follows immediately from the definitions of (17.2.1) and those of derived functors that if $\dim.\mathrm{proj}(M) \leqslant n$ (resp. $\dim.\mathrm{inj}(M) \leqslant n$), we have $\mathrm{L}^i\mathrm{T}(M) = 0$ (resp. $\mathrm{R}^i\mathrm{T}(M) = 0$) for all $i > n$. $\mathbf{0_{IV\text{-}1}}$ | 43

(iii) If we suppose A Noetherian and M of finite type, the last interpretation of the projective dimension given in (17.2.1) shows that if $\dim.\mathrm{proj}(M) = n$, M admits a left resolution of length n formed of projective modules *of finite type*. If moreover A is a Noetherian *local* ring, M admits a resolution of length n by *free* modules of finite type, a projective module of finite type then being free (Bourbaki, *Alg. comm.*, chap. II, §3, nº 2, cor. 2 of prop. 5).

Lemma (17.2.3). — *Let A be a ring, M an A-module. For* $\dim.\mathrm{inj}(M) \leqslant n$*, it is necessary and sufficient that for every monogenic A-module N, we have* $\mathrm{Ext}^{n+1}_A(N, M) = 0$.

Proof. With the notation of (17.2.1), it suffices to prove that C is injective; for every A-module N, $\mathrm{Ext}^{n+1}_A(N, M)$ is isomorphic to $\mathrm{Ext}^1_A(N, \mathrm{C})$ (M, V, 7), so we have $\mathrm{Ext}^1_A(N, \mathrm{C}) = 0$ for every module N of the form $A/\mathfrak{J}$, where $\mathfrak{J}$ is any ideal of A. The exact sequence of Ext then shows that the canonical homomorphism $\mathrm{Hom}(A, \mathrm{C}) \to \mathrm{Hom}(\mathfrak{J}, \mathrm{C})$ is surjective for every ideal $\mathfrak{J}$ of A, which implies that C is an injective A-module (M, I, 3.2). ☐

Lemma (17.2.4). — *Let A be a Noetherian local ring, M an A-module of finite type. For* $\dim.\mathrm{proj}(M) \leqslant n$*, it is necessary and sufficient that for every monogenic A-module N, we have* $\mathrm{Ext}^{n+1}_A(M, N) = 0$.

Proof. We know in fact (M, VI, 2.5) that the condition $\dim.\mathrm{proj}(M) \leqslant n$ is equivalent to $\mathrm{Ext}^{n+1}_A(M, N) = 0$ for every A-module N of finite type; to see that the condition of the statement is also sufficient, we argue by induction on the number m of generators of N: there is a submodule N_1 of N generated by $m-1$ elements and such that $\mathrm{N}_2 = N/\mathrm{N}_1$ is monogenic; from the exact sequence $0 \to \mathrm{N}_1 \to N \to \mathrm{N}_2 \to 0$, we then deduce the exact sequence $\mathrm{Ext}^{n+1}_A(M, \mathrm{N}_1) \to \mathrm{Ext}^{n+1}_A(M, N) \to \mathrm{Ext}^{n+1}_A(M, \mathrm{N}_2)$ and the induction hypothesis shows that the condition of the statement indeed implies $\mathrm{Ext}^{n+1}_A(M, N) = 0$. ☐

Corollary (17.2.5). — *Let A be a Noetherian ring, M an A-module. We have*

(17.2.5.1) $$\dim.\mathrm{inj}_A(M) = \sup_{\mathfrak{m}} \big(\dim.\mathrm{inj}_{A_\mathfrak{m}}(M_\mathfrak{m})\big)$$

and if M is of finite type

(17.2.5.2) $$\dim.\mathrm{proj}_A(M) = \sup_{\mathfrak{m}} \big(\dim.\mathrm{proj}_{A_\mathfrak{m}}(M_\mathfrak{m})\big)$$

where $\mathfrak{m}$ ranges over the set of prime ideals (or the set of maximal ideals) of A.

Proof. Indeed, if N is an A-module of finite type (thus of finite presentation), we have, for every multiplicative subset S of A and for all $i \geqslant 0$ **$0_{\text{IV-1}}$** | 44

$$S^{-1}\mathrm{Ext}^i_A(N, M) = \mathrm{Ext}^i_{S^{-1}A}(S^{-1}N, S^{-1}M)$$

by flatness, considering a free resolution of M and using the fact that the preceding relation is true for $i = 0$ (Bourbaki, *Alg. comm.*, chap. II, §2, nº 7, prop. 19). In particular $\mathrm{Ext}^i_{A_\mathfrak{m}}(A_\mathfrak{m}/\mathfrak{J}A_\mathfrak{m}, M_\mathfrak{m}) = (\mathrm{Ext}^i_A(A/\mathfrak{J}, M))_\mathfrak{m}$ for every prime ideal $\mathfrak{m}$ and every ideal $\mathfrak{J}$ of A; taking into account (17.2.3) and the fact that every ideal of $A_\mathfrak{m}$ is of the form $\mathfrak{J}A_\mathfrak{m}$ for a suitable ideal $\mathfrak{J}$ of A, we deduce formula (17.2.5.1) from what precedes and from Bourbaki, *Alg. comm.*, chap. II, §3, nº 3, th. 1. We proceed similarly for (17.2.5.2) using this time (17.2.4) and interchanging the roles of M and N. ☐

For Noetherian rings and modules of finite type, the study of projective or injective dimension is thus reduced by (17.2.5) to the case of local rings. We then have the

Lemma (17.2.6). — *Let A be a Noetherian local ring, k its residue field, M an A-module of finite type. For* $\dim.\mathrm{proj}(M) \leqslant n$*, it is necessary and sufficient that* $\mathrm{Tor}^A_i(M, k) = 0$ *for $i > n$, and it suffices that* $\mathrm{Tor}^A_{n+1}(M, k) = 0$.

Proof. The necessity is a special case of the remark (17.2.2, (ii)), applied to the covariant functor $M \mapsto k \otimes_A M$. To prove the sufficiency, it suffices, with the notation of (17.2.1), to establish that R is projective when the P_i are assumed of finite type; now $\mathrm{Tor}^A_{n+1}(M, k)$ is isomorphic to $\mathrm{Tor}^A_1(\mathrm{R}, k)$ (M, V, 7); and we know that, since R is of finite type, the condition $\mathrm{Tor}^A_1(\mathrm{R}, k) = 0$ implies that R is free (Bourbaki, *Alg. comm.*, chap. II, §3, nº 2, cor. 2 of prop. 5). ☐

Corollary (17.2.7). — *Under the hypotheses of (17.2.6), let x be an M-regular element of A belonging to the maximal ideal of A; then we have*

(17.2.7.1) $$\dim.\mathrm{proj}(M/xM) = \dim.\mathrm{proj}(M) + 1.$$

Proof. Indeed, from the exact sequence $0 \to M \xrightarrow{x} M \to M/xM \to 0$ defined by multiplication by x in M, we deduce by the exact sequence of Tor:

$$\mathrm{Tor}_i^A(M,k) \xrightarrow{x} \mathrm{Tor}_i^A(M/xM,k) \longrightarrow \mathrm{Tor}_{i-1}^A(M,k) \xrightarrow{x} \mathrm{Tor}_{i-1}^A(M,k)$$

for all $i \geqslant 1$. Now, for every A-module N, the homothety of ratio x in $M \otimes_A N$ arises equally well from the homothety of ratio x in M as from the homothety of ratio x in N; we conclude immediately, since the homothety of ratio x in k is zero by definition, that for every i, the homomorphism $\mathrm{Tor}_i^A(M,k) \xrightarrow{x} \mathrm{Tor}_i^A(M,k)$ is zero; in other words, we have the exact sequence

$$0 \longrightarrow \mathrm{Tor}_i^A(M,k) \longrightarrow \mathrm{Tor}_i^A(M/xM,k) \longrightarrow \mathrm{Tor}_{i-1}^A(M,k) \longrightarrow 0.$$

If $\dim.\mathrm{proj}(M) = n$, we have $\mathrm{Tor}_n^A(M,k) \neq 0$ and $\mathrm{Tor}_{n+1}^A(M,k) = \mathrm{Tor}_{n+2}^A(M,k) = 0$ by (17.2.6). It thus follows from what precedes that $\mathrm{Tor}_{n+1}^A(M/xM,k) \neq 0$ and $\mathrm{Tor}_{n+2}^A(M/xM,k) = 0$, so $\dim.\mathrm{proj}(M/xM) = n+1$ by (17.2.6). □

Proposition (17.2.8). — (M. Auslander) *Let A be a ring. The following conditions are equivalent:*

a) *Every A-module is of projective dimension $\leqslant n$.*
a') *Every A-module of finite type is of projective dimension $\leqslant n$.*
b) *Every A-module is of injective dimension $\leqslant n$.*
c) *For every pair of A-modules M, N we have $\mathrm{Ext}_A^{n+1}(M,N) = 0$.*
c') *For every pair of A-modules M, N such that M is of finite type (or only monogenic), we have $\mathrm{Ext}_A^{n+1}(M,N) = 0$.*

Proof. This follows immediately from (17.2.1) and (17.2.3). □

The smallest number n (integer or $+\infty$) for which the equivalent conditions of (17.2.8) are satisfied is called the *global cohomological dimension* (or simply *cohomological dimension*) of A and denoted $\dim.\mathrm{coh}(A)$. **0_IV-1** | 45

Proposition (17.2.9). — *Let A be a Noetherian ring. The following conditions are equivalent:*

a) $\dim.\mathrm{coh}(A) \leqslant n$.
b) *Every A-module of finite type is of injective dimension $\leqslant n$.*
c) *For every pair of A-modules of finite type, M, N, we have $\mathrm{Ext}_A^{n+1}(M,N) = 0$.*

Proof. This follows immediately from the definition and from (17.2.4). □

Corollary (17.2.10). — *If A is a Noetherian ring, we have*

(17.2.10.1)
$$\dim.\mathrm{coh}(A) = \sup_{\mathfrak{m}} \left(\dim.\mathrm{coh}(A_{\mathfrak{m}})\right)$$

where $\mathfrak{m}$ ranges over the spectrum of A (or the set of maximal ideals of A).

Proof. This follows immediately from (17.2.9) and (17.2.5). □

Proposition (17.2.11). — *Let A be a Noetherian local ring, k its residue field. For $\dim.\mathrm{coh}(A) \leqslant n$, it is necessary that $\mathrm{Tor}_i^A(k,k) = 0$ for $i > n$, and it suffices that $\mathrm{Tor}_{n+1}^A(k,k) = 0$.*

Proof. Taking into account (17.2.6), it suffices to prove that the relations $\dim.\mathrm{coh}(A) \leqslant n$ and $\dim.\mathrm{proj}_A(k) \leqslant n$ are equivalent. It is clear that the first implies the second by definition. Conversely, if $\dim.\mathrm{proj}_A(k) \leqslant n$, we have $\mathrm{Tor}_i^A(M,k) = 0$ for $i > n$ and for every A-module M by (17.2.2, (ii)); thus $\dim.\mathrm{proj}(M) \leqslant n$, which proves the proposition by (17.2.8). □

Corollary (17.2.12). — *Let A be a Noetherian ring. For $\dim.\mathrm{coh}(A) \leqslant n$, it is necessary that, for every maximal ideal $\mathfrak{m}$ of A, we have $\mathrm{Tor}_i^{A_{\mathfrak{m}}}(A/\mathfrak{m}, A/\mathfrak{m}) = 0$ for $i > n$, and it suffices that these relations be satisfied for $i = n+1$.*

Proof. This follows immediately from (17.2.11) and (17.2.10). □

Proposition (17.2.13). — *Let A, B be two Noetherian local rings, $\varphi : A \to B$ a local homomorphism making B a flat A-module. Then we have*

(17.2.13.1)
$$\dim.\mathrm{coh}(A) \leqslant \dim.\mathrm{coh}(B).$$

Proof. Suppose that $\dim.\mathrm{coh}(B) = n$ is finite; it suffices to prove that for every pair (M, N) of A-modules of finite type, we have $\mathrm{Tor}_i^A(M, N) = 0$ for $i > n$ (17.2.11). Since B is a faithfully flat A-module ($\mathbf{0}_\mathrm{I}$, 6.6.2), it amounts to the same ($\mathbf{0}_\mathrm{I}$, 6.4.1) to show that

$$\mathrm{Tor}_i^A(M, N) \otimes_A B = 0. \tag{17.2.13.2}$$

Now, if $\mathrm{L}_\bullet = (\mathrm{L}_j)$ is a right resolution of M by free A-modules, it follows from the fact that B is a flat A-module that $\mathrm{L}_\bullet \otimes_A B = (\mathrm{L}_j \otimes_A B)$ is a right resolution of the B-module $M \otimes_A B$ by free B-modules; moreover, we have $(\mathrm{L}_j \otimes_A B) \otimes_B (N \otimes_A B) = (\mathrm{L}_j \otimes_A N) \otimes_A B$, whence we conclude immediately that the first term of (17.2.13.2) is equal to $\mathrm{Tor}_i^B(M \otimes_A B, N \otimes_A B)$; the hypothesis on B implies that this B-module is zero for $i > n$ (17.2.2, (ii)), whence the conclusion. □ $\mathbf{0}_{\mathbf{IV\text{-}1}}$ | 46

(17.2.14). Let $(X, \mathscr{O}_X)$ be a ringed space, $\mathscr{F}$ an $\mathscr{O}_X$-Module; we call the *pointwise projective dimension* (resp. *injective dimension*) of $\mathscr{F}$ and denote $\dim.\mathrm{proj}(\mathscr{F})$ (resp. $\dim.\mathrm{inj}(\mathscr{F})$) the number $\sup_{x \in X}(\dim.\mathrm{proj}(\mathscr{F}_x))$ (resp. $\sup_{x \in X}(\dim.\mathrm{inj}(\mathscr{F}_x))$). We call the *pointwise cohomological dimension* of X and denote $\dim.\mathrm{coh}(X)$ the number $\sup_{x \in X}(\dim.\mathrm{coh}(\mathscr{O}_x))$. It follows from (17.2.5) and (17.2.10) that when A is a Noetherian ring, M an A-module of finite type and $X = \mathrm{Spec}(A)$, we have $\dim.\mathrm{proj}(\widetilde{M}) = \dim.\mathrm{proj}(M)$, $\dim.\mathrm{inj}(\widetilde{M}) = \dim.\mathrm{inj}(M)$ and $\dim.\mathrm{coh}(X) = \dim.\mathrm{coh}(A)$. We call the *projective dimension* (resp. *injective dimension*) of $\mathscr{F}$ at a point $x \in X$ the projective (resp. injective) dimension of $\mathscr{F}_x$, and the *cohomological dimension of X at a point x* the cohomological dimension of $\mathscr{O}_x$.

Proposition (17.2.15). — *Let X, Y be two ringed spaces in Noetherian local rings, $f : X \to Y$ a flat morphism. If $\dim.\mathrm{coh}(X) \leqslant n$, then Y is of cohomological dimension $\leqslant n$ at every point of $f(X)$.*

Proof. This follows immediately from (17.2.13). □

17.3. Cohomological theory of regular rings

Theorem (17.3.1). — (Hilbert-Serre) *Let A be a Noetherian local ring. For A to be of finite cohomological dimension, it is necessary and sufficient that A be regular; we then have*

$$\dim.\mathrm{coh}(A) = \dim(A). \tag{17.3.1.1}$$

Proof. Suppose A regular; let $\mathfrak{m}$ be its maximal ideal, $\mathbf{x} = (x_i)_{1 \leqslant i \leqslant n}$ a regular system of parameters of A (17.1.6); consider the Koszul complex $\mathrm{K}_\bullet(\mathbf{x})$ (**III**, 1.1.1), which is formed of free A-modules, with $\mathrm{K}_i(\mathbf{x}) = 0$ for $i > n$; since (x_i) is a regular sequence, we have $\mathrm{H}_i(\mathrm{K}_\bullet(\mathbf{x})) = 0$ for $i > 0$ (**III**, 1.1.4 and 1.1.3.3) and $\mathrm{H}_0(\mathrm{K}_\bullet(\mathbf{x})) = A/(x_1A + \cdots + x_nA) = A/\mathfrak{m} = k$; the $\mathrm{K}_i(\mathbf{x})$ thus form a free resolution of k of length n. Now, the fact that the x_i belong to $\mathfrak{m}$ immediately implies that in the complex $\mathrm{K}_\bullet(\mathbf{x}, k) = \mathrm{K}_\bullet(\mathbf{x}) \otimes_A k$, the boundary operator is zero in all dimensions, so that we have, by definition, $\mathrm{Tor}_i^A(k, k) = \bigwedge^i(k^n)$; the equality (17.3.1.1) thus follows immediately from (17.2.11) (this result is essentially the "syzygy theorem" of Hilbert).

Let us now show that if A is a Noetherian local ring, $\mathfrak{m}$ its maximal ideal, and if $\dim.\mathrm{proj}_A(\mathfrak{m})$ is *finite*, then A is regular, which will finish proving (17.3.1). We proceed by induction on $n = \mathrm{rg}_k(\mathfrak{m}/\mathfrak{m}^2)$. For $n = 0$, we have $\mathfrak{m} = 0$ and the assertion is trivial. □

Lemma (17.3.1.2). — (Nagata) *If every element of $\mathfrak{m} - \mathfrak{m}^2$ is a zero divisor in A, there exists $c \neq 0$ in A such that $c\mathfrak{m} = 0$ (in other words $\mathfrak{m} \in \mathrm{Ass}(A)$).*

Proof. We may restrict to the case $\mathfrak{m} \neq 0$, hence $\mathfrak{m} \neq \mathfrak{m}^2$. The hypothesis implies that $\mathfrak{m} - \mathfrak{m}^2$ is contained in the union of the ideals $\mathfrak{p}_i$ of $\mathrm{Ass}(A)$ (Bourbaki, *Alg. comm.*, chap. IV, §1, n° 1, cor. 3 of prop. 2); thus $\mathfrak{m}$ is contained in the union of $\mathfrak{m}^2$ and the $\mathfrak{p}_i$ and since $\mathfrak{m} \not\subset \mathfrak{m}^2$ (Bourbaki, *Alg. comm.*, chap. II, §1, n° 1, prop. 2); $\mathfrak{m}$ being maximal, this proves the lemma. □ $\mathbf{0}_{\mathbf{IV\text{-}1}}$ | 47

Lemma (17.3.1.3). — *If $a \in \mathfrak{m} - \mathfrak{m}^2$, $\mathfrak{m}/Aa$ is isomorphic to a direct factor of $\mathfrak{m}/a\mathfrak{m}$.*

Proof. There exists a minimal system of generators of $\mathfrak{m}$ containing a (whose images in $\mathfrak{m}/\mathfrak{m}^2$ form a basis of this k-vector space); let $\mathfrak{b}$ be the ideal generated by the elements of this system other than a. Since the relation $xa \in \mathfrak{b}$ implies $x \in \mathfrak{m}$ (considering the image of xa in $\mathfrak{m}/\mathfrak{m}^2$), we have $\mathfrak{b} \cap Aa \subset a\mathfrak{m}$

whence a homomorphism $\mathfrak{b}/(\mathfrak{b} \cap Aa) \to \mathfrak{m}/a\mathfrak{m}$ deduced from the injection $\mathfrak{b} \to \mathfrak{m}$ by passing to quotients, and which is injective. Moreover, $\mathfrak{b} + Aa = \mathfrak{m}$, and the composite homomorphism

$$\mathfrak{m}/Aa = (\mathfrak{b} + Aa)/Aa \xrightarrow{\sim} \mathfrak{b}/(\mathfrak{b} \cap Aa) \longrightarrow \mathfrak{m}/a\mathfrak{m} \longrightarrow \mathfrak{m}/Aa$$

is the identity; whence the lemma. □

Lemma (17.3.1.4). — *Let A be a Noetherian local ring, $\mathfrak{m}$ its maximal ideal, E an A-module of finite type and of finite projective dimension. If $a \in \mathfrak{m}$ is A-regular and E-regular, then E/aE is an (A/aA)-module of finite projective dimension, at most equal to* $\dim.\mathrm{proj}_A(E)$.

Proof. We argue by induction on $h = \dim.\mathrm{proj}_A(E)$, the case $h = 0$ being trivial since then E is a projective A-module, hence E/aE is a projective (A/aA)-module. There exists an exact sequence

$$0 \longrightarrow N \longrightarrow L \longrightarrow E \longrightarrow 0$$

where L is free and $\dim.\mathrm{proj}_A(N) = h - 1$ (17.2.2, (iii)), N being of finite type. Moreover, the sequence

$$0 \longrightarrow N/aN \longrightarrow L/aL \longrightarrow E/aE \longrightarrow 0$$

is exact (15.1.18). Since a is A-regular, it is also N-regular since L is free; the induction hypothesis implies that N/aN is an (A/aA)-module of projective dimension $\leqslant h - 1$, and since L/aL is a free (A/aA)-module, E/aE is an (A/aA)-module of projective dimension $\leqslant h$. □ **$0_{\text{IV-1}}$** | 48

Let us now examine two cases:

I. — Suppose first that every element of $\mathfrak{m} - \mathfrak{m}^2$ is a zero divisor in A, in which case (17.3.1.2) there exists $c \neq 0$ in A such that $c\mathfrak{m} = 0$. Let us show then that $\mathfrak{m} = 0$. If this were not the case, note first that $\mathfrak{m}$ could not be a projective A-module, since it would be free (Bourbaki, *Alg. comm.*, chap. II, §3, n$^{\text{o}}$ 2, cor. 2 of prop. 5), which contradicts the relation $c\mathfrak{m} = 0$. We would thus have $n = \dim.\mathrm{coh}(A) \geqslant 1$. Since $\mathfrak{m} \in \mathrm{Ass}(A)$, there would exist an exact sequence of A-homomorphisms

$$0 \longrightarrow k \longrightarrow A \longrightarrow E \longrightarrow 0.$$

But this is absurd, since, in view of the relation $n \geqslant 1$, the exact sequence of Tor would give the exact sequence $0 \to \mathrm{Tor}^A_{n+1}(E, k) \to \mathrm{Tor}^A_n(k, k) \to 0$; but we have $\mathrm{Tor}^A_{n+1}(E, k) = 0$ (17.2.2, (ii)) and $\mathrm{Tor}^A_n(k, k) \neq 0$ (17.2.11) and we have reached a contradiction.

II. — We can thus restrict to the case where there exists $a \in \mathfrak{m} - \mathfrak{m}^2$ that is A-regular, and consequently also $\mathfrak{m}$-regular. Consider the ring $A' = A/aA$ and its maximal ideal $\mathfrak{m}' = \mathfrak{m}/aA$; it is clear that $\mathrm{rg}_k(\mathfrak{m}'/\mathfrak{m}'^2) = n - 1$. By (17.3.1.4), $\mathfrak{m}/a\mathfrak{m}$ is an A'-module of finite projective dimension, hence so is $\mathfrak{m}' = \mathfrak{m}/aA$, which is a direct factor of it (17.3.1.3) and (17.2.1). The induction hypothesis implies therefore that $A' = A/aA$ is regular, which proves by (17.1.8) that A is regular.

Corollary (17.3.2). — *If A is a regular local ring, $A_{\mathfrak{p}}$ is regular for every prime ideal $\mathfrak{p}$ of A.*

Proof. Indeed, we have seen (17.2.10) that $\dim.\mathrm{coh}(A_{\mathfrak{p}}) \leqslant \dim.\mathrm{coh}(A)$, so the conclusion follows from (17.3.1). □

Proposition (17.3.3). — *Let A, B be two Noetherian local rings, $\varphi : A \to B$ a local homomorphism, $\mathfrak{m}$ (resp. $\mathfrak{n}$) the maximal ideal of A (resp. B), $k = A/\mathfrak{m}$ (resp. $k' = B/\mathfrak{n}$) the residue field of A (resp. B). We thus have a canonical homomorphism of k'-vector spaces*

(17.3.3.1) $$\psi : (\mathfrak{m}/\mathfrak{m}^2) \otimes_k k' \longrightarrow \mathfrak{n}/\mathfrak{n}^2.$$

(i) *If B is regular and B is a flat A-module, A is regular.*

(ii) *The following conditions are equivalent:*

- a) *B is regular and the homomorphism ψ (17.3.3.1) is injective.*
- b) *A and B are regular, and for a regular system of parameters $(x_i)_{1 \leqslant i \leqslant m}$ of A, the $\varphi(x_i)$ are part of a regular system of parameters of B (in which case this property holds for every regular system of parameters of A).*
- c) *B and $B \otimes_A k$ are regular, and B is a flat A-module.*
- d) *A and $B \otimes_A k$ are regular, and B is a flat A-module.*

e) *A and $B \otimes_A k$ are regular, and we have*

(17.3.3.2) $$\dim(B) = \dim(A) + \dim(B \otimes_A k).$$

Proof. (i) We have $\dim.\mathrm{coh}(A) \leqslant \dim.\mathrm{coh}(B)$ by (17.2.13), so it suffices to apply (17.3.1). $\mathbf{0}_{\textbf{IV-1}}$ | 49

(ii) When A is assumed regular and (x_i) is a regular system of parameters of A, saying that B is a flat A-module is equivalent, by (15.1.21), to saying that the sequence of $y_i = \varphi(x_i)$ is B-regular (since $B \otimes_A k$ is a flat k-module). On the other hand, since $\dim(A) = m$ and the sequence (y_i) generates the ideal $\mathfrak{m}B$, the relation (17.3.3.2), which can also be written $\dim(B/\mathfrak{m}B) = \dim(B) - m$, is equivalent to saying that the sequence $(y_i)_{1 \leqslant i \leqslant m}$ is part of a system of parameters of B (16.3.7). We thus see that conditions b), d) and e) are respectively equivalent to the following:

b') A and B are regular and $(y_i)_{1 \leqslant i \leqslant m}$ is part of a regular system of parameters of B.
d') A is regular, $B/(\sum y_i B)$ is regular and the sequence (y_i) is B-regular.
e') A is regular, $B/(\sum y_i B)$ is regular, (y_i) is part of a system of parameters of B.

Now, b') and e') are equivalent by (17.1.7), and since d') implies e') and is implied by b') (17.1.7), it is equivalent to both. The conjunction of b) and d) trivially implies c), and by (i), c) implies d); we have thus proved the equivalence of b), c), d) and e). Moreover, it is clear that b) implies a), the classes of the x_i in $\mathfrak{m}/\mathfrak{m}^2$ then forming a basis of this k-vector space and the classes of the y_i in $\mathfrak{n}/\mathfrak{n}^2$ a free system of this k'-vector space. It thus remains to prove that a) implies e). Set $V = \mathfrak{m}/\mathfrak{m}^2$, $W = \mathfrak{n}/\mathfrak{n}^2$; it is immediate that $\psi(V \otimes_k k') = (\mathfrak{n}^2 + \mathfrak{m}B)/\mathfrak{n}^2$. On the one hand, by (16.3.9)

(17.3.3.3) $$\dim(B) \leqslant \dim(A) + \dim(B \otimes_A k);$$

secondly (16.2.6), we have

(17.3.3.4) $$\dim(A) \leqslant \mathrm{rg}_k(V \otimes_k k').$$

Finally, in the local ring $B \otimes_A k = B/\mathfrak{m}B$, $\mathfrak{n}' = \mathfrak{n}/\mathfrak{m}B$ is the maximal ideal, k' the residue field, and $\mathfrak{n}'/\mathfrak{n}'^2$ is isomorphic to $\mathfrak{n}/(\mathfrak{n}^2 + \mathfrak{m}B) = W/\psi(V \otimes_k k')$; we thus have, by (16.2.6)

(17.3.3.5) $$\dim(B \otimes_A k) \leqslant \mathrm{rg}_{k'} W - \mathrm{rg}_{k'} \psi(V \otimes_k k').$$

Finally, since B is assumed regular, we have $\dim(B) = \mathrm{rg}_{k'} W$ (17.1.1); we thus conclude from (17.3.3.3), (17.3.3.4) and (17.3.3.5) that

$$\mathrm{rg}_{k'} W \leqslant \dim(A) + \dim(B \otimes_A k) \leqslant \mathrm{rg}_{k'} W + \mathrm{rg}_{k'}(V \otimes_k k') - \mathrm{rg}_{k'} \psi(V \otimes_k k')$$

and saying that the two extreme terms of this inequality are equal means that ψ is injective. Condition a) thus necessarily implies that in each of the relations (17.3.3.3), (17.3.3.4) and (17.3.3.5), the two sides are equal; now, equality in (17.3.3.4) (resp. (17.3.3.5)) means that A (resp. $B \otimes_A k$) is regular (17.1.1); we have thus proved that a) implies e). □

Proposition (17.3.4). — *Let A be a regular local ring of dimension n, $\mathfrak{m}$ its maximal ideal. For every non-zero A-module of finite type M, we have*

(17.3.4.1) $$\mathrm{prof}(M) + \dim.\mathrm{proj}(M) = n.$$

Proof. We argue by induction on $m = \mathrm{prof}(M)$. If $m = 0$, we know (16.4.6, (i)) that there exists a sub-A-module N of M isomorphic to $k = A/\mathfrak{m}$; applying the Tor exact sequence to the exact sequence $0 \to N \to M \to M/N \to 0$, we obtain an exact sequence

$$\mathrm{Tor}^A_{n+1}(M/N, k) \longrightarrow \mathrm{Tor}^A_n(N, k) \longrightarrow \mathrm{Tor}^A_n(M, k),$$

and the hypothesis that A is regular implies $\mathrm{Tor}^A_{n+1}(M/N, k) = 0$ ((17.3.1.1) and (17.2.6)), so $\mathrm{Tor}^A_n(k, k)$ is isomorphic to a submodule of $\mathrm{Tor}^A_n(M, k)$; applying again (17.3.1.1) and (17.2.6), we see that $\mathrm{Tor}^A_n(M, k) \neq 0$, so $\dim.\mathrm{proj}(M) \geqslant n$ by (17.2.6); but since $\dim.\mathrm{proj}(M) \leqslant n$ by (17.3.1.1), we indeed have $\dim.\mathrm{proj}(M) = n$. Suppose now $m > 0$, and let x be an M-regular element belonging to $\mathfrak{m}$; we then know (16.4.6, (i)) that $\mathrm{prof}(M/xM) = m - 1$, and on the other hand (17.2.7) $\dim.\mathrm{proj}(M/xM) = \dim.\mathrm{proj}(M) + 1$; the induction hypothesis immediately proves the relation (17.3.4.1). □

$\mathbf{0}_{\textbf{IV-1}}$ | 50

Corollary (17.3.5). — (i) *Let A be a regular local ring of dimension n; for an A-module $M \neq 0$ of finite type to be free, it is necessary and sufficient that M be a Cohen-Macaulay A-module of dimension n.*

(ii) *Let A be a regular local ring, B a local ring, $\rho : A \to B$ a local homomorphism making B an A-module of finite type. For B to be a free A-module, it is necessary and sufficient that B be a Cohen-Macaulay ring and that ρ be injective (or, equivalently (16.1.5), that $\dim(B) = \dim(A)$).*

Proof. (i) This follows from (17.3.4.1) and from the fact that for an A-module of finite type, it is equivalent to saying that this module is projective or free (Bourbaki, *Alg. comm.*, chap. II, §3, n° 2, cor. 2 of prop. 5); the free A-modules of finite type M are thus characterised by the relation $\operatorname{dim.proj}(M) = 0$ (17.2.2, (i)).

(ii) To say that B is a Cohen-Macaulay ring is equivalent to saying that B is a Cohen-Macaulay A-module (16.5.3), so it suffices to apply (i), since $\dim B = \dim A$ (16.1.5). □

(17.3.6). We say that a Noetherian ring A is *regular* if for every prime ideal $\mathfrak{p}$ of A, the local ring $A_\mathfrak{p}$ is regular; when A is itself a local ring, it follows from (17.3.2) that this definition is equivalent to that of (17.1.2). For A to be regular, it suffices, by (17.3.2), that $A_\mathfrak{m}$ be regular for every *maximal* ideal $\mathfrak{m}$ of A. Moreover, it follows immediately from this definition that for every multiplicative subset S of A, $S^{-1}A$ is regular.

Proposition (17.3.7). — *If A is a regular Noetherian ring, every polynomial ring $A[\mathrm{T}_1, \ldots, \mathrm{T}_n]$ is regular.*

Proof. It clearly suffices to prove that the polynomial ring $B = A[\mathrm{T}]$ is regular; since B is a free A-module, for every prime ideal $\mathfrak{q}$ of B, $B_\mathfrak{q}$ is a flat $A_\mathfrak{p}$-module, where $\mathfrak{p} = \mathfrak{q} \cap A$ ($\mathbf{0}_\mathbf{I}$, 6.3.1); it thus suffices, by (17.3.3), to prove that $B_\mathfrak{q}/\mathfrak{p}B_\mathfrak{q}$ is regular, and since this ring is a local ring at a prime ideal of $A_\mathfrak{p}[\mathrm{T}]/\mathfrak{p}A_\mathfrak{p}[\mathrm{T}] = k[\mathrm{T}]$ (where k is the residue field $A_\mathfrak{p}/\mathfrak{p}A_\mathfrak{p}$), it suffices to prove that $k[\mathrm{T}]$ is regular; now, $\mathrm{C} = k[\mathrm{T}]$ being principal, the local rings of C are discrete valuation rings or a field (for the ideal (0)), thus regular (17.1.4), which concludes the proof. □ **Err**$_\mathrm{IV}$

Corollary (17.3.8). — *If A is a regular ring, every formal power series ring $A[[\mathrm{T}_1, \ldots, \mathrm{T}_n]]$ is regular.*

Proof. Let $\mathfrak{J}$ be the ideal generated by the T_i in the polynomial ring $A[\mathrm{T}_1, \ldots, \mathrm{T}_n]$; since the latter is regular by (17.3.7), and $A[[\mathrm{T}_1, \ldots, \mathrm{T}_n]]$ is the completion of $A[\mathrm{T}_1, \ldots, \mathrm{T}_n]$ for the $\mathfrak{J}$-preadic topology (Bourbaki, *Alg. comm.*, chap. III, §2, n° 12, *Example* 1), the conclusion follows from the following lemma. □

Lemma (17.3.8.1). — *Let A be a regular ring, $\mathfrak{J}$ an ideal of A, $\widehat{A}$ the separated completion of A for the $\mathfrak{J}$-preadic topology. Then $\widehat{A}$ is regular.*

Proof. It suffices in fact (17.3.6) to see that for every maximal ideal $\mathfrak{n}$ of $\widehat{A}$, the local ring $\widehat{A}_\mathfrak{n}$ is regular; we know (Bourbaki, *Alg. comm.*, chap. III, §3, n° 4, prop. 8) that $\mathfrak{n}$ is of the form $\mathfrak{m}\widehat{A}$, where $\mathfrak{m}$ is a maximal ideal of A containing $\mathfrak{J}$, and that the canonical homomorphism $A \to \widehat{A}$ gives an injective homomorphism $A_\mathfrak{m} \to \widehat{A}_\mathfrak{n}$, such that the $\mathfrak{n}\widehat{A}_\mathfrak{n}$-preadic topology of $\widehat{A}_\mathfrak{n}$ induces on $A_\mathfrak{m}$ the $\mathfrak{m}A_\mathfrak{m}$-preadic topology, and that $A_\mathfrak{m}$ is dense in $\widehat{A}_\mathfrak{n}$ for the $\mathfrak{n}\widehat{A}_\mathfrak{n}$-preadic topology; consequently the completions of the Noetherian local rings $A_\mathfrak{m}$ and $\widehat{A}_\mathfrak{n}$ are canonically isomorphic. Now, by hypothesis $A_\mathfrak{m}$ is regular, hence so is its completion (17.1.5) and since the completion of $\widehat{A}_\mathfrak{n}$ is regular, it follows that $\widehat{A}_\mathfrak{n}$ is regular by (17.1.5). □ $\mathbf{0}_{\mathbf{IV\text{-}1}}$ | 51

Corollary (17.3.9). — *Let A be a Noetherian ring, quotient of a regular Noetherian ring B. If C is an A-algebra of finite type, every ring of fractions $S^{-1}C$ of C is a quotient of a regular ring.*

Proof. Indeed, C is a quotient of a polynomial ring $A[\mathrm{T}_1, \ldots, \mathrm{T}_n]$; since $A = B/\mathfrak{J}$, where $\mathfrak{J}$ is an ideal of B, we have $A[\mathrm{T}_1, \ldots, \mathrm{T}_n] = B[\mathrm{T}_1, \ldots, \mathrm{T}_n]/\mathfrak{J}B[\mathrm{T}_1, \ldots, \mathrm{T}_n]$; by (17.3.7), we may restrict to the case where C is a quotient of a regular ring B'; but if S' is the inverse image of S in B', S' is a multiplicative subset of B' and C is a quotient ring of $S'^{-1}B'$, so that ultimately everything reduces to seeing that when C is regular, $S^{-1}C$ is also regular, which we saw in (17.3.6). □

The importance of quotients of regular rings comes among other things from the property that they are *catenary* rings (16.5.12).

All the important rings in the applications to algebraic geometry are quotients of regular rings.

§18. Supplement on extensions of algebras

This paragraph assembles a certain number of functorial constructions on rings, which will be used repeatedly in §§ 19 and 20; it contains no non-trivial result.

18.1. Inverse images of augmented rings

(18.1.1). Given a ring A (not necessarily commutative), the category of *A-rings* has as objects the pairs (B, ρ) formed of a ring B and a homomorphism of rings $\rho : A \to B$, for morphisms (also called *A-homomorphisms*) the homomorphisms of rings $u : B \to C$ such that, if $\rho : A \to B$ and $\sigma : A \to C$ are the homomorphisms (called *structural*) defining the structure of A-ring on B and C respectively, the diagram

(18.1.1.1)
$$\begin{tikzcd} B \arrow[r, "u"] & C \\ & A \arrow[ul, "\rho"] \arrow[u, "\sigma"'] \end{tikzcd}$$

is commutative. The *kernel* $\mathfrak{J}$ of u is a bilateral ideal that is an *A-bimodule* (for ρ).

If $f : A' \to A$ is a homomorphism of rings, for every A-ring (B, ρ), $(B, \rho \circ f)$ is an A'-ring, and if $u : B \to C$ is an A-homomorphism from the A-ring (B, ρ) to the A-ring (C, σ), it is also an A'-homomorphism from the A'-ring $(B, \rho \circ f)$ to the A'-ring $(C, \sigma \circ f)$; one thus defines a canonical functor from the category of A-rings into that of A'-rings. **$0_{IV\text{-}1}$** | 52

(18.1.2). Let B, E, F be three A-rings, $f : E \to B$, $g : F \to B$ two A-homomorphisms. Recall that one calls *fibre product* of E and F over B (for the homomorphisms f and g) and one denotes $E \times_B F$ the subring of the product $E \times F$ formed of the pairs (x, y) such that $f(x) = g(y)$; the restrictions $p_1 : G \to E$, $p_2 : G \to F$ of the projections pr_1 and pr_2 to G are still called the *canonical projections*; the structure of A-ring of G is defined by the homomorphism $\alpha \mapsto (\rho(\alpha), \sigma(\alpha))$ (where $\rho : A \to E$ and $\sigma : A \to F$ are the structural homomorphisms), which indeed maps A into G by virtue of (18.1.1). The characteristic property of $E \times_B F$ is that, for every pair of A-homomorphisms $u : C \to E$, $v : C \to F$ such that $f \circ u = g \circ v$, there exists one and only one A-homomorphism $w : C \to G$ such that $u = p_1 \circ w$, $v = p_2 \circ w$. One can still say that $E \times_B F$ is the *projective limit* of the projective system formed by B, E, F and the A-homomorphisms f, g, in the category of A-rings (**0_{III}**, 8.1.9).

(18.1.3). Let $\mathfrak{J}$ be the bilateral ideal of E, kernel of f; it is immediate that the kernel $\mathfrak{J}'$ of $p_2 : G \to F$ is the ideal formed of the elements $(x, 0)$ where $x \in \mathfrak{J}$; the restriction $i_1 : \mathfrak{J}' \to \mathfrak{J}$ of p_1 is an isomorphism of rings without identity, and also an isomorphism of A-bimodules. Similarly, if $\mathfrak{K}$ is the kernel of g, the kernel $\mathfrak{K}'$ of $p_1 : G \to E$ is the ideal of the elements $(0, y)$ where $y \in \mathfrak{K}$, and the restriction $i_2 : \mathfrak{K}' \to \mathfrak{K}$ of p_2 is an isomorphism (in the same sense). Finally, it is clear that the kernel of the A-homomorphism $q = f \circ p_1 = g \circ p_2$ of $E \times_B F$ into B is $\mathfrak{J} \times \mathfrak{K} = \mathfrak{J}' \oplus \mathfrak{K}'$, so that one has a commutative diagram

(18.1.3.1)
$$\begin{tikzcd} 0 \arrow[dr] & & 0 \arrow[d] & 0 \arrow[d] \\ & \mathfrak{J}' \oplus \mathfrak{K}' \arrow[r] \arrow[d] \arrow[dr] & \mathfrak{K}' \arrow[r, "i_2", "\sim"'] \arrow[d, "j"] & \mathfrak{K} \arrow[d, "p_2"] \\ 0 \arrow[r] & \mathfrak{J}' \arrow[r] \arrow[d, "i_1", "\sim"'] & G \arrow[r] \arrow[d, "p_1"] \arrow[dr, "q"] & F \arrow[d, "g"] \\ 0 \arrow[r] & \mathfrak{J} \arrow[r] & E \arrow[r, "f"'] & B \end{tikzcd}$$

The definitions and results of (18.1.2) and (18.1.3) extend immediately to the fibre product of any *family* $(E_\lambda)_{\lambda \in I}$ of A-rings defined by a family of A-homomorphisms $f_\lambda : E_\lambda \to B$. We leave the formulation of these results to the reader.

(18.1.4). Following the terminology of (M, VIII), we call an A-ring E equipped with a *surjective* A-homomorphism (called the *augmentation* of E), $f : E \to B$, an *A-ring augmented over B*; the kernel

$\mathfrak{J}$ of f is called the *augmentation ideal*. One says that the A-augmented ring E is *trivial* if there exists an A-homomorphism $s : B \to E$ that is *right inverse* of the augmentation $f : E \to B$ (in other words $f \circ s = 1_B$). The exact sequence of A-bimodules

$$0 \longrightarrow \mathfrak{J} \longrightarrow E \xrightarrow{f} B \longrightarrow 0$$

is then *split*; in other words, one can identify the A-bimodule E with $B \times \mathfrak{J}$, and the multiplication in E is then given by $\mathbf{0_{IV\text{-}1}}$ | 53

$$(b, z)(b', z') = (bb', bz' + zb' + zz'),$$

$\mathfrak{J}$ being considered as a B-bimodule by means of $s : B \to E$.

(18.1.5). With the notations of (18.1.2), suppose that the A-homomorphism f makes E into an A-ring *augmented over* B. Then it is clear that $p_2 : G \to F$ is also surjective, in other words G is given a structure of A-ring *augmented over* F, that one calls the *inverse image* by $g : F \to B$ of the augmented A-ring E.

Proposition (18.1.6). — *For the inverse image $G = E \times_B F$ by $g : F \to B$ of the augmented A-ring E to be a trivial augmented A-ring, it is necessary and sufficient that there exists an A-homomorphism $u : F \to E$ making the diagram*

$$\begin{tikzcd} & F \arrow[dl, "u"'] \arrow[d, "g"] \\ E \arrow[r, "f"'] & B \end{tikzcd}$$

commutative.

Proof. The condition is evidently necessary, taking $u = p_1 \circ s$, where $s : F \to G$ is an A-homomorphism right inverse of p_2. Conversely, if there exists such an A-homomorphism u, the existence of the right inverse s of p_2 follows from the universal property of the fibre product (18.1.2) applied to the A-homomorphisms $u : F \to E$ and $1_F : F \to F$.

This result implies in particular that if E is a trivial augmented A-ring, so is every inverse image. □

(18.1.7). Let us take up again the situation described in (18.1.2) and (18.1.3); on $\mathfrak{R}$ one has evidently a structure of G-*bimodule*, coming from its structure of F-bimodule and the homomorphism of rings $p_2 : G \to F$. As i_2 is bijective one has moreover an injection $\theta = j \circ i_2^{-1} : \mathfrak{R} \to G$, which is a homomorphism of G-*bimodules*. We shall now see conversely that, when one supposes moreover that f and g are *surjective*, in other words that E and F are A-rings *augmented* over B, the data of such a homomorphism θ allows us to reconstruct the augmented ring E (over B) from the augmented ring G (over F).

More precisely, suppose we are given an A-ring F augmented over B and an A-ring G augmented over F, the augmentation ideals being denoted $\mathfrak{R}$ and $\mathfrak{J}'$ respectively:

(18.1.7.1)
$$\begin{tikzcd} & & 0 \arrow[d] & & \\ & & \mathfrak{R} \arrow[dl, "\theta"] \arrow[d] & & \\ 0 \arrow[r] & \mathfrak{J}' \arrow[r] & G \arrow[r, "h"'] & F \arrow[r] \arrow[d, "g"] & 0 \\ & & & B \arrow[d] & \\ & & & 0 & \end{tikzcd}$$

The homomorphism h defines on all the ideals of F (and in particular on $\mathfrak{R}$) a structure of G-bimodule. Let $\theta : \mathfrak{R} \to G$ be a homomorphism of G-bimodules making the diagram (18.1.7.1) commutative; this implies that θ is *injective* and that $\mathfrak{J}' \cap \theta(\mathfrak{R}) = 0$; as $\theta(\mathfrak{R})$ is a bilateral ideal of $\mathbf{0_{IV\text{-}1}}$ | 54

G, and $h(\theta(\mathfrak{N})) = \mathfrak{N}$, the composite homomorphism $g \circ h : G \to B$ factors as $G \xrightarrow{q} G/\theta(\mathfrak{N}) \xrightarrow{f} B$, where f is surjective; moreover the image $\mathfrak{J}$ of $\mathfrak{J}'$ in $E = G/\theta(\mathfrak{N})$ is the kernel of f (the kernel of $g \circ h$ being $\mathfrak{J}' \oplus \theta(\mathfrak{N})$), and the restriction to $\mathfrak{J}'$ of the canonical homomorphism $q : G \to E$ is injective. One can therefore form the *fibre product* $G' = E \times_B F$, and as the two A-homomorphisms $q : G \to E$ and $h : G \to F$ are such that $f \circ q = g \circ h$, they define a unique A-homomorphism $u : G' \to G$ by the universal property of G' (18.1.2); we shall now see that u is *bijective*. It suffices to prove this when u is considered as a homomorphism of A-bimodules; but one then notes that u is compatible with the finite filtrations on G' and G formed respectively by G' and $\mathfrak{J}'' = \mathrm{Ker}(G' \to F)$, and by G and $\mathfrak{J}'$; moreover, one has seen (18.1.3) that $\mathrm{gr}_0\, u : F \to F$ is the identity and that $\mathrm{gr}_1\, u : \mathfrak{J}'' \to \mathfrak{J}'$ is bijective, hence u itself is bijective (Bourbaki, *Alg. comm.*, chap. III, § 2, no. 8, cor. 3 of th. 1).

18.2. Extensions of a ring by a bimodule

(18.2.1). Let E be an A-ring augmented over B, $f : E \to B$ the augmentation, $\mathfrak{J} = \mathrm{Ker}(f)$ the augmentation ideal. If $\mathfrak{J}^2 = 0$, $\mathfrak{J}$ is not only an E-bimodule but also a *B-bimodule* since B is isomorphic to $E/\mathfrak{J}$; more precisely, every $b \in B$ is of the form $f(x)$ with $x \in E$, and if z, z' are in $\mathfrak{J}$, one has $(x+z)z' = xz'$ (resp. $z'(x+z) = z'x$) so that the value of xz' (resp. $z'x$) does not depend on the element $x \in f^{-1}(b)$, and one can write bz' (resp. $z'b$) which defines the structure of B-bimodule considered. Conversely, if $\mathfrak{J}$ is equipped with a structure of B-bimodule such that $xz' = f(x)z'$ and $z'x = z'f(x)$ for $x \in E$ and $z' \in \mathfrak{J}$, it is clear that $\mathfrak{J}^2 = 0$.

(18.2.2). One calls *A-extension of an A-ring B by a B-bimodule L* an *exact* sequence of homomorphisms of A-bimodules

$$0 \longrightarrow L \xrightarrow{j} E \xrightarrow{f} B \longrightarrow 0$$

where E is an A-ring, f an A-homomorphism of rings and one has, for $x \in E$ and $z \in L$,

$$j(f(x)z) = xj(z), \quad j(zf(x)) = j(z)x$$

hence (18.2.1) $j(L)$ is a bilateral ideal of square zero of E. By abuse of language one also says that E is an extension of B by L. One says that two A-extensions E, E' of B by L are *A-equivalent* if there exists an isomorphism of A-rings $u : E \xrightarrow{\sim} E'$ making the diagram

(18.2.2.1)
$$\begin{tikzcd}
& & E \arrow[dd, "u"', "\wr"] \arrow[dr] & & \\
0 \arrow[r] & L \arrow[ur] \arrow[dr] & & B \arrow[r] & 0 \\
& & E' \arrow[ur] & &
\end{tikzcd}$$

commutative.

(18.2.3). One says that an A-extension E of B by a B-bimodule L is *A-trivial* if E is a trivial augmented $\mathbf{0}_{\mathbf{IV}\text{-}\mathbf{1}}$ | 55
A-ring (over B) (18.1.4). One defines on the A-bimodule product $B \times L$ a structure of A-ring by setting $(x,s)(y,t) = (xy, xt + sy)$, as one easily checks, and the canonical maps $j : L \to B \times L$ and $f : B \times L \to B$ define an A-extension of B by L that is A-trivial, the canonical map $g : B \to B \times L$ being an A-homomorphism right inverse of f. One says this extension is the *trivial type extension* of B by L and one denotes it $D_B(L)$; it is immediate that every A-trivial A-extension of B by L is A-equivalent to $D_B(L)$.

One will note that every extension of the A-ring A itself by an A-bimodule is necessarily A-trivial.

(18.2.4). Given two A-extensions $L \xrightarrow{j} E \xrightarrow{f} B$, $L' \xrightarrow{j'} E' \xrightarrow{f'} B'$, a *morphism* of the first into the second is by definition a triplet of homomorphisms of A-bimodules (u, v, w) such that the diagram

(18.2.4.1)
$$\begin{tikzcd}
0 \arrow[r] & L \arrow[r, "j"] \arrow[d, "w"'] & E \arrow[r, "f"] \arrow[d, "u"'] & B \arrow[r] \arrow[d, "v"'] & 0 \\
0 \arrow[r] & L' \arrow[r, "j'"'] & E' \arrow[r, "f'"'] & B' \arrow[r] & 0
\end{tikzcd}$$

is commutative, u and v being A-homomorphisms of *rings* and w being such that $w(bz) = v(b)w(z)$ and $w(zb) = w(z)v(b)$ for $z \in L$ and $b \in B$ (in other words, the pair (v, w) constitutes a *di-homomorphism* of the B-bimodule L into the B'-bimodule L'); it is clear that if (u', v', w') is a morphism from $L' \to E' \to B'$ into an A-extension $L'' \to E'' \to B''$, $(u' \circ u, v' \circ v, w' \circ w)$ is still a morphism, which justifies the terminology.

The consideration of the two commutative squares of the diagram (18.2.4.1) will lead us to two operations on extensions of A-rings.

(18.2.5). In the first place, consider an A-extension E' of B' by L'

$$0 \longrightarrow L' \xrightarrow{j'} E' \xrightarrow{f'} B' \longrightarrow 0$$

and an A-homomorphism of rings $v : B \to B'$, and let $F = E' \times_{B'} B$ be the *inverse image* of E' (18.1.5), so that one has a commutative diagram

$$\begin{tikzcd}
0 \arrow[r] & L_0 \arrow[r] \arrow[d, "i"] & F \arrow[r, "p_2"] \arrow[d, "p_1"] & B \arrow[r] \arrow[d, "v"] & 0 \\
0 \arrow[r] & L' \arrow[r, "j'"'] & E' \arrow[r, "f'"'] & B' \arrow[r] & 0
\end{tikzcd}$$

where the two lines are exact, p_1 and p_2 are canonical homomorphisms and i is bijective; one sees from the definition (18.1.2) and (18.1.3) that $L_0^2 = 0$, so that one can consider F as an A-extension of B by L', called the *inverse image by v* of the extension E' of B' by L' (where L' is naturally considered as a B-bimodule by means of the homomorphism of rings v). The functorial character of the fibre product with respect to each of the factors shows moreover that if one has a morphism of two extensions of B' $\mathbf{0}_{\mathbf{IV}\text{-}\mathbf{1}}$ | 56

$$\begin{tikzcd}
0 \arrow[r] & L'_1 \arrow[r] \arrow[d, "h"] & E'_1 \arrow[r] \arrow[d, "g"] & B' \arrow[r] \arrow[d, "1_{B'}"] & 0 \\
0 \arrow[r] & L'_2 \arrow[r] & E'_2 \arrow[r] & B' \arrow[r] & 0
\end{tikzcd}$$

one deduces from it a morphism *inverse image by v*

$$\begin{tikzcd}
0 \arrow[r] & L'_1 \arrow[r] \arrow[d, "h"] & E'_1 \times_{B'} B \arrow[r] \arrow[d, "g \times_{B'} 1_B"] & B \arrow[r] \arrow[d, "1_B"] & 0 \\
0 \arrow[r] & L'_2 \arrow[r] & E'_2 \times_{B'} B \arrow[r] & B \arrow[r] & 0.
\end{tikzcd}$$

In particular, if E'_1 and E'_2 are A-equivalent A-extensions of B' by L', their inverse images by v are A-equivalent A-extensions of B by L'.

The definition of the fibre product shows that when one has a morphism (18.2.4.1) of A-extensions, it *factors through* the inverse image of E' by v; more precisely, there exists a unique A-homomorphism $u_0 : E \to F = E' \times_{B'} B$ making the diagram

$$\begin{tikzcd}
0 \arrow[r] & L \arrow[r, "j"] \arrow[d, "w_0"] & E \arrow[r, "f"] \arrow[d, "u_0"] & B \arrow[r] \arrow[d, "1_B"] & 0 \\
0 \arrow[r] & L_0 \arrow[r] \arrow[d, "i"] & F \arrow[r, "p_2"] \arrow[d, "p_1"] & B \arrow[r] \arrow[d, "v"] & 0 \\
0 \arrow[r] & L' \arrow[r, "j'"'] & E' \arrow[r, "f'"'] & B' \arrow[r] & 0
\end{tikzcd}$$

commutative, where w_0 is the restriction of u_0 to L and $p_1 \circ u_0 = u$, $i \circ w_0 = w$.

(18.2.6). Let us study the inverse image of extensions by surjective A-homomorphisms. Consider a surjective A-homomorphism $v : B \to B'$, an A-extension F of B by a B-bimodule L, and the bilateral ideal $\mathfrak{N}$ of B, kernel of v (which can be considered as an F-bimodule by means of the augmentation

$F \to B$); one has seen (18.1.7) that every homomorphism of F-bimodules $\theta : \mathfrak{R} \to F$ making the diagram

$$\begin{tikzcd} & \mathfrak{R} \arrow[dl, bend right, "\theta"'] \arrow[d] \\ F \arrow[r] & B \end{tikzcd}$$

commutative determines an extension E' of $B' = B/\mathfrak{R}$ by L whose inverse image by $v : B \to B'$ is A-equivalent to F, and that every A-extension E of B' by L having this last property is obtained in this way (up to A-equivalence). Moreover, for two homomorphisms θ_1, θ_2 of F-bimodules of $\mathfrak{R}$ into F to give two A-equivalent A-extensions of B' by L, it is necessary and sufficient that there exists an *A-equivalence* u of the A-extension F onto itself such that $\theta_2 = u \circ \theta_1$; this follows at once from what $\mathbf{0_{IV\text{-}1}}$ | 57
was seen in (18.2.5) and from the definition of the canonical bijection of F onto the fibre product $E' \times_{B'} B$ (18.1.7).

(18.2.7). Consider now the left square of (18.2.4.1), and recall first the notion of *amalgamated sum* in the category of A-bimodules: given three A-bimodules X, Y, Z and two A-homomorphisms $f : X \to Y$, $g : X \to Z$, the amalgamated sum $Y \oplus_X Z$ is the *inductive limit* of the inductive system formed by X, Y, Z and the A-homomorphisms f, g in the category of A-bimodules ($\mathbf{0_{III}}$, 8.1.11). One defines this A-bimodule as quotient of the product $Y \times Z$ by the sub-A-bimodule M image of X by the homomorphism $x \mapsto (f(x), -g(x))$. Its characteristic property is that, for every pair of homomorphisms of A-bimodules $u : Y \to T$, $v : Z \to T$ such that $u \circ f = v \circ g$, there exists a unique homomorphism $w : Y \oplus_X Z \to T$ such that $u = w \circ j_1$ and $v = w \circ j_2$, where $j_1 : Y \to Y \oplus_X Z$ and $j_2 : Z \to Y \oplus_X Z$ are the canonical maps.

(18.2.8). Consider now an A-extension E of B by a B-bimodule L:

$$0 \longrightarrow L \xrightarrow{j} E \xrightarrow{f} B \longrightarrow 0$$

and let moreover $w : L \to L'$ be a homomorphism of *B-bimodules*. Let H be the A-bimodule amalgamated sum $E \oplus_L L'$; let us show how one can equip it with a structure of *A-ring* and define an *A-extension*

$$0 \longrightarrow L' \longrightarrow H \longrightarrow B \longrightarrow 0.$$

Let us note for this that L' is equipped with a structure of *E-bimodule* by means of the augmentation homomorphism $E \to B$; one can therefore form the A-extension of trivial type $G = D_E(L')$ (18.2.3). Consider then the map $\theta : z \mapsto (j(z), -w(z))$ from L into G; it is a homomorphism of *G-bimodules* (L being considered as a G-bimodule by means of the canonical homomorphism $\rho : G \to E$). Indeed, for $(x, z') \in G$ and $z \in L$, one has $(j(z), -w(z))(x, z') = (j(z)x, j(z)z' - w(z)f(x))$; but $j(z)z' = f(j(z))z' = 0$ by definition of the structure of E-bimodule on L', and $w(z)f(x) = w(zf(x))$ by definition of the structure of B-bimodule on L'; one thus verifies that θ is also a homomorphism of G-modules on the left. One can then apply the result of (18.1.7) to the diagram

$$\begin{tikzcd} & & 0 \arrow[d] & & \\ & & L \arrow[dl, "\theta"'] \arrow[d, "j"] & & \\ 0 \arrow[r] & L' \arrow[r] & G \arrow[r, "p"'] & E \arrow[r] \arrow[d, "f"] & 0 \\ & & & B \arrow[d] & \\ & & & 0 & \end{tikzcd}$$

As $H = G/\theta(L)$ by definition, our assertion is an immediate consequence of (18.1.7).

One says that the A-extension H of B by L' is *deduced from E by the homomorphism $w : L \to L'$*. The $\mathbf{0_{IV\text{-}1}}$ | 58
functorial character of the amalgamated sum in each of the summands shows moreover that if one

has a morphism of extensions

$$\begin{tikzcd}
0 \arrow[r] & L \arrow[r] \arrow[d, "\wr 1_L"] & E_1 \arrow[r] \arrow[d, "g"] & B_1 \arrow[r] \arrow[d, "h"] & 0 \\
0 \arrow[r] & L \arrow[r] & E_2 \arrow[r] & B_2 \arrow[r] & 0
\end{tikzcd}$$

one deduces from it canonically a morphism of deduced extensions

$$\begin{tikzcd}
0 \arrow[r] & L' \arrow[r] \arrow[d, "\wr 1_{L'}"] & E_1 \oplus_L L' \arrow[r] \arrow[d, "g \oplus_L 1_{L'}"] & B_1 \arrow[r] \arrow[d, "h"] & 0 \\
0 \arrow[r] & L' \arrow[r] & E_2 \oplus_L L' \arrow[r] & B_2 \arrow[r] & 0
\end{tikzcd}$$

In particular, if E_1 and E_2 are A-equivalent A-extensions of B by L, the extensions of B by L' obtained by w are A-equivalent.

When one has a morphism (18.2.4.1) of A-extensions, it factors through the A-extension H of B by L' deduced from E by the homomorphism $w : L \to L'$ (where L' being considered as B-bimodule by means of the homomorphism of rings $v : B \to B'$): in fact, the definition of the amalgamated sum shows that there exists a unique A-homomorphism $u_0 : H \to E'$ of A-bimodules, making the diagram

$$\begin{tikzcd}
0 \arrow[r] & L \arrow[r, "j"] \arrow[d, "w_0"] & E \arrow[r, "f"] \arrow[d, "j_1"] & B \arrow[r] \arrow[d, "\wr 1_B"] & 0 \\
0 \arrow[r] & L'_0 \arrow[r, "j_2"] \arrow[d, "\wr j_0"] & H \arrow[r, "f_0"] \arrow[d, "u_0"] & B \arrow[r] \arrow[d, "v"] & 0 \\
0 \arrow[r] & L' \arrow[r, "j'"'] & E' \arrow[r, "f'"'] & B' \arrow[r] & 0
\end{tikzcd}$$

commutative, with $u = u_0 \circ j_1$, $w = j_0 \circ w_0$, j_1 and j_2 being the canonical homomorphisms; one verifies immediately that u_0 is also a homomorphism of rings.

Let us note moreover the functorial properties relative to trivial extensions:

Proposition (18.2.9). — *Let B, B' be two A-rings, L a B-bimodule, L' a B'-bimodule, $v : B \to B'$ an A-homomorphism of rings, $w : L \to L'$ a homomorphism of A-bimodules such that (v, w) is a di-homomorphism of bimodules. Then there exists a unique A-homomorphism of rings $u : D_B(L) \to D_{B'}(L')$ making the diagrams commutative*

$$\begin{tikzcd}
D_B(L) \arrow[r, "u"] & D_{B'}(L') \\
B \arrow[u] \arrow[r, "v"'] & B' \arrow[u]
\end{tikzcd}
\qquad
\begin{tikzcd}
D_B(L) \arrow[r, "u"] & D_{B'}(L') \\
L \arrow[u] \arrow[r, "w"'] & L' \arrow[u]
\end{tikzcd}$$

where the vertical arrows are the canonical injections.

$\mathbf{0}_{\mathbf{IV}\text{-}\mathbf{1}}$ | 59

Proof. Indeed, u cannot be other than the map $(x, s) \mapsto (v(x), w(s))$ and it remains to verify that it is an A-homomorphism of rings, which follows trivially from the definition (18.2.3). One notes that u also makes commutative the diagram

$$\begin{tikzcd}
D_B(L) \arrow[r, "u"] \arrow[d] & D_{B'}(L') \arrow[d] \\
B \arrow[r, "v"'] & B'
\end{tikzcd}$$

where this time the vertical arrows are the augmentations. □

Proposition (18.2.10). — *Let B be an A-ring, L a B-bimodule, and E an A-extension of B by L. There is a bijection from the set G of homomorphisms of B-rings from B into E (in other words, the set of A-homomorphisms right inverse to the augmentation $E \to B$) onto the set G' of A-equivalences from $D_B(L)$ onto E: to every $g \in G$ it assigns the A-equivalence $g' : (x,s) \mapsto g(x) + s$, and the inverse map assigns to every $g' \in G'$ the B-homomorphism $x \mapsto g'(x,0)$.*

Proof. This follows immediately from the definitions. □

18.3. The group of classes of A-extensions

(18.3.1). Consider a fixed A-ring B and a fixed B-bimodule L; then the relation "E and E' are A-equivalent" between A-extensions E, E' of B by L is an equivalence relation and for this relation one can speak of the *set* of classes of A-equivalent A-extensions of B by L. To see this, it suffices to remark that, for every $x \in B$, if c_x is an element of E whose image in B is x, every $z \in E$ can be written in one and only one way in the form $c_x + t$, where $t \in L$, and one can write $c_{x+y} = c_x + c_y + \varphi(x,y)$, $c_{xy} = c_x c_y + \psi(x,y)$, where $\varphi(x,y)$ and $\psi(x,y)$ are elements of L, the maps φ and ψ from $B \times B$ into L being the expressions of the fact that E is an A-ring, which we shall not write out here. Every A-extension of B by L is therefore A-equivalent to an A-extension whose underlying set is $B \times L$, whence our conclusion follows immediately.

(18.3.2). The A-ring B being fixed, denote provisionally by $T(L)$ the set of classes of A-extensions of B by L. For every B-homomorphism of B-bimodules $w : L \to L'$, one defines canonically a map $T(w) : T(L) \to T(L')$ by associating to the class of an A-extension E of B by L the class of the A-extension $E \oplus_L L'$ deduced from E by w, by virtue of (18.2.8). If $w' : L' \to L''$ is a second homomorphism of B-bimodules, one has also

$$T(w' \circ w) = T(w') \circ T(w). \tag{18.3.2.1}$$

Indeed, one knows that there exists a canonical isomorphism of A-bimodules

$$E \oplus_L L'' \xrightarrow{\sim} (E \oplus_L L') \oplus_{L'} L''$$

by virtue of the general properties of inductive limits (cf. for example (**I**, 3.3.9)), and it is immediate to verify that it is indeed an A-equivalence of A-extensions, hence relation (18.3.2.1). If $\mathbf{C}_B$ denotes the category of B-bimodules, one sees that one has thus defined a *covariant functor* $T : \mathbf{C}_B \to \mathbf{Sets}$. $\mathbf{0_{IV\text{-}1}}$ | 60

(18.3.3). Consider now a family $(L_\alpha)_{\alpha \in I}$ of B-bimodules and their product $L = \prod_\alpha L_\alpha$; the projections $\mathrm{pr}_\alpha : L \to L_\alpha$ define applications

$$T(\mathrm{pr}_\alpha) : T(L) \longrightarrow T(L_\alpha),$$

hence a canonical map

$$\prod_\alpha T(\mathrm{pr}_\alpha) : T(L) \longrightarrow \prod_{\alpha \in I} T(L_\alpha). \tag{18.3.3.1}$$

We shall see that this map is *bijective*. Indeed, for every $\alpha \in I$, let E_α be an A-extension of B by L_α, and let F be the *fibre product* of the E_α on B (18.1.3); it is immediate that F is an A-extension of B by $L = \prod_\alpha L_\alpha$, and that if one replaces each E_α by an A-equivalent A-extension E'_α, the fibre product F' of the E'_α on B is A-equivalent to F. One has thus defined a map $\prod_\alpha T(L_\alpha) \to T(L)$ and it is clear that this map is the inverse of (18.3.3.1), hence our assertion. One will identify canonically $T(L)$ with $\prod_\alpha T(L_\alpha)$ by the preceding map. One verifies also immediately that if $(L'_\alpha)_{\alpha \in I}$ is a second family of B-bimodules and, for each α, $w_\alpha : L_\alpha \to L'_\alpha$ a homomorphism of B-bimodules, then, setting $w = \prod_\alpha w_\alpha : L \to L' = \prod_\alpha L'_\alpha$, $T(w)$ identifies with $\prod_\alpha T(w_\alpha)$ when one makes the preceding identification.

(18.3.4). For a B-bimodule L, the addition is a homomorphism $s : L \times L \to L$ of B-*bimodules*, and so is the symmetry $t : L \to L$ of the additive law of L. One deduces from them a law of composition

$$T(s) : T(L) \times T(L) \longrightarrow T(L)$$

in $T(L)$ by virtue of (18.3.3), and this law is a law of *commutative group* of which $T(t)$ is the symmetry, as it follows from the definition of an object in groups by means of commutative diagrams ($\mathbf{0}_{\mathrm{III}}$, 8.2.5

and 8.2.6). We shall denote by $\mathrm{Exan}_A(B,L)$ the commutative group thus defined and we say it is the *group of classes of A-extensions of B by L.*

(18.3.5). Denote by $\boldsymbol{K}$ the category whose objects are the triplets (A,B,L) where A is a ring, B an A-ring and L a B-bimodule; the *morphisms* of this category are the triplets (u,v,w) where $u : A' \to A$ and $v : B' \to B$ are two homomorphisms of rings making commutative the left square of the diagram

$$\begin{tikzcd} A \arrow[r] & B & L \arrow[d, "w"] \\ A' \arrow[u, "u"] \arrow[r] & B' \arrow[u, "v"] & L' \end{tikzcd}$$

where the horizontal arrows are the structural homomorphisms; finally $w : L \to L'$ is a homomorphism of commutative groups such that one has $w(v(b')z) = b'w(z)$ and $w(zv(b')) = w(z)b'$ for all $z \in L$ and $b' \in B'$ (in other words, w is a homomorphism of B'-bimodules when L is equipped with its structure of B'-bimodule defined by v). The composition of morphisms is defined by $(u',v',w') \circ (u,v,w) = (u \circ u', v \circ v', w' \circ w)$, which is immediately verified. We propose to show that **$0_{\text{IV-1}}$ | 61**

$$(A,B,L) \longmapsto \mathrm{Exan}_A(B,L) \tag{18.3.5.1}$$

is a *covariant functor* from the category $\boldsymbol{K}$ into the category $\boldsymbol{Ab}$ of commutative groups. It is therefore a matter of defining for every triplet (u,v,w) as above, a homomorphism of commutative groups

$$(u,v,w)_* : \mathrm{Exan}_A(B,L) \longrightarrow \mathrm{Exan}_{A'}(B',L').$$

By virtue of the definition of morphisms in $\boldsymbol{K}$, one can write

$$(u,v,w) = (1_{A'}, 1_{B'}, w) \circ (1_{A'}, v, 1_L) \circ (u, 1_B, 1_L)$$

where, in the first factor, L is equipped with its structure of B'-bimodule defined by v; we shall therefore define $(u,v,w)_*$ when two of the three homomorphisms u, v, w are reduced to the identity.

(18.3.6). We take first $(1_A, 1_B, w)_*$ the map

$$w_* : \mathrm{Exan}_A(B,L) \longrightarrow \mathrm{Exan}_A(B,L') \tag{18.3.6.1}$$

denoted $T(w)$ in (18.3.2); it is immediate to verify that it is a homomorphism of groups, this property expressing the commutativity of diagrams, transformed by T of analogous diagrams for L and L'.

The map $(1_A, v, 1_L)_*$ is the map

$$v^* : \mathrm{Exan}_A(B,L) \longrightarrow \mathrm{Exan}_A(B',L) \tag{18.3.6.2}$$

defined in the following way: if E is an A-extension of B by L, one has seen that $E \times_B B'$ is an A-extension of B' by L (18.2.5) and that if one replaces E by an A-equivalent A-extension E', $E' \times_B B'$ is A-equivalent to $E \times_B B'$; the image by v^* of the class of E is the class of $E \times_B B'$. One verifies immediately that if $w : L \to L'$ is a homomorphism of B-bimodules, the diagram

$$\begin{tikzcd} \mathrm{Exan}_A(B,L) \arrow[r, "v^*"] \arrow[d, "w_*"'] & \mathrm{Exan}_A(B',L) \arrow[d, "w_*"] \\ \mathrm{Exan}_A(B,L') \arrow[r, "v^*"'] & \mathrm{Exan}_A(B',L') \end{tikzcd} \tag{18.3.6.3}$$

is commutative, L and L' being considered as B'-bimodules by means of v in the right column. Replacing L and L' by $L \times L$ and L, and w by the addition s in L, one concludes as above that v^* is indeed a *homomorphism of groups*.

$0_{\text{IV-1}}$ | 62

(18.3.6.4). Finally, the map $(u, 1_B, 1_L)_*$ is the map

$$u^* : \mathrm{Exan}_A(B,L) \longrightarrow \mathrm{Exan}_{A'}(B,L) \tag{1}$$

which is obtained by associating to an A-extension E of B by L the ring E considered as an A'-*ring* by means of u (18.1.1), which is evidently also an A'-extension of B by L, B being also considered as A'-ring by means of u; it is clear that an A-equivalence is also an A'-equivalence, whence the map

(18.3.6.4), which, for every homomorphism $w : L \to L'$ of B-bimodules, also makes the diagram commutative:

(18.3.6.5)
$$\begin{tikzcd} \mathrm{Exan}_A(B,L) \arrow[r, "u^*"] \arrow[d, "w_*"'] & \mathrm{Exan}_{A'}(B,L) \arrow[d, "w_*"] \\ \mathrm{Exan}_A(B,L') \arrow[r, "u^*"'] & \mathrm{Exan}_{A'}(B,L') \end{tikzcd}$$

One deduces as above that u^* is indeed a homomorphism of groups.

This being so, one sets $(u,v,w)_* = (1_{A'}, 1_{B'}, w)_* \circ (1_{A'}, v, 1_L)_* \circ (u, 1_B, 1_L)_*$ and one verifies easily, by reason of the commutativity of the diagrams (18.3.6.3) and (18.3.6.5), that one has $(u \circ u', v \circ v', w' \circ w)_* = (u', v', w')_* \circ (u,v,w)_*$, which finishes the proof that (18.3.5.1) is a functor.

The existence of the homomorphism of groups (18.3.6.1) shows in particular that if E is a trivial A-extension of B by L, the extension $E \oplus_L L'$ of B by L' defined in (18.2.8) is also trivial, which one moreover verifies directly without difficulty.

On the other hand, for every element z of the *centre* Z of B, the homothety $h_z : y \mapsto yz = zy$ is an endomorphism of the B-bimodule L, hence $(h_z)_*$ is an endomorphism of the commutative group $\mathrm{Exan}_A(B,L)$, and by functoriality, these endomorphisms define on $\mathrm{Exan}_A(B,L)$ a structure of *Z-module*.

(18.3.7). Let A, A' be two rings, $u : A' \to A$ a homomorphism, B an A-ring and L a B-bimodule. The *kernel* of the homomorphism of groups

$$u^* : \mathrm{Exan}_A(B,L) \longrightarrow \mathrm{Exan}_{A'}(B,L)$$

is formed by definition of classes of A-extensions of B by L that are A'-trivial when one considers them as A'-extensions by means of u. One denotes this kernel by the notation $\mathrm{Exan}_{A/A'}(B,L)$ when this causes no confusion.

If Λ is a ring, and if one has a commutative diagram of Λ-*homomorphisms* of Λ-rings

(18.3.7.1)
$$\begin{tikzcd} B' \arrow[r] & B \\ A' \arrow[u] \arrow[r] & A \arrow[u] \end{tikzcd}$$

one deduces from it canonically homomorphisms **$0_{\text{IV-1}}$** | 63

(18.3.7.2)
$$\mathrm{Exan}_{A/\Lambda}(B,L) \longrightarrow \mathrm{Exan}_{A'/\Lambda}(B,L) \longrightarrow \mathrm{Exan}_{A'/\Lambda}(B',L)$$

which arise from the commutativity of the diagram

$$\begin{tikzcd} \mathrm{Exan}_A(B,L) \arrow[r] \arrow[d] & \mathrm{Exan}_{A'}(B,L) \arrow[r] \arrow[d] & \mathrm{Exan}_{A'}(B',L) \arrow[d] \\ \mathrm{Exan}_\Lambda(B,L) \arrow[r] & \mathrm{Exan}_\Lambda(B,L) \arrow[r] & \mathrm{Exan}_\Lambda(B',L) \end{tikzcd}$$

where the arrows are deduced from those of (18.3.7.1) by functoriality.

Proposition (18.3.8). — *Let B be a ring, $\mathfrak{J}$ a bilateral ideal of B, and $C = B/\mathfrak{J}$ the quotient ring; $\mathfrak{J}/\mathfrak{J}^2$ is then canonically equipped with a structure of C-bimodule. For every C-bimodule L, let $\mathrm{Hom}_C(\mathfrak{J}/\mathfrak{J}^2, L)$ denote the additive group of homomorphisms of C-bimodules from $\mathfrak{J}/\mathfrak{J}^2$ into L. One defines then an isomorphism of commutative groups*

(18.3.8.1)
$$\eta_L : \mathrm{Hom}_C(\mathfrak{J}/\mathfrak{J}^2, L) \xrightarrow{\sim} \mathrm{Exan}_B(C,L)$$

by associating to every C-homomorphism $w : \mathfrak{J}/\mathfrak{J}^2 \to L$ (which is a fortiori *a B-homomorphism) the class of the extension $(B/\mathfrak{J}^2) \oplus_{(\mathfrak{J}/\mathfrak{J}^2)} L$ deduced from the extension $B/\mathfrak{J}^2$ of C by $\mathfrak{J}/\mathfrak{J}^2$ by means of w; the inverse isomorphism associates to a class of B-extension E of C by L the homomorphism w such that the composite $\mathfrak{J} \to \mathfrak{J}/\mathfrak{J}^2 \xrightarrow{w} L$ is the restriction to $\mathfrak{J}$ of the structural homomorphism $B \to E$.*

Proof. Let $F = B/\mathfrak{J}^2$, which is a B-extension of C by $\mathfrak{J}/\mathfrak{J}^2$. For every B-extension $0 \to L \xrightarrow{j} E \xrightarrow{p} C \to 0$ of C by L, the structural homomorphism $f : B \to E$ is such that the composite $B \xrightarrow{f} E \xrightarrow{p} C$ is the canonical homomorphism $B \to B/\mathfrak{J} = C$. As the image of $\mathfrak{J}$ by $p \circ f$ is zero, $f(\mathfrak{J})$ is contained in the kernel $j(L)$, and as $j(L)$ is of square zero, $f(\mathfrak{J}^2) = 0$; hence f factors as $B \to B/\mathfrak{J}^2 = F \xrightarrow{u} E$, and if w is the restriction of u to $\mathfrak{J}/\mathfrak{J}^2$, one has a commutative diagram

$$\begin{tikzcd} 0 \arrow[r] & \mathfrak{J}/\mathfrak{J}^2 \arrow[r] \arrow[d, "w"] & F \arrow[r, "g"] \arrow[d, "u"] & C \arrow[r] \arrow[d, "1_C", "\wr"'] & 0 \\ 0 \arrow[r] & L \arrow[r, "j"'] & E \arrow[r, "p"'] & C \arrow[r] & 0 \end{tikzcd}$$

in other words $(u, 1_C, w)$ is a morphism of extensions (18.2.4). One deduces from it a morphism of extensions

$$\begin{tikzcd} 0 \arrow[r] & L \arrow[r] \arrow[d, "1_L", "\wr"'] & E' \arrow[r] \arrow[d, "u'"] & C \arrow[r] \arrow[d, "1_C", "\wr"'] & 0 \\ 0 \arrow[r] & L \arrow[r, "j"'] & E \arrow[r, "p"'] & C \arrow[r] & 0 \end{tikzcd}$$

where $E' = F \oplus_{(\mathfrak{J}/\mathfrak{J}^2)} L$ (18.2.8); it remains to prove that u' is a B-*equivalence*, which will establish that η_L is bijective. By the construction in (18.2.8), it suffices (in view of (18.1.7)) to prove that the inverse image G of the extension E of C by the canonical homomorphism $g : F \to C$ is F-*trivial*, which is evident since g factors as $F \xrightarrow{u} E \xrightarrow{p} C$ (18.1.6). $\mathbf{0_{IV\text{-}1}}$ | 64

It remains to see that η_L is a homomorphism of *groups*; now, for every B-homomorphism $h : L \to L'$, it is immediate that the diagram

$$\begin{tikzcd} \mathrm{Hom}_C(\mathfrak{J}/\mathfrak{J}^2, L) \arrow[r, "\eta_L"] \arrow[d, "\mathrm{Hom}(1,h)"] & \mathrm{Exan}_B(C, L) \arrow[d, "h_*"] \\ \mathrm{Hom}_C(\mathfrak{J}/\mathfrak{J}^2, L') \arrow[r, "\eta_{L'}"'] & \mathrm{Exan}_B(C, L') \end{tikzcd}$$

is commutative. It suffices to apply this remark to the homomorphism $L \times L \to L$ defining the addition to conclude. □

18.4. Extensions of algebras

(18.4.1). Let A be a *commutative* ring. The category of A-*algebras* is then a full subcategory of that of A-rings, characterized by the fact that the structural homomorphisms $\rho : A \to B$ are *central*.

If B is an A-algebra, L a B-bimodule, it is immediate that the A-extension of trivial type $D_B(L)$ is an A-algebra. Similarly, in the construction of (18.2.5) (resp. of (18.2.8)), if B, B' and E' (resp. B and E) are A-algebras, it is the same for $E' \times_{B'} B$ (resp. for $E \oplus_L L'$). Finally, if B is an A-algebra and E an A-extension of B by a B-bimodule L that is an A-algebra, every A-extension E' of B by L, A-*equivalent* to E, is also an A-algebra. One deduces then immediately from the definition (18.3.4) that the classes of equivalent A-extensions of B by L which are A-*algebras* form a *subgroup*, denoted $\mathrm{Exal}_A(B, L)$, of $\mathrm{Exan}_A(B, L)$. Let $\boldsymbol{K}'$ be the full subcategory of $\boldsymbol{K}$ defined in (18.3.5), whose objects (A, B, L) are such that A is commutative and B an A-algebra. Then what precedes shows that

$$(A, B, L) \longmapsto \mathrm{Exal}_A(B, L)$$

is a *covariant functor* from $\boldsymbol{K}'$ to $\boldsymbol{Ab}$. The results of (18.3.7) are unchanged when one replaces Exan everywhere by Exal.

(18.4.2). Suppose always A commutative. The remarks of (18.4.1) remain valid when one replaces "algebra" by "commutative algebra" and "bimodule" by "module". If B is a commutative A-algebra and L a B-module,

the classes of equivalent A-extensions of B by L which are commutative A-*algebras* (or, what amounts to the same thing, commutative A-*rings*) form a *subgroup* of $\mathrm{Exal}_A(B, L)$, denoted $\mathbf{0_{IV\text{-}1}}$ | 65

$\mathrm{Exalcom}_A(B, L)$. If $\boldsymbol{K}''$ is the full subcategory of $\boldsymbol{K}'$ where A and B are commutative and L a B-module,

$$(A, B, L) \longmapsto \mathrm{Exalcom}_A(B, L)$$

is still a *covariant functor* from $\boldsymbol{K}''$ to $\boldsymbol{Ab}$. One can also replace Exan by Exalcom in (18.3.7). Finally, if in (18.3.8), one supposes B to be a commutative ring and L a C-*module*, the same reasoning gives a canonical isomorphism

$$\mathrm{Hom}_C(\mathfrak{J}/\mathfrak{J}^2, L) \xrightarrow{\sim} \mathrm{Exalcom}_B(C, L) \tag{18.4.2.1}$$

where the first member is the group of homomorphisms of C-*modules*.

(18.4.3). Let A be a commutative ring. An important case of extensions of A-algebras is formed of A-algebras E, extensions of an A-algebra B by a B-bimodule L such that E, as A-*module*, is the *trivial* extension of the A-module B by the A-module L; in other words, the exact sequence of A-*modules* $0 \to L \to E \to B \to 0$ is *split*. One says then that E is a *Hochschild extension* of B by L. This will always be the case when B is a *projective* A-module, and in particular when A is a commutative *field*. As an A-module, one can identify E with $B \times L$, the multiplication in E being given by $(x, s)(y, t) = (xy, xt + sy + f(x, y))$ with $f(x, y) \in L$. If one writes that this multiplication defines on $B \times L$ a structure of A-algebra, one finds (M, XIV, 2) that f must be an A-*bilinear* map of $B \times B$ into L, such that

$$f(xy, z) + f(x, y)z = xf(y, z) + f(x, yz) \tag{18.4.3.1}$$

in other words, f is a 2-*cocycle* on B with values in L, in the sense of Hochschild; for the extension E to be A-trivial, it is necessary and sufficient that

$$f(x, y) = xg(y) - g(xy) + g(x)y \tag{18.4.3.2}$$

where g is an A-*linear* map of B into L, in other words f must be a 2-*coboundary* in the sense of Hochschild. One deduces from it that the classes of Hochschild extensions of B by L form a subgroup of $\mathrm{Exal}_A(B, L)$, isomorphic to the *Hochschild cohomology group* $\mathrm{H}^2_A(B, L)$.

If B is a commutative A-algebra, and L a B-module, the commutative Hochschild extensions of B by L correspond to the *symmetric* 2-cocycles, i.e. those such that $f(y, x) = f(x, y)$. The classes of commutative Hochschild extensions of B by L form therefore a subgroup of $\mathrm{Exalcom}_A(B, L)$, isomorphic to the subgroup of $\mathrm{H}^2_A(B, L)$ image of the group of symmetric 2-cocycles, which we shall denote $\mathrm{H}^2_A(B, L)^s$.

(18.4.4). Let us restrict to the case where A and B are *commutative* and L a B-module, and recall in this case the equivalent definition of the Hochschild cohomology groups $\mathrm{H}^i_A(B, L)$ (M, IX, 6). One considers a complex $\mathrm{P}_\bullet = (\mathrm{P}_n)_{n \geqslant 0}$ of B-modules, where $\mathrm{P}_n = B^{\otimes(n+1)} = B \otimes_A B \otimes \cdots \otimes_A B$ ($n+1$ times), the structure of B-module being defined

by $x(y_1 \otimes y_2 \otimes \cdots \otimes y_{n+1}) = (xy_1) \otimes y_2 \otimes \cdots \otimes y_{n+1}$; the differential, of degree -1, $d_n : \mathrm{P}_n \to \mathrm{P}_{n-1}$, is defined by **0_IV-1** | 66

$$\begin{aligned} d_n(x_1 \otimes x_2 \otimes \cdots \otimes x_{n+1}) = (x_1x_2) \otimes x_3 \otimes \cdots \otimes x_{n+1} - x_1 \otimes (x_2x_3) \otimes \cdots \otimes x_{n+1} + \cdots \\ + (-1)^{n-1} x_1 \otimes x_2 \otimes \cdots \otimes (x_n x_{n+1}) + (-1)^n (x_{n+1}x_1) \otimes x_2 \otimes \cdots \otimes x_n \end{aligned}$$

which is B-linear since B is commutative.

A 2-cocycle of this complex with values in L is a B-linear map h from $B \otimes_A B \otimes_A B$ to L such that $h(d_3(x \otimes y \otimes z \otimes t)) = 0$; but since $h(x \otimes y \otimes z) = xh(1 \otimes y \otimes z)$, the cocycle h is determined by the A-bilinear map $(y, z) \mapsto f(y, z) = h(1 \otimes y \otimes z)$ from $B \times B$ to L, and writing the preceding condition for h gives back condition (18.4.3.1) for f. Similarly, a 2-coboundary is a map of the form $x \otimes y \otimes z \mapsto h'(d_2(x \otimes y \otimes z))$, where $h' : B \otimes_A B \to L$ is linear; here again h' is determined by the A-linear map $g : y \mapsto h'(1 \otimes y)$ from B to L. One then obtains $h'(d_2(1 \otimes x \otimes y)) = xg(y) - g(xy) + yg(x)$, which gives back (18.4.3.2). One proceeds similarly for the 1-cocycles and one sees that one has

$$\mathrm{H}^i_A(B, L) = \mathrm{H}^i(\mathrm{Hom}_B(\mathrm{P}_\bullet, L)). \tag{18.4.4.1}$$

(18.4.5). Under the conditions of (18.4.4), one can reinterpret in the same way the group $\mathrm{H}^2_A(B, L)^s$ (18.4.3). For this, modify the complex $\mathrm{P}_\bullet$ in degree 3 considering a new complex

$$\mathrm{P}'_\bullet : \mathrm{P}'_3 \xrightarrow{d'_3} \mathrm{P}_2 \xrightarrow{d_2} \mathrm{P}_1;$$

we take $\mathrm{P}'_3 = \mathrm{P}_3 \oplus (B \otimes_A B \otimes_A B)$, d'_3 coinciding with d_3 on P_3, and being given by

$$d'_3(x \otimes y \otimes z) = x \otimes y \otimes z - x \otimes z \otimes y.$$

The relation $d_2 d'_3 = 0$ follows from the above with the commutativity of B. With the notations introduced above, a 2-cocycle of $\mathrm{P}'_\bullet$ corresponds now to an A-bilinear map f of $B \times B$ into L that is *symmetric* and satisfies (18.4.3.1); consequently, one has $\mathrm{H}^2_A(B, L)^s = \mathrm{H}^2(\mathrm{Hom}_B(\mathrm{P}'_\bullet, L))$.

(18.4.6). In the particular case where one considers a commutative *field* k, an extension K of k, one has $\mathrm{Ext}^1_K(M, L) = 0$ whatever the K-vector spaces L, M and consequently (M, VI, 3.3 *a*)), one has a canonical isomorphism

$$\mathrm{H}^i_k(K, L) \simeq \mathrm{Hom}_K(\mathrm{H}_i(\mathrm{P}_\bullet), L) \tag{18.4.6.1}$$

and similarly

$$\mathrm{H}^2_k(K, L)^s \simeq \mathrm{Hom}_K(\mathrm{H}_2(\mathrm{P}'_\bullet), L). \tag{18.4.6.2}$$

18.5. Case of topological rings

(18.5.1). Let A and B be two *topological* rings whose topologies are *linear*, $\rho : A \to B$ a continuous homomorphism, L a topological B-bimodule, and suppose that there exists an *open* bilateral ideal $\mathfrak{R}_0$ of B such that $\mathfrak{R}_0.L = L.\mathfrak{R}_0 = 0$, so that L can be considered as a $(B/\mathfrak{R})$-bimodule for every open $\mathbf{0_{IV\text{-}1}}$ | 67
bilateral ideal $\mathfrak{R} \subset \mathfrak{R}_0$. Let then $\mathfrak{R} \subset \mathfrak{R}_0$ be an open bilateral ideal of B and $\mathfrak{J}$ an open bilateral ideal of A such that $\rho(\mathfrak{J}) \subset \mathfrak{R}$, so that $B/\mathfrak{R}$ can be considered as a discrete $(A/\mathfrak{J})$-ring; the preceding remark proves that the group $\mathrm{Exan}_{A/\mathfrak{J}}(B/\mathfrak{R}, L)$ is defined. Moreover, if $\mathfrak{R}' \subset \mathfrak{R}$ and $\mathfrak{J}' \subset \mathfrak{J}$ are open bilateral ideals of B and A, respectively, such that $\rho(\mathfrak{J}') \subset \mathfrak{R}'$, one has by (18.3.5.1) a canonical homomorphism

$$\mathrm{Exan}_{A/\mathfrak{J}}(B/\mathfrak{R}, L) \longrightarrow \mathrm{Exan}_{A/\mathfrak{J}'}(B/\mathfrak{R}', L). \tag{18.5.1.1}$$

The set of pairs of open bilateral ideals $(\mathfrak{J}, \mathfrak{R})$ such that $\rho(\mathfrak{J}) \subset \mathfrak{R} \subset \mathfrak{R}_0$ is evidently directed for the relation "$\mathfrak{J} \supset \mathfrak{J}'$ and $\mathfrak{R} \supset \mathfrak{R}'$" and the maps (18.5.1.1) define an *inductive system* of additive groups with this set as index set. One sets, by abuse of notation (since it is no longer a matter of a group of extensions in bijective natural correspondence with a set of extensions)

$$\mathrm{Exantop}_A(B, L) = \varinjlim \mathrm{Exan}_{A/\mathfrak{J}}(B/\mathfrak{R}, L). \tag{18.5.1.2}$$

To say that the second member of (18.5.1.2) is *zero* means therefore that, for every pair of open bilateral ideals $\mathfrak{J} \subset A$, $\mathfrak{R} \subset B$ such that $\rho(\mathfrak{J}) \subset \mathfrak{R} \subset \mathfrak{R}_0$ and every $(A/\mathfrak{J})$-extension E of $B/\mathfrak{R}$ by L, there exist two open ideals $\mathfrak{J}' \subset \mathfrak{J}$, $\mathfrak{R}' \subset \mathfrak{R}$ such that $\rho(\mathfrak{J}') \subset \mathfrak{R}'$ and the inverse image of E by the homomorphism $B/\mathfrak{R}' \to B/\mathfrak{R}$ is *trivial*.

We leave to the reader the analogous definition of the inductive limits $\mathrm{Exaltop}_A(B, L)$ and $\mathrm{Exalcotop}_A(B, L)$ from $\mathrm{Exal}_{A/\mathfrak{J}}(B/\mathfrak{R}, L)$ and $\mathrm{Exalcom}_{A/\mathfrak{J}}(B/\mathfrak{R}, L)$ when A is commutative and B is a topological A-algebra (resp. a commutative topological A-algebra).

(18.5.2). If one has a commutative diagram of continuous homomorphisms of rings

$$\begin{tikzcd} B' \arrow[r] & B \\ A' \arrow[u] \arrow[r] & A \arrow[u] \end{tikzcd}$$

one deduces from it canonically two homomorphisms of additive groups

$$\mathrm{Exantop}_A(B, L) \longrightarrow \mathrm{Exantop}_{A'}(B, L) \longrightarrow \mathrm{Exantop}_{A'}(B', L)$$

by passage to the inductive limit from (18.3.5.1).

By virtue of the exactness of the $\varinjlim$ functor in the category of commutative groups, the kernel of the homomorphism

$$\mathrm{Exantop}_A(B, L) \longrightarrow \mathrm{Exantop}_{A'}(B, L)$$

is the inductive limit of the kernels of the homomorphisms

$$\mathrm{Exan}_{A/\mathfrak{J}}(B/\mathfrak{R}, L) \longrightarrow \mathrm{Exan}_{A'/\mathfrak{J}'}(B/\mathfrak{R}, L)$$

where one took for $\mathfrak{J}'$ the inverse image of $\mathfrak{J}$; one denotes this kernel $\mathrm{Exantop}_{A/A'}(B, L)$. One defines similarly $\mathrm{Exaltop}_{A/A'}(B, L)$ and $\mathrm{Exalcotop}_{A/A'}(B, L)$. Finally, if one has a homomorphism of B-bimodules $L \to L'$, one obtains canonically a homomorphism of additive groups **$0_{\text{IV-1}}$** | 68

$$\mathrm{Exantop}_A(B, L) \longrightarrow \mathrm{Exantop}_A(B, L')$$

by passage to the inductive limit from (18.3.6.1).

(18.5.3). Given a topological ring C and two topological C-bimodules M, N, one denotes $\mathrm{Hom.\ cont}_C(M, N)$ the additive group of C-homomorphisms *continuous* from M into N.

Lemma (18.5.3.1). — *Let C be a topological ring, E, L two topological C-bimodules; suppose that the topologies are linear, that L is discrete and annihilated by an open bilateral ideal of C. Then one has a canonical isomorphism*

$$\varinjlim \mathrm{Hom}_{C/\mathfrak{R}}(E/V, L) \xrightarrow{\sim} \mathrm{Hom.\ cont}_C(E, L) \tag{18.5.3.2}$$

where in the first member the inductive limit is taken over the directed set of pairs $(\mathfrak{R}, V)$ such that $\mathfrak{R}$ is an open bilateral ideal of C, V an open sub-C-bimodule of E, such that $\mathfrak{R}.L = L.\mathfrak{R} = 0$, $\mathfrak{R}.E \subset V$, $E.\mathfrak{R} \subset V$.

Proof. As $C/\mathfrak{R}$ and E/V are discrete, one has canonical homomorphisms

$$w_{\mathfrak{R},V} : \mathrm{Hom}_{C/\mathfrak{R}}(E/V, L) \longrightarrow \mathrm{Hom.\ cont}_C(E, L)$$

forming an inductive system, hence a homomorphism from the first member of (18.5.3.2) to $\mathrm{Hom.\ cont}_C(E, L)$. As the homomorphism $E/V' \to E/V$ is surjective for $V' \subset V$, it follows immediately from the definition that

$$\mathrm{Hom}_{C/\mathfrak{R}}(E/V, L) \longrightarrow \mathrm{Hom}_{C/\mathfrak{R}}(E/V', L)$$

is injective whenever $\mathfrak{R}.L = L.\mathfrak{R} = 0$, $\mathfrak{R}.E \subset V'$, and $E.\mathfrak{R} \subset V'$. The same is clearly true of

$$\mathrm{Hom}_{C/\mathfrak{R}}(E/V, L) \longrightarrow \mathrm{Hom}_{C/\mathfrak{R}'}(E/V, L)$$

for $\mathfrak{R}' \subset \mathfrak{R}$; hence the homomorphism (18.5.3.2) is injective. On the other hand, if u is a continuous C-homomorphism from E to L, its kernel is an open sub-bimodule V_0 of E. Choose an open bilateral ideal $\mathfrak{R}_0$ of C such that $\mathfrak{R}_0.L = L.\mathfrak{R}_0 = 0$, $\mathfrak{R}_0.E \subset V_0$, and $E.\mathfrak{R}_0 \subset V_0$. Then u is the canonical image of a $(C/\mathfrak{R}_0)$-homomorphism from E/V_0 to L, so (18.5.3.2) is surjective. □

This being so, the proposition (18.3.8) generalizes as follows to topological rings:

Proposition (18.5.4). — *Let B be a topological ring linearly topologized, $\mathfrak{J}$ a bilateral ideal of B, $C = B/\mathfrak{J}$ the quotient topological ring; $\mathfrak{J}/\mathfrak{J}^2$ (where $\mathfrak{J}$ is equipped with the topology induced by that of B and $\mathfrak{J}/\mathfrak{J}^2$ with the quotient topology of that of $\mathfrak{J}$) is then canonically equipped with a structure of topological C-bimodule. For every discrete C-bimodule L annihilated by an open bilateral ideal of C, there exists then a canonical isomorphism*

$$\mathrm{Hom.\ cont}_C(\mathfrak{J}/\mathfrak{J}^2, L) \xrightarrow{\sim} \mathrm{Exantop}_B(C, L). \tag{18.5.4.1}$$

Proof. Indeed, for every open $\mathfrak{R}$ of B such that $(\mathfrak{J} + \mathfrak{R})/\mathfrak{J}$ annihilates L, one has, by (18.3.8), a canonical isomorphism[17]

$$\mathrm{Hom}_{B/(\mathfrak{J}+\mathfrak{R})}((\mathfrak{J} + \mathfrak{R})/(\mathfrak{J}^2 + \mathfrak{R}), L) \xrightarrow{\sim} \mathrm{Exan}_{B/\mathfrak{R}}(B/(\mathfrak{J} + \mathfrak{R}), L)$$

and it suffices to pass to the inductive limit, taking into account (18.5.3.1). □

§19. Formally smooth algebras and Cohen rings

19.0. Introduction

(19.0.1). In Chapter IV, we will introduce and study, among other things, an important class of morphisms of preschemes, the *smooth* morphisms[18]. One of their fundamental properties (and **$0_{\text{IV-1}}$** | 69

[17] The French source prints "(18.3.9)", but § 18.3 ends at (18.3.8), which is precisely the isomorphism used here.

[18] Also called *simple* morphisms in certain recent works (inspired by the classical terminology of "simple point"); this terminology lends itself however to confusion, notably in the theory of algebraic groups.

which, together with a finiteness condition, characterizes them) is a property of *lifting of morphisms*: if $f : X \to Y$ is a smooth morphism, $g : Y' \to Y$ a morphism, then for every morphism $h : Y'' \to Y'$ making Y'' a prescheme "slightly different" from Y', every Y-morphism $Y'' \to X$ factorizes as $Y'' \xrightarrow{h} Y' \to X$. More precisely, let us restrict to the case where $Y = \operatorname{Spec}(A)$, $X = \operatorname{Spec}(B)$ are affine; B is then called a *formally smooth* A-algebra if, for every A-algebra C and every nilpotent ideal $\mathfrak{J}$ of C, every A-homomorphism $B \to C/\mathfrak{J}$ *lifts to* $B \to C \to C/\mathfrak{J}$. In other words, the map

$$\operatorname{Hom}_A(B, C) \longrightarrow \operatorname{Hom}_A(B, C/\mathfrak{J})$$

is *surjective*. In many applications, X will appear as a contravariant representable functor $Y' \mapsto F(Y')$ from the category of Y-preschemes to that of sets, so that ($\mathbf{0}_{\mathbf{III}}$, 8.1.8) one will have $F(Y') = \operatorname{Hom}_Y(Y', X)$. In the affine case, setting $F^0(C) = F(\operatorname{Spec}(C))$, the verification of the fact that, under the conditions above, $F^0(C) \to F^0(C/\mathfrak{J})$ is *surjective* (which can be done even without knowing that F is representable) will establish that f is smooth, provided the additional finiteness condition is satisfied.

(19.0.2). For *topological algebras* over a topological ring A, there is an analogous notion of *formally smooth algebra* that we will not specify here (cf. (19.3.1)). The study of these notions is first done from an elementary point of view in § 19, then, with the aid of the properties of differentials that will be developed in §§ 20 and 21, more delicate theorems will be proved in § 22. Let us summarize here the main results on formally smooth algebras:

I. — Let A, B be two Noetherian local rings, $\varphi : A \to B$ a local homomorphism, k the residue field of A, and let $B_0 = B \otimes_A k$; we equip A, B, and B_0 with their preadic topologies and k with the discrete topology. Then, for B to be a formally smooth A-algebra, it is necessary and sufficient that B be a *flat* A-module and that B_0 be a formally smooth k-algebra (19.7.1). This theorem thus reduces formal smoothness, for Noetherian local rings, to the same question for Noetherian local rings that are algebras over a field.

II. — Let k be a field, A a Noetherian local ring that is a k-algebra. For A to be formally smooth, it is necessary and sufficient that A be *geometrically regular* over k, that is to say that for every finite extension k' of k, the semi-local ring $A \widehat{\otimes}_k k'$ be
regular (22.5.8); the completion $\widehat{A}$ of A is then isomorphic to a power series ring $K[[T_1, \ldots, T_n]]$ $\mathbf{0}_{\mathbf{IV\text{-}1}}$ | 70
(19.6.5). Moreover, the k-algebra structure of A, when A is assumed complete and formally smooth over k, is entirely determined by the residue field K of A and the dimension of A; the latter can furthermore be arbitrary subject to the inequality $\dim(A) \geqslant \operatorname{rg}_k(\Gamma_{K/k})$, where $\Gamma_{K/k}$ is the "module of imperfection" of K (22.2.6).

In particular, for an extension K of k to be formally smooth, it is necessary and sufficient that K be a *separable* extension of k (19.6.1).

III. — Let A be a Noetherian local ring, $\mathfrak{J}$ an ideal of A distinct from A, $A_0 = A/\mathfrak{J}$, B_0 a complete Noetherian local ring, $A_0 \to B_0$ a local homomorphism making B_0 a formally smooth A_0-algebra. Then there exists a complete Noetherian local ring B, a local homomorphism $A \to B$ making B a flat A-module, and an A_0-isomorphism $B \otimes_A A_0 \xrightarrow{\sim} B_0$ (so that, by I), B is a formally smooth A-algebra); moreover B is determined by these properties up to isomorphism (19.7.2). This theorem contains in particular the *theorems of Cohen* on the structure of complete Noetherian local rings (19.8), which will play an important role in §§ 6 and 7 of Chapter IV.

IV. — The interest in the study of formally smooth Noetherian local rings over another comes from the following "pointwise" characterization of smooth morphisms: if X and Y are locally Noetherian preschemes, $f : X \to Y$ a morphism locally of finite type, then, for f to be smooth, it is necessary and sufficient that for every $x \in X$, the ring $\mathscr{O}_x$ be formally smooth over $\mathscr{O}_{f(x)}$. In particular, if $Y = \operatorname{Spec}(k)$, where k is a perfect field, to say that f is smooth is equivalent to saying that X is a *regular* prescheme.

V. — Finally, we will see in §§ 20, 21, and 22 that the notion of formally smooth algebra is introduced naturally in the theory of *Kähler differentials*, the two theories shedding light on each other.

(19.0.3). Throughout this section and the following ones, topological rings and modules will be assumed to be *linearly topologized* ($\mathbf{0}_{\mathbf{I}}$, 7.1.1); the topological rings considered will be assumed to be *commutative*, unless explicit mention to the contrary. Recall that if A and B are two topological rings, $\rho : A \to B$ a ring homomorphism defining on B a structure of A-algebra, we say that B is a *topological A-algebra* if ρ is continuous for the topologies considered.

For brevity, in a topological ring A (resp. a topological A-module M), we will say "fundamental system of open ideals (resp. submodules)" instead of "fundamental system of neighbourhoods of 0 consisting of ideals (resp. submodules)".

Given a topological ring A and a topological A-module M, the sets $\mathfrak{J}M$, where $\mathfrak{J}$ ranges over a fundamental system of open ideals in A, form a fundamental system of open submodules of a topology on M making M a topological A-module, called the topology *derived* from that of A.

Let M be a topological A-module whose topology is *less fine* than the topology derived from that of A; then, if N is an open submodule of M, the discrete A-module M/N is annihilated by an open ideal $\mathfrak{R}$ of A, since by hypothesis there exists such an ideal $\mathfrak{R}$ with $\mathfrak{R} \cdot M \subset N$.

If M and N are two topological A-modules whose topologies are both derived from that of A, then every A-homomorphism $u : M \to N$ is *continuous*, since for every neighbourhood V of 0 in N, there exists by hypothesis an open ideal $\mathfrak{J}$ of A such that $\mathfrak{J}N \subset V$, and one thus has $u(\mathfrak{J}M) \subset \mathfrak{J}N \subset V$. $\mathbf{0_{IV\text{-}1}}$ | 71

When B is a topological A-algebra, the topology on B *derived* from that of A is *finer* than the topology given on B, since for every open ideal $\mathfrak{R}$ of B, there is by hypothesis an open ideal $\mathfrak{J}$ of A such that $\mathfrak{J}B \subset \mathfrak{R}$.

19.1. Formal epimorphisms and monomorphisms

Proposition (19.1.1). — *Let A be a topological ring, M, N two topological A-modules, (W_λ) a fundamental system of open submodules in N, $u : M \to N$ a continuous A-homomorphism, $\widehat{M}$, $\widehat{N}$ the separated completions of M and N, $\widehat{u} : \widehat{M} \to \widehat{N}$ the continuous extension of u to the separated completions.*

(i) The following conditions are equivalent:
- *a) $u(M)$ is dense in N.*
- *a′) $\widehat{u}(\widehat{M})$ is dense in $\widehat{N}$.*
- *a″) For all λ, the composite homomorphism $M \xrightarrow{u} N \to N/W_\lambda$ is surjective.*

(ii) The following conditions are equivalent:
- *b) The inverse image by u of the topology of N is equal to the topology of M.*
- *b′) $\widehat{u}$ is an isomorphism of the topological $\widehat{A}$-module $\widehat{M}$ onto the sub-$\widehat{A}$-module $\widehat{u}(\widehat{M})$ of $\widehat{N}$ (which is necessarily closed).*
- *b″) The $u^{-1}(W_\lambda)$ form a fundamental system of neighbourhoods of 0 in M.*

This follows immediately from the definition of separated completions, and from the fact that N/W_λ is discrete.

(19.1.2). When the equivalent conditions of (i) (resp. (ii)) in (19.1.1) are satisfied, we say that u is a *formal epimorphism* (resp. a *formal monomorphism*). We say that u is a *formal bimorphism* if it is both a formal epimorphism and a formal monomorphism; this amounts to the same, by virtue of (19.1.1), as saying that $\widehat{u}$ is an *isomorphism* of the topological $\widehat{A}$-module $\widehat{M}$ onto the topological $\widehat{A}$-module $\widehat{N}$.

Proposition (19.1.3). — *Let A be a topological ring, M, N two topological A-modules, $u : M \to N$ a continuous A-homomorphism, (V_λ), (W_λ) two fundamental systems of open submodules in M and N respectively, having the same index set, and such that $u(V_\lambda) \subset W_\lambda$ for all λ; let $u_\lambda : M/V_\lambda \to N/W_\lambda$ be the homomorphism induced by u by passing to quotients. Then:*

(i) For u to be a formal epimorphism, it is necessary and sufficient that, for all λ, u_λ be surjective.

(ii) For u to be a formal monomorphism, it is necessary and sufficient that, for all λ, there exist μ such that $V_\mu \subset V_\lambda$ and that $\mathrm{Ker}(u_\mu)$ be contained in the kernel V_λ/V_μ of the canonical map $M/V_\mu \to M/V_\lambda$.

(iii) For u to be a formal bimorphism, it is necessary and sufficient that, for all λ, u_λ be surjective and that there exist μ such that $V_\mu \subset V_\lambda$ and that the canonical homomorphism $M/V_\mu \to M/V_\lambda$ factorize as $M/V_\mu \xrightarrow{u_\mu} N/W_\mu \xrightarrow{h} M/V_\lambda$ (where the homomorphism $N/W_\mu \to M/V_\lambda$ is necessarily unique). $\mathbf{0_{IV\text{-}1}}$ | 72

Proof. Assertion (i) is immediate; on the other hand, $\mathrm{Ker}(u_\mu) = u^{-1}(W_\mu)/V_\mu$, and the kernel of the canonical map $M/V_\mu \to M/V_\lambda$ is V_λ/V_μ; the condition of (ii) thus amounts to saying that $u^{-1}(W_\mu) \subset V_\lambda$, and assertion (ii) follows immediately; finally, when u_μ is surjective, to say that $\mathrm{Ker}(u_\mu)$ is contained in V_λ/V_μ, or to say that $M/V_\mu \to M/V_\lambda$ factorizes as $v \circ u_\mu$, where

v is a homomorphism $N/W_\mu \to M/V_\lambda$, is the same thing, since N/W_μ then identifies with $(M/V_\mu)/\operatorname{Ker}(u_\mu)$. □

Corollary (19.1.4). — *Let A be a topological ring, M, N two topological A-modules whose topologies are derived from that of A, $u : M \to N$ a formal epimorphism. Let $(\mathfrak{J}_\lambda)$ be a fundamental system of open ideals in A. For u to be a formal bimorphism, it is necessary and sufficient that for all λ, the homomorphism $u_\lambda : M/\mathfrak{J}_\lambda M \to N/\mathfrak{J}_\lambda N$ induced by u by passing to quotients is bijective.*

Proof. Indeed, $u(\mathfrak{J}_\lambda M) \subset \mathfrak{J}_\lambda N$ and one can apply the criterion (19.1.3), (iii); but if one has a factorization $M/\mathfrak{J}_\mu M \xrightarrow{u_\mu} N/\mathfrak{J}_\mu N \xrightarrow{v} M/\mathfrak{J}_\lambda M$, the image of $\mathfrak{J}_\lambda M/\mathfrak{J}_\mu M$ by u_μ is $\mathfrak{J}_\lambda N/\mathfrak{J}_\mu N$, hence the image of $\mathfrak{J}_\lambda N/\mathfrak{J}_\mu N$ by v is 0 and v factorizes as

$$N/\mathfrak{J}_\mu N \longrightarrow N/\mathfrak{J}_\lambda N \xrightarrow{v'} M/\mathfrak{J}_\lambda M;$$

but then the automorphism identical to that of $M/\mathfrak{J}_\lambda M$ factorizes as

$$M/\mathfrak{J}_\lambda M \xrightarrow{u_\lambda} N/\mathfrak{J}_\lambda N \xrightarrow{v'} M/\mathfrak{J}_\lambda M,$$

which shows that u_λ is injective, and as we already know it is surjective, this proves the corollary. □

Proposition (19.1.5). — *Let A be a topological ring, M, N two topological A-modules, and $u : M \to N$ a continuous A-homomorphism. The following conditions are equivalent:*

a) For every discrete topological A-module E and every continuous A-homomorphism $v : M \to E$, there exists a continuous A-homomorphism $w : N \to E$ such that $v = w \circ u$.

b) For every open submodule V' of M, there exist an open submodule W'' of N, an open submodule $V'' \subset V' \cap u^{-1}(W'')$, and a homomorphism $h : N/W'' \to M/V'$ such that the canonical homomorphism $M/V'' \to M/V'$ factorizes as

$$M/V'' \xrightarrow{u''} N/W'' \xrightarrow{h} M/V',$$

where u'' is induced by u by passing to quotients.

Proof. To see that a) implies b), apply a) to $E = M/V'$ and to the canonical homomorphism $v : M \to M/V'$. Then $W'' = w^{-1}(0)$ is an open submodule of N and $V'' = u^{-1}(W'')$ is an open submodule of M contained in V'; these submodules and the homomorphism $h : N/W'' \to M/V'$ induced by w answer the question. Conversely, to show that b) implies a), one may restrict to the case where v is surjective, replacing E by $v(M)$; then $V' = \operatorname{Ker}(v)$ is an open submodule of M, so E is isomorphic to the discrete A-module M/V', and applying b) gives

the desired continuous A-homomorphism w by taking the composite $N \to N/W'' \xrightarrow{h} M/V'$, the **0_IV-1** | 73
diagram

$$\begin{tikzcd} M \arrow[r, "u"] \arrow[d] & N \arrow[d] \\ M/V'' \arrow[r, "u''"'] & N/W'' \end{tikzcd}$$

being commutative. □

When the equivalent conditions of (19.1.5) are satisfied, we say that u is *formally left invertible*; since condition b) of (19.1.5) implies $u^{-1}(W'') \subset V'$, u is then a formal monomorphism. The terminology is further justified by the following corollaries.

Corollary (19.1.6). — *If there exists a continuous $\widehat{A}$-homomorphism $s : \widehat{N} \to \widehat{M}$ such that $s \circ \widehat{u} = 1_{\widehat{M}}$, then u is formally left invertible.*

Note that $\widehat{u}$ is then a topological isomorphism of $\widehat{M}$ onto a *topological direct summand* of $\widehat{N}$. To prove (19.1.6), it suffices to note that, with the notation of (19.1.5), a), $v : M \to E$ extends to a continuous $\widehat{A}$-homomorphism $\widehat{v} : \widehat{M} \to E$ since E is discrete; let $j : M \to \widehat{M}$ and $j' : N \to \widehat{N}$ be the canonical homomorphisms. Then, setting $w = \widehat{v} \circ s \circ j'$, one has $w \circ u = \widehat{v} \circ s \circ \widehat{u} \circ j = \widehat{v} \circ j = v$.

Corollary (19.1.7). — *Suppose that the topologies of M and N are derived from that of A, and let $(\mathfrak{J}_\lambda)$ be a fundamental system of open ideals in A. For u to be formally left invertible, it is necessary and sufficient that, for every λ, the homomorphism*

$$u_\lambda : M/\mathfrak{J}_\lambda M \longrightarrow N/\mathfrak{J}_\lambda N$$

induced by u by passing to quotients be left invertible (in other words, be an isomorphism of $M/\mathfrak{J}_\lambda M$ onto a direct summand of $N/\mathfrak{J}_\lambda N$).

Indeed, the condition is sufficient, since for $V' = \mathfrak{J}_\lambda M$ in condition b) of (19.1.5), one answers the question by taking $W'' = \mathfrak{J}_\lambda N$, $V'' = V'$, and h such that $h \circ u_\lambda$ is the identity on $M/\mathfrak{J}_\lambda M$. Conversely, if u is formally left invertible, then for every λ, by (19.1.5), b), there are μ with $\mathfrak{J}_\mu \subset \mathfrak{J}_\lambda$ and a homomorphism $h : N/\mathfrak{J}_\mu N \to M/\mathfrak{J}_\lambda M$ such that the canonical homomorphism $M/\mathfrak{J}_\mu M \to M/\mathfrak{J}_\lambda M$ factorizes as

$$M/\mathfrak{J}_\mu M \xrightarrow{u_\mu} N/\mathfrak{J}_\mu N \xrightarrow{h} M/\mathfrak{J}_\lambda M.$$

But since $h(\mathfrak{J}_\lambda(N/\mathfrak{J}_\mu N)) \subset \mathfrak{J}_\lambda(M/\mathfrak{J}_\lambda M) = 0$, h factorizes canonically as

$$N/\mathfrak{J}_\mu N \longrightarrow N/\mathfrak{J}_\lambda N \xrightarrow{s} M/\mathfrak{J}_\lambda M,$$

and it is immediate that s is a left inverse of u_λ.

Proposition (19.1.8). — *Let A be a topological ring admitting a countable decreasing fundamental system $(\mathfrak{J}_n)$ of open ideals. Let M, N be two topological A-modules whose topologies are derived from that of A, and let $u : M \to N$ be an A-homomorphism. Set $M_n = M/\mathfrak{J}_n M$, $N_n = N/\mathfrak{J}_n N$, and let $u_n : M_n \to N_n$ be the $(A/\mathfrak{J}_n)$-homomorphism induced by u by passing to quotients. Suppose that, for every n, $P_n = \mathrm{Coker}(u_n)$ is a projective $(A/\mathfrak{J}_n)$-module and that M is separated and complete. Then u is formally left invertible if and only if u is left invertible (and u is then a topological isomorphism of M onto a topological direct summand of N).*

$0_{\text{IV-1}}$ | 74

Proof. By (19.1.7), one has commutative diagrams

$$\begin{tikzcd}
0 \arrow[r] & M_n \arrow[r, "u_n"] & N_n \arrow[r, "p_n"] & P_n \arrow[r] & 0 \\
0 \arrow[r] & M_{n+1} \arrow[r, "u_{n+1}"'] \arrow[u, "f"] & N_{n+1} \arrow[r, "p_{n+1}"'] \arrow[u, "g"] & P_{n+1} \arrow[r] \arrow[u, "h"] & 0
\end{tikzcd}$$

whose rows are split exact sequences; in other words, for every n there exists a homomorphism $s_n : P_n \to N_n$ such that $p_n \circ s_n = 1_{P_n}$. We show by induction on n that homomorphisms $s'_n : P_n \to N_n$ can be defined so that $p_n \circ s'_n = 1_{P_n}$ and the diagrams

$$\begin{tikzcd}
P_n \arrow[r, "s'_n"] & N_n \\
P_{n+1} \arrow[r, "s'_{n+1}"'] \arrow[u, "h"] & N_{n+1} \arrow[u, "g"']
\end{tikzcd}$$

are commutative. Indeed, $g \circ s_{n+1} - s'_n \circ h$ is a homomorphism from P_{n+1} into

$$u_n(M_n) = u_{n+1}(M_{n+1})/\mathfrak{J}_n u_{n+1}(M_{n+1});$$

since P_{n+1} is a projective $(A/\mathfrak{J}_{n+1})$-module, this homomorphism factorizes as

$$P_{n+1} \xrightarrow{t_{n+1}} u_{n+1}(M_{n+1}) \longrightarrow u_{n+1}(M_{n+1})/\mathfrak{J}_n u_{n+1}(M_{n+1}),$$

whence $s'_{n+1} = s_{n+1} - t_{n+1}$ answers the question. The decomposition of N_n as the direct sum of $u_n(M_n)$ and $s'_n(P_n)$ then immediately gives a homomorphism $w_n : N_n \to M_n$ which is a left inverse of u_n and makes the diagrams

$$\begin{tikzcd} N_n \arrow[r, "w_n"] & M_n \\ N_{n+1} \arrow[u, "g"] \arrow[r, "w_{n+1}"'] & M_{n+1} \arrow[u, "f"'] \end{tikzcd}$$

commutative. The inverse system (w_n) therefore has an inverse limit $\widehat{w} : \widehat{N} \to \widehat{M} = M$. Composing with the canonical homomorphism $N \to \widehat{N}$ gives a homomorphism $w : N \to M$ such that, for every n, the endomorphism $(w \circ u)_n$ of $M_n = M/\mathfrak{J}_n M$ induced by $w \circ u$ is the identity. Thus $w \circ u = 1_M$ because M is separated and complete. □

Proposition (19.1.9). — *Let A be a preadmissible topological ring ($\mathbf{0_I}$, 7.1.2), $\mathfrak{Q}$ an ideal of definition of A, and $(\mathfrak{J}_\lambda)$ a fundamental system of open ideals in A. Let M, N be two topological A-modules whose topologies are derived from that of A, such that for every λ, $N/\mathfrak{J}_\lambda N$ is a projective $(A/\mathfrak{J}_\lambda)$-module (cf. (19.2.3)). Let $u : M \to N$ be an A-homomorphism. Then the following conditions are equivalent:*

a) u is formally left invertible.

b) The homomorphism $u_0 : M/\mathfrak{Q}M \to N/\mathfrak{Q}N$ induced by u by passing to quotients is left invertible. $\mathbf{0_{IV\text{-}1}}$ | 75

Proof. By (19.1.7), condition a) is equivalent to u_λ being left invertible for every λ. Since $\mathfrak{Q}$ is open, and therefore contains some $\mathfrak{J}_\lambda$, it follows at once that u_0 is left invertible. Conversely, to show that b) implies a), note that for every λ, $\mathfrak{Q}/\mathfrak{J}_\lambda$ is by hypothesis a nilpotent ideal of $A/\mathfrak{J}_\lambda$. The assertion follows from the next proposition. □

Proposition (19.1.10). — *Let A be a ring, M, N two A-modules, with N projective, and let $u : M \to N$ be an A-homomorphism. Let $\mathfrak{J}$ be an ideal of A; suppose that one of the following conditions holds:*

(i) $\mathfrak{J}$ is nilpotent.

(ii) $\mathfrak{J}$ is contained in the radical of A and M is of finite type.

Then u is left invertible if and only if the homomorphism $u_0 : M/\mathfrak{J}M \to N/\mathfrak{J}N$ of $(A/\mathfrak{J})$-modules induced by u by passing to quotients is left invertible.

Proof. The condition is plainly necessary; let us prove that it is sufficient. Let v_0 be a left inverse of u_0. The composite $N \to N/\mathfrak{J}N \xrightarrow{v_0} M/\mathfrak{J}M$ factorizes as $N \xrightarrow{v} M \to M/\mathfrak{J}M$ because N is projective. Then $w = v \circ u$ is an endomorphism of M whose induced endomorphism w_0 of $M/\mathfrak{J}M$ is the identity, and it is enough to prove that w is bijective (for then $w^{-1} \circ v$ is a left inverse of u). We distinguish the two cases.

(i) For every n one has the commutative diagram

$$\begin{tikzcd} (\mathfrak{J}^n/\mathfrak{J}^{n+1}) \otimes_{A/\mathfrak{J}} (M/\mathfrak{J}M) \arrow[r] \arrow[d, "1\otimes\mathrm{gr}^0(w)"'] & \mathfrak{J}^n M/\mathfrak{J}^{n+1}M \arrow[d, "\mathrm{gr}^n(w)"] \\ (\mathfrak{J}^n/\mathfrak{J}^{n+1}) \otimes_{A/\mathfrak{J}} (M/\mathfrak{J}M) \arrow[r] & \mathfrak{J}^n M/\mathfrak{J}^{n+1}M \end{tikzcd}$$

in which the horizontal arrows are surjective. Since $\mathrm{gr}^0(w) = w_0$ is the identity, so is $\mathrm{gr}^n(w)$, which is therefore, a fortiori, bijective. The $\mathfrak{J}$-preadic filtration on M is finite because $\mathfrak{J}$ is nilpotent, so w is bijective (Bourbaki, *Alg. comm.*, Chap. III, § 2, no. 8, Cor. 3 of Th. 1).

(ii) It suffices to show that, for every maximal ideal $\mathfrak{m}$ of A, the endomorphism $w_\mathfrak{m}$ of $M_\mathfrak{m}$ is bijective (Bourbaki, *Alg. comm.*, Chap. II, § 3, no. 3, Th. 1). Since $\mathfrak{J}A_\mathfrak{m} \subset \mathfrak{m}A_\mathfrak{m}$ and $A_\mathfrak{m}/\mathfrak{J}A_\mathfrak{m} = (A/\mathfrak{J})_\mathfrak{m}$, we are reduced to proving the proposition when A is local. Moreover, one may suppose that $\mathfrak{J}$ is the maximal ideal $\mathfrak{J}_0$ of A, because if u_0 is left invertible, so is $u_{00} : M/\mathfrak{J}_0 M \to N/\mathfrak{J}_0 N$, obtained by tensoring u_0 with $1_{A/\mathfrak{J}_0}$, since $\mathbf{0_{IV\text{-}1}}$ | 76

$$M/\mathfrak{J}_0 M = (M/\mathfrak{J}M) \otimes_{A/\mathfrak{J}} (A/\mathfrak{J}_0).$$

[19] Suppose then that $\mathfrak{J}$ is maximal, so that $A/\mathfrak{J}$ is a field. It plainly suffices to prove that M is a free A-module under the hypotheses of the statement: indeed, $\det(w_0)$ is then the canonical image of

[19]The French source prints $N/\mathfrak{J}_0 M$ as the codomain of u_{00}; the module type requires $N/\mathfrak{J}_0 N$.

$\det(w)$ in $A/\mathfrak{J}$, hence $\det(w) \notin \mathfrak{J}$ and is therefore invertible. Now $M/\mathfrak{J}M$ is a finite-dimensional free $(A/\mathfrak{J})$-vector space, so there are a finite free A-module L and an A-homomorphism $f : L \to M$ such that the induced homomorphism $f_0 : L/\mathfrak{J}L \to M/\mathfrak{J}M$ is bijective. Since M is of finite type, f is surjective by Nakayama's lemma (Bourbaki, *Alg. comm.*, Chap. II, § 3, no. 2, Cor. 1 of Prop. 4). Moreover, if $g = u \circ f$, then the induced homomorphism $g_0 : L/\mathfrak{J}L \to N/\mathfrak{J}N$ is left invertible, and since L is free, the preceding observation shows that g itself is left invertible. This plainly implies that f is injective, completing the proof. □

Let us mention in passing the following corollaries of (19.1.10).

Corollary (19.1.11). — *Let A be a local ring, k its residue field, M a finite-type A-module, N a projective A-module, and $u : M \to N$ a homomorphism. Then u is left invertible if and only if there exists a system of generators $(x_i)_{1 \leqslant i \leqslant m}$ of M such that the images of the $x_i \otimes 1$ under $u \otimes 1 : M \otimes_A k \to N \otimes_A k$ are linearly independent in $N \otimes_A k$; the x_i then form a basis of M.*

The condition is plainly necessary, since if u is left invertible, M is a finite-type projective A-module and hence free. Conversely, if the condition holds, the $x_i \otimes 1$ plainly form a basis of $M \otimes_A k$ and $u \otimes 1$ is left invertible; apply (19.1.10) to the maximal ideal $\mathfrak{J}$ of A.

Corollary (19.1.12). — *Let A be a ring, M a finite-type A-module, N a projective A-module, and $u : M \to N$ a homomorphism. For every prime ideal $\mathfrak{p} \in \operatorname{Spec}(A)$, the following conditions are equivalent:*

- *a) $u_{\mathfrak{p}} : M_{\mathfrak{p}} \to N_{\mathfrak{p}}$ is left invertible.*
- *b) $u \otimes 1 : M \otimes_A k(\mathfrak{p}) \to N \otimes_A k(\mathfrak{p})$ is injective (where $k(\mathfrak{p})$ denotes the residue field of A at $\mathfrak{p}$).*
- *c) There is a finite system of elements $x_i \in M$ $(1 \leqslant i \leqslant m)$ whose images generate $M_{\mathfrak{p}}$, and a system of m linear forms y_i^* on N $(1 \leqslant i \leqslant m)$ such that $\det(\langle y_i^*, u(x_j)\rangle) \notin \mathfrak{p}$.*
- *d) There exists $f \in A - \mathfrak{p}$ such that $u_f : M_f \to N_f$ is left invertible.*

Moreover, the set of $\mathfrak{p} \in \operatorname{Spec}(A)$ satisfying these conditions is open in $\operatorname{Spec}(A)$.

The last assertion is an immediate consequence of d). Since N is projective, it is a direct summand of a free A-module $A^{(I)}$; and since M is of finite type, $u(M)$ is contained in a submodule of $A^{(I)}$ of the form A^n for finite n. Since each of a), b), c), and d) is equivalent to the corresponding assertion with N replaced by $N \oplus P$ (with u still mapping M into N), we are reduced to the case where N is free of finite type. Clearly d) implies a), and a) and b) are equivalent by (19.1.11). Moreover, a) implies that $M_{\mathfrak{p}}$ is free by (19.1.11), so a) implies c) by choosing the x_i so that their images form a basis of this

$A_{\mathfrak{p}}$-module and noting that, because N is free of finite type, every linear form on $N_{\mathfrak{p}}$ can be written v/f, where $f \in A - \mathfrak{p}$ and v is a linear form on N. Clearly c) implies b), so it remains to see that a) implies d). Since N is finitely presented, $(\operatorname{Hom}_A(N, M))_{\mathfrak{p}}$ identifies canonically with $\operatorname{Hom}_{A_{\mathfrak{p}}}(N_{\mathfrak{p}}, M_{\mathfrak{p}})$ (Bourbaki, *Alg. comm.*, Chap. II, § 2, no. 7, Prop. 19). If $w_{\mathfrak{p}}$ is a left inverse of $u_{\mathfrak{p}}$, there are a homomorphism $w : N \to M$ and an element $f \in A - \mathfrak{p}$ such that $w_{\mathfrak{p}} = w \otimes (1/f)1_{A_{\mathfrak{p}}}$. The relation $w_{\mathfrak{p}} \circ u_{\mathfrak{p}} = 1_{M_{\mathfrak{p}}}$ can therefore also be written $(w \circ u) \otimes 1_{A_{\mathfrak{p}}} = f.1_{M_{\mathfrak{p}}}$. Since M is of finite type, there is $g \in A - \mathfrak{p}$ such that the endomorphism $g((w \circ u) - f.1_M)$ vanishes on all generators of M, and hence is zero. Put $h = fg$, $u_h = u \otimes 1_{A_h}$, and $w_h = w \otimes 1_{A_h}$. Then $w_h(u_h(z)) = (f/1)z$ for every $z \in M_h$; since $h/1$ is invertible in A_h, so is $f/1$, and $(f/1)^{-1}w_h$ is a left inverse of u_h. This completes the proof. $\mathbf{0_{IV\text{-}1}}$ | 77

Proposition (19.1.13). — *Suppose the hypotheses of (19.1.9) hold, and suppose in addition that $(\mathfrak{J}_\lambda)$ is a decreasing sequence $(\mathfrak{J}_n)$ and that M is separated and complete. Then conditions a) and b) of (19.1.9) are also equivalent to:*

- *c) u is left invertible.*

We already know that c) implies a) by (19.1.6). Conversely, if a) holds, then with the notation of (19.1.8), M_n is a direct summand of the projective $(A/\mathfrak{J}_n)$-module N_n; hence P_n is also isomorphic to a direct summand of N_n and is therefore projective. It remains only to apply (19.1.8).

Finally, note the following proposition.

Proposition (19.1.14). — *Let A be a ring, M a finite-type A-module, N a projective A-module, and $u : M \to N$ an A-homomorphism.*

(i) *The homomorphism u is left invertible if and only if, for every maximal ideal $\mathfrak{m}$ of A, $u_{\mathfrak{m}} : M_{\mathfrak{m}} \to N_{\mathfrak{m}}$ is left invertible.*

(ii) *Let A' be an A-algebra which is a faithfully flat A-module. Then u is left invertible if and only if $u \otimes 1 : M \otimes_A A' \to N \otimes_A A'$ is left invertible.*

As in (19.1.12), it suffices to consider the case where N is free of finite type. Then saying that u is left invertible means that u is injective and that the quotient module $P = N/u(M)$ is projective, since $u(M)$ is then a direct summand of N. Also, since M is of finite type, P is finitely presented.

(i) Necessity is clear. Conversely, if the condition holds, u is injective (Bourbaki, *Alg. comm.*, Chap. II, § 3, no. 3, Th. 1), and since $P_{\mathfrak{m}} = N_{\mathfrak{m}}/u_{\mathfrak{m}}(M_{\mathfrak{m}})$ is projective for every $\mathfrak{m}$, it follows that P is projective (*loc. cit.*, § 5, no. 2, Th. 1).

(ii) Again, necessity is immediate. Conversely, if the condition holds, u is injective ($\mathbf{0_I}$, 6.4.1), and since $P \otimes_A A' = \operatorname{Coker}(u \otimes 1)$ is projective, hence flat, it follows that P is a flat A-module ($\mathbf{0_I}$, 6.6.3), and therefore projective because it is finitely presented (Bourbaki, *Alg. comm.*, Chap. II, § 5, no. 2, Cor. 2 of Th. 1).

$\mathbf{0_{IV\text{-}1}}$ | 78

Remark (19.1.15). — The notion dual to that of a formally left invertible homomorphism is that of a *formally right invertible* homomorphism. Such a continuous A-homomorphism $u : M \to N$ satisfies, by definition, the following condition: for every open submodule W' of N, there exist an open submodule $V' \subset u^{-1}(W')$ of M, an open submodule $W'' \subset W'$ of N, and a homomorphism $h : N/W'' \to M/V'$ such that the canonical homomorphism $N/W'' \to N/W'$ factorizes as

$$N/W'' \xrightarrow{h} M/V' \xrightarrow{u'} N/W',$$

where u' is induced by u by passing to quotients. This implies that u is a formal epimorphism. If there exists a continuous $\widehat{A}$-homomorphism $r : \widehat{N} \to \widehat{M}$ such that $\widehat{u} \circ r = 1_{\widehat{N}}$, then u is immediately seen to be formally right invertible. Under the hypotheses of (19.1.7), u is formally right invertible if and only if every u_λ is right invertible (that is, if $\operatorname{Ker}(u_\lambda)$ is a direct summand of $M/\mathfrak{J}_\lambda M$ and u_λ is an isomorphism from a complement of $\operatorname{Ker}(u_\lambda)$ onto $N/\mathfrak{J}_\lambda N$). We leave to the reader the statements and proofs of the propositions corresponding to (19.1.8) and (19.1.9): in the analogue of (19.1.8), one must suppose M separated and complete and M_n a projective $(A/\mathfrak{J}_n)$-module; in the analogue of (19.1.9), one must omit the hypothesis on the $N/\mathfrak{J}_\lambda N$, but instead suppose that, for every λ, $M/\mathfrak{J}_\lambda M$ is a projective $(A/\mathfrak{J}_\lambda)$-module.

19.2. Formally projective modules

Definition (19.2.1). — Let A be a topological ring. A topological A-module M is said to be *formally projective* if it satisfies the following condition: for every open ideal $\mathfrak{J}$ of A, every pair of discrete $(A/\mathfrak{J})$-modules P, Q, every surjective A-homomorphism $u : P \to Q$, and every continuous A-homomorphism $v : M \to Q$, there exists a continuous A-homomorphism $w : M \to P$ such that $v = u \circ w$.

(19.2.2). To verify the condition of (19.2.1), one may plainly restrict, replacing Q by $v(M)$ and P by $u^{-1}(v(M))$, to the case where v itself is surjective. Then Q is isomorphic to M/V, where V is an open submodule of M such that $\mathfrak{J}M \subset V$. The condition of (19.2.1) is therefore equivalent to requiring that, for every discrete $(A/\mathfrak{J})$-module P and every surjective A-homomorphism $u : P \to M/V$, there exist an open submodule $V' \subset V$ of M and an A-homomorphism $w : M/V' \to P$ such that the canonical homomorphism $M/V' \to M/V$ factorizes as

$$M/V' \xrightarrow{w} P \xrightarrow{u} M/V.$$

It suffices to verify this condition when $\mathfrak{J}$ ranges over a fundamental system of neighbourhoods of 0 in A formed of ideals.

(19.2.3). Suppose that there exist a fundamental system $(\mathfrak{J}_\lambda)$ of open ideals in A and a fundamental system (V_λ) of open submodules of M, with the same index set, such that for every λ, M/V_λ is a projective $(A/\mathfrak{J}_\lambda)$-module. Then M is formally projective. Indeed, with the notation of (19.2.2), choose λ such that $\mathfrak{J}_\lambda \subset \mathfrak{J}$ and $V_\lambda \subset V$. Since P is also an $(A/\mathfrak{J}_\lambda)$-module, the factorization of the canonical homomorphism $M/V_\lambda \to M/V$ as $M/V_\lambda \to P \to M/V$ follows from its being an $(A/\mathfrak{J}_\lambda)$-homomorphism and from the projectivity of M/V_λ.

When the stronger condition in this paragraph holds, M is said to be *strictly formally projective*.

Proposition (19.2.4). — *Let A be a topological ring, and let M be a topological A-module whose topology is derived from that of A. Then M is formally projective if and only if it is strictly formally projective.*

$\mathbf{0_{IV\text{-}1}}$ | 79

Proof. We have just seen that the condition is sufficient. Conversely, suppose that M is formally projective, and let $(\mathfrak{J}_\lambda)$ be a fundamental system of open ideals in A. For each λ, let P be a free $(A/\mathfrak{J}_\lambda)$-module and let $u : P \to M/\mathfrak{J}_\lambda M$ be a surjective $(A/\mathfrak{J}_\lambda)$-homomorphism. There is then a $\mathfrak{J}_\mu \subset \mathfrak{J}_\lambda$ such that the canonical homomorphism $M/\mathfrak{J}_\mu M \to M/\mathfrak{J}_\lambda M$ factorizes as

$$M/\mathfrak{J}_\mu M \xrightarrow{w} P \xrightarrow{u} M/\mathfrak{J}_\lambda M.$$

But since $w(\mathfrak{J}_\lambda(M/\mathfrak{J}_\mu M)) \subset \mathfrak{J}_\lambda P = 0$, w factorizes through a map $v : M/\mathfrak{J}_\lambda M \to P$, and it is clear that $u \circ v$ is the identity on $M/\mathfrak{J}_\lambda M$. Thus this $(A/\mathfrak{J}_\lambda)$-module is projective. □

Proposition (19.2.5). — *Let A be a topological ring, M a topological A-module.*

(i) The module M is formally projective (resp. strictly formally projective) if and only if the topological $\widehat{A}$-module $\widehat{M}$ is so.

(ii) Let A' be a topological A-algebra. If M is formally projective (resp. strictly formally projective), then $M \otimes_A A'$, equipped with the tensor-product topology, is a formally projective (resp. strictly formally projective) topological A'-module.

Proof. (i) When $\mathfrak{J}$ (resp. V) ranges over the open ideals of A (resp. the open submodules of M), the separated completion $\widehat{\mathfrak{J}}$ (resp. $\widehat{V}$) ranges over the open ideals of $\widehat{A}$ (resp. the open submodules of $\widehat{M}$), and $\widehat{A}/\widehat{\mathfrak{J}} = A/\mathfrak{J}$ (resp. $\widehat{M}/\widehat{V} = M/V$), up to canonical isomorphism. Since formal projectivity (resp. strict formal projectivity) involves only the $A/\mathfrak{J}$ and the M/V, assertion (i) follows immediately.

(ii) Suppose first that M is formally projective and put $M' = M \otimes_A A'$. Let $\mathfrak{J}'$ be an open ideal of A', let P' and Q' be two discrete $(A'/\mathfrak{J}')$-modules, let $u' : P' \to Q'$ be a surjective A'-homomorphism, and let $v' : M' \to Q'$ be a continuous A'-homomorphism. There is an open ideal $\mathfrak{J}$ of A such that $\mathfrak{J}A' \subset \mathfrak{J}'$, so P' and Q' are also discrete $(A/\mathfrak{J})$-modules. Applying formal projectivity to the continuous composite $v : M \xrightarrow{j} M' \xrightarrow{v'} Q'$, one obtains a continuous A-homomorphism $w : M \to P'$ such that $v = u' \circ w$. Since P' is a topological A'-module, w factorizes as $M \xrightarrow{j} M' \xrightarrow{w'} P'$, where w' is a continuous A'-homomorphism; from $v' \circ j = (u' \circ w') \circ j$ one concludes that $v' = u' \circ w'$.

Now suppose that M is strictly formally projective. Let $(\mathfrak{J}_\lambda)$ (resp. (V_λ)) be a fundamental system of open ideals (resp. open submodules) in A (resp. M), with M/V_λ projective over $A/\mathfrak{J}_\lambda$, and let $(\mathfrak{J}'_\mu)$ be a fundamental system of open ideals in A'. A fundamental system of neighbourhoods of 0 in M' is formed by

$$W_{\lambda\mu} = \mathrm{Im}(M \otimes_A \mathfrak{J}'_\mu) + \mathrm{Im}(V_\lambda \otimes_A A'),$$

where λ and μ satisfy $\mathfrak{J}_\lambda A' \subset \mathfrak{J}'_\mu$. Since

$$(M \otimes_A A')/W_{\lambda\mu} = (M/V_\lambda) \otimes_{A/\mathfrak{J}_\lambda} (A'/\mathfrak{J}'_\mu)$$

and M/V_λ is projective over $A/\mathfrak{J}_\lambda$, the module $M'/W_{\lambda\mu}$ is projective over $A'/\mathfrak{J}'_\mu$.

□

19.3. Formally smooth algebras

Definition (19.3.1). — Let A be a topological ring, B a topological A-algebra. We say that B is a *formally smooth* A-algebra if, for every discrete topological A-algebra C, and every nilpotent ideal $\mathfrak{J}$ of C, every continuous A-homomorphism $u : B \to C/\mathfrak{J}$ *factorizes* as $B \xrightarrow{v} C \xrightarrow{\varphi} C/\mathfrak{J}$, where v is a continuous A-homomorphism and φ the canonical homomorphism.

The definition (19.3.1) amounts to saying that the following property holds: $\mathbf{0}_{\mathbf{IV\text{-}1}}$ | 80

(P) For every open ideal $\mathfrak{R}$ of the A-algebra B and every A-homomorphism $u' : B/\mathfrak{R} \to C/\mathfrak{J}$, there exists an open ideal $\mathfrak{R}' \subset \mathfrak{R}$ of B such that the homomorphism $B \to B/\mathfrak{R} \xrightarrow{u'} C/\mathfrak{J}$ factorizes as
$$B \longrightarrow B/\mathfrak{R}' \xrightarrow{v'} C \longrightarrow C/\mathfrak{J},$$
where v' is an A-homomorphism.

Indeed, if $u : B \to C/\mathfrak{J}$ is a continuous A-homomorphism, its kernel $\mathfrak{R}$ is an open ideal of B, and if (P) is satisfied, it suffices to take u' and to take for v the composition $B \to B/\mathfrak{R} \xrightarrow{v'} C$ to satisfy the conditions of (19.3.1). Conversely, suppose B is a formally smooth A-algebra; let there be given an open ideal $\mathfrak{R}$ of B and a continuous A-homomorphism $u' : B/\mathfrak{R} \to C/\mathfrak{J}$; if $v : B \to C$ is a continuous A-homomorphism such that u factorizes as $B \xrightarrow{v} C \to C/\mathfrak{J}$, the ideal $\mathfrak{R}' = \operatorname{Ker}(v) \cap \mathfrak{R}$ of B is open and contained in $\mathfrak{R}$; by taking v' to factorize as $B \to B/\mathfrak{R}' \xrightarrow{v'} C$, and v' clearly satisfies the condition (P).

Proposition (19.3.2). — *Let A be a discrete ring, V a projective A-module; the symmetric algebra $B = \mathrm{S}^{\bullet}_A(V)$, equipped with the discrete topology, is a formally smooth A-algebra.*

Proof. Indeed, the notations C and $\mathfrak{J}$ having the same meaning as in (19.3.1), let $u : B \to C/\mathfrak{J}$; as V is projective, u_1, the restriction of u to V, lifts to a homomorphism of A-modules $v_1 : V \to C$ such that u_1 factorizes as $V \xrightarrow{v_1} C \xrightarrow{\varphi} C/\mathfrak{J}$; and v_1 extends to a homomorphism of A-algebras $v : \mathrm{S}^{\bullet}_A(V) \to C$, and v coincides with u in V, hence $\varphi \circ v = u$, which proves the proposition. □

Corollary (19.3.3). — *If A is a discrete ring, every polynomial algebra $B = A[T_\alpha]_{\alpha \in I}$, equipped with the discrete topology, is a formally smooth A-algebra.*

Proposition (19.3.4). — *Let A be a topological ring, and let $B = A[[T_\alpha]]_{\alpha \in I}$ be a ring of formal power series $\sum c_\lambda T^\lambda$ (algebra large over A of the monoid $\mathbf{N}^{(I)}$, identified as a topological A-module with the product $A^{\mathbf{N}^{(I)}}$). If one equips B with the product topology, B is a formally smooth topological A-algebra.*

Let $(\mathfrak{L}_\mu)_{\mu \in M}$ be a fundamental system of open ideals of A. For every finite subset H of I, every $\mu \in M$, and every integer n, let $\mathfrak{K}_{H,\mu,n}$ be the neighbourhood of 0 in B consisting of the families (c_λ) such that $c_\lambda \in \mathfrak{L}_\mu$ whenever $\lambda = (\lambda_\alpha)_{\alpha \in I}$ satisfies $\lambda_\alpha = 0$ for $\alpha \notin H$ and $\sum_{\alpha \in H} \lambda_\alpha \leqslant n$. The $\mathfrak{K}_{H,\mu,n}$ plainly form a fundamental system of neighbourhoods of 0 in B and are ideals of B; hence the product topology is compatible with the A-algebra structure of B.

We first record the following lemma.

Lemma (19.3.4.1). — *Let E be a discrete A-algebra.*

(i) *If $f : B \to E$ is a continuous A-homomorphism, there exists a finite subset H of I such that $f(T_\alpha) = 0$ for $\alpha \notin H$, and $f(T_\alpha)$ is nilpotent in E for every $\alpha \in H$.*

(ii) *Conversely, let H be a finite subset of I and $(z_\alpha)_{\alpha \in H}$ a family of nilpotent elements of E. There exists a unique continuous A-homomorphism $g : B \to E$ such that $g(T_\alpha) = z_\alpha$ for $\alpha \in H$ and $g(T_\alpha) = 0$ for $\alpha \notin H$.*

$\mathbf{0}_{\mathbf{IV\text{-}1}}$ | 81

Proof. Assertion (i) follows immediately from the fact that $f^{-1}(0)$ is a neighbourhood of 0 in the product A-module $A^{\mathbf{N}^{(I)}}$: thus $f(T^\lambda) = 0$ except for finitely many $\lambda \in \mathbf{N}^{(I)}$.

For (ii), the polynomial ring $B' = A[T_\alpha]_{\alpha \in I}$ is dense in B. Existence and uniqueness on B' are immediate. Continuity follows from nilpotence: if $z_\alpha^n = 0$ for all $\alpha \in H$, then $g(T^\lambda) = 0$ unless $\lambda_\alpha = 0$ for $\alpha \notin H$ and $\lambda_\alpha \leqslant n$ for $\alpha \in H$, and there are only finitely many such λ. □

Proof of Proposition (19.3.4). Let C and $\mathfrak{J}$ have the meaning of (19.3.1), and let $u : B \to C/\mathfrak{J}$ be a continuous A-homomorphism. By (19.3.4.1), $u(T_\alpha) = 0$ except for the indices in a finite subset H of I, and the elements $z_\alpha = u(T_\alpha)$, $\alpha \in H$, are nilpotent in $C/\mathfrak{J}$. Since $\mathfrak{J}$ is nilpotent, choose nilpotent elements $x_\alpha \in C$ lifting the z_α. The lemma gives a continuous A-homomorphism $v : B \to C$ such that $v(T_\alpha) = x_\alpha$ for $\alpha \in H$ and $v(T_\alpha) = 0$ otherwise. Then u is the composite $B \xrightarrow{v} C \to C/\mathfrak{J}$. □

Proposition (19.3.5). — *Let A be a topological ring.*

(i) *A is a formally smooth A-algebra.*
(ii) *If B is a formally smooth A-algebra and C a formally smooth B-algebra, then C is a formally smooth A-algebra.*
(iii) *Let B be a formally smooth A-algebra, A' a topological A-algebra; then the topological A'-algebra $B \otimes_A A'$ ($\mathbf{0_I}$, 7.7.5 and 7.7.6) is formally smooth.*
(iv) *Let B be a topological A-algebra, S (resp. T) a multiplicative subset of A (resp. B) such that the canonical image of S in B is contained in T. If B is a formally smooth A-algebra, then $T^{-1}B$ is an $S^{-1}A$-algebra formally smooth.*
(v) *Let B_i ($1 \leqslant i \leqslant n$) be topological A-algebras. For $\prod_{i=1}^n B_i$ to be a formally smooth A-algebra, it is necessary and sufficient that each of the B_i be so.*

$\mathbf{0_{IV\text{-}1}}$ | 82

Proof. (i) If C is a discrete A-algebra and $\varphi : C \to C/\mathfrak{J}$ is the canonical homomorphism onto any quotient A-algebra of C, the *only* A-homomorphism from A to $C/\mathfrak{J}$ is the composite $A \xrightarrow{\psi} C \xrightarrow{\varphi} C/\mathfrak{J}$, where ψ defines the A-algebra structure of C; since ψ is continuous, the condition of (19.3.1) is trivially satisfied.

(ii) Let $\alpha : A \to B$ and $\beta : B \to C$ be the continuous homomorphisms defining respectively the A-algebra structure on B and the B-algebra structure on C, so that $\beta \circ \alpha$ defines the A-algebra structure on C. Let E be a discrete A-algebra, $\mathfrak{L}$ a nilpotent ideal of E, and $u : C \to E/\mathfrak{L}$ a continuous A-homomorphism. Since B is a formally smooth A-algebra, $u \circ \beta : B \to E/\mathfrak{L}$ factorizes as $B \xrightarrow{v} E \to E/\mathfrak{L}$, where v is a continuous A-homomorphism. The homomorphisms v and $u \circ \beta$ then define on E and $E/\mathfrak{L}$ respectively topological B-algebra structures for which $E/\mathfrak{L}$ is still the discrete quotient algebra of E. Moreover, u is a continuous B-homomorphism, and hence factorizes as $C \xrightarrow{w} E \to E/\mathfrak{L}$, where w is a continuous B-homomorphism; since $w \circ \beta \circ \alpha$ is the homomorphism defining the A-algebra structure on E, w is indeed a continuous A-homomorphism.

(iii) Let C be a discrete topological A'-algebra, $\mathfrak{J}$ a nilpotent ideal of C, and $u : B \otimes_A A' \to C/\mathfrak{J}$ a continuous A'-homomorphism. Composing u with the canonical homomorphism $\rho : B \to B \otimes_A A'$ gives a continuous A-homomorphism, which by hypothesis factorizes as $B \xrightarrow{v} C \to C/\mathfrak{J}$. If $\sigma : A' \to B \otimes_A A'$ and $w : A' \to C$ are the canonical homomorphisms, equality of the composites $A \to B \xrightarrow{v} C$ and $A \to A' \xrightarrow{w} C$ gives a continuous ring homomorphism $f : B \otimes_A A' \to C$ such that $v = f \circ \rho$ and $w = f \circ \sigma$ ($\mathbf{0_I}$, 7.7.6). Comparing the composites from B and A' shows that u factorizes as $B \otimes_A A' \xrightarrow{f} C \to C/\mathfrak{J}$, proving (iii).

(iv) The topology on $S^{-1}A$ (resp. $T^{-1}B$) has as a fundamental system of neighbourhoods of 0 the ideals $S^{-1}\mathfrak{J}$ (resp. $T^{-1}\mathfrak{R}$), where $\mathfrak{J}$ (resp. $\mathfrak{R}$) ranges over a fundamental system of open ideals of A (resp. B) ($\mathbf{0_I}$, 7.6.1). Let C be a discrete topological $S^{-1}A$-algebra, $\mathfrak{J}$ a nilpotent ideal of C, and $u : T^{-1}B \to C/\mathfrak{J}$ a continuous $S^{-1}A$-homomorphism. The composite $B \to T^{-1}B \xrightarrow{u} C/\mathfrak{J}$ factorizes as $B \xrightarrow{v} C \to C/\mathfrak{J}$. For every $t \in T$, $u(t/1)$ is invertible in $C/\mathfrak{J}$; since $\mathfrak{J}$ is nilpotent, $v(t)$ is invertible in C ($\mathbf{0_I}$, 7.1.12). Thus v factorizes through a continuous homomorphism $w : T^{-1}B \to C$ ($\mathbf{0_I}$, 7.6.6). The canonical diagrams show that w is an $S^{-1}A$-homomorphism and that u is the composite $T^{-1}B \xrightarrow{w} C \to C/\mathfrak{J}$.

(v) This is immediate: giving a continuous A-homomorphism from $B = \prod_{i=1}^n B_i$ to C (resp. $C/\mathfrak{J}$) is equivalent to giving n continuous A-homomorphisms $B_i \to C$ (resp. $B_i \to C/\mathfrak{J}$), and every such homomorphism from a factor gives by composition a continuous homomorphism from B.

□

$\mathbf{0}_{\mathbf{IV\text{-}1}}$ | 83

Proposition (19.3.6). — *Let A be a topological ring, B a topological A-algebra, $\widehat{A}$ and $\widehat{B}$ the separated completions of A and B, so that $\widehat{B}$ is a topological $\widehat{A}$-algebra. The following conditions are equivalent:*

a) B is a formally smooth A-algebra.
b) $\widehat{B}$ is a formally smooth A-algebra.
c) $\widehat{B}$ is a formally smooth $\widehat{A}$-algebra.

Proof. Of course, the structure of $\widehat{A}$-algebra on $\widehat{B}$ is defined by the homomorphism $\widehat{\varphi}$, where $\varphi : A \to B$ is the homomorphism defining the structure of A-algebra on B. As every discrete A-algebra C is separated and complete, it is also a $\widehat{A}$-algebra (by canonical prolongation of the homomorphism from A to C), and a continuous A-homomorphism from B to C gives by extension a canonical $\widehat{A}$-homomorphism (and *a fortiori* an A-homomorphism) from $\widehat{B}$ to C (in other words, every continuous A-homomorphism $B \to C$ factorizes as $B \to \widehat{B} \to C$ uniquely). These remarks and the definition (19.3.1) immediately imply the proposition. ☐

Corollary (19.3.7). — *Under the hypotheses of (19.3.5), (iv), the topological $A\{S^{-1}\}$-algebra $B\{T^{-1}\}$ is formally smooth.*

This follows from the definitions ($\mathbf{0_I}$, 7.6.1 and 7.6.7), (19.3.5), (iv), and (19.3.6).

Proposition (19.3.8). — *Let A be a topological ring, B a topological A-algebra, and suppose that for every open ideal $\mathfrak{K}$ of B, $\mathfrak{K}^2$ is also open. Let A', B' be the rings A and B equipped with topologies finer than the initial topologies, and suppose that the canonical homomorphism $\varphi : A \to B$ is still a continuous homomorphism from A' to B'. Then, if B' is a formally smooth A'-algebra, B is a formally smooth A-algebra.*

Proof. It suffices to apply the following lemma: ☐

Lemma (19.3.8.1). — *Let C be a discrete A-algebra, $\mathfrak{J}$ a nilpotent ideal of C. Suppose that the square of every open ideal of B is also open. Then, if a composite homomorphism $v : B \xrightarrow{u} C \to C/\mathfrak{J}$ is continuous, the homomorphism u is continuous.*

Proof. Indeed, $\mathfrak{K} = u^{-1}(\mathfrak{J})$ is the kernel of v, and it is open by hypothesis; as $\mathfrak{J}^n = 0$, $\mathfrak{K}^n$ is contained in $\operatorname{Ker}(u)$; but by induction on h, it follows from the hypothesis that $\mathfrak{K}^{2^h}$ is also open, hence $\mathfrak{K}^n$ for all n, and consequently $\operatorname{Ker}(u)$ is also open, which proves our assertion. ☐

Note that the hypothesis on B means that the topology of B is the supremum of the $\mathfrak{K}$-preadic topologies, where $\mathfrak{K}$ ranges over the open ideals of B. If B is a preadic ring ($\mathbf{0_I}$, 7.1.9), this condition is always satisfied.

(19.3.9). We will now see that the property of being formally smooth implies properties of "lifting" of homomorphisms under more general conditions than those of the definition (19.3.1).

$\mathbf{0}_{\mathbf{IV\text{-}1}}$ | 84

Proposition (19.3.10). — *Let A be a topological ring, B a formally smooth topological A-algebra. Let C be a topological A-algebra, $\mathfrak{J}$ an ideal of C, satisfying the following conditions:*

1° *C is metrizable and complete.*
2° *$\mathfrak{J}$ is closed and the sequence $(\mathfrak{J}^n)$ tends to 0.*

Then, every continuous A-homomorphism $u : B \to C/\mathfrak{J}$ factorizes as $B \xrightarrow{v} C \to C/\mathfrak{J}$, where v is a continuous A-homomorphism.

Proof. Let $(\mathfrak{Q}_n)$ be a decreasing sequence of ideals of C forming a fundamental system of neighbourhoods of 0 in this algebra; as there exists k such that $\mathfrak{J}^k \subset \mathfrak{Q}_n$, $(\mathfrak{J} + \mathfrak{Q}_n)/\mathfrak{Q}_n$ is nilpotent. For all n, let u_n be the continuous A-homomorphism $B \xrightarrow{u} C/\mathfrak{J} \to C/(\mathfrak{J} + \mathfrak{Q}_n) = (C/\mathfrak{Q}_n)/((\mathfrak{J} + \mathfrak{Q}_n)/\mathfrak{Q}_n)$; by hypothesis u_n factorizes as $B \xrightarrow{v_n} C/\mathfrak{Q}_n \xrightarrow{\varphi_n} C/(\mathfrak{J} + \mathfrak{Q}_n)$, where v_n is a continuous A-homomorphism. Let us show that one can choose step by step the v_n so that v_n factorizes as

$$B \xrightarrow{v_{n+1}} C/\mathfrak{Q}_{n+1} \longrightarrow C/\mathfrak{Q}_n$$

for all n (in other words, the v_n form a *projective system* of homomorphisms). This will follow from the following lemma: ☐

Lemma (19.3.10.1). — *Let B be a formally smooth A-algebra, E, E' two discrete topological A-algebras, $\mathfrak{N}$ (resp. $\mathfrak{N}'$) a nilpotent ideal of E (resp. E'), $f : E \to E'$ a surjective A-homomorphism such that $f(\mathfrak{N}) \subset \mathfrak{N}'$, $f' : E/\mathfrak{N} \to E'/\mathfrak{N}'$ the homomorphism induced by f by passing to quotients. Let $u : B \to E/\mathfrak{N}$ be a continuous A-homomorphism, u' the composite homomorphism $B \xrightarrow{u} E/\mathfrak{N} \xrightarrow{f'} E'/\mathfrak{N}'$, and let $v' : B \to E'$ be a continuous A-homomorphism such that u' factorizes as $B \xrightarrow{v'} E' \to E'/\mathfrak{N}'$. Then there exists a continuous A-homomorphism $v : B \to E$ such that v' factorizes as $B \xrightarrow{v} E \xrightarrow{f} E'$.*

Proof. In the commutative diagram

$$\begin{tikzcd} E \arrow[r, "f"] \arrow[d] & E' \arrow[d] \\ E/\mathfrak{N} \arrow[r, "f'"'] & E'/\mathfrak{N}' \end{tikzcd}$$

all the homomorphisms are surjective. If $\mathfrak{L} = \operatorname{Ker}(f)$, then E' is identified with $E/\mathfrak{L}$ and $\mathfrak{N}'$ with $(\mathfrak{N} + \mathfrak{L})/\mathfrak{L}$. We shall use the following elementary lemma. □

Lemma (19.3.10.2). — *Let F be a ring, not necessarily commutative, and let $\mathfrak{a}$ and $\mathfrak{b}$ be two-sided ideals of F. Then the fibre product*

$$(F/\mathfrak{a}) \times_{F/(\mathfrak{a}+\mathfrak{b})} (F/\mathfrak{b})$$

is canonically identified with $F/(\mathfrak{a} \cap \mathfrak{b})$.

Proof. This is the special case of (18.1.7) obtained by replacing, in diagram (18.1.7.1), G by $F/(\mathfrak{a} \cap \mathfrak{b})$, $\mathfrak{J}'$ by $\mathfrak{b}/(\mathfrak{a} \cap \mathfrak{b})$, F by $F/\mathfrak{b}$, $\mathfrak{K}$ by $(\mathfrak{a} + \mathfrak{b})/\mathfrak{b}$, B by $F/(\mathfrak{a} + \mathfrak{b})$, and θ by the canonical isomorphism

$$(\mathfrak{a} + \mathfrak{b})/\mathfrak{b} \xrightarrow{\sim} \mathfrak{a}/(\mathfrak{a} \cap \mathfrak{b}).$$

□

$0_{\text{IV-1}}$ | 85

Continuation of the proof of Lemma (19.3.10.1). By (19.3.10.2), the commutativity of

$$\begin{tikzcd} B \arrow[r, "v'"] \arrow[d, "u"'] & E' = E/\mathfrak{L} \arrow[d] \\ E/\mathfrak{N} \arrow[r, "f'"'] & E'/\mathfrak{N}' \end{tikzcd}$$

gives a homomorphism $w : B \to E/(\mathfrak{N} \cap \mathfrak{L})$ through which both v' and u factor. Its kernel contains $\operatorname{Ker}(u) \cap \operatorname{Ker}(v')$, and is therefore open; thus w is continuous. The ideal $\mathfrak{N} \cap \mathfrak{L}$ is nilpotent, so formal smoothness of B gives a continuous A-homomorphism $v : B \to E$ lifting w. It follows at once that $f \circ v = v'$, as required. □

Continuation of the proof of Proposition (19.3.10). Apply (19.3.10.1) with

$$E = C/\mathfrak{Q}_{n+1}, \quad E' = C/\mathfrak{Q}_n,$$

$$\mathfrak{N} = (\mathfrak{J} + \mathfrak{Q}_{n+1})/\mathfrak{Q}_{n+1}, \quad \mathfrak{N}' = (\mathfrak{J} + \mathfrak{Q}_n)/\mathfrak{Q}_n,$$

and with u, u', v' replaced respectively by u_{n+1}, u_n, v_n. It produces v_{n+1} compatible with v_n.

Since C is separated and complete, $C = \varprojlim C/\mathfrak{Q}_n$, and $v = \varprojlim v_n$ is a continuous A-homomorphism $B \to C$. Because $\mathfrak{J}$ is closed, $\mathfrak{J} = \bigcap_n (\mathfrak{J} + \mathfrak{Q}_n)$. Moreover, $C/\mathfrak{J}$ is metrizable and complete and the ideals $(\mathfrak{J} + \mathfrak{Q}_n)/\mathfrak{J}$ form a fundamental system of neighbourhoods of 0; hence

$$C/\mathfrak{J} = \varprojlim C/(\mathfrak{J} + \mathfrak{Q}_n).$$

Thus $\varprojlim \varphi_n$ is the canonical map $\varphi : C \to C/\mathfrak{J}$, while $\varprojlim u_n = u$. Consequently $u = \varphi \circ v$. □

Corollary (19.3.11). — *Let A be a topological ring, B a formally smooth topological A-algebra, C a Noetherian complete local ring, $\mathfrak{J}$ an ideal distinct from C, $\varphi : A \to C$ a continuous homomorphism making C a topological A-algebra. Then every continuous A-homomorphism $u_0 : B \to C_0 = C/\mathfrak{J}$ factorizes as $B \xrightarrow{u} C \to C/\mathfrak{J}$, where u is a continuous A-homomorphism.*

Proof. All the conditions of (19.3.10) are indeed satisfied ($\mathbf{0_I}$, 7.3.5). □

Proposition (19.3.12). — *Let A be a topological ring, B a formally smooth A-algebra, C a topological A-algebra, and $\mathfrak{J}$ an ideal of C, satisfying the following conditions:*

1° *There exists a fundamental system of open ideals $\mathfrak{Q}_\lambda$ of C, such that the $C_\lambda = C/\mathfrak{Q}_\lambda$ are Artinian rings and that $C \xrightarrow{\sim} \varprojlim C_\lambda$.*

2° *$\mathfrak{J}$ is closed in C and topologically nilpotent.*

3° *The square of every open ideal of B is open.*

Under these conditions, every continuous A-homomorphism $u : B \to C/\mathfrak{J}$ factorizes as $B \xrightarrow{v} C \to C/\mathfrak{J}$, where v is a continuous A-homomorphism.

Proof. Let $\mathfrak{J}_\lambda = (\mathfrak{J} + \mathfrak{Q}_\lambda)/\mathfrak{Q}_\lambda$ be the canonical image of $\mathfrak{J}$ in C_λ, which is a nilpotent ideal, and let u_λ be the composite $B \xrightarrow{u} C/\mathfrak{J} \to C_\lambda/\mathfrak{J}_\lambda = C/(\mathfrak{J} + \mathfrak{Q}_\lambda)$. We first show that every A-homomorphism $w : B \to C$ through which u factorizes is necessarily continuous. For every λ, there is an open ideal $\mathfrak{R}$ of B such that $u(\mathfrak{R}) \subset (\mathfrak{J} + \mathfrak{Q}_\lambda)/\mathfrak{J}$, and hence $w(\mathfrak{R}) \subset \mathfrak{J} + \mathfrak{Q}_\lambda$. There is therefore a power $\mathfrak{R}^{2^m}$ such that $w(\mathfrak{R}^{2^m}) \subset \mathfrak{Q}_\lambda$; this proves the assertion, since $\mathfrak{R}^{2^m}$ is open in B. It is thus enough to find an A-homomorphism w with the preceding property without separately requiring continuity.

Now

$$\mathrm{Hom}_A(B, C) = \varprojlim_\lambda \mathrm{Hom}_A(B, C_\lambda).$$

For each λ, $\mathrm{Hom}_A(B, C_\lambda)$ is closed in the C_λ-module C_λ^B with its product topology, for which it is linearly compact because C_λ is Artinian. For each λ, let W_λ be the set of $w_\lambda \in \mathrm{Hom}_A(B, C_\lambda)$ such $\mathbf{0_{IV\text{-}1}}$ | 86 that u_λ factorizes as $B \xrightarrow{w_\lambda} C_\lambda \to C_\lambda/\mathfrak{J}_\lambda$. The set W_λ is a closed affine subspace of the C_λ-module $\mathrm{Hom}_A(B, C_\lambda)$ and is nonempty because B is formally smooth. In $E_\lambda = \prod_{\mu \leqslant \lambda} \mathrm{Hom}_A(B, C_\mu)$, let U_λ be the closed affine subspace of the families $(w_\mu)_{\mu \leqslant \lambda}$ such that $w_\mu = \varphi_{\mu\lambda} \circ w_\lambda$ for $\mu \leqslant \lambda$ and $w_\lambda \in W_\lambda$, where $\varphi_{\mu\lambda} : C_\lambda \to C_\mu$ is the canonical homomorphism. Finally let V_λ be the closed affine subspace in $\prod_\mu \mathrm{Hom}_A(B, C_\mu)$ equal to the product of U_λ and the $\mathrm{Hom}_A(B, C_\mu)$ for $\mu \not\leqslant \lambda$. It remains to observe that the intersection of the V_λ is nonempty, for an element w of this intersection belongs by definition to $\varprojlim_\lambda \mathrm{Hom}_A(B, C_\lambda)$.[20]

Moreover, since $\mathfrak{J}$ is closed and $C = \varprojlim_\lambda C_\lambda$ is linearly compact, $C/\mathfrak{J}$ identifies with $\varprojlim_\lambda C_\lambda/\mathfrak{J}_\lambda$, and the canonical map $\psi : C \to C/\mathfrak{J}$ with $\varprojlim_\lambda \psi_\lambda$, where $\psi_\lambda : C_\lambda \to C_\lambda/\mathfrak{J}_\lambda$ is canonical. As in (19.3.10), we conclude that $\psi \circ w = u$. □

19.4. First criteria for formal smoothness

Proposition (19.4.1). — *Let A be a topological ring, B a topological A-algebra; suppose that there exist two decreasing filtering families $(\mathfrak{J}_\alpha)_{\alpha \in I}$, $(\mathfrak{R}_\alpha)_{\alpha \in I}$ of ideals of A and B respectively, such that:*

1° *$(\mathfrak{J}_\alpha)$ tends to 0 in A and $(\mathfrak{R}_\alpha)$ tends to 0 in B;*

2° *for all $\alpha \in I$, we have $\mathfrak{J}_\alpha B \subset \mathfrak{R}_\alpha$ (so that $B/\mathfrak{R}_\alpha$ is an $(A/\mathfrak{J}_\alpha)$-topological algebra);*

3° *for all $\alpha \in I$, $B/\mathfrak{R}_\alpha$ is a formally smooth $(A/\mathfrak{J}_\alpha)$-algebra.*

Then B is a formally smooth A-algebra.

Proof. Let C be a discrete A-algebra, $\mathfrak{L}$ a nilpotent ideal of C, and $\mathfrak{R}$ an open ideal of B; by hypothesis there exists $\alpha \in I$ such that $\mathfrak{R}_\alpha \subset \mathfrak{R}$, so $B/\mathfrak{R}$ is a quotient of $B/\mathfrak{R}_\alpha$. Every A-homomorphism $u' : B/\mathfrak{R} \to C/\mathfrak{L}$ is also an $(A/\mathfrak{J}_\alpha)$-homomorphism, so there exists an open ideal $\mathfrak{R}'$ of B such that $\mathfrak{R}_\alpha \subset \mathfrak{R}' \subset \mathfrak{R}$ and the composite $B/\mathfrak{R}_\alpha \to B/\mathfrak{R} \xrightarrow{u'} C/\mathfrak{L}$ factorizes as $B/\mathfrak{R}_\alpha \to B/\mathfrak{R}' \to C \to C/\mathfrak{L}$, where the second homomorphism is an $(A/\mathfrak{J}_\alpha)$-homomorphism. The conclusion follows from the remark after (19.3.1). □

[20] The printed proof has a gap here: sets of algebra homomorphisms are not modules under pointwise addition, and for a general nilpotent ideal the lift fibre need not be an affine subspace. Thus the stated linear-compactness argument does not by itself prove that this intersection is nonempty; a separate compatible-lifting argument is required.

Corollary (19.4.2). — *Let A be a topological ring, B a topological A-algebra, $(\mathfrak{J}_\alpha)_{\alpha\in I}$ a decreasing filtering family of ideals of A tending to 0. For B to be a formally smooth A-algebra, it is necessary and sufficient that for all $\alpha \in I$, setting $A_\alpha = A/\mathfrak{J}_\alpha$, $B_\alpha = B/\mathfrak{J}_\alpha B$, B_α be a formally smooth A_α-algebra.*

Proof. The condition is sufficient by (19.4.1), and it is also necessary by (19.3.5), (iii). □

Proposition (19.4.3). — *Let A be a topological ring, B a topological A-algebra. Suppose that for every discrete A-algebra C and every ideal $\mathfrak{J}$ of C such that $\mathfrak{J}^2 = 0$, every continuous A-homomorphism $u : B \to C/\mathfrak{J}$ factorizes as $B \xrightarrow{v} C \to C/\mathfrak{J}$, where v is a continuous A-homomorphism. Then B is a formally smooth A-algebra.*

Proof. With the same notation, let $\mathfrak{N}$ be any nilpotent ideal of C, and consider a continuous A-homomorphism $u' : B \to C/\mathfrak{N}$. Suppose $\mathfrak{N}^m = 0$, and set $C_i = C/\mathfrak{N}^i$ for $1 \leqslant i \leqslant m$, so that $C_m = C$, that $\mathfrak{N}^{i-1}/\mathfrak{N}^i$ is an ideal of square zero in C_i, and $C_i = C_{i+1}/\mathfrak{J}_{i+1}$; the hypothesis then gives by induction on i the existence of continuous A-homomorphisms $u_i : B \to C_i$ such that $u_1 = u'$ and that u_i factorizes as $B \xrightarrow{u_{i+1}} C_{i+1} \to C_{i+1}/\mathfrak{J}_{i+1} = C_i$; whence the conclusion. □

Proposition (19.4.4). — *Let A be a topological ring, B a topological A-algebra (commutative). For B to be a formally smooth A-algebra, it is necessary and sufficient that for every discrete topological B-module L, annihilated by an open ideal of B, we have (cf. (18.5.1))* $\mathbf{0_{IV\text{-}1}}$ | 87

$$\mathrm{Exalcotop}_A(B, L) = 0.$$

Proof. Let $(\mathfrak{N}_\lambda)$ be a fundamental decreasing system of open ideals of B and set $B_\lambda = B/\mathfrak{N}_\lambda$. Consider a discrete topological A-algebra C and an ideal $\mathfrak{J}$ of C such that $\mathfrak{J}^2 = 0$, so that C is an A-extension of $C/\mathfrak{J}$ by $\mathfrak{J}$; suppose given an A-homomorphism $u : B_\lambda \to C/\mathfrak{J}$ and form the A-extension E_λ of B_λ by $\mathfrak{J}$, inverse image of C by the homomorphism u (18.2.5); it is a topological A-algebra for the discrete topology. If $\mathrm{Exalcotop}_A(B, L) = 0$, there exists by definition (18.5.1) a μ such that $\mathfrak{N}_\mu \subset \mathfrak{N}_\lambda$ and the inverse image extension E_μ is A-trivial; but this means (18.1.6) that there exists a continuous A-homomorphism $v : B_\mu \to E_\lambda$ such that the canonical homomorphism $B_\mu \to B_\lambda$ factorizes as $B_\mu \xrightarrow{v} E_\lambda \to B_\lambda$; we conclude immediately that $B_\mu \to B_\lambda \xrightarrow{u} C/\mathfrak{J}$ factorizes as $B_\mu \xrightarrow{v} E_\lambda \to C \to C/\mathfrak{J}$, and this proves, by virtue of (19.3.1) and (19.4.3), that B is a formally smooth A-algebra. The converse is immediate, applying (19.3.1) to the case where C is a topological A-algebra which is an A-extension of B_λ by L, and to the identical homomorphism $B_\lambda \to B_\lambda = C/L$. □

When A and B are discrete rings, the criterion of formal smoothness (19.4.4) reduces to

(19.4.4.1) $$\mathrm{Exalcom}_A(B, L) = 0 \qquad \text{for all } B\text{-modules } L;$$

in other words, *every commutative A-extension of B by a B-module must be A-trivial*.

Corollary (19.4.5). — *Let A be a topological ring (commutative), B a topological A-algebra (commutative).*

(i) *Suppose that B is a formally smooth A-algebra. Then, for every open ideal $\mathfrak{N}$ of B, every $(B/\mathfrak{N})$-module L, and every Hochschild A-bilinear symmetric 2-cocycle f of $(B/\mathfrak{N}) \times (B/\mathfrak{N})$ in L (18.4.3), there exists an open ideal $\mathfrak{N}' \subset \mathfrak{N}$ such that, if $\varphi : B/\mathfrak{N}' \to B/\mathfrak{N}$ is the canonical homomorphism, $f \circ (\varphi \times \varphi)$ is a Hochschild A-bilinear 2-coboundary of $(B/\mathfrak{N}') \times (B/\mathfrak{N}')$ in L.*

(ii) *If B is a formally projective A-module (19.2.1) and if the condition of* (i) *is satisfied, B is a formally smooth A-algebra.*

Proof. (i) The 2-cocycle f defines an A-extension of Hochschild C of $B/\mathfrak{N}$ by L (18.4.3). Applying (19.3.1) to C, to the ideal of square zero L of C, and to the identical homomorphism $B/\mathfrak{N} \to B/\mathfrak{N} = C/L$, we deduce the condition (i) by virtue of (18.4.3).

(ii) Let us apply the criterion (19.4.3), considering an open ideal $\mathfrak{J}$ of A, an open ideal $\mathfrak{N}$ of B, and an $(A/\mathfrak{J})$-extension E of $B/\mathfrak{N}$ by L. As B is a formally projective A-module, the canonical continuous A-linear map $\rho : B \to B/\mathfrak{N}$ factorizes as $B \xrightarrow{w} E \to B/\mathfrak{N}$, where w is a continuous A-linear map (19.2.1), which itself factorizes as $B \to B/\mathfrak{N}' \xrightarrow{w'} E$ where $\mathfrak{N}'$ is an open ideal of B contained in $\mathfrak{N}$; replacing $\mathfrak{J}$ by a smaller ideal, one can suppose that $\mathfrak{J}B \subset \mathfrak{N}'$. Then the inverse image of the extension E of $B/\mathfrak{N}$ by L, via the canonical homomorphism

$B/\mathfrak{R}' \to B/\mathfrak{R}$, is an $(A/\mathfrak{J})$-extension *of Hochschild* E' of $B/\mathfrak{R}'$ by L; applying (i) to a cocycle defining this extension (18.4.3), we conclude that there exists an open ideal $\mathfrak{R}'' \subset \mathfrak{R}'$ of B such that the inverse image E'' of E by $B/\mathfrak{R}'' \to B/\mathfrak{R}$ is A-trivial, Q.E.D. **0IV-1** | 88

□

Corollary (19.4.6). — *Let A be a topological ring, B a topological A-algebra which is a formally projective A-module. Let A' be an A-algebra equipped with the topology derived from that of A. Suppose furthermore that A' is a faithfully flat A-module, and that one of the following conditions is satisfied:*

1° *There exists a fundamental system $(\mathfrak{J}_\lambda)$ of open ideals of A and a fundamental system $(\mathfrak{M}_\lambda)$ of open ideals of B, with the same index set, such that for all λ we have $\mathfrak{J}_\lambda B \subset \mathfrak{M}_\lambda$ and $B/\mathfrak{M}_\lambda$ is a projective $(A/\mathfrak{J}_\lambda)$-module of finite type.*

2° *A' is a projective A-module of finite type.*

Then, for $B' = B \otimes_A A'$ (equipped with the tensor product topology) to be a formally smooth A'-algebra, it is necessary and sufficient that B be a formally smooth A-algebra.

Proof. The sufficiency of the condition is contained in (19.3.5), (iii), without any additional hypothesis on A'. To prove the converse, we apply the criterion (19.4.5); under hypothesis 2°, we will again denote by $(\mathfrak{M}_\lambda)$ a fundamental system of open ideals of B, and for each λ, by $\mathfrak{J}_\lambda$ an open ideal of A such that $\mathfrak{J}_\lambda B \subset \mathfrak{M}_\lambda$; in both cases, we set $A_\lambda = A/\mathfrak{J}_\lambda$, $B_\lambda = B/\mathfrak{M}_\lambda$, $A'_\lambda = A_\lambda \otimes_A A'$, $B'_\lambda = B_\lambda \otimes_A A'$. Let f be a Hochschild A_λ-bilinear symmetric 2-cocycle of $B_\lambda \times B_\lambda$ in a B_λ-module L; by extension of scalars, we deduce a Hochschild A'_λ-bilinear symmetric 2-cocycle of $B'_\lambda \times B'_\lambda$ in $L' = L \otimes_A A'$. As B' is by hypothesis a formally smooth A'-algebra, there exists by (19.4.5), (i), a μ such that $\mathfrak{M}_\mu \subset \mathfrak{M}_\lambda$ and such that, if $\varphi' : B'_\mu \to B'_\lambda$ is the canonical homomorphism, the image c' of $f' \circ (\varphi' \times \varphi')$ in the Hochschild group $\mathrm{H}^2_{A'_\mu}(B'_\mu, L')^s$ is zero; it is clear that if $\varphi : B_\mu \to B_\lambda$ is the canonical homomorphism, and c the class of $f \circ (\varphi \times \varphi)$ in the group $\mathrm{H}^2_{A_\mu}(B_\mu, L)^s$, then c' is the canonical image of c. Now, if $\mathrm{P}_\bullet$ is the complex relative to the rings A_μ and B_μ defined in (18.4.5), the analogous complex relative to the rings A'_μ and B'_μ is evidently $\mathrm{P}_\bullet \otimes_A A'$; under hypothesis 1°, the construction of $\mathrm{P}_\bullet$ shows that it is a projective A_μ-module of finite type. One concludes from Bourbaki, *Alg.*, chap. II, 3e éd., § 5, n° 3, prop. 7 that, under both hypotheses, one has, up to canonical isomorphism,

$$\mathrm{Hom}_{A'_\mu}(\mathrm{P}_\bullet \otimes_A A', L \otimes_A A') = \mathrm{Hom}_{A_\mu}(\mathrm{P}_\bullet, L) \otimes_A A'.$$

As A' is a flat A-module, one has by (18.4.5)

$$\mathrm{H}^2_{A'_\mu}(B'_\mu, L')^s = (\mathrm{H}^2_{A_\mu}(B_\mu, L)^s) \otimes_A A'$$

and one can therefore write $c' = c \otimes 1$; but as A' is a faithfully flat A-module, the hypothesis $c' = 0$ implies $c = 0$, which completes the proof. □

Proposition (19.4.7). — *Let A be a preadmissible topological ring, $\mathfrak{J}$ an ideal of definition of A ($\mathbf{0_I}$, 7.1.2), B a topological A-algebra which is a formally projective A-module. Consider the topological quotient rings $A_0 = A/\mathfrak{J}$, $B_0 = B/\mathfrak{J}B$; then, for B to be a formally smooth A-algebra, it is necessary and sufficient that B_0 be a formally smooth A_0-algebra.*

Proof. The necessity of the condition follows from (19.4.2). To see that it is sufficient, we first note that, by considering a fundamental system of open neighbourhoods of 0 in A formed by ideals $\mathfrak{J}_\lambda$ contained in $\mathfrak{J}$, one can by virtue of (19.4.2) reduce to the case where A is discrete, since $B/\mathfrak{J}_\lambda B$ is a formally projective $(A/\mathfrak{J}_\lambda)$-module (19.2.5); by definition of a preadmissible ring, $\mathfrak{J}$ is then nilpotent. It furthermore suffices to prove the proposition when $\mathfrak{J}^2 = 0$, for if $\mathfrak{J}^m = 0$, one applies it successively to the rings $A_k = A/\mathfrak{J}^k$ and $B_k = B/\mathfrak{J}^k B$ and to the ideal $\mathfrak{J}^{k-1}/\mathfrak{J}^k$ of A_k for $k = 2, 3, \ldots, m$, noting (19.2.5) that $B_k = B \otimes_A A_k$ is a formally projective A_k-module. Let us apply the criterion (19.4.5), (ii), considering an open ideal $\mathfrak{R}$ of B and a Hochschild A-bilinear symmetric 2-cocycle f of $(B/\mathfrak{R}) \times (B/\mathfrak{R})$ in a $(B/\mathfrak{R})$-module L. Consider first the special case where $\mathfrak{J}L = 0$, so that L can also be viewed as a $(B_0/\mathfrak{R}B_0)$-module, and f factorizes as **0IV-1** | 89

$$(B/\mathfrak{R}) \times (B/\mathfrak{R}) \longrightarrow (B_0/\mathfrak{R}B_0) \times (B_0/\mathfrak{R}B_0) \xrightarrow{f_0} L$$

where f_0 is a Hochschild bilinear symmetric 2-cocycle. By hypothesis, there exists an open ideal $\mathfrak{R}' \subset \mathfrak{R}$ in B and an A_0-linear map $g_0 : B_0/\mathfrak{R}'B_0 \to L$ such that $f_0(\varphi_0(x), \varphi_0(y)) = xg_0(y) - g_0(xy) + g_0(x)y$ for x, y in $B_0/\mathfrak{R}'B_0$, where $\varphi_0 : B_0/\mathfrak{R}'B_0 \to B_0/\mathfrak{R}B_0$ is the canonical homomorphism. One concludes immediately that the composite A-linear map $g : B/\mathfrak{R}' \to B_0/\mathfrak{R}'B_0 \xrightarrow{g_0} L$ is such that $dg = f \circ (\varphi \times \varphi)$, where $\varphi : B/\mathfrak{R}' \to B/\mathfrak{R}$ is the canonical homomorphism.

Let us now pass to the general case, and consider first the $(B/\mathfrak{R})$-module $L/\mathfrak{J}L = L'$, for which $\mathfrak{J}L' = 0$; if f' is the composite A-bilinear map $(B/\mathfrak{R}) \times (B/\mathfrak{R}) \xrightarrow{f} L \to L'$, f' is again a symmetric Hochschild 2-cocycle, and by the preceding, there exists an open ideal $\mathfrak{R}' \subset \mathfrak{R}$ in B and an A-linear map $g' : B/\mathfrak{R}' \to L'$ satisfying $dg' = f' \circ (\varphi' \times \varphi')$ for the canonical map $\varphi' : B/\mathfrak{R}' \to B/\mathfrak{R}$. As B is a formally projective A-module, there exists an A-linear map $g_1 : B/\mathfrak{R}'_1 \to L$ lifting $B/\mathfrak{R}'_1 \to B/\mathfrak{R}' \xrightarrow{g'} L'$. Consider then the Hochschild 2-cocycle

$$f_1(x, y) = f(\varphi_1(x), \varphi_1(y)) - xg_1(y) + g_1(xy) - g_1(x)y,$$

a symmetric A-bilinear map of $(B/\mathfrak{R}'_1) \times (B/\mathfrak{R}'_1)$ in L. The choice of g_1 implies that f_1 takes its values in $\mathfrak{J}L$. As $\mathfrak{J}(\mathfrak{J}L) = 0$, one can again apply the first case, so there exists an open ideal $\mathfrak{R}'' \subset \mathfrak{R}'_1$ and an A-linear map $g_2 : B/\mathfrak{R}'' \to \mathfrak{J}L$ such that

$$f_1(\varphi_2(x), \varphi_2(y)) = xg_2(y) - g_2(xy) + g_2(x)y$$

in $(B/\mathfrak{R}'') \times (B/\mathfrak{R}'')$, where $\varphi_2 : B/\mathfrak{R}'' \to B/\mathfrak{R}'_1$ is the canonical map; the A-linear map $g = g_2 + g_1 \circ \varphi_2 : B/\mathfrak{R}'' \to L$ therefore satisfies $dg = f \circ (\varphi \times \varphi)$ for the canonical map $\varphi : B/\mathfrak{R}'' \to B/\mathfrak{R}$. ☐

19.5. Formal smoothness and associated graded rings

(19.5.1). Let C be a topological ring (commutative), V a topological C-module, and consider the symmetric algebra $\mathbf{S}^*_C(V) = \bigoplus_{n \geqslant 0} \mathbf{S}^n_C(V)$, which we will canonically equip with a *linear topology*, compatible with its C-algebra structure. For this, consider an open submodule U of V, and the *graded ideal* $U.\mathbf{S}^*_C(V)$ it generates in $\mathbf{S}^*_C(V)$; we take as fundamental system of neighbourhoods of 0 in $\mathbf{S}^*_C(V)$ the set of sums $\mathfrak{a}.\mathbf{S}^*_C(V) + U.\mathbf{S}^*_C(V)$, where $\mathfrak{a}$ (resp. U) runs through a fundamental system of open ideals (resp. of open submodules) of C (resp. V). We note that if the topology of V is less fine than the topology derived from that of C, one can restrict to pairs $(\mathfrak{a}, U)$ such that $\mathfrak{a}V \subset U$, so $\mathfrak{a}.\mathbf{S}^*_C(V) + U.\mathbf{S}^*_C(V) = \mathfrak{a}.1_C + U.\mathbf{S}^*_C(V)$; in this case the topology induced on each $\mathbf{S}^n_C(V)$ for $n \geqslant 1$ has as a fundamental system of neighbourhoods of 0 the $U.\mathbf{S}^{n-1}_C(V)$, where U runs through the open submodules of V; in particular, on $V = \mathbf{S}^1_C(V)$, it coincides with the given topology (in general it is less fine than the latter). Furthermore, in all cases, the *topological algebra* $\mathbf{S}^*_C(V)$ thus defined is, for the categories of topological C-modules and of topological C-algebras, the solution of the same universal problem as for the categories of C-modules and C-algebras. Indeed, let E be a topological C-algebra, $u : V \to E$ a homomorphism of C-modules, $\mathbf{S}(u) = \widetilde{u}$ its canonical extension to $\mathbf{S}^*_C(V)$. Suppose u continuous; then, if $\mathfrak{b}$ is an open ideal of E, its inverse image $U = u^{-1}(\mathfrak{b})$ is an open C-submodule of V, and the image by $\widetilde{u}$ of $U.\mathbf{S}^*_C(V)$ is therefore contained in $\mathfrak{b}$; as moreover there exists an open ideal $\mathfrak{a}$ of C such that $\mathfrak{a}.E \subset \mathfrak{b}$, hence $\widetilde{u}(\mathfrak{a}.\mathbf{S}^*_C(V)) \subset \mathfrak{b}$, this proves that $\widetilde{u}$ is continuous. Conversely, if $\widetilde{u}$ is continuous, and if $\mathfrak{b}$ is an open ideal of E, there exists an open submodule U of V such that $\widetilde{u}(U.\mathbf{S}^*_C(V)) \subset \mathfrak{b}$, and in particular $\widetilde{u}(U.1_C) \subset \mathfrak{b}$, that is $u(U) \subset \mathfrak{b}$, so u is continuous. We also recall that one has a canonical isomorphism of topological C-modules (discrete) $\mathbf{0_{IV\text{-}1}}$ | 90

$$\mathbf{S}^n_C(V)/U.\mathbf{S}^{n-1}_C(V) \xrightarrow{\sim} \mathbf{S}^n_C(V/U). \tag{19.5.1.1}$$

(19.5.2). Let A be a topological ring, B a topological A-algebra (commutative), $\mathfrak{J}$ an ideal of B (not necessarily open or closed); in all that follows, we equip $\mathfrak{J}$ and the $\mathfrak{J}^n$ ($n \geqslant 2$) with the topology induced from that of B, the quotients $C = B/\mathfrak{J}$, $\mathfrak{J}^n/\mathfrak{J}^{n+1} = \mathrm{gr}^n_{\mathfrak{J}}(B)$ with the quotient topology, so that the $\mathfrak{J}^n/\mathfrak{J}^{n+1}$ are topological C-modules; the canonical injection $\mathfrak{J}/\mathfrak{J}^2 \to \mathrm{gr}^*_{\mathfrak{J}}(B)$ extends to a homomorphism (not topological at first) of C-algebras

$$\varphi : \mathbf{S}^*_C(\mathfrak{J}/\mathfrak{J}^2) \longrightarrow \mathrm{gr}^*_{\mathfrak{J}}(B)$$

which for each n gives a surjective homomorphism of C-modules

(19.5.2.1) $$\varphi_n : \mathbf{S}^n_C(\mathfrak{J}/\mathfrak{J}^2) \longrightarrow \mathfrak{J}^n/\mathfrak{J}^{n+1} = \mathrm{gr}^n_{\mathfrak{J}}(B).$$

When $\mathbf{S}^n_C(\mathfrak{J}/\mathfrak{J}^2)$ is equipped with the topology defined in (19.5.1), the homomorphisms φ_n are continuous, by virtue of the universal property (19.5.1) of $\mathbf{S}^*_C(\mathfrak{J}/\mathfrak{J}^2)$ applied to the topological algebra $E = \mathrm{gr}_{\mathfrak{J}/\mathfrak{J}^{n+1}}(B/\mathfrak{J}^{n+1})$ equipped with the product topology of those of the $\mathfrak{J}^k/\mathfrak{J}^{k+1}$, and to the canonical injection $\mathfrak{J}/\mathfrak{J}^2 \to E$. Note that here the topology of $\mathfrak{J}/\mathfrak{J}^2$ is less fine than that of C (this latter topology on $\mathfrak{J}/\mathfrak{J}^2$ being also the topology derived from that of B). $\mathbf{0}_{\mathbf{IV\text{-}1}}$ | 91

Theorem (19.5.3). — *Let A be a topological ring, B a topological A-algebra, $\mathfrak{J}$ an ideal of B, $C = B/\mathfrak{J}$ the topological quotient A-algebra. Suppose that the discrete A-algebra C is formally smooth. Then:*

(i) *If B is a formally smooth A-algebra, $\mathfrak{J}/\mathfrak{J}^2$ is a topologically formally projective C-module (19.2.1).*

(ii) *If B is a formally smooth A-algebra and a preadmissible ring ($\mathbf{0_I}$, 7.1.2), the homomorphisms φ_n (19.5.2) are formal bimorphisms (19.1.2).*

(iii) *Conversely, suppose that B is preadmissible, that the sequence $(\mathfrak{J}^n)$ tends to 0 in B, that $\mathfrak{J}/\mathfrak{J}^2$ is a formally projective C-module, and that the φ_n are formal bimorphisms. Then B is a formally smooth A-algebra.*

The proof of this theorem is long and encumbered with technical details; we will therefore begin by proving a simpler corollary, where the guiding ideas appear more clearly; this corollary is moreover the particular case of the theorem (19.5.3) that will be most frequently used in the sequel.

Corollary (19.5.4). — *Let A be a topological ring, B a topological A-algebra, $\mathfrak{J}$ an ideal of B such that the topology of B is the $\mathfrak{J}$-preadic topology. Suppose that the discrete A-algebra $C = B/\mathfrak{J}$ is formally smooth. Then the three following conditions are equivalent:*

a) *B is a formally smooth A-algebra.*

b) *$\mathfrak{J}/\mathfrak{J}^2$ is a projective C-module and the canonical homomorphism*

$$\varphi : \mathbf{S}^*_C(\mathfrak{J}/\mathfrak{J}^2) \longrightarrow \mathrm{gr}_{\mathfrak{J}}(B)$$

is bijective.

c) *The separated completion $\widehat{B}$ of B is a topological $\widehat{A}$-algebra isomorphic to an $\widehat{A}$-algebra of the form $\widehat{B'}$, where $B' = \mathbf{S}^*_C(V)$, V being a projective C-module and B' being equipped with the B'^{+}-preadic topology, where B'^{+} is the ideal of augmentation.*

(19.5.4.1). Let us first prove that *a*) implies that $\mathfrak{J}/\mathfrak{J}^2$ is a projective C-module. Let P and Q be two C-modules, $u : P \to Q$ a surjective C-homomorphism, and $v : \mathfrak{J}/\mathfrak{J}^2 \to Q$ a C-homomorphism. The ring $B/\mathfrak{J}^2$ being viewed as a B-extension of C by $\mathfrak{J}/\mathfrak{J}^2$, we deduce from v a B-extension $E = (B/\mathfrak{J}^2) \oplus_{(\mathfrak{J}/\mathfrak{J}^2)} Q$ of C by Q (18.2.8). As C is a discrete formally smooth A-algebra, the extension E is A-trivial (19.4.4) and can therefore be identified with $\mathrm{D}_C(Q)$ (18.2.3). The surjective homomorphism $u : P \to Q$ then canonically defines a surjective A-homomorphism $\psi : \mathrm{D}_C(P) \to \mathrm{D}_C(Q)$ (18.2.9) whose kernel is an ideal $\mathfrak{L}$ of the extension $E' = \mathrm{D}_C(P)$, contained in P, and *a fortiori* of square zero. Let $f : B \to E = E'/\mathfrak{L}$ be the homomorphism defining the B-algebra structure of E: as $\mathfrak{L}$ is of square zero and B is a formally smooth A-algebra, f factorizes as $B \xrightarrow{g} E' \to E'/\mathfrak{L}$, where g is a continuous A-homomorphism. The diagram $\mathbf{0}_{\mathbf{IV\text{-}1}}$ | 92

$$\begin{tikzcd} E' \arrow[r, "\psi"] & E \\ B \arrow[u, "g"] \arrow[r, "\theta"'] & B/\mathfrak{J}^2 \arrow[u, "v'"'] \end{tikzcd}$$

where v' is deduced from v (18.2.8), is commutative. Moreover, the image of $\mathfrak{J}$ by $\psi \circ g$ is contained in Q, so the image of $\mathfrak{J}$ by g is contained in P, and the image of $\mathfrak{J}^2$ by g is zero. Restricting g and θ to $\mathfrak{J}$, one obtains a commutative diagram

$$\begin{tikzcd} P \arrow[r, "u"] & Q \\ \mathfrak{J}/\mathfrak{J}^2 \arrow[u, "w"] \arrow[ur, "v"'] & \end{tikzcd}$$

which proves that the C-module $\mathfrak{J}/\mathfrak{J}^2$ is projective.

(19.5.4.2). Let us prove secondly that $a)$ implies that φ is bijective, which will complete the proof that $a)$ implies $b)$. Set $E_n = B/\mathfrak{J}^{n+1}$, and denote by F_n the quotient of $\mathbf{S}^*_C(\mathfrak{J}/\mathfrak{J}^2)$ by the $(n+1)$-th power of its ideal of augmentation. As $\mathfrak{J}^{n+1}$ is nilpotent in E_n and C is a discrete formally smooth A-algebra, the identity automorphism of C factorizes as $C \xrightarrow{f} E_n \to C = E_n/(\mathfrak{J}/\mathfrak{J}^{n+1})$ where f is an A-homomorphism; moreover, $\mathfrak{J}/\mathfrak{J}^2$ being a projective C-module, the identity of $\mathfrak{J}/\mathfrak{J}^2$ factorizes as $\mathfrak{J}/\mathfrak{J}^2 \xrightarrow{g} \mathfrak{J}/\mathfrak{J}^{n+1} \to \mathfrak{J}/\mathfrak{J}^2$, and from f and g one obtains canonically a homomorphism of C-algebras $\mathbf{S}^*_C(\mathfrak{J}/\mathfrak{J}^2) \to E_n$ which annihilates on the $(n+1)$-th power of the ideal of augmentation, whence, passing to the quotient, a surjective homomorphism of algebras $v : F_n \to E_n$ such that $\mathrm{gr}^0(v)$ and $\mathrm{gr}^1(v)$ are the identity automorphisms of C and of $\mathfrak{J}/\mathfrak{J}^2$. By definition of the canonical homomorphism φ, we see that $\mathrm{gr}^j(v) = \varphi_j$ for all $j \leqslant n$. Note now that the kernel $\mathfrak{N}$ is a nilpotent ideal of F_n, so that E_n is identified with $F_n/\mathfrak{N}$. As B is a formally smooth A-algebra, the canonical A-homomorphism $p_n : B \to E_n = B/\mathfrak{J}^{n+1}$, which is continuous, factorizes as $B \xrightarrow{w} F_n \xrightarrow{v} E_n$, where w is a continuous A-homomorphism; as $\mathrm{gr}^0(v)$ is the identity, $w(\mathfrak{J})$ is contained in the ideal of augmentation of F_n, hence $w(\mathfrak{J}^{n+1}) = 0$, so w factorizes as $B \xrightarrow{p_n} E_n \xrightarrow{w'} F_n$, and the composite $E_n \xrightarrow{w'} F_n \xrightarrow{v} E_n$ is the identity. Moreover, since $\mathrm{gr}^0(v)$ and $\mathrm{gr}^1(v)$ are the identity automorphisms of C and $\mathfrak{J}/\mathfrak{J}^2$, the same is true of $\mathrm{gr}^0(w')$ and $\mathrm{gr}^1(w')$. Since $\mathrm{gr}^*(E_n)$ is generated by $\mathrm{gr}^1(E_n)$, the composite

$$\mathrm{gr}^j(F_n) \xrightarrow{\varphi_j} \mathrm{gr}^j(E_n) \xrightarrow{\mathrm{gr}^j(w')} \mathrm{gr}^j(F_n)$$

is the identity for every $j \leqslant n$, because this is true for $j = 0$ and $j = 1$. Taking $j = n$ proves that φ_n is injective, which completes the proof that $a)$ implies $b)$.

(19.5.4.3). Let us next prove that $b)$ implies $a)$. The same reasoning as at the beginning of (19.5.4.2) $\mathbf{0_{IV\text{-}1}}$ | 93
proves the existence of a surjective A-homomorphism of algebras $v : F_n \to E_n$ such that $\mathrm{gr}^j(v) = \varphi_j$ for all j and the filtrations of F_n and E_n are finite; we conclude that v is *bijective* (Bourbaki, *Alg. comm.*, chap. III, §2, n° 8, cor. 3 of th. 1). Let now G be a discrete topological A-algebra, $\mathfrak{N}$ an ideal of square zero in G, $f : B \to G/\mathfrak{N}$ a continuous A-homomorphism of algebras. As G is discrete, there exists an integer m such that f annihilates on $\mathfrak{J}^m$, so f factorizes as $B \to E_n \xrightarrow{f_n} G/\mathfrak{N}$, where we take $n = 2m$. One has therefore by composition a continuous A-homomorphism $r : C \to F_n \xrightarrow{v} E_n \xrightarrow{f_n} G/\mathfrak{N}$, and as C is a discrete formally smooth A-algebra, r factorizes as $C \xrightarrow{r'} G \to G/\mathfrak{N}$, so G is thus equipped with a structure of C-algebra. On the other hand, the restriction to $\mathfrak{J}/\mathfrak{J}^2$ of the C-homomorphism $f'_n : F_n \xrightarrow{v} E_n \xrightarrow{f_n} G/\mathfrak{N}$ is a C-linear map $g : \mathfrak{J}/\mathfrak{J}^2 \to G/\mathfrak{N}$. As $\mathfrak{J}/\mathfrak{J}^2$ is a projective C-module, g factorizes as $\mathfrak{J}/\mathfrak{J}^2 \xrightarrow{h} G \to G/\mathfrak{N}$, where h is a C-linear map. By extension, one deduces a homomorphism of C-algebras $w : \mathbf{S}^*_C(\mathfrak{J}/\mathfrak{J}^2) \to G$, and by construction every element of degree m has as its image under w an element of $\mathfrak{N}$, so every element of degree $n = 2m$ has zero image since $\mathfrak{N}^2 = 0$; in other words, w factorizes as $\mathbf{S}^*_C(\mathfrak{J}/\mathfrak{J}^2) \to F_n \xrightarrow{w'} G$. By construction, the composite $F_n \xrightarrow{w'} G \xrightarrow{\theta} G/\mathfrak{N}$ coincides with f'_n in C and in $\mathfrak{J}/\mathfrak{J}^2$, hence is equal to f'_n. Finally, the composite $B \to E_n \xrightarrow{w' \circ v^{-1}} G$ being equal to f, one sees that B is a formally smooth A-algebra.

(19.5.4.4). It remains to prove the equivalence of $a)$ and $c)$. In the first place, $c)$ implies that B' is a formally smooth C-algebra for the discrete topology (19.3.2), hence also for the B'^+-preadic topology (19.3.8). As C is a formally smooth A-algebra, B' is also a formally smooth A-algebra (19.3.5), (ii), and finally $\widehat{B'}$ is a formally smooth $\widehat{A}$-algebra (19.3.6); hence B is a formally smooth A-algebra (19.3.6). It remains to see that $a)$ implies $c)$. Note first that C is a formally smooth A-algebra, the identical homomorphism $C \to B/\mathfrak{J}$ factorizes as $C \to \widehat{B} \to B/\mathfrak{J}$, where $C \to \widehat{B}$ is an A-homomorphism (19.3.10); hence $\widehat{B}$, and therefore all the $B/\mathfrak{J}^{n+1}$, are equipped with structures of C-algebras. On the other hand, as $\mathfrak{J}/\mathfrak{J}^2$ is a projective C-module by b), the canonical injection $\mathfrak{J}/\mathfrak{J}^2 \to B/\mathfrak{J}^2$ allows one to form a projective system of C-homomorphisms $u_n : \mathfrak{J}/\mathfrak{J}^2 \to B/\mathfrak{J}^{n+1}$ for $n \geqslant 1$, hence also (by the universal property of the symmetric algebra) a projective system of homomorphisms of C-algebras $v_n : \mathbf{S}^*_C(\mathfrak{J}/\mathfrak{J}^2) = B' \to B/\mathfrak{J}^{n+1}$; moreover it is clear that v_n annihilates on $(B'^{+})^{n+1}$ and as $\mathrm{gr}^0(v_n) = \varphi_0$ and $\mathrm{gr}^1(v_n) = \varphi_1$, one has $\mathrm{gr}^j(v_n) = \varphi_j$ for $0 \leqslant j \leqslant n$. As the φ_j are isomorphisms by b), and the filtrations of $B'/(B'^{+})^{n+1}$ and of $B/\mathfrak{J}^{n+1}$ are finite, one concludes that v_n is *bijective* for all n (Bourbaki, *Alg. comm.*, chap. III, § 2, n° 8, cor. 3 of th. 1); whence c) by passage to the projective limit. **$0_{\text{IV-1}}$** | 94

Remark (19.5.5). — Under the general hypotheses of (19.5.4), suppose furthermore that $\mathfrak{J}$ is a *maximal* ideal of B, so that $C = B/\mathfrak{J}$ is a field, and that $\mathfrak{J}/\mathfrak{J}^2$ is a vector space of *finite* dimension. Then the conditions a), b) and c) of (19.5.4) are also equivalent to the following:

d) *Given* a polynomial algebra $E = C[T_1, \dots, T_n]$ over the field C, and denoting by $\mathfrak{n}$ the maximal ideal of E generated by the T_i ($1 \leqslant i \leqslant n$), then for every ideal $\mathfrak{b}$ of E containing a power $\mathfrak{n}^k$, every homomorphism $v : B \to E/\mathfrak{b}$ of C-augmented A-algebras factorizes as
$$B \xrightarrow{w} E/\mathfrak{n}^k \longrightarrow E/\mathfrak{b},$$
where w is an A-homomorphism.

Indeed, $\mathfrak{J}/\mathfrak{J}^2$ being here a free C-module, it suffices to verify that condition d) implies that the canonical homomorphism $\varphi : \mathbf{S}^*_C(\mathfrak{J}/\mathfrak{J}^2) \to \mathrm{gr}^*_{\mathfrak{J}}(B)$ is bijective. Here $\mathbf{S}^*_C(\mathfrak{J}/\mathfrak{J}^2)$ identifies with the polynomial algebra $E = C[T_1, \dots, T_n]$, where $n = \mathrm{rg}_C(\mathfrak{J}/\mathfrak{J}^2)$, and the ideal of augmentation of E is the ideal $\mathfrak{n}$ generated by the T_i. For every integer $k \geqslant 0$, formal smoothness of the discrete A-algebra C gives, as in (19.5.4.2), a surjective A-homomorphism
$$f : E/\mathfrak{n}^{k+1} \longrightarrow B/\mathfrak{J}^{k+1}$$
such that $\mathrm{gr}^j(f) = \varphi_j$ for every $j \leqslant k$. If $\mathfrak{b}/\mathfrak{n}^{k+1} = \mathrm{Ker}(f)$, then $B/\mathfrak{J}^{k+1}$ identifies with $E/\mathfrak{b}$, and condition d) factorizes the canonical homomorphism $B \to B/\mathfrak{J}^{k+1}$ as
$$B \xrightarrow{w} E/\mathfrak{n}^{k+1} \xrightarrow{f} B/\mathfrak{J}^{k+1}.$$
Since $\mathrm{gr}^0(f)$ is the identity, $w(\mathfrak{J}) \subset \mathfrak{n}/\mathfrak{n}^{k+1}$, hence $w(\mathfrak{J}^{k+1}) = 0$. As in (19.5.4.2), it follows that φ_k is injective for every k, which proves the assertion.

(19.5.6). *Proof of the theorem* (19.5.3). — Let $(\mathfrak{b}_\alpha)$ be a fundamental decreasing system of open ideals of B. Set
$$B_\alpha = B/\mathfrak{b}_\alpha, \qquad C_\alpha = B/(\mathfrak{b}_\alpha + \mathfrak{J}), \qquad \mathfrak{J}_\alpha = (\mathfrak{b}_\alpha + \mathfrak{J})/\mathfrak{b}_\alpha,$$
so that
$$C_\alpha = B_\alpha/\mathfrak{J}_\alpha \qquad \text{and} \qquad \mathfrak{J}^n_\alpha/\mathfrak{J}^{n+1}_\alpha = (\mathfrak{b}_\alpha + \mathfrak{J}^n)/(\mathfrak{b}_\alpha + \mathfrak{J}^{n+1}).$$
The C-modules
$$((\mathfrak{b}_\alpha \cap \mathfrak{J}^n) + \mathfrak{J}^{n+1})/\mathfrak{J}^{n+1}$$
of $\mathfrak{J}^n/\mathfrak{J}^{n+1}$ form a fundamental system of open submodules of the topological C-module $\mathfrak{J}^n/\mathfrak{J}^{n+1}$. Since
$$(\mathfrak{b}_\alpha \cap \mathfrak{J}^n) + \mathfrak{J}^{n+1} = \mathfrak{J}^n \cap (\mathfrak{b}_\alpha + \mathfrak{J}^{n+1}),$$
we have
$$\begin{aligned}\mathfrak{J}^n/((\mathfrak{b}_\alpha \cap \mathfrak{J}^n) + \mathfrak{J}^{n+1}) &= \mathfrak{J}^n/(\mathfrak{J}^n \cap (\mathfrak{b}_\alpha + \mathfrak{J}^{n+1})) \\ &= (\mathfrak{b}_\alpha + \mathfrak{J}^n)/(\mathfrak{b}_\alpha + \mathfrak{J}^{n+1}) = \mathfrak{J}^n_\alpha/\mathfrak{J}^{n+1}_\alpha.\end{aligned}$$

(19.5.6.1). Let P, Q be two discrete C_α-modules and let $u : P \to Q$ be a surjective C_α-homomorphism. The discrete ring $B/(\mathfrak{b}_\alpha + \mathfrak{J}^2)$ is a B-extension of C_α by the square-zero ideal $\mathfrak{J}_\alpha/\mathfrak{J}^2_\alpha$. Let $v : \mathfrak{J}/\mathfrak{J}^2 \to Q$ be a continuous C-homomorphism. After replacing $\mathfrak{b}_\alpha$, if necessary, by a smaller open ideal of B, we may suppose that the kernel of v contains the open C-submodule $((\mathfrak{b}_\alpha \cap \mathfrak{J}) + \mathfrak{J}^2)/\mathfrak{J}^2$. Passing to the quotient gives a C_α-homomorphism of discrete modules $v' : \mathfrak{J}_\alpha/\mathfrak{J}^2_\alpha \to Q$. Let E_α be the B_α-extension of C_α by Q deduced from $B/(\mathfrak{b}_\alpha + \mathfrak{J}^2)$ by means of v', and let $v'_* : B/(\mathfrak{b}_\alpha + \mathfrak{J}^2) \to E_\alpha$

be the corresponding B_α-homomorphism (18.2.8). The algebra E_α is a discrete topological A-algebra, and the canonical isomorphism $C_\alpha \xrightarrow{\sim} E_\alpha/Q$ gives by composition a continuous A-homomorphism $f : C \to C_\alpha \to E_\alpha/Q$. Since Q is square zero in E_α and C is a formally smooth A-algebra, f factorizes as $C \xrightarrow{g} E_\alpha \to E_\alpha/Q$, where g is a continuous A-homomorphism. As g is continuous and E_α discrete, there exists $\beta \geqslant \alpha$ such that g factorizes as $C \to C_\beta \xrightarrow{g'} E_\alpha$. Let E_β be the A-extension of C_β by Q which is the inverse image of E_α under the canonical homomorphism $C_\beta \to C_\alpha$. The existence of g' (with composite $C_\beta \to E_\alpha \to C_\alpha$ equal to the canonical homomorphism) is equivalent to E_β being an *A-trivial* extension, so it may be identified with $\mathrm{D}_{C_\beta}(Q)$. The surjective homomorphism $u : P \to Q$ then canonically defines a

surjective homomorphism $\mathrm{D}_{C_\beta}(P) \to \mathrm{D}_{C_\beta}(Q)$ (18.2.9), whose kernel is an ideal $\mathfrak{L}$ of the extension **$0_{\mathrm{IV}\text{-}1}$** | 95
$E'_\beta = \mathrm{D}_{C_\beta}(P)$, contained in P, and *a fortiori* square zero. Let $f' : B \to E_\beta = E'_\beta/\mathfrak{L}$ be the continuous A-homomorphism defining the topological B-algebra structure of E_β. Since $\mathfrak{L}$ is square zero and B is a formally smooth A-algebra, f' factorizes as $B \xrightarrow{h'} E'_\beta \to E'_\beta/\mathfrak{L}$, where h' is a continuous A-homomorphism. The construction of E'_β gives by composition an A-homomorphism $\psi : E'_\beta \to E_\beta \to E_\alpha$, and the diagram

$$\begin{tikzcd} E'_\beta \arrow[r, "\psi"] & E_\alpha \\ B \arrow[u, "h'"] \arrow[r, "\theta"'] & B/(\mathfrak{b}_\alpha + \mathfrak{J}^2) \arrow[u, "v'_*"'] \end{tikzcd}$$

is commutative. Moreover, the image of $\mathfrak{J}$ under $\psi \circ h'$ is contained in Q, so its image under h' is contained in P, and the image of $\mathfrak{J}^2$ under h' is zero. Restricting h' and θ to $\mathfrak{J}$ gives a commutative diagram

$$\begin{tikzcd} P \arrow[r, "u"] & Q \\ \mathfrak{J}/\mathfrak{J}^2 \arrow[u, "w"] \arrow[ur, "v"'] & \end{tikzcd}$$

where w is continuous. Thus $\mathfrak{J}/\mathfrak{J}^2$ is a formally projective C-module.

(19.5.6.2). For all $n \geqslant 0$, we set $E_n = B/\mathfrak{J}^{n+1}$, so that $E_0 = C$; and we set

$$E_{\alpha,n} = B/(\mathfrak{b}_\alpha + \mathfrak{J}^{n+1}) = B_\alpha/\mathfrak{J}_\alpha^{n+1},$$

a discrete quotient ring. Likewise, in $\mathrm{gr}^n_{\mathfrak{J}}(B) = \mathfrak{J}^n/\mathfrak{J}^{n+1}$, we have seen that the $((\mathfrak{b}_\alpha \cap \mathfrak{J}^n) + \mathfrak{J}^{n+1})/\mathfrak{J}^{n+1}$ form a fundamental system of open submodules. Consider the symmetric algebra $\mathbf{S}^*_{C_\alpha}(\mathfrak{J}_\alpha/\mathfrak{J}_\alpha^2)$; we denote by $F_{\alpha,n}$ the quotient of $\mathbf{S}^*_{C_\alpha}(\mathfrak{J}_\alpha/\mathfrak{J}_\alpha^2)$ by the $(n+1)$-th power of its ideal of augmentation. For a fixed $n \geqslant 1$, it follows from (19.5.1.1) that the $\mathbf{S}^n_{C_\alpha}(\mathfrak{J}_\alpha/\mathfrak{J}_\alpha^2)$ are the quotients of $\mathbf{S}^n_C(\mathfrak{J}/\mathfrak{J}^2)$ by a fundamental system of open submodules within this topological C-module.

To abbreviate the language, we will say that for $\alpha \leqslant \beta$, the canonical homomorphisms $B_\beta \to B_\alpha$, $C_\beta \to C_\alpha$, $\mathfrak{J}_\beta/\mathfrak{J}_\beta^2 \to \mathfrak{J}_\alpha/\mathfrak{J}_\alpha^2$, $E_{\beta,n} \to E_{\alpha,n}$, $F_{\beta,n} \to F_{\alpha,n}$, etc., are *homomorphisms of transition*.

Lemma (19.5.6.3). — *Suppose that C is a formally smooth A-algebra, that the ring B is preadmissible, and that the C-module $\mathfrak{J}/\mathfrak{J}^2$ is formally projective. Then:*

(i) *For every α, there exists $\beta \geqslant \alpha$ and a surjective A-algebra homomorphism*

$$v_{\alpha\beta} : F_{\beta,n} \longrightarrow E_{\alpha,n}$$

such that $\mathrm{gr}^0(v_{\alpha\beta}) : C_\beta \to C_\alpha$ and $\mathrm{gr}^1(v_{\alpha\beta}) : \mathfrak{J}_\beta/\mathfrak{J}_\beta^2 \to \mathfrak{J}_\alpha/\mathfrak{J}_\alpha^2$ are the homomorphisms of transition;

(ii) *If β and $v_{\alpha\beta}$ satisfy the conditions of* (i)*, then for every $\gamma \geqslant \beta$, there exists $\delta \geqslant \gamma$ and a surjective A-algebra homomorphism $v_{\gamma\delta} : F_{\delta,n} \to E_{\gamma,n}$ satisfying the conditions of* (i) *(for γ and δ) and making commutative the diagram*

$$\begin{tikzcd} F_{\beta,n} \arrow[r, "v_{\alpha\beta}"] & E_{\alpha,n} \\ F_{\delta,n} \arrow[u] \arrow[r, "v_{\gamma\delta}"'] & E_{\gamma,n} \arrow[u] \end{tikzcd}$$

where the vertical arrows are the homomorphisms of transition.

(19.5.6.4). (i) In the discrete topological A-algebra $E_{\alpha,n}$, the ideal $\mathfrak{J}_\alpha/\mathfrak{J}_\alpha^{n+1}$ is nilpotent, and the isomorphism $C_\alpha \xrightarrow{\sim} E_{\alpha,n}/(\mathfrak{J}_\alpha/\mathfrak{J}_\alpha^{n+1})$ gives by composition a continuous A-homomorphism $C \to C_\alpha \to E_{\alpha,n}/(\mathfrak{J}_\alpha/\mathfrak{J}_\alpha^{n+1})$;

as C is a formally smooth A-algebra, this homomorphism factorizes as $C \xrightarrow{f_\alpha} E_{\alpha,n} \to$ **$0_{\text{IV-1}}$** | 96
$E_{\alpha,n}/(\mathfrak{J}_\alpha/\mathfrak{J}_\alpha^{n+1})$, where f_α is a continuous A-homomorphism; hence $\mathfrak{J}_\alpha/\mathfrak{J}_\alpha^{n+1}$ becomes, by means of f_α, a topological C-module annihilated by an open ideal of C. The hypothesis that $\mathfrak{J}/\mathfrak{J}^2$ is a formally projective C-module then implies the existence of a continuous C-linear map $g_\alpha : \mathfrak{J}/\mathfrak{J}^2 \to \mathfrak{J}_\alpha/\mathfrak{J}_\alpha^{n+1}$ making commutative the diagram

$$\begin{tikzcd} \mathfrak{J}_\alpha/\mathfrak{J}_\alpha^{n+1} \arrow[r] & \mathfrak{J}_\alpha/\mathfrak{J}_\alpha^2 \\ & \mathfrak{J}/\mathfrak{J}^2 \arrow[u] \arrow[ul, "g_\alpha"] \end{tikzcd}$$

As f_α and g_α are continuous, there exists $\beta \geqslant \alpha$ such that these homomorphisms factorize through

$$C \longrightarrow C_\beta \xrightarrow{f'_{\alpha\beta}} E_{\alpha,n}$$

$$\mathfrak{J}/\mathfrak{J}^2 \longrightarrow \mathfrak{J}_\beta/\mathfrak{J}_\beta^2 \xrightarrow{g'_{\alpha\beta}} \mathfrak{J}_\alpha/\mathfrak{J}_\alpha^{n+1}$$

and from $f'_{\alpha\beta}$ and $g'_{\alpha\beta}$, one obtains a homomorphism of C_β-algebras

$$\mathbf{S}^*_{C_\beta}(\mathfrak{J}_\beta/\mathfrak{J}_\beta^2) \longrightarrow E_{\alpha,n}$$

which, by the definition of $g'_{\alpha\beta}$, vanishes on the $(n+1)$-th power of the augmentation ideal of $\mathbf{S}^*_{C_\beta}(\mathfrak{J}_\beta/\mathfrak{J}_\beta^2)$; passing to the quotient by this power gives the desired homomorphism $v_{\alpha\beta}$, taking into account the definitions of f_α and g_α; the surjectivity of $v_{\alpha\beta}$ follows from that of the two homomorphisms $\mathrm{gr}^0(v_{\alpha\beta})$ and $\mathrm{gr}^1(v_{\alpha\beta})$, since this implies that $\mathrm{gr}(v_{\alpha\beta})$ is surjective (the graded algebra $\mathrm{gr}^*(E_{\alpha,n})$ being generated by $\mathrm{gr}^0(E_{\alpha,n})$ and $\mathrm{gr}^1(E_{\alpha,n})$), and as the filtrations considered are finite, one can apply Bourbaki, *Alg. comm.*, chap. III, § 2, n° 8, cor. 3 of th. 1.

(ii) The hypothesis that B is preadmissible means that one can suppose all the $\mathfrak{b}_\alpha$ contained in the same $\mathfrak{b}_{\alpha_0}$, whose powers tend to 0. This implies in particular that the kernel of the transition homomorphism $E_{\gamma,n} \to E_{\alpha,n}$, equal to $(\mathfrak{b}_\alpha + \mathfrak{J}^{n+1})/(\mathfrak{b}_\gamma + \mathfrak{J}^{n+1})$, is *nilpotent*; applying the lemma (19.3.10.1), one sees that one can choose f_γ so that the diagram

$$\begin{tikzcd} & E_{\alpha,n} \\ C \arrow[ur, "f_\alpha"] \arrow[r, "f_\gamma"'] & E_{\gamma,n} \arrow[u] \end{tikzcd}$$

(where the vertical arrow is the transition homomorphism) is commutative. The hypothesis that $\mathfrak{J}/\mathfrak{J}^2$ is a formally projective C-module furthermore allows one to choose

$g_\gamma : \mathfrak{J}/\mathfrak{J}^2 \to \mathfrak{J}_\gamma/\mathfrak{J}_\gamma^{n+1}$ so that the diagram

$$\begin{tikzcd}
\mathfrak{J}_\alpha/\mathfrak{J}_\alpha^{n+1} \arrow[r] & \mathfrak{J}_\alpha/\mathfrak{J}_\alpha^2 \\
\mathfrak{J}_\gamma/\mathfrak{J}_\gamma^{n+1} \arrow[u] \arrow[r] & \mathfrak{J}_\gamma/\mathfrak{J}_\gamma^2 \arrow[u] \\
 & \mathfrak{J}/\mathfrak{J}^2 \arrow[u, "p_\gamma"'] \arrow[ul, "g_\gamma"] \arrow[uul, "g_\alpha"']
\end{tikzcd}$$

is commutative. Indeed, the image of $\mathfrak{J}/\mathfrak{J}^2$ under (g_α, p_γ) in $(\mathfrak{J}_\alpha/\mathfrak{J}_\alpha^{n+1}) \times (\mathfrak{J}_\gamma/\mathfrak{J}_\gamma^2)$ is contained, by the definition of g_α and the relation $\beta \leqslant \gamma$, in the canonical image Q of $P = \mathfrak{J}_\gamma/\mathfrak{J}_\gamma^{n+1}$ in this product module. Apply the definition (19.2.1) to the surjective homomorphism $P \to Q$ and to $(g_\alpha, p_\gamma) : \mathfrak{J}/\mathfrak{J}^2 \to Q$. This choice of f_γ and g_γ allows $v_{\gamma\delta}$ to be constructed as in (i) while also making the diagram (19.5.6.4) commutative.

$\mathbf{0_{IV\text{-}1}}$ | 97

Lemma (19.5.6.5). — *Suppose that the A-algebras B and C are formally smooth and that B is preadmissible (so that, by (19.5.6.1), the conditions of (19.5.6.3) are satisfied). For every pair of indices $\alpha \leqslant \beta$ and every homomorphism $v_{\alpha\beta} : F_{\beta,n} \to E_{\alpha,n}$ satisfying the conditions of (19.5.6.3),* (i), *there exists an index $\lambda \geqslant \beta$ and an A-algebra homomorphism*

$$w_{\beta\lambda} : E_{\lambda,n} \longrightarrow F_{\beta,n}$$

such that: 1° $\mathrm{gr}^0(w_{\beta\lambda}) : C_\lambda \to C_\beta$ *and* $\mathrm{gr}^1(w_{\beta\lambda}) : \mathfrak{J}_\lambda/\mathfrak{J}_\lambda^2 \to \mathfrak{J}_\beta/\mathfrak{J}_\beta^2$ *are the transition homomorphisms;* 2° *the composite $E_{\lambda,n} \xrightarrow{w_{\beta\lambda}} F_{\beta,n} \xrightarrow{v_{\alpha\beta}} E_{\alpha,n}$ is the transition homomorphism.*

Proof. Apply (19.5.6.3), (ii), with $\gamma = \beta$. This gives $\delta \geqslant \beta$ and $v_{\beta\delta} : F_{\delta,n} \to E_{\beta,n}$. Recall that $v_{\beta\delta}$ is surjective. Its kernel $\mathfrak{N}$ is nilpotent: the augmentation ideal $F_{\delta,n}^+$ is nilpotent by definition, while the kernel of $\mathrm{gr}^0(v_{\beta\delta}) : C_\delta \to C_\beta$ is nilpotent because B is preadmissible. Thus $E_{\beta,n}$ identifies with $F_{\delta,n}/\mathfrak{N}$. Since B is a formally smooth A-algebra, the continuous canonical A-homomorphism $p_{\beta,n} : B \to E_{\beta,n}$ factorizes as

$$B \xrightarrow{w} F_{\delta,n} \xrightarrow{v_{\beta\delta}} E_{\beta,n},$$

where w is continuous. As $F_{\delta,n}$ is discrete, there exists $\lambda \geqslant \delta$ such that w vanishes on $\mathfrak{b}_\lambda$, and hence w factorizes as

$$B \longrightarrow B/\mathfrak{b}_\lambda \xrightarrow{w'_\lambda} F_{\delta,n}.$$

Consider the composite

$$B/\mathfrak{b}_\lambda \xrightarrow{w'_\lambda} F_{\delta,n} \xrightarrow{q_{\beta\delta}} F_{\beta,n},$$

where $q_{\beta\delta}$ is the transition homomorphism. We have $\mathrm{gr}^0(q_{\beta\delta}) = \mathrm{gr}^0(v_{\beta\delta}) : C_\delta \to C_\beta$, the transition homomorphism. Since $v_{\alpha\beta} \circ q_{\beta\delta} \circ w'_\lambda$ is the canonical homomorphism $B/\mathfrak{b}_\lambda \to B/(\mathfrak{b}_\alpha + \mathfrak{J}^{n+1})$, the image of $\mathfrak{J}_\lambda = (\mathfrak{b}_\lambda + \mathfrak{J})/\mathfrak{b}_\lambda$ under $q_{\beta\delta} \circ w'_\lambda$ is contained in the augmentation ideal $F_{\beta,n}^+$. Consequently the image of $\mathfrak{J}_\lambda^{n+1} = (\mathfrak{b}_\lambda + \mathfrak{J}^{n+1})/\mathfrak{b}_\lambda$ is zero. Thus $q_{\beta\delta} \circ w'_\lambda$ factorizes as

$$B/\mathfrak{b}_\lambda \longrightarrow B/(\mathfrak{b}_\lambda + \mathfrak{J}^{n+1}) = E_{\lambda,n} \xrightarrow{w_{\beta\lambda}} F_{\beta,n},$$

and $E_{\lambda,n} \xrightarrow{w_{\beta\lambda}} F_{\beta,n} \xrightarrow{v_{\alpha\beta}} E_{\alpha,n}$ is the transition homomorphism. The preceding argument also shows that $\mathrm{gr}^0(w_{\beta\lambda})$ is the transition homomorphism $C_\lambda \to C_\beta$, because it is the composite

$$B/(\mathfrak{b}_\lambda + \mathfrak{J}) \longrightarrow \mathrm{gr}^0(F_{\delta,n}) \xrightarrow{\mathrm{gr}^0(q_{\beta\delta})} \mathrm{gr}^0(F_{\beta,n})$$

and $v_{\beta\delta} \circ w$ is canonical. Moreover, $\mathrm{gr}^1(q_{\beta\delta}) = \mathrm{gr}^1(v_{\beta\delta})$ by (19.5.6.3), and the same argument shows that $\mathrm{gr}^1(w_{\beta\lambda})$ is the transition homomorphism. $\square$

(19.5.6.6). *Proof of* (19.5.3), (ii). — To show that φ_n is a formal bimorphism, we apply the criterion of (19.1.3); the conditions of (19.5.6.5) being satisfied by hypothesis, choose, for every α, homomorphisms $v_{\alpha\beta}$ and $w_{\beta\lambda}$ satisfying the conclusions of that lemma. The homomorphism

$$\mathrm{gr}^n(v_{\alpha\beta}) : \mathrm{gr}^n(F_{\beta,n}) \longrightarrow \mathrm{gr}^n(E_{\alpha,n})$$

is the homomorphism

$$\varphi_{\alpha\beta,n} : \mathbf{S}^n_{C_\beta}(\mathfrak{J}_\beta/\mathfrak{J}_\beta^2) \longrightarrow \mathfrak{J}_\alpha^n/\mathfrak{J}_\alpha^{n+1}$$

deduced from (19.5.2.1) by passage to quotients. Indeed, (19.5.6.3) and the definition of φ show inductively that $\mathrm{gr}^j(v_{\alpha\beta}) = \varphi_{\alpha\beta,j}$ for all $j \leqslant n$. Since φ_n is surjective, it is *a fortiori* a formal epimorphism. Moreover, the composite

$$\mathrm{gr}^j(F_{\lambda,n}) \xrightarrow{\varphi_{\lambda\lambda,j}} \mathrm{gr}^j(E_{\lambda,n}) \xrightarrow{\mathrm{gr}^j(w_{\beta\lambda})} \mathrm{gr}^j(F_{\beta,n})$$

is the transition homomorphism: this holds for $j = 0, 1$ by (19.5.6.5), and then for every $j \leqslant n$ because $\mathrm{gr}^*(E_{\lambda,n})$ is generated by $\mathrm{gr}^1(E_{\lambda,n})$. After composing with the transition map to $\mathrm{gr}^n(F_{\alpha,n})$, the transition homomorphism $\mathrm{gr}^n(F_{\lambda,n}) \to \mathrm{gr}^n(F_{\alpha,n})$ therefore factors as

$$\mathrm{gr}^n(F_{\lambda,n}) \xrightarrow{\varphi_{\lambda\lambda,n}} \mathrm{gr}^n(E_{\lambda,n}) \longrightarrow \mathrm{gr}^n(F_{\alpha,n}),$$

which is precisely the criterion of (19.1.3).

Lemma (19.5.6.7). — *Suppose that B is preadmissible, that $\mathfrak{J}/\mathfrak{J}^2$ is a formally projective C-module, that C* **$0_{\text{IV-1}}$** | 98
is a formally smooth A-algebra, and that the φ_n are formal bimorphisms. Then, for every pair $\alpha \leqslant \beta$ and every homomorphism $v_{\alpha\beta} : F_{\beta,n} \to E_{\alpha,n}$ satisfying (19.5.6.3), (i), *there exists $\gamma \geqslant \beta$ such that, for every $\mu \geqslant \gamma$, there is a commutative diagram*

$$\begin{tikzcd} F_{\beta,n} \arrow[r, "v_{\alpha\beta}"] & E_{\alpha,n} \\ & E_{\mu,n} \arrow[ul, "u_{\beta\mu}"'] \arrow[u, "p_{\alpha\mu}"'] \end{tikzcd}$$

of A-homomorphisms, where $p_{\alpha\mu}$ is the transition homomorphism.

Proof. Apply the criterion of (19.1.3) to each φ_j, $0 \leqslant j \leqslant n$. There exist $\gamma \geqslant \beta$ and uniquely determined surjective C_γ-linear homomorphisms

$$w^j_{\beta\gamma} : \mathrm{gr}^j(E_{\gamma,n}) \longrightarrow \mathrm{gr}^j(F_{\beta,n})$$

such that

$$\mathrm{gr}^j(F_{\gamma,n}) \xrightarrow{\varphi_{\gamma\gamma,j}} \mathrm{gr}^j(E_{\gamma,n}) \xrightarrow{w^j_{\beta\gamma}} \mathrm{gr}^j(F_{\beta,n})$$

is the transition homomorphism. The same γ may be chosen for all j, since there are only finitely many of them. By uniqueness and because φ is a homomorphism of graded algebras, the family $w_{\beta\gamma} = (w^j_{\beta\gamma})_{0\leqslant j\leqslant n}$ is a homomorphism of graded C_γ-algebras

$$\mathrm{gr}^\bullet(E_{\gamma,n}) \longrightarrow \mathrm{gr}^\bullet(F_{\beta,n}) = F_{\beta,n}.$$

Since $\varphi_{\gamma\gamma,0}$ and $\varphi_{\gamma\gamma,1}$ are the identity homomorphisms, $w^0_{\beta\gamma} : C_\gamma \to C_\beta$ and $w^1_{\beta\gamma} : \mathfrak{J}_\gamma/\mathfrak{J}_\gamma^2 \to \mathfrak{J}_\beta/\mathfrak{J}_\beta^2$ are the transition homomorphisms. The same therefore holds for $\mathrm{gr}^0(v_{\alpha\beta} \circ w_{\beta\gamma})$ and $\mathrm{gr}^1(v_{\alpha\beta} \circ w_{\beta\gamma})$; since $\mathrm{gr}^\bullet(E_{\gamma,n})$ is generated by $\mathrm{gr}^1(E_{\gamma,n})$, it follows that $\mathrm{gr}^j(v_{\alpha\beta} \circ w_{\beta\gamma})$ is also the transition homomorphism for $0 \leqslant j \leqslant n$.

Apply now (19.5.6.3), (ii), to α, β, and γ; this gives diagram (19.5.6.4) with $\delta \geqslant \gamma$. Repeat the argument at the beginning after replacing α and β by γ and δ. One obtains $\lambda \geqslant \delta$ and a commutative diagram

$$\begin{tikzcd}
\mathrm{gr}^\bullet(E_{\gamma,n}) \arrow[r, "w_{\beta\gamma}"] & F_{\beta,n} \arrow[r, "v_{\alpha\beta}"] & E_{\alpha,n} \\
\mathrm{gr}^\bullet(E_{\lambda,n}) \arrow[r, "w_{\delta\lambda}"'] \arrow[u, "\mathrm{gr}^\bullet(p_{\gamma\lambda})"'] & F_{\delta,n} \arrow[r, "v_{\gamma\delta}"'] \arrow[u, "q_{\beta\delta}"'] & E_{\gamma,n} \arrow[u, "p_{\alpha\gamma}"'] \arrow[ul, dashed, "u_{\beta\gamma}"']
\end{tikzcd}$$

whose vertical arrows are the transition homomorphisms. It remains to prove the existence of $u_{\beta\gamma}$ making the diagram commute, and for this it plainly suffices to show

$$\mathrm{Ker}(v_{\gamma\delta}) \subset \mathrm{Ker}(q_{\beta\delta}),$$

since $v_{\gamma\delta}$ and $q_{\beta\delta}$ are surjective. As $w_{\delta\lambda}$ is surjective, this relation is equivalent to

$$\begin{aligned}\mathrm{Ker}(v_{\gamma\delta} \circ w_{\delta\lambda}) &\subset \mathrm{Ker}(q_{\beta\delta} \circ w_{\delta\lambda}) \\ &= \mathrm{Ker}\big(w_{\beta\gamma} \circ \mathrm{gr}(p_{\gamma\lambda})\big).\end{aligned}$$

But we saw above that $\mathrm{gr}(p_{\gamma\lambda}) = \mathrm{gr}(v_{\gamma\delta} \circ w_{\delta\lambda})$, and clearly

$$\begin{aligned}\mathrm{Ker}(v_{\gamma\delta} \circ w_{\delta\lambda}) &\subset \mathrm{Ker}\big(\mathrm{gr}(v_{\gamma\delta} \circ w_{\delta\lambda})\big) \\ &= \mathrm{Ker}(\mathrm{gr}(p_{\gamma\lambda})) \subset \mathrm{Ker}\big(w_{\beta\gamma} \circ \mathrm{gr}(p_{\gamma\lambda})\big).\end{aligned}$$

This proves the lemma: for every $\mu \geqslant \gamma$, define $u_{\beta\mu}$ as the composite

$$E_{\mu,n} \xrightarrow{p_{\gamma\mu}} E_{\gamma,n} \xrightarrow{u_{\beta\gamma}} F_{\beta,n}.$$

□

(19.5.6.8). *Proof of* (19.5.3), (iii). — Let G be a discrete topological A-algebra, $\mathfrak{N}$ an ideal of square zero in G, and $f : B \to G/\mathfrak{N}$ a continuous A-homomorphism of algebras. As $G/\mathfrak{N}$ is discrete, there exists α such that f annihilates $\mathfrak{b}_\alpha$; moreover, as $\mathfrak{J}^m \subset \mathfrak{b}_\alpha$ for a sufficiently large m, f factors as

$$B \xrightarrow{p_\alpha} E_{\alpha,n} \xrightarrow{f_{\alpha,n}} G/\mathfrak{N},$$

where $n = 2m$. By (19.5.6.3), there exist $\beta \geqslant \alpha$ and $v_{\alpha\beta} : F_{\beta,n} \to E_{\alpha,n}$; thus

$$F_{\beta,n} \xrightarrow{v_{\alpha\beta}} E_{\alpha,n} \xrightarrow{f_{\alpha,n}} G/\mathfrak{N} \tag{19.5.6.9}$$

is a continuous A-homomorphism. Since $F_{\beta,n}$ is a C_β-algebra, hence *a fortiori* a discrete topological C-algebra, (19.5.6.9) gives by composition a continuous A-homomorphism $r : C \to F_{\beta,n} \to G/\mathfrak{N}$. Since, on the other hand, C is a formally smooth A-algebra,
this homomorphism factorizes as $r : C \xrightarrow{r'} G \to G/\mathfrak{N}$, where r' is a continuous A-homomorphism, $\mathbf{0}_{\mathbf{IV}\text{-}\mathbf{1}}$ | 99
thereby giving G the structure of a discrete topological C-algebra. Composing (19.5.6.9) with

$$\mathfrak{J}/\mathfrak{J}^2 \longrightarrow \mathfrak{J}_\beta/\mathfrak{J}_\beta^2 \longrightarrow F_{\beta,n}$$

gives a continuous C-homomorphism $g : \mathfrak{J}/\mathfrak{J}^2 \to G/\mathfrak{N}$. Since $\mathfrak{J}/\mathfrak{J}^2$ is formally projective, g lifts to a continuous C-homomorphism $h : \mathfrak{J}/\mathfrak{J}^2 \to G$. As G is discrete, there exists $\gamma \geqslant \beta$ such that h annihilates the image of $((\mathfrak{b}_\gamma \cap \mathfrak{J}) + \mathfrak{J}^2)/\mathfrak{J}^2$ and r' annihilates the image of $(\mathfrak{b}_\gamma + \mathfrak{J})/\mathfrak{J}$. Thus h factors through a C_γ-homomorphism $\mathfrak{J}_\gamma/\mathfrak{J}_\gamma^2 \to G$, and hence extends to

$$w_\gamma : \mathbf{S}^*_{C_\gamma}(\mathfrak{J}_\gamma/\mathfrak{J}_\gamma^2) \longrightarrow G.$$

Every element of degree m has image in $\mathfrak{N}$, so every element of degree $n = 2m$ has image zero; consequently w_γ factors as $F_{\gamma,n} \xrightarrow{w'_\gamma} G$.

Applying (19.5.6.7) to $v_{\alpha\gamma} = v_{\alpha\beta} \circ q_{\beta\gamma} : F_{\gamma,n} \to E_{\alpha,n}$ gives $\delta \geqslant \gamma$ and $u_{\gamma\delta} : E_{\delta,n} \to F_{\gamma,n}$ such that $v_{\alpha\gamma} \circ u_{\gamma\delta} = p_{\alpha\delta}$. One obtains the commutative diagram

$$\begin{tikzcd}
 & & E_{\alpha,n} \arrow[r, "f_{\alpha,n}"] & G/\mathfrak{R} \\
 & & F_{\beta,n} \arrow[u, "v_{\alpha\beta}"'] & \\
B \arrow[r, "p_\delta"'] & E_{\delta,n} \arrow[uur, "p_{\alpha\delta}"] \arrow[r, "u_{\gamma\delta}"'] & F_{\gamma,n} \arrow[u, "q_{\beta\gamma}"'] \arrow[r, "w'_\gamma"] & G \arrow[uu]
\end{tikzcd}$$

of continuous A-homomorphisms. The composite $f' : B \to G$ along the bottom row satisfies $f = (G \to G/\mathfrak{R}) \circ f'$, proving that B is a formally smooth A-algebra. The proof of (19.5.3) is complete.

Corollary (19.5.7). — *Let A be a topological ring, B a topological A-algebra, $(\mathfrak{b}_\lambda)$ a fundamental system of open ideals of B, $\mathfrak{J}$ an ideal of B, and $C = B/\mathfrak{J}$ the topological quotient A-algebra. Set $C_\lambda = B/(\mathfrak{b}_\lambda + \mathfrak{J})$. Suppose that:*

1° *for all n, the topology induced on $\mathfrak{J}^n$ by that of B is also the topology of the B-module $\mathfrak{J}^n$ deduced from the topology of B (19.0.2); this condition is satisfied in particular if B is Noetherian and its topology is preadic ($\mathbf{0_I}$, 7.3.2);*

2° *C is a formally smooth A-algebra.*

Under these conditions:

(i) *If B is a formally smooth A-algebra, then, for all λ, $(\mathfrak{J}/\mathfrak{J}^2) \otimes_C C_\lambda$ is a projective C_λ-module.*

(ii) *If B is a formally smooth A-algebra and a preadmissible ring, then, for all λ, the canonical homomorphism*

(19.5.7.1)
$$\varphi_\lambda = \varphi \otimes 1_{C_\lambda} : \mathbf{S}^*_{C_\lambda}((\mathfrak{J}/\mathfrak{J}^2) \otimes_C C_\lambda) \longrightarrow \mathrm{gr}_{\mathfrak{J}}(B) \otimes_C C_\lambda$$

is bijective. $\mathbf{0_{IV\text{-}1}}$ | 100

(iii) *Conversely, suppose that B is preadmissible, that the sequence $(\mathfrak{J}^n)$ tends to 0, and that, for all λ, $(\mathfrak{J}/\mathfrak{J}^2) \otimes_C C_\lambda$ is a projective C_λ-module and the homomorphism (19.5.7.1) is bijective. Then B is a formally smooth A-algebra.*

Proof. Indeed, the topology of $\mathfrak{J}/\mathfrak{J}^2$ and those of the $\mathbf{S}^n_C(\mathfrak{J}/\mathfrak{J}^2)$ are then also deduced from that of B (19.5.1); the conclusions are immediate consequences of (19.5.3) and of the criteria of (19.1.4) and (19.2.4) specialized to this type of topology. □

Remark (19.5.8). — Suppose that $\mathfrak{J}/\mathfrak{J}^2$ is a C-module of finite type and that, for the quotient topology inherited from B, C is a Zariski ring. Let $\mathfrak{r}$ be an ideal of definition of C, so that the $\mathfrak{r}^n$ form a fundamental system of neighbourhoods of 0 in C. Then the conclusions of (i) and (ii) in (19.5.7) may be replaced by the following:

(i') $\mathfrak{J}/\mathfrak{J}^2$ is a projective C-module.

(ii') The canonical homomorphism

$$\varphi : \mathbf{S}^*_C(\mathfrak{J}/\mathfrak{J}^2) \longrightarrow \mathrm{gr}_{\mathfrak{J}}(B)$$

is bijective.

Indeed, it is clear that (i') implies the conclusion of (i) in (19.5.7). Conversely, if $(\mathfrak{J}/\mathfrak{J}^2) \otimes_C C_\lambda$ is a projective C_λ-module for all λ, then $(\mathfrak{J}/\mathfrak{J}^2) \otimes_C (C/\mathfrak{r}^n)$ is a projective, hence flat, $(C/\mathfrak{r}^n)$-module for every n; one concludes that $\mathfrak{J}/\mathfrak{J}^2$ is a flat C-module ($\mathbf{0_{III}}$, 10.2.2), hence projective since it is finitely presented (Bourbaki, *Alg. comm.*, chap. II, §5, nº 2, cor. 2 of th. 1). On the other hand, the C-modules $\mathbf{S}^n_C(\mathfrak{J}/\mathfrak{J}^2)$ and $\mathrm{gr}^n_{\mathfrak{J}}(B)$ are of finite type, and when C is a Zariski ring it is equivalent to saying that φ_n is bijective or that $\varphi_n \otimes 1_{C_\lambda}$ is bijective for all λ (Bourbaki, *Alg. comm.*, chap. III, §3, nº 5, prop. 9); therefore (ii) is equivalent to (ii').

19.6. The case of algebras over a field

Theorem (19.6.1) (Cohen). — *Let k be a field, K an extension of k, k and K being equipped with the discrete topologies. For K to be a formally smooth k-algebra, it is necessary and sufficient that K be a separable extension of k.*

Proof. The necessity of the condition will be established in (19.6.5.1) (and of course is not used until then); we will content ourselves here with proving that the condition is *sufficient*. We distinguish two cases:

I. — K is a separable extension of finite type of k. We know then (Bourbaki, *Alg.*, chap. V, § 9, n° 3, th. 2) that there exists a pure sub-extension $K' = k(T_1, \ldots, T_n)$ of K such that K is a finite separable algebraic extension of K'. In view of (19.3.5), (iii), one can therefore reduce to the case where $K = K'$, or to the case where K is algebraically finite over k. In the first case, $A = k[T_1, \ldots, T_n]$ is a formally smooth k-algebra (19.3.3), hence $k(T_1, \ldots, T_n) = S^{-1}A$ where $S = A - \{0\}$ is also formally smooth (19.3.5), (iv). In the second case, *all* Hochschild cohomology groups $\mathrm{H}^n_k(K, L)$ are zero for every (K, K)-bimodule L: indeed, if one considers the k-algebra tensor product $C = K \otimes_k K$, L is a C-module on the left and the cohomology group $\mathrm{H}^n_k(K, L)$ is equal to $\mathrm{Ext}^n_C(K, L)$, where K is also viewed as (K, K)-bimodule, hence as a left C-module (M, IX, 4). Now, as K is a finite separable $\mathbf{0_{IV\text{-}1}}$ | 101
extension of k, we know that $K \otimes_k K$ is a direct product of extensions of k, one of which is K itself (Bourbaki, *Alg.*, chap. VIII, § 8, prop. 3); this implies that K is a *projective* C-module, whence our assertion. Every k-extension of K of zero kernel L is therefore k-trivial, and *a fortiori* all commutative k-extensions are trivial, whence the theorem in this case (19.4.4).

II. — General case. — With the notation of (18.4.5), it suffices to prove that $\mathrm{Hom}_K(\mathrm{H}_2(\mathrm{P}'_\bullet), L) = 0$ for *every* K-vector space L, which means that $\mathrm{H}_2(\mathrm{P}'_\bullet) = 0$. If K is a union of a filtering family of sub-extensions $K^{(\alpha)}$ of k, $\mathrm{P}'_\bullet$ is the *inductive limit* of the corresponding complexes $\mathrm{P}'^{(\alpha)}_\bullet$, since the $\varinjlim$ functor commutes with the tensor product in the category of k-modules; by the exactness of the $\varinjlim$ functor in this category, one has $\mathrm{H}_2(\mathrm{P}'_\bullet) = \varinjlim \mathrm{H}_2(\mathrm{P}'^{(\alpha)}_\bullet)$. As K is separable, it follows that the same holds for every sub-extension of K and that K is a union of sub-extensions of finite type, so the first part of the proof implies that K is a formally smooth k-algebra, Q.E.D. □

Corollary (19.6.2). — *Let A be a separated complete local ring, K its residue field, k a subfield of K such that K is a separable extension of k. Then there exists a subfield K' of A containing k, such that the restriction to K' of the canonical homomorphism $A \to K$ is an isomorphism of K' onto K.*

Proof. Let $\mathfrak{m}$ be the maximal ideal of A. By the hypothesis and (19.6.1), K is a formally smooth k-algebra; applying (19.3.10) (replacing C by A and $\mathfrak{J}$ by $\mathfrak{m}$), one sees that the identity automorphism of $K = A/\mathfrak{m}$ factorizes as $K \xrightarrow{u} A \to A/\mathfrak{m}$, where u is a k-homomorphism, hence necessarily a k-isomorphism of K onto a subfield K' of A containing k. □

Corollary (19.6.3). — *Let A be a Noetherian complete local ring, $\mathfrak{m}$ its maximal ideal, k its residue field. The following conditions are equivalent:*

a) A contains a subfield.

b) If p is the characteristic of k, one has $pA = 0$.

c) There exists a field K such that A is isomorphic to a quotient ring of a formal power series ring $B = K[[T_1, \ldots, T_n]]$.

When this is the case, one can suppose that A is isomorphic to $B/\mathfrak{b}$, where $\mathfrak{b}$ is contained in the square of the maximal ideal of B.

Proof. It is immediate that c) implies a), since A is $\neq 0$ because it is a local ring; as K is a field and the composite homomorphism $K \xrightarrow{\varphi} B \to A$ (where φ is the canonical injection) is not zero, it is injective. To see that a) implies b), it suffices to remark that if K is a subfield of A, K is isomorphic to a subfield of k and has therefore the same characteristic p; as $p.1 = 0$ in K, hence in A, one has $pA = 0$. Conversely, b) implies a), for the composite of the canonical homomorphisms $\mathbf{Z} \xrightarrow{j} A \to k$ has kernel $p\mathbf{Z}$, and one has $j(p\mathbf{Z}) = 0$, hence $\mathrm{Ker}(j) = p\mathbf{Z}$ and A contains a ring A' isomorphic to $\mathbf{Z}/p\mathbf{Z}$ and not meeting $\mathfrak{m}$; if $p > 0$, A' is a field; otherwise,

$\mathbf{0_{IV\text{-}1}}$ | 102

every element of A' being invertible in A, the field of fractions of A' (isomorphic to $\mathbf{Q}$) is also contained in A.

Let us prove finally that $a)$ implies $c)$; the condition $a)$ implies that A contains a prime subfield k_0, isomorphic to the prime subfield of k, and whose k is therefore a separable extension. Applying (19.6.2), one sees that there exists an isomorphism f of k onto a subfield K of A. On the other hand, let $(x_i)_{1\leqslant i\leqslant n}$ be a system of elements of $\mathfrak{m}$ such that the classes mod. $\mathfrak{m}^2$ of the x_i form a basis (over k) of $\mathfrak{m}/\mathfrak{m}^2$. Since A is complete, there exists a continuous ring homomorphism $u : k[[T_1, \ldots, T_n]] \to A$ such that u equals f on k and $u(T_i) = x_i$ for all i, and this homomorphism is surjective by virtue of the choice of the x_i (Bourbaki, *Alg. comm.*, chap. III, § 2, n° 9, prop. 11). ☐

Theorem (19.6.4). — *Let k be a field, A a local Noetherian k-algebra, $\mathfrak{m}$ its maximal ideal, $K = A/\mathfrak{m}$ its residue field, A being equipped with the $\mathfrak{m}$-preadic topology. Suppose that K is a separable extension of k. Then the following conditions are equivalent:*

- *a) A is a formally smooth k-algebra.*
- *b) The completion $\widehat{A}$ of A is k-isomorphic to a formal power series ring $K[[T_1, \ldots, T_n]]$ (where the k-algebra structure is defined by the composite homomorphism $k \xrightarrow{\varphi} K \xrightarrow{\psi} K[[T_1, \ldots, T_n]]$, where ψ is the canonical injection and φ the homomorphism defining the extension structure of K).*
- *b′) $\widehat{A}$ is a formal power series ring isomorphic to $K[[T_1, \ldots, T_n]]$.*
- *c) A is a regular local ring.*

Proof. The fact that $a)$ implies $b)$ is the particular case of (19.5.4) (equivalence of $a)$ and $c)$) obtained by replacing A by k, B by A, and $\mathfrak{J}$ by $\mathfrak{m}$, taking into account (19.6.1). It is clear that $b)$ implies $b')$ and $b')$ implies $c)$ by (17.1.1). Finally, if $c)$ holds, it follows from (17.1.1), $a)$, and from (19.5.4) (equivalence of $b)$ and $a)$), applied with $A = k$, $B = A$, $\mathfrak{J} = \mathfrak{m}$, and $C = K = A/\mathfrak{m}$, that A is a formally smooth k-algebra. ☐

Corollary (19.6.5). — *Let k be a field, A a local Noetherian k-algebra, $\mathfrak{m}$ its maximal ideal, A being equipped with the $\mathfrak{m}$-preadic topology. Suppose that A is a formally smooth k-algebra; then A is* geometrically regular *over k, in other words (cf.* **IV***, 6.7.6), for every finite extension k' of k, the semi-local ring $A' = A \otimes_k k'$ is regular (17.3.6). Furthermore, if K is the residue field of A, $\widehat{A}$ is isomorphic to a formal power series ring $K[[T_1, \ldots, T_n]]$.*

Proof. As $\widehat{A}' = \widehat{A} \otimes_k k'$, it follows from (19.3.6) and (17.1.5) (applied to the maximal ideals of A') that one can reduce to the case where A is complete; then A' is a formally smooth k'-algebra (19.3.5), (iii) and is moreover a direct product of k'-local algebras, which are also formally smooth (19.3.5), (v). One is therefore reduced to proving that A is *regular*. Let k_0 be the prime subfield of k; as k is a separable extension of k_0, it is a formally smooth k_0-algebra (19.6.1), and by the hypothesis, so is A (19.3.5), (ii). As the residue field K of A is a separable extension of k_0, one can then apply (19.6.4) to A and k_0, whence the conclusion. ☐

$\mathbf{0_{IV\text{-}1}}$ | 103

Corollary (19.6.5.1). — *Let A be a Noetherian local ring, k a subfield of A such that A is a formally smooth k-algebra (for its preadic topology). Then every field K such that $k \subset K \subset A$ is a separable extension of k.*

Proof. Indeed, for every finite extension k' of k, the ring $K \otimes_k k'$ is identified with a subring of $A' = A \otimes_k k'$; as A' is a regular ring, hence reduced, so is $K \otimes_k k'$, which proves that K is a separable extension of k (Bourbaki, *Alg.*, chap. VIII, § 7, n° 3, th. 1). ☐

We note that this proves the necessity of the condition in the statement of (19.6.1).

Remark (19.6.5.2). — If K is a *non-separable* extension of k, the formal power series ring $K[[T_1, \ldots, T_n]]$ is therefore *not* a formally smooth k-algebra (for the usual k-algebra structure recalled in (19.6.4)). On the other hand, there exist formally smooth k-algebras A which are complete Noetherian local rings whose residue field K is a non-separable extension of k (for example the completions of the localizations of $B = k[T_1, \ldots, T_n]$ at maximal ideals $\mathfrak{n}$ such that $B/\mathfrak{n}$ is a finite non-separable algebraic extension of k); such a ring cannot therefore be k-isomorphic to $K[[T_1, \ldots, T_n]]$ even though it is *isomorphic* to it by virtue of (19.6.5).

One can in certain cases sharpen the corollary (19.6.5):

Proposition (19.6.6). — *Let k be a field, A a local Noetherian k-algebra, $\mathfrak{m}$ its maximal ideal, A being equipped with the $\mathfrak{m}$-preadic topology. Suppose that the residue field $K = A/\mathfrak{m}$ of A is such that there exists a finite radicial extension k_0 of k for which the residue field of the local ring $K \otimes_k k_0$ is a separable extension of k_0 (we will express this property later by saying that K is of* finite radicial multiplicity *over k (**IV**, 4.7.4) and we will see that this condition is always satisfied when K is an extension of finite type of k). Then the following conditions are equivalent:*

- *a) A is a formally smooth k-algebra.*
- *b) There exists a finite radicial extension k' of k such that $\widehat{A} \otimes_k k'$ is k'-isomorphic to a formal power series algebra $K'[[T_1, \ldots, T_n]]$, where K' is a separable extension of k'.*
- *b′) There exists a finite extension k' of k such that the semi-local ring $\widehat{A} \otimes_k k'$ has at least one local component which is k'-isomorphic to a formal power series algebra $K'[[T_1, \ldots, T_n]]$, where K' is a separable extension of k'.*
- *c) A is geometrically regular over k (19.6.5).*

Proof. Note first that if k' is a finite radicial extension of k, there is only a single maximal ideal of $A' = A \otimes_k k'$ above $\mathfrak{m}$, formed of elements whose p^h-th power (p being the characteristic of k) is in $\mathfrak{m}$ for a suitable h (Bourbaki, *Alg. comm.*, chap. V, § 2, n° 3, lemma 4); A' is therefore a local ring, and so is $K \otimes_k k' = (A \otimes_k k')/(\mathfrak{m} \otimes_k k')$; moreover, these two local rings have the same residue field. We recall, on the other hand, that if K is a separable extension of k, then, for every finite extension k'' of k, $K \otimes_k k''$ is a direct product of fields (Bourbaki, *Alg.*, chap. VIII, § 7, n° 3, cor. 1 of th. 1); therefore $\mathfrak{m} \otimes_k k''$ is the radical of $A \otimes_k k''$, and the field components of $K \otimes_k k''$ are the residue fields at the maximal ideals of $A \otimes_k k''$;

furthermore, these fields are separable extensions of k'', since for every extension k_1 of k'', $K \otimes_k k_1 = (K \otimes_k k'') \otimes_{k''} k_1$ has no radical (*loc. cit.*, th. 1). Applying these remarks to the field K of finite radicial multiplicity over k, one sees that for *every* finite extension k'' of k_0, $(K \otimes_k k'')_{\text{red}}$ is separable over k''. $\mathbf{0_{IV\text{-}1}}$ | 104

Let us pass to the proof of (19.6.6). It is trivial that b) implies b'). Let us show that b') implies a). Set $B' = K'[[T_1, \ldots, T_n]]$. The hypothesis that K' is separable over k' entails, by the preceding remarks, that for every finite extension k'' of k', the components of the complete semi-local ring $B' \otimes_{k'} k''$ (equal to the formal power series ring $(K' \otimes_{k'} k'')[[T_1, \ldots, T_n]]$) are the rings $K''_i[[T_1, \ldots, T_n]]$, where the K''_i are the field components of $K' \otimes_{k'} k''$. Since the local components of $B' \otimes_{k'} k''$ are also local components of

$$\widehat{A} \otimes_k k'' = (\widehat{A} \otimes_k k') \otimes_{k'} k'',$$

the hypothesis b') remains true when k' is replaced by any one of its finite extensions. In particular, one can suppose k' *quasi-Galois*, hence a Galois extension of a radicial extension k'_0 of k; $A' = \widehat{A} \otimes_k k'$ can then be written $A'_0 \otimes_{k'_0} k'$, where $A'_0 = \widehat{A} \otimes_k k'_0$ is a complete local ring. We know (Bourbaki, *Alg.*, chap. VIII, § 8, prop. 4) that A' is a direct product of local rings isomorphic to A'_0 as k'_0-algebras. Now one of these rings is, by hypothesis, k'-isomorphic to a formal power series ring $K'[[T_1, \ldots, T_n]]$, where K' is a separable extension of k', hence also a separable extension of k'_0. In view of (19.6.4), A'_0 is therefore a formally smooth k'_0-algebra. But as k'_0 is a k-module which is faithfully flat, projective and of finite type, one concludes by (19.4.7) that $\widehat{A}$ is a formally smooth k-algebra.

We have already seen (19.6.5) that a) implies c); it remains to verify that c) implies b). If c) holds, then, for every finite radicial extension k' of k containing k_0, $A \otimes_k k'$ is a regular local ring whose residue field K' is a separable extension of k'. It follows from (19.6.4) that its completion $\widehat{A} \otimes_k k'$ is k'-isomorphic to a formal power series ring $K'[[T_1, \ldots, T_n]]$. □

Remarks (19.6.7). — (i) We note that the hypothesis that K is of finite radicial multiplicity over k was only used in the proof of the implication $b') \Rightarrow a)$.

(ii) We will prove later (22.5.8) that a) and c) are equivalent, *without* any hypothesis on the extension K of k.

19.7. The case of local homomorphisms; existence and uniqueness theorems In this section, whenever a semi-local ring is considered as a topological ring, it is always understood that it is endowed with its $\mathfrak{r}$-preadic topology, where $\mathfrak{r}$ is its radical. Every local homomorphism of local rings is thus automatically continuous.

Theorem (19.7.1). — *Let A, B be two local Noetherian rings, $\mathfrak{m}$, $\mathfrak{n}$ their respective maximal ideals, $k = A/\mathfrak{m}$ the residue field of A; suppose that A and B are equipped respectively with the $\mathfrak{m}$-preadic and $\mathfrak{n}$-preadic topologies. Let $\varphi : A \to B$ be a local homomorphism, and set $B_0 = B \otimes_A k$. The following properties are equivalent:*

a) *B is a formally smooth A-algebra.* $\mathbf{0_{IV\text{-}1}}$ | 105
b) *B is a flat A-module and $B_0 = B/\mathfrak{m}B$ (equipped with the quotient topology) is a formally smooth k-algebra.*

Proof. The proof is carried out in several steps.

(19.7.1.1) Let us first show that b) implies a); we will apply the criterion (19.4.7), with $\mathfrak{J} = \mathfrak{m}$; by virtue of the second hypothesis in b), it suffices to show that B is a *formally projective* A-module. The hypothesis implies that for all $h > 0$, $B/\mathfrak{m}^h B$ is a flat $(A/\mathfrak{m}^h)$-module ($\mathbf{0_{III}}$, 10.2.1); as the $\mathfrak{m}^h$ form a fundamental system of neighbourhoods of 0 in A and $(B/\mathfrak{m}^h B) \otimes_{A/\mathfrak{m}^h} k = B_0$, we can replace A and B by $A/\mathfrak{m}^h$ and $B/\mathfrak{m}^h B$ respectively, and thus suppose that A is *Artinian* (hence discrete). As B_0 is a k-algebra formally smooth, it is a regular ring (19.6.5); let $(x_i^0)_{1\leqslant i\leqslant n}$ be a regular system of parameters for B_0 (17.1.6), and for each i, let $x_i \in B$ be such that x_i^0 is its image in $B_0 = B/\mathfrak{m}B$; as the x_i^0 generate the maximal ideal $\mathfrak{n}_0 = \mathfrak{n}/\mathfrak{m}B$ of B_0, the ideals $\mathfrak{Q}_m = \sum_{i=1}^n (x_i^0)^m B_0$ (for $m > 0$) form a fundamental system of neighbourhoods of 0 in B_0, since $\mathfrak{Q}_m$ is evidently contained in $\mathfrak{n}_0^m$, and on the other hand contains $\mathfrak{n}_0^{mn}$. Set $\mathfrak{J}_m = \sum_{i=1}^n x_i^m B$ for all $m > 0$; it is clear that $\mathfrak{n} = \mathfrak{J}_1 + \mathfrak{m}B$; as there exists $h > 0$ such that $\mathfrak{m}^h = 0$, one has $\mathfrak{n}^m \subset \mathfrak{J}_1^{m-h} \subset \mathfrak{n}^{m-h}$ for $m > h$, and as we have seen that $\mathfrak{J}_m \supset \mathfrak{J}_1^{mn}$, the $\mathfrak{J}_m$ form a fundamental system of neighbourhoods of 0 in B. The whole argument then amounts to proving that the $B/\mathfrak{J}_m$ are *free* A-modules, and it amounts to the same to verify that these are *flat* A-modules ($\mathbf{0_{III}}$, 10.1.3). Now, the hypothesis that (x_i^0) is a B_0-regular sequence of elements of the maximal ideal of B_0 implies the same property for the sequence $(x_i^0)^m$ $(1 \leqslant i \leqslant n)$ for all $m > 0$ (15.1.20); the conclusion thus follows from (15.1.16), b) and c). ☐

Lemma (19.7.1.2). — *Let A be a topological ring, B, C two topological A-algebras that are local Noetherian rings. Suppose further that C is complete and that the residue field $B/\mathfrak{m}$ of B is an A-module of finite type. Let E be the completed tensor product $B\widehat{\otimes}_A C$. Then:*

(i) *E is a complete semi-local Noetherian ring.*
(ii) *The ideal $\mathfrak{m}E$ is contained in the radical of E, and for all $h > 0$, $E/\mathfrak{m}^h E$ is isomorphic to $(B/\mathfrak{m}^h) \otimes_A C$.*
(iii) *If C is a flat A-module, E is a flat B-module.*

Proof. By definition, E is the separated completion of the tensor product $B \otimes_A C$ for the topology defined by the ideals $\operatorname{Im}(\mathfrak{m}^i \otimes_A C) + \operatorname{Im}(B \otimes_A \mathfrak{n}'^j)$ ($\mathbf{0_I}$, 7.7.5). If one sets $\mathfrak{r} = \operatorname{Im}(\mathfrak{m} \otimes_A C) + \operatorname{Im}(B \otimes_A \mathfrak{n}')$, one has $\mathfrak{r}^{2i} \subset \operatorname{Im}(\mathfrak{m}^i \otimes_A C) + \operatorname{Im}(B \otimes_A \mathfrak{n}'^i) \subset \mathfrak{r}^i$, so E is also the separated completion of $B \otimes_A C$ for the $\mathfrak{r}$-preadic topology. By hypothesis, $(B \otimes_A C)/\mathfrak{r} = (B/\mathfrak{m}) \otimes_A (C/\mathfrak{n}')$ is a $(C/\mathfrak{n}')$-module of finite type, hence an Artinian ring; moreover, $\mathfrak{r}/\mathfrak{r}^2$, being a quotient of $((\mathfrak{m}/\mathfrak{m}^2) \otimes_A C) \oplus (B \otimes_A (\mathfrak{n}'/\mathfrak{n}'^2))$, is a $(B \otimes_A C)$-module of finite type; applying ($\mathbf{0_I}$, 7.2.11), one sees that E is a *Noetherian* ring; moreover, $E/\mathfrak{r}E$, isomorphic to $(B \otimes_A C)/\mathfrak{r}$, being Artinian, E is *semi-local*. Note now that E, which is isomorphic to $\varprojlim_{i,j}((B/\mathfrak{m}^i) \otimes_A (C/\mathfrak{n}'^j))$, is also isomorphic, by the theorem of the double projective limit, to $\varprojlim_i(\varprojlim_j((B/\mathfrak{m}^i) \otimes_A (C/\mathfrak{n}'^j)))$; but $\varprojlim_j((B/\mathfrak{m}^i) \otimes_A (C/\mathfrak{n}'^j))$ is the separated $\mathbf{0_{IV\text{-}1}}$ | 106
completion of $(B/\mathfrak{m}^i) \otimes_A C$, and as C is complete, this is none other than $(B/\mathfrak{m}^i) \otimes_A C$ itself, since $B/\mathfrak{m}^i$ is an A-module of finite type (as $\mathfrak{m}/\mathfrak{m}^i$ is a $(B/\mathfrak{m})$-module of finite type ($\mathbf{0_I}$, 7.3.6)). One therefore has $E = \varprojlim_i((B/\mathfrak{m}^i) \otimes_A C)$. For every integer $h > 0$, $\mathfrak{m}^h E$, being an ideal of E, is closed in E ($\mathbf{0_I}$, 7.3.5), hence complete, and on the other hand it is evidently dense in $\varprojlim_i(\operatorname{Im}(\mathfrak{m}^h/\mathfrak{m}^{h+i}) \otimes_A C)$, hence equal to this projective limit. Moreover, all the projective systems considered are defined by *surjective* homomorphisms; it follows therefore from ($\mathbf{0_{III}}$, 13.2.2) that $E/\mathfrak{m}^h E$ is isomorphic to

$(B/\mathfrak{m}^h) \otimes_A C = (B \otimes_A C)/\operatorname{Im}(\mathfrak{m}^h \otimes_A C)$. In particular $\operatorname{Im}(\mathfrak{m} \otimes_A C) \subset \mathfrak{r}$, which shows that $\mathfrak{m}E$ is contained in $\mathfrak{r}E$, hence in the radical of E. Finally, the hypothesis that C is a flat A-module implies that $(B/\mathfrak{m}^h) \otimes_A C = E/\mathfrak{m}^h E$ is a flat $(B/\mathfrak{m}^h)$-module for all $h > 0$: since B and E are Noetherian and $\mathfrak{m}E$ is contained in the radical of E, it follows from ($\mathbf{0_{III}}$, 10.2.2) that E is a flat B-module. ☐

Lemma (19.7.1.3). — *Let A be a local Noetherian ring, $\mathfrak{m}$ its maximal ideal, k its residue field, B_0 a local Noetherian k-algebra; suppose that B_0 is complete and regular. Then there exists a topological A-algebra B that is a complete local Noetherian ring, a flat A-module, and such that B_0 is k-isomorphic to $B \otimes_A k = B/\mathfrak{m}B$.*

Proof. As $\widehat{A}$ is flat over A and has the same residue field, we can restrict to the case where A is *complete*.

Let K be the residue field of B_0, and let us distinguish two cases:

Case I: K is a *separable* extension of k. By virtue of (19.6.4), B_0 is k-isomorphic to a formal power series ring $K[[T_1, \dots, T_n]]$. When $B_0 = K$, the lemma has already been proved ($\mathbf{0_{III}}$, 10.3.1); let C be a complete local Noetherian ring that is a flat A-module and such that $C \otimes_A k$ is isomorphic to K. For $n \geqslant 1$, it suffices to take (using the preceding notation) $B = C[[T_1, \dots, T_n]]$; indeed it is known (Bourbaki, *Alg. comm.*, chap. III, § 3, n° 4, cor. 3 of th. 1) that B is a flat C-module, hence also a flat A-module, and on the other hand, it is immediate that $C[[T_1, \dots, T_n]] \otimes_A k$ is isomorphic to $(C/\mathfrak{m}C)[[T_1, \dots, T_n]] = B_0$.

Case II: K is of *characteristic* $p > 0$, and is therefore of the same characteristic as k. Denote by P the prime field $\mathbf{F}_p$, and by $W(P)$ the complete local ring of p-adic numbers $\mathbf{Z}_p$, which is a complete discrete valuation ring (hence *regular*), with P as residue field. Let us first show that there exists a continuous ring homomorphism $W(P) \to A$, thus making A into a $W(P)$-*topological algebra*. Indeed, if $j : \mathbf{Z} \to A$ is the canonical homomorphism, one has $j(p\mathbf{Z}) \subset \mathfrak{m}$ by hypothesis, whence $j^{-1}(\mathfrak{m}) = p\mathbf{Z}$, and j therefore factors as $\mathbf{Z} \to \mathbf{Z}_{p\mathbf{Z}} \xrightarrow{f} A$, where f is a local homomorphism, hence continuous, which (since A is complete) extends by continuity to the desired homomorphism $W(P) \to A$.

As k is a separable extension of P, case I) shows that there is a local homomorphism $W(P) \to W(k)$, where $W(k)$ is a complete local Noetherian ring and a flat $W(P)$-module, such that $W(k) \otimes_{W(P)} P$ is isomorphic to k. Moreover, as the uniformiser p of $W(P)$ is a $W(k)$-regular element by flatness ($\mathbf{0_I}$, 6.3.4), and as $W(k)/pW(k) = k$, the maximal ideal of $W(k)$ is $pW(k)$, which implies that this ring $\mathbf{0_{IV\text{-}1}}$ | 107
is a *complete discrete valuation ring* (Bourbaki, *Alg. comm.*, chap. VI, § 3, n° 5, prop. 9). By (19.7.1.1) (as k is separable over P, hence a formally smooth P-algebra (19.6.1)), one sees that $W(k)$ is a $W(P)$-algebra *formally smooth*. The continuous $W(P)$-homomorphism $W(k) \to k$ therefore factors as $W(k) \to A \to k$ (19.3.11), which allows us to consider A as a $W(k)$-topological algebra. Applying now case I) to B_0 considered as a P-algebra and to $W(P)$, one sees that there exists a $W(P)$-algebra B_P which is a complete local Noetherian ring, a flat $W(P)$-module, and such that $B_P \otimes_{W(P)} P$ is P-isomorphic to B_0. Using again the fact that $W(k)$ is a $W(P)$-algebra formally smooth, one sees by (19.3.11) that the homomorphism $W(k) \to k \to B_0$ factors as $W(k) \to B_P \to B_0$; moreover, as $k = W(k)/pW(k)$, one has $B_P \otimes_{W(k)} k = B_P/pB_P = B_P \otimes_{W(P)} P = B_0$. Let us show that B_P is a flat $W(k)$-module; as $W(k)$ is a discrete valuation ring with p as uniformiser, it suffices to verify that B_P is a $W(k)$-module *without torsion* ($\mathbf{0_I}$, 6.3.4), or equivalently that p is a B_P-regular element, which follows from the fact that B_P is a flat $W(P)$-module ($\mathbf{0_I}$, 6.3.4).

Set now

$$B = B_P \widehat{\otimes}_{W(k)} A$$

and note that the residue field of A being equal to that of $W(k)$, is *a fortiori* a $W(k)$-module of finite type. It follows first from (19.7.1.2) that B is a complete semi-local Noetherian ring, $\mathfrak{m}B$ is contained in the radical of B; moreover $B/\mathfrak{m}B$ is k-isomorphic to $B_P \otimes_{W(k)} k = B_0$, hence B is in fact a *local* ring. As B_P is a flat $W(k)$-module, (19.7.1.2) shows finally that B is a flat A-module. Q.E.D. ☐

Lemma (19.7.1.4). — *Let A be a ring, $\mathfrak{J}$ an ideal of A, M, N two A-modules separated for the $\mathfrak{J}$-preadic topology. Suppose further that N is complete for the $\mathfrak{J}$-preadic topology and that M is a flat A-module. Let $u : N \to M$ be an A-homomorphism; if $u \otimes 1 : N \otimes_A (A/\mathfrak{J}) \to M \otimes_A (A/\mathfrak{J})$ is bijective, then u is bijective.*

Proof. The graded modules being taken relative to the $\mathfrak{J}$-preadic filtrations, it follows from the hypotheses on M and N relative to the $\mathfrak{J}$-preadic topologies that it suffices to prove that $\mathrm{gr}(u) : \mathrm{gr}_\bullet(N) \to \mathrm{gr}_\bullet(M)$ is *bijective* (Bourbaki, *Alg. comm.*, chap. III, § 2, n° 8, cor. 3 of th. 1). Now, there is a commutative diagram

$$\begin{tikzcd} \mathrm{gr}_0(N) \otimes_{A_0} \mathrm{gr}_\bullet(A) \arrow[r, "\mathrm{gr}_0(u)\otimes 1"] \arrow[d, "\varphi_N"'] & \mathrm{gr}_0(M) \otimes_{A_0} \mathrm{gr}_\bullet(A) \arrow[d, "\varphi_M"] \\ \mathrm{gr}_\bullet(N) \arrow[r, "\mathrm{gr}(u)"'] & \mathrm{gr}_\bullet(M) \end{tikzcd}$$

where $A_0 = A/\mathfrak{J} = \mathrm{gr}_0(A)$, and φ_M and φ_N are the canonical maps ($\mathbf{0_{III}}$, 10.1.1.2). By hypothesis, $\mathbf{0_{IV\text{-}1}}$ | 108
$\mathrm{gr}_0(u)$ is bijective as well as φ_M ($\mathbf{0_{III}}$, 10.2.1), and φ_N is surjective; one deduces first that $\mathrm{gr}_0(u) \otimes 1$ is bijective, then that φ_N is injective, hence bijective, and finally that $\mathrm{gr}(u)$ is bijective. □

Lemma (19.7.1.5). — *Let A be a Noetherian ring, $\mathfrak{J}$ an ideal of A, B, B' two A-algebras that are local Noetherian rings, the homomorphisms $A \to B$, $A \to B'$ being continuous for the $\mathfrak{J}$-preadic topology on A. Suppose that:*

1° *B and B' are complete for the $\mathfrak{J}$-preadic topologies;*
2° *B is a formally smooth A-algebra;*
3° *B' is a flat A-module.*

Set $A_0 = A/\mathfrak{J}$, and let $u_0 : B \otimes_A A_0 \to B' \otimes_A A_0$ be an A_0-isomorphism; then there exists an A-isomorphism $u : B \to B'$ such that $u_0 = u \otimes 1$ (which implies that B' is also a formally smooth A-algebra and B is a flat A-module).

Proof. Set $B_0 = B \otimes_A A_0$, $B'_0 = B' \otimes_A A_0$. Note that if $\mathfrak{m}$ and $\mathfrak{m}'$ are the maximal ideals of B and B', the $\mathfrak{J}$-preadic topologies on B and B' are separated since $\mathfrak{J}B \subset \mathfrak{m}$ and $\mathfrak{J}B' \subset \mathfrak{m}'$; moreover, as $\mathfrak{J}B'$ is closed in B' for the $\mathfrak{J}$-preadic topology, the composite homomorphism $B \to B_0 \xrightarrow{u_0} B'_0$, which is continuous for the $\mathfrak{J}$-preadic topologies, factors as $B \xrightarrow{u} B' \to B'_0$, where u is a continuous A-homomorphism (19.3.10). One has $u_0 = u \otimes 1$, and the hypothesis that u_0 is bijective implies that u is bijective, by virtue of (19.7.1.4). □

(19.7.1.6) *End of the proof of* (19.7.1). — To finish proving (19.7.1), it remains to show that *a*) implies *b*); it is already known that *a*) implies that B_0 is a k-algebra formally smooth (19.3.5), (iii), hence it suffices to prove that B is a flat A-module. It amounts to the same to establish that $\widehat{B}$ is a flat $\widehat{A}$-module (Bourbaki, *Alg. comm.*, chap. III, § 5, n° 4, prop. 4), and one knows that $\widehat{B}$ is an $\widehat{A}$-algebra formally smooth (19.3.6); one can therefore restrict to the case where A and B are *complete*. As B_0 is a k-algebra formally smooth, it is a regular ring (19.6.5) and complete ($\mathbf{0_I}$, 6.3.5); applying (19.7.1.3), one sees that there exists an A-algebra B' which is a complete local Noetherian ring and a flat A-module, a local homomorphism $A \to B'$, and a k-isomorphism $B_0 \simeq B'_0 = B' \otimes_A k$. It then suffices to apply (19.7.1.5) (taking $\mathfrak{J}$ to be the maximal ideal of A) to obtain that B is A-isomorphic to B', hence is a flat A-module. Q.E.D.

Theorem (19.7.2). — *Let A be a local Noetherian ring, $\mathfrak{J}$ an ideal contained in the maximal ideal of A, $A_0 = A/\mathfrak{J}$, B_0 a complete local Noetherian ring, $A_0 \to B_0$ a local homomorphism making B_0 into a formally smooth A_0-algebra. Then there exists a complete local Noetherian ring B, a local homomorphism $A \to B$ making B into a flat A-module, and an A_0-isomorphism $u : B \otimes_A A_0 \xrightarrow{\sim} B_0$. If (B', u') is a pair satisfying the same conditions as (B, u), there exists an A-isomorphism $v : B \xrightarrow{\sim} B'$ making the diagram*

$$\begin{tikzcd} B \otimes_A A_0 \arrow[rr, "v\otimes 1", "\sim"'] \arrow[dr, "\sim", "u"'] & & B' \otimes_A A_0 \arrow[dl, "\sim"', "u'"] \\ & B_0 & \end{tikzcd}$$

commutative.

$\mathbf{0_{IV\text{-}1}}$ | 109

Proof. Let $\mathfrak{m}$ be the maximal ideal of A, so that $\mathfrak{m}_0 = \mathfrak{m}/\mathfrak{J}$ is the maximal ideal of A_0, A and A_0 having the same residue field k. Set $B_{00} = B_0 \otimes_{A_0} k$; as B_{00} is a formally smooth k-algebra (19.3.5), (iii), it is a regular local ring (19.6.5); applying (19.7.1.3), one sees that there exists a topological A-algebra B which is a complete local Noetherian ring, a flat A-module, and for which one has a k-isomorphism $u_{00} : B \otimes_A k \xrightarrow{\sim} B_{00}$. Note that by virtue of (19.7.1), B is a formally smooth A-algebra, hence $B \otimes_A A_0 = B/\mathfrak{J}B$ is a formally smooth A_0-algebra (19.3.5), (iii) and a complete local Noetherian ring; moreover, B_0 is a flat A_0-module by virtue of the hypothesis and of (19.7.1); as one has a k-isomorphism $u_{00} : B \otimes_A k = (B \otimes_A A_0) \otimes_{A_0} k \xrightarrow{\sim} B_0 \otimes_{A_0} k = B_{00}$, one deduces from (19.7.1.5), applied by replacing A by A_0 and $\mathfrak{J}$ by $\mathfrak{m}_0$, that there exists an A_0-isomorphism $u : B \otimes_A A_0 \xrightarrow{\sim} B_0$ such that $u_{00} = u \otimes 1$. As for the uniqueness assertion, note that the ideals $\mathfrak{J}^h B$ (resp. $\mathfrak{J}^h B'$) are closed in B (resp. B') ($\mathbf{0_I}$, 7.3.5), hence B and B' are separated and complete for the $\mathfrak{J}$-preadic topologies (Bourbaki, *Top. gén.*, chap. III, 3ᵉ éd., § 3, n° 5, cor. 2 of prop. 9); one has by hypothesis an A_0-isomorphism $v_0 : B \otimes_A A_0 \xrightarrow{\sim} B' \otimes_A A_0$ such that $u'v_0 = u$; as B is a formally smooth A-algebra and B' a flat A-module, one can apply (19.7.1.5), whence the existence of the A-isomorphism v answering the question. □

Remarks (19.7.3). — (i) We note that the uniqueness assertion in (19.7.2) is still valid if one only supposes that B and B' are complete *for the $\mathfrak{J}$-preadic topologies*. We do not know whether one can similarly improve the existence assertion, that is, whether one can dispense with assuming the local ring B_0 to be complete (for its $\mathfrak{n}_0$-preadic topology, where $\mathfrak{n}_0$ denotes its maximal ideal) by only requiring that B be complete for the $\mathfrak{J}$-preadic topology. When A_0 is complete for the $\mathfrak{m}$-preadic topology, one can see that this problem reduces to the following: if B_0 is a regular local Noetherian ring (not necessarily complete) containing the prime field $\mathbf{F}_p = \mathbf{Z}/p\mathbf{Z}$, does there exist for every $n > 1$ a flat $(\mathbf{Z}/p^n\mathbf{Z})$-algebra B such that B/pB is isomorphic to B_0?

(ii) We note that in general, the isomorphism v whose existence is asserted in (19.7.2) is *not unique* (cf. (19.8.7)).

19.8. Cohen algebras and Cohen rings; application to the structure of complete local rings The results of this section are immediate applications of the theorems of (19.7), but deserve to be stated explicitly because of their practical importance.

Definition (19.8.1). — Let A, B be two local Noetherian rings, $\mathfrak{m}$ the maximal ideal of A, $k = A/\mathfrak{m}$ its residue field, $\varphi : A \to B$ a local homomorphism, making B into an A-algebra. We say that B is a *Cohen A-algebra* if it satisfies the following conditions:

(i) B is a complete ring.
(ii) B is a flat A-module.
(iii) $B \otimes_A k$ is a field (in other words, $\mathfrak{m}B$ is the maximal ideal of B) which is a separable extension of k.

$\mathbf{0_{IV\text{-}1}}$ | 110

Theorem (19.8.2). — *Let A be a local Noetherian ring, k its residue field.*

(i) *If B is a Cohen A-algebra, B is a formally smooth A-algebra. For every complete local Noetherian ring C, every local homomorphism $A \to C$ and every ideal $\mathfrak{J} \neq C$ in C, every A-homomorphism $B \to C/\mathfrak{J}$ therefore factors as $B \xrightarrow{v} C \to C/\mathfrak{J}$, where v is an A-homomorphism (necessarily local).*
(ii) *For every field K, separable extension of k, there exists a Cohen A-algebra B such that $B \otimes_A k$ is k-isomorphic to K, and such an A-algebra is unique up to isomorphism.*

Proof. As $B \otimes_A k$ is a separable field extension of k, it is a formally smooth k-algebra (19.6.1), so assertion (i) follows from (19.7.1). To prove (ii), one can restrict to the case where A is *complete*, for it amounts to the same to say that B is a flat A-module or a flat $\widehat{A}$-module ($\mathbf{0_{III}}$, 10.2.3), one has $\mathfrak{m}B = \mathfrak{m}\widehat{A}B$ and k is the residue field of $\widehat{A}$. It then suffices to apply (19.7.2) taking $\mathfrak{J} = \mathfrak{m}$ and $B_0 = K$ (and using (19.6.1)). □

Definition (19.8.3). — A *prime local ring* is a local ring of the form $\mathbf{Z}_{p\mathbf{Z}}$, where $p\mathbf{Z}$ is a prime ideal of $\mathbf{Z}$. A *complete prime local ring* is the completion of a prime local ring.

The prime local rings are therefore of two kinds:

1° Those corresponding to maximal ideals $p\mathbf{Z}$ where $p \neq 0$ is a prime number; $\mathbf{Z}_{p\mathbf{Z}}$ is a discrete valuation ring, whose completion is the ring of p-adic integers usually denoted $\mathbf{Z}_p$.[21]

2° For the prime ideal $p\mathbf{Z} = (0)$, $\mathbf{Z}_{p\mathbf{Z}}$ is the field of rational numbers $\mathbf{Q}$, which is identical to its completion (the topology being naturally the topology of a local Noetherian ring, hence discrete here).

The terminology of (19.8.3), analogous to that of "prime fields", is justified in the same way: for every local ring A, consider the canonical homomorphism $\varphi : \mathbf{Z} \to A$, and let $p\mathbf{Z}$ be the inverse image under this homomorphism of the maximal ideal $\mathfrak{m}$ of A; $p\mathbf{Z}$ is a prime ideal of $\mathbf{Z}$ and the preceding homomorphism therefore factors as $\mathbf{Z} \to \mathbf{Z}_{p\mathbf{Z}} \xrightarrow{\psi} A$; moreover, as φ is the *unique* homomorphism of $\mathbf{Z}$ into A, p and ψ are determined in a unique way. In other words, for every local ring A, there is a unique homomorphism $\psi : P \to A$, where P is a prime local ring; if moreover A is separated and complete, one can extend this homomorphism by completion, and there is thus a unique homomorphism $\widehat{\psi} : \widehat{P} \to A$, where $\widehat{P}$ is a complete prime local ring. Moreover, ψ gives by passage to quotients a homomorphism of the residue field $\mathbf{F}_p$ if $p > 0$ (resp. $\mathbf{Q}$ if $p = 0$) into the residue field k of A, and p is therefore the *characteristic* of k.

If one takes in particular A to be a prime local ring (resp. complete prime local ring), one sees that there exists in such a ring only *a single endomorphism*, namely the identity.

Definition (19.8.4). — Let A be a local ring, $P \to A$ the unique homomorphism from a prime local ring P into A, p the characteristic of the residue fields of P and A. We say that A is a *Cohen ring* if it is a Cohen P-algebra, that is (19.8.1), if: $\mathbf{0_{IV\text{-}1}}$ | 111

1° A is Noetherian and complete.

2° A is a flat P-module (which also amounts to saying that A is a flat $\widehat{P}$-module (Bourbaki, *Alg. comm.*, chap. III, § 5, n° 4, prop. 4)).

3° A/pA is a field (necessarily separable over the residue field of P, this field being prime).

If $p = 0$, these conditions are equivalent to saying that A is a field of characteristic 0. If $p > 0$, one necessarily has $pA \neq 0$; condition 3° means that pA is the maximal ideal $\mathfrak{m}$ of A; condition 2° means that p is A-regular, since P is a discrete valuation ring ($\mathbf{0_I}$, 6.3.4). Hence A is a regular ring (17.1.1), *d*)) of dimension 1, and therefore a discrete valuation ring, complete by virtue of 1°; in summary:

Proposition (19.8.5). — *The Cohen rings are the fields of characteristic* 0 *and the complete discrete valuation rings whose residue field has characteristic* $p > 0$*, and whose maximal ideal is generated by* $p \cdot 1$ *(*1 *being the unity of the ring).*

We note that in the second case, $p \cdot 1 \neq 0$ since p is A-regular, hence one can identify $p \cdot 1$ with the integer p; the canonical homomorphism $\mathbf{Z}_p \to A$ is injective, and one identifies $p \cdot 1$ with the element p of $\mathbf{Z}_p$; one says in this case that A is a *p-ring* (or *Cohen p-ring*).

Theorem (19.8.6). — (Cohen). —

(i) *Let W be a Cohen ring, C a complete local Noetherian ring, $\mathfrak{J}$ an ideal of C distinct from C. Then every local homomorphism $u : W \to C/\mathfrak{J}$ factors as $W \xrightarrow{v} C \to C/\mathfrak{J}$ where v is a local homomorphism.*

(ii) *Let K be a field. There exists a Cohen ring W whose residue field is isomorphic to K. If W' is a second Cohen ring, K' its residue field, every isomorphism $u : K \xrightarrow{\sim} K'$ arises by passage to quotients from an isomorphism $v : W \xrightarrow{\sim} W'$.*

Proof. This is nothing other than (19.8.2) applied to the case where A is a prime local ring. □

Remarks (19.8.7). — (i) When K is of characteristic 0, part (ii) of (19.8.6) becomes trivial.

(ii) The homomorphism v of (19.8.6), (i) is *not* necessarily determined uniquely by u, as is shown already by the case where W is a field of characteristic 0, $\mathfrak{J}^2 = 0$ and u is an isomorphism (cf. (21.5.5)). Similarly, in (19.8.6), (ii), the isomorphism v is not necessarily determined uniquely

[21] This notation, now universally used, is in conflict with the notation A_f adopted in ($\mathbf{0_I}$, 1.2.3): with $A = \mathbf{Z}$ and $f = p$, A_f denotes the ring of rational numbers of the form k/p^n ($k \in \mathbf{Z}$, n an integer $\geqslant 0$); we will always avoid using the notation $\mathbf{Z}_p$ to denote this latter ring.

by u (cf. (21.5.5)). However, when K is *perfect* and of characteristic $p > 0$, one will see (21.5.5) that in (19.8.6), (ii) the isomorphism v is unique. One will also see later that in this case W identifies with the ring $W_\infty(K)$ of *Witt vectors of infinite length* over K.

(iii) In (19.8.6), (i), one can weaken the hypotheses on C by using (19.3.10) and (19.3.12).

Theorem (19.8.8). — (Cohen). — *Let A be a complete local Noetherian ring, k its residue field.* $\mathbf{0_{IV\text{-}1}}$ | 112

(i) *There exists a Cohen ring W such that A is isomorphic to a quotient ring of a formal power series ring $W[[T_1, \ldots, T_n]]$ (and in particular A is isomorphic to a quotient of a complete regular local ring (17.3.8)). If A contains a field, it is isomorphic to a quotient ring of $k[[T_1, \ldots, T_n]]$.*

(ii) *Suppose moreover that A is an integral domain. Then there exists a subring B of A such that: 1° B is isomorphic to a formal power series ring over a ring C which is a field or a Cohen ring (which implies that B is a complete regular local ring (17.3.8)); 2° B has the same residue field as A and the injection $B \to A$ is a local homomorphism; 3° A is a finite B-algebra.*

Proof. Let $\mathfrak{m}$ be the maximal ideal of A. There exists a Cohen ring W whose residue field is isomorphic to k (19.8.6), (ii); one therefore has a homomorphism $W \to A/\mathfrak{m}$, which then factors as $W \xrightarrow{u} A \to A/\mathfrak{m}$, where u is a local homomorphism (19.8.6), (i). For every finite family $(x_i)_{1 \leqslant i \leqslant n}$ of elements of $\mathfrak{m}$, there then exists a local homomorphism $v : W[[T_1, \ldots, T_n]] \to A$ extending u and such that $v(T_i) = x_i$ for all i (Bourbaki, *Alg. comm.*, chap. III, § 4, n° 5, prop. 6). When A contains a field, it contains a prime field P, of which k is an extension (necessarily separable), and therefore A contains a field isomorphic to k (19.6.2); one can then replace W by k in the preceding definition of v.

(i) Let us first take the x_i to be a system of generators of $\mathfrak{m}$. As W has the same residue field as A, and the classes of the x_i generate the graded ring $\mathrm{gr}_\bullet(A)$ as a k-algebra, $\mathrm{gr}(v) : \mathrm{gr}_\bullet(W[[T_1, \ldots, T_n]]) \to \mathrm{gr}_\bullet(A)$ is surjective; one deduces that v is itself surjective (Bourbaki, *Alg. comm.*, chap. III, § 2, n° 8, cor. 2 of th. 1). We recall that the case where A contains a field has already been seen and is included here only for convenience (19.6.3).

(ii) If A contains a field, it contains a field k' isomorphic to k as we have seen; one then considers a system of parameters $(y_j)_{1 \leqslant j \leqslant m}$ of A (16.3.6), one takes $B = k[[T_1, \ldots, T_m]]$ and one considers the local homomorphism $w : B \to A$ which coincides in k with an isomorphism $k \to k'$ and is such that $w(T_j) = y_j$ for $1 \leqslant j \leqslant m$. If A does not contain a field, the unique homomorphism $\mathbf{Z}_{p\mathbf{Z}} \to A$ (19.8.3) is necessarily injective (for otherwise, as A is an integral domain, its kernel would be the maximal ideal of $\mathbf{Z}_{p\mathbf{Z}}$ and its image would be isomorphic to a field; moreover one has $p > 0$ by hypothesis, $\mathbf{Z}_{p\mathbf{Z}}$ being a field if $p = 0$); the element $p \cdot 1$ of A (identified with p) is a non-zero-divisor in A, and is contained in $\mathfrak{m}$, hence (16.3.4) and (16.3.7) there exists a family $(z_i)_{1 \leqslant i \leqslant m-1}$ which, with p, forms a system of parameters of A. The Cohen ring W considered at the beginning of the proof is then a discrete valuation ring whose residue field is isomorphic to k, in which p generates the maximal ideal (19.8.5), and the homomorphism $u : W \to A$ defined at the beginning maps p to itself. One then takes $B = W[[T_1, \ldots, T_{m-1}]]$ and considers the local homomorphism $w : B \to A$ which coincides with u in W and is such that $w(T_i) = z_i$ for $1 \leqslant i \leqslant m - 1$. In both cases, if $\mathfrak{n}$ is $\mathbf{0_{IV\text{-}1}}$ | 113
the maximal ideal of B, it is clear that $\mathfrak{n}A$ is an ideal of definition of A; as moreover $B/\mathfrak{n}$ and $A/\mathfrak{m}$ are isomorphic, A is a quasi-finite B-module ($\mathbf{0_I}$, 7.4.4), hence a B-module of finite type since B is complete and A is separated for the $\mathfrak{n}$-preadic topologies ($\mathbf{0_I}$, 7.4.1). On the other hand, in both cases one has $\dim(B) = \dim(A) = m$; in the first case, this follows from (17.1.4), (iii); in the second, one sees directly that p and the T_i ($1 \leqslant i \leqslant m - 1$) form a B-regular sequence generating $\mathfrak{n}$, or one can also use the fact that these elements generate $\mathfrak{n}$ and that $\dim(B) \geqslant \dim(A)$ by (16.3.10). As A and B are integral domains, one finally deduces from (16.3.10) that w is injective, which completes the proof. □

Corollary (19.8.9). — *Let A be a complete local Noetherian integral domain containing a field k_0; let k be the residue field of A, and suppose that k is finite over k_0. Then, in the conclusion of (19.8.8), (ii), one can replace 1° and 2° by the condition that B is of the form $k_0[[T_1, \ldots, T_n]]$, the canonical injection $B \to A$ being a local k_0-homomorphism (for the usual k_0-algebra structure of B).*

Proof. Indeed, taking up the proof of (19.8.8), (ii), one defines this time $w : k_0[[T_1, \ldots, T_n]] \to A$ as coinciding in k_0 with the identity and mapping T_j to y_j for $1 \leqslant j \leqslant n$. The hypothesis that k is of finite degree over k_0 again implies that A is a quasi-finite B-module, hence of finite type by ($\mathbf{0_I}$, 7.4.1), and one concludes as in (19.8.8). □

Corollary (19.8.10). — *Let A be a local Artinian ring whose maximal ideal $\mathfrak{m}$ is of square zero; then there exists a regular local Noetherian ring B, with maximal ideal $\mathfrak{n}$, such that A is isomorphic to $B/\mathfrak{n}^2$.*

Proof. Let K be the residue field $A/\mathfrak{m}$ of A, and n the rank of $\mathfrak{m}/\mathfrak{m}^2 = \mathfrak{m}$ over K. If A contains a field, it follows from (19.6.3) that A is isomorphic to $B/\mathfrak{b}$, where $B = K[[T_1, \ldots, T_n]]$ and $\mathfrak{b}$ is contained in the square of the maximal ideal $\mathfrak{n}$ of B; but as $\operatorname{long}(B/\mathfrak{n}^2) = n+1 = \operatorname{long}(A)$, one necessarily has $\mathfrak{b} = \mathfrak{n}^2$.

Suppose next that A does not contain a field; this implies that K is of characteristic $p > 0$ and that $p \cdot 1 \neq 0$ in A (19.6.3); hence $p \cdot 1$ is an element of $\mathfrak{m}$, and there are therefore $n-1$ other elements x_i ($2 \leqslant i \leqslant n$) of $\mathfrak{m}$ forming with $p \cdot 1$ a basis of $\mathfrak{m}$ over K. Let W be a Cohen ring whose residue field is isomorphic to K; W is a discrete valuation ring in which p generates the maximal ideal; one has seen in the proof of (19.8.8) that there is a homomorphism $u : W \to A$ mapping p to itself and which by passage to quotients gives the identity on K. One takes $B = W[[T_2, \ldots, T_n]]$ and considers the local homomorphism $w : B \to A$ which coincides with u in W and is such that $w(T_i) = x_i$ for $2 \leqslant i \leqslant n$. It is clear that w is surjective and that its kernel $\mathfrak{b}$ is contained in the square of the maximal ideal $\mathfrak{n} = pB + BT_2 + \ldots + BT_n$ of B; as $\operatorname{long}(B/\mathfrak{n}^2) = n+1 = \operatorname{long}(A)$, one again has $\mathfrak{b} = \mathfrak{n}^2$. □

Proposition (19.8.11). — *Let A be a local Artinian ring, $\mathfrak{m}$ its maximal ideal, k its residue field. For A to be isomorphic to a quotient ring of a Cohen ring, it is necessary and sufficient that $\mathfrak{m}$ be generated by $p \cdot 1$, where p is the characteristic of k.*

Proof. The condition is evidently necessary (19.8.5). To see that it is sufficient, one observes, as at the beginning of the proof of (19.8.8), that there exists a Cohen ring W whose residue field is isomorphic to k and a local homomorphism $u : W \to A$. Moreover, if one considers the composite homomorphism $\mathbf{Z}_{p\mathbf{Z}} \to W \xrightarrow{u} A$ (which is necessarily the unique homomorphism of $\mathbf{Z}_{p\mathbf{Z}}$ into A), one sees that the image under u of the element $p \cdot 1$ of W is the element $p \cdot 1$ of A; as the element $p \cdot 1$ of W generates the maximal ideal of this ring, one deduces immediately from the hypothesis that $\operatorname{gr}(u) : \operatorname{gr}_\bullet(W) \to \operatorname{gr}_\bullet(A)$ is surjective, and therefore so is u (Bourbaki, *Alg. comm.*, chap. III, §2, n° 8, cor. 2 of th. 1). □ $\mathbf{0_{IV\text{-}1}}$ | 114

19.9. Relatively formally smooth algebras

Definition (19.9.1). — Let Λ be a topological ring, A a topological Λ-algebra, B a topological A-algebra. We say that B is a *formally smooth A-algebra relative to* Λ if, for every discrete topological A-algebra C, and every nilpotent ideal $\mathfrak{J}$ of C, every continuous A-homomorphism $u_0 : B \to C/\mathfrak{J}$ which factors as $B \xrightarrow{u} C \to C/\mathfrak{J}$, where u is a continuous Λ-homomorphism, also factors as $B \xrightarrow{v} C \to C/\mathfrak{J}$, where v is a continuous A-homomorphism.

It follows from this definition that if B is a *formally smooth* A-algebra, then B is also formally smooth relative to Λ, for every structure of topological Λ-algebra defined on A (in other words, every continuous ring homomorphism $\Lambda \to A$).

Proposition (19.9.2). — *Let Λ be a topological ring, A a topological Λ-algebra.*

(i) *A is a Λ-algebra formally smooth relative to Λ.*
(ii) *If B is an A-algebra formally smooth relative to Λ and C is a B-algebra formally smooth relative to Λ, then C is an A-algebra formally smooth relative to Λ.*
(iii) *Let B be an A-algebra formally smooth relative to Λ, A' a topological A-algebra, then the topological A'-algebra $B \otimes_A A'$ is formally smooth relative to Λ.*
(iv) *Let B be a topological A-algebra, S (resp. T) a multiplicative subset of A (resp. B) such that the canonical image of S in B is contained in T. If B is an A-algebra formally smooth relative to Λ, then $T^{-1}B$ is an $S^{-1}A$-algebra formally smooth relative to Λ.*
(v) *Let B_i ($1 \leqslant i \leqslant n$) be topological A-algebras. For $\prod_{i=1}^n B_i$ to be an A-algebra formally smooth relative to Λ, it is necessary and sufficient that each of the B_i be so.*

Proof. Assertion (i) is trivial, and the proof of the others closely follows the proofs of (19.3.5); it is therefore left to the reader. □

Corollary (19.9.3). — *Let A be a topological ring, A' and B two topological A-algebras. Then the topological A-algebra $B' = B \otimes_A A'$ is a B-algebra formally smooth relative to A.*

Proof. This follows from (19.9.2), (i) and (iii). □

Proposition (19.9.4). — *Let Λ be a topological ring, A a topological Λ-algebra, B a topological A-algebra. The following conditions are equivalent:*

a) *B is an A-algebra formally smooth relative to Λ.*
b) *$\widehat{B}$ is an A-algebra formally smooth relative to Λ.*
c) *$\widehat{B}$ is an $\widehat{A}$-algebra formally smooth relative to Λ.*
d) *$\widehat{B}$ is an $\widehat{A}$-algebra formally smooth relative to $\widehat{\Lambda}$.*

Proof. The proof is again left to the reader, modelled on that of (19.3.6). □

$\mathbf{0_{IV\text{-}1}}$ | 115

(19.9.5). Similarly, the statement (19.3.8) is still valid (with the same proof) when one replaces "formally smooth" by "formally smooth relative to Λ". If in the statement of (19.3.10) one replaces "formally smooth" by "formally smooth relative to Λ", the conclusion is replaced by the following (the proof remaining essentially unchanged): *every continuous A-homomorphism $u_0 : B \to C/\mathfrak{J}$ which factors as $B \xrightarrow{u} C \to C/\mathfrak{J}$, where u is a continuous Λ-homomorphism, also factors as $B \xrightarrow{v} C \to C/\mathfrak{J}$, where v is a continuous A-homomorphism.*

(19.9.6). The criteria for formal smoothness (19.4.1) and (19.4.2) are also valid when one replaces "formally smooth" by "formally smooth relative to Λ", the proofs remaining practically unchanged.

Proposition (19.9.7). — *Let Λ be a topological ring, A a topological Λ-algebra, B a topological A-algebra. Suppose that for every discrete A-algebra C and every ideal $\mathfrak{J}$ of C such that $\mathfrak{J}^2 = 0$, every continuous A-homomorphism $u_0 : B \to C/\mathfrak{J}$ which factors as $B \xrightarrow{u} C \to C/\mathfrak{J}$, where u is a continuous Λ-homomorphism, also factors as $B \xrightarrow{v} C \to C/\mathfrak{J}$, where v is a continuous A-homomorphism. Then B is an A-algebra formally smooth relative to Λ.*

Proof. The proof of (19.4.3) transcribes immediately. □

Proposition (19.9.8). — *Let Λ be a topological ring, A a topological Λ-algebra, B a topological A-algebra. For B to be an A-algebra formally smooth relative to Λ, it is necessary and sufficient that for every discrete topological B-module L, annihilated by an open ideal of B, one has (cf. 18.4.2)*

$$\mathrm{Exalcotop}_{A/\Lambda}(B, L) = 0.$$

Proof. Using the notation of the proof of (19.4.4), it suffices to note here that one can suppose that the extension E_Λ of B_Λ is Λ-trivial; the rest of the proof is then unchanged. □

When Λ, A and B are discrete rings, the criterion (19.9.8) reduces to

(19.9.8.1) $$\mathrm{Exalcom}_{A/\Lambda}(B, L) = 0 \quad \text{for every } B\text{-module } L;$$

in other words, *every commutative A-extension of B by a B-module, which is also Λ-trivial, is also A-trivial.*

19.10. Formally unramified algebras and formally étale algebras

(19.10.1). We will also need two notions closely related to that of a formally smooth algebra.

Definition (19.10.2). — Let A be a topological ring, B a topological A-algebra. We say that B is a *formally unramified* A-algebra if, for every A-homomorphism $p : E \to C$ of discrete A-algebras, whose kernel is nilpotent, and every continuous A-homomorphism $u : B \to C$, there exists *at most one* continuous A-homomorphism $v : B \to E$ such that u factors as $B \xrightarrow{v} E \xrightarrow{p} C$. We say that B is a *formally étale* A-algebra if it is formally smooth and formally unramified, in other words, if, for every surjective A-homomorphism $p : E \to C$ of discrete A-algebras, whose kernel is nilpotent, and for every continuous A-homomorphism $u : B \to C$, there exists *one and only one* continuous A-homomorphism $v : B \to E$ such that u factors as $B \xrightarrow{v} E \xrightarrow{p} C$.

$\mathbf{0}_{\mathbf{IV\text{-}1}}$ | 116

Examples (19.10.3). — We restrict here to *discrete* rings.

(i) If the structural homomorphism $\rho : A \to B$ is *surjective*, B is a *formally unramified* A-algebra, for with the notation of (19.10.2), the composite homomorphism $A \xrightarrow{\rho} B \xrightarrow{v} E$ must be the structural homomorphism, hence v is unique (if it exists). On the other hand, B is formally smooth if and only if $\ker(\rho) = \ker(\rho)^2$.

(ii) Let A be a ring, S a multiplicative subset of A; then $B = S^{-1}A$ is a *formally étale* A-algebra. Indeed, let $j : A \to B$ be the canonical homomorphism, $\rho : A \to E$ a ring homomorphism, $\mathfrak{J}$ a nilpotent ideal of E, $p : E \to C = E/\mathfrak{J}$ the canonical homomorphism. If $u : B \to C$ is an A-homomorphism, $u(s/1)$ is invertible in C for $s \in S$ since $s/1$ is invertible in B; but $u(s/1) = p(\rho(s))$, and as $\mathfrak{J}$ is nilpotent, the fact that the image of $\rho(s)$ in $E/\mathfrak{J}$ is invertible implies that $\rho(s)$ is itself invertible in E ($\mathbf{0}_{\mathbf{I}}$, 7.1.12); one concludes that ρ factors in a unique way as $A \xrightarrow{j} B \xrightarrow{v} E$, and one evidently has $u \circ j = (p \circ v) \circ j$, whence $u = p \circ v$, which proves our assertion.

(iii) A finite separable extension k' of a field k is a formally smooth k-algebra (19.6.1); we will see later that for a *finite type* extension K of a field k to be a formally étale k-algebra, it is necessary and sufficient that it be formally unramified, and this is also equivalent to K being a finite and separable extension of k (21.7.4).

(iv) A polynomial algebra $A[X_\alpha]_{\alpha \in I}$ over a ring A is *formally smooth* (19.3.3) but *not formally étale* if I is non-empty, as follows immediately from the definitions.

Remark (19.10.4). — The same reasoning as in (19.4.3) shows that in order to verify that a topological A-algebra B is formally unramified, one can, in the definition (19.10.2), restrict to the case where the kernel of $p : E \to C$ is of *square zero*; one can moreover restrict to the case where $u(B) \subset p(E)$ (for otherwise there is no v factoring u) and, replacing C by $u(B)$ and E by $p^{-1}(u(B))$, suppose u and p *surjective*.

§20. Derivations and differentials

The notions introduced in this section will be taken up again in geometric form in chapter IV, §16, and will play an important role in the study of preschemes. Their importance in this chapter stems first from their relations with the notion of a formally smooth algebra, and in particular from the theorems (20.4.9), (20.5.7) and (20.5.12), which will be translated into geometric language in the section of chapter IV devoted to smooth morphisms, and are in constant use in the applications. On the other hand, the differential notions will serve to prove in §22 important criteria for regularity which will play an essential role in the detailed study of Noetherian local rings made in §7 of chapter IV. $\mathbf{0}_{\mathbf{IV\text{-}1}}$ | 116

20.1. Derivations and algebra extensions $\mathbf{0}_{\mathbf{IV\text{-}1}}$ | 117

Proposition (20.1.1). — *Let A be a ring (not necessarily commutative), B, E, C A-rings, $p : E \to C$ an A-homomorphism whose kernel $\mathfrak{Q}$ is of square zero, $u : B \to C$ an A-homomorphism. Suppose that there exists an A-homomorphism $v_0 : B \to E$ such that u factors as $B \xrightarrow{v_0} E \xrightarrow{p} C$. Then the set of A-homomorphisms $v : B \to E$ such that $u = p \circ v$ is identical to the set of maps $v_0 + D$, where $D : B \to \mathfrak{Q}$ is a map satisfying the two following conditions:*

(i) *D is a homomorphism of A-bimodules.*
(ii) *For all f, g in B, one has*

$$D(fg) = f.D(g) + D(f).g. \tag{20.1.1.1}$$

Proof. To say that $p(v(f)) = p(v_0(f))$ for $f \in B$ means that $D(f) = v(f) - v_0(f)$ belongs to $\mathfrak{Q}$; if one writes $v(fg) = v(f)v(g)$, one obtains the relation (20.1.1.1), $\mathfrak{Q}$ being of square zero, and condition (i) follows from the fact that v and v_0 are A-homomorphisms.

If $\rho : A \to B$ is the structural homomorphism, one deduces from (20.1.1.1) that one has $D(\rho(a)f) = \rho(a)D(f) + D(\rho(a))f$ for all $a \in A$; but one must also have $D(\rho(a)f) = \rho(a)D(f)$ by (i), hence, setting $f = 1$, one obtains

$$D(\rho(a)) = 0 \qquad \text{for} \quad a \in A;$$

conversely, if D is null on $\rho(A)$ and satisfies (20.1.1.1), it also satisfies (i). □

Definition (20.1.2). — Given an A-ring B and a B-bimodule L, we call an *A-derivation* of B into L a map $D : B \to L$ satisfying conditions (i) and (ii) of (20.1.1).

It follows from (20.1.1) that the kernel of an A-derivation $D : B \to L$ is a sub-A-ring of B.

One sometimes calls a *derivation* of B into L a $\mathbf{Z}$-derivation, that is, an additive map of B into L satisfying (20.1.1.1); one then has $D(1) = 0$ for such a map. If B is an algebra over a *prime field* P, every $\mathbf{Z}$-derivation of B is a P-derivation: this is evident from the above if P is of characteristic > 0, and otherwise, the relation $n \cdot n^{-1} = 1$ for $n \in \mathbf{Z}$ gives

$$nD(n^{-1}) = 0$$

hence $D(n^{-1}) = 0$ since P is of characteristic 0.

It follows immediately from the definition (20.1.2) that if D, D' are two A-derivations of B into L, then so is $D - D'$. In other words, the set of A-derivations of B into L is endowed with a structure of *additive group*; we denote this group $\operatorname{Der}_A(B, L)$. If A is *commutative*, B a commutative *A-algebra*, and L a B-module, then, for every A-derivation D of B into L and every $b \in B$, bD is again an A-derivation of B into L, in other words $\operatorname{Der}_A(B, L)$ is then endowed with a structure of *B-module*.

Proposition (20.1.1) can be interpreted in the following way: $\mathbf{0}_{\mathbf{IV\text{-}1}}$ | 118

Corollary (20.1.3). — *Given two A-homomorphisms of A-rings $p : E \to C$, $u : B \to C$ where the first has kernel $\mathfrak{Q}$ of square zero, the set of A-homomorphisms $v : B \to E$ such that $u = p \circ v$ is either empty or a principal homogeneous space for the group $\operatorname{Der}_A(B, \mathfrak{Q})$.*

In particular:

Corollary (20.1.4). — *Let A be a ring, C an A-ring, L a C-bimodule, E an A-extension of C by L, $p : E \to C$ the augmentation. The map which, to every derivation $D \in \operatorname{Der}_A(C, L)$, associates the map $x \mapsto x + D(p(x))$ is an isomorphism of the group $\operatorname{Der}_A(C, L)$ onto the group of A-equivalences of E with itself.*

Proof. Apply (20.1.1) for $B = E$, $v_0 = \mathrm{I}_E$: the set of A-homomorphisms $v : E \to E$ such that $p \circ v = p$ is identical to the set of maps $v = \mathrm{I}_E + D'$, where $D' \in \operatorname{Der}_A(E, L)$. To say that such an A-homomorphism v is an A-equivalence amounts to saying that v restricts to the canonical injection on L, or equivalently that $D'(x) = 0$ in L; but this also means that D' factors as $E \xrightarrow{p} C \xrightarrow{D} L$, where D is an A-derivation. Whence the corollary. □

For trivial extensions, (20.1.3) gives:

Corollary (20.1.5). — *Let A be a ring, B, C two A-rings, L a C-bimodule, $u : B \to C$ an A-homomorphism; the map which, to every derivation $D \in \mathrm{Der}_A(B, L)$, associates the map $\alpha : x \mapsto (u(x), D(x))$ is a bijection onto the set of A-homomorphisms $v : B \to D_C(L)$ (cf. 18.2.3) such that u factors as $B \xrightarrow{v} D_C(L) \to C$.*

More particularly:

Corollary (20.1.6). — *Let A be a ring, B an A-ring, L a B-bimodule. If, to every derivation $D \in \mathrm{Der}_A(B, L)$, one associates: 1° the A-equivalence $(x, y) \mapsto (x, y + D(x))$ of the extension $D_B(L)$ with itself; 2° the A-homomorphism $x \mapsto (x, D(x))$ of B into $D_B(L)$, inverse on the right of the augmentation homomorphism $D_B(L) \to B$; one defines canonical bijections between:*

(i) *the set $\mathrm{Der}_A(B, L)$;*
(ii) *the set of A-equivalences of $D_B(L)$ with itself;*
(iii) *the set of A-homomorphisms inverse on the right of the augmentation homomorphism $D_B(L) \to B$.*

We note that the bijection thus established between (i) and (ii) respects the group structures, and that the bijection between (ii) and (iii) is none other than the bijection already defined in (18.3.8).

Corollary (20.1.7). — *Let A be a ring, C an A-ring, L an A-bimodule, E a trivial A-extension of C by L, $p : E \to C$ the augmentation. The set of A-derivations D of E into L such that $D(x) = x$ in L is identical to the set of maps $x \mapsto x - w(p(x))$, where w runs through the set of A-homomorphisms inverse on the right of p.*

Proof. It suffices to apply (20.1.1) for $B = E$, $v_0 = \mathrm{I}_E$; if $v = \mathrm{I}_E - D$, the condition $D(x) = x$ for $x \in L$ is equivalent to $v(x) = 0$ for $x \in L$, that is, $v = w \circ p$, where $w : C \to E$ is an A-homomorphism; the condition $p \circ v = p$ then gives $p \circ w = \mathrm{I}_C$, i.e., w is inverse on the right of p. □

20.2. Functorial properties of derivations $\mathbf{0_{IV\text{-}1}}$ | 119

(20.2.1). Let A be a ring, B an A-ring, L a B-bimodule; if L' is a second B-bimodule and $w : L \to L'$ a homomorphism of B-bimodules, it is clear that the map $D \mapsto w \circ D$ is a homomorphism of additive groups

$$w_0 : \mathrm{Der}_A(B, L) \longrightarrow \mathrm{Der}_A(B, L') \tag{20.2.1.1}$$

and if $w' : L' \to L''$ is a second homomorphism of B-bimodules, one has $(w' \circ w)_0 = w'_0 \circ w_0$. When A is commutative, B a commutative A-algebra and L a B-module, (20.2.1.1) is a homomorphism of B-*modules*.

In the second place, let B' be an A-ring, $v : B' \to B$ an A-homomorphism which makes L into a B'-bimodule; then the map $D \mapsto D \circ v$ is a homomorphism of additive groups,

$$v^0 : \mathrm{Der}_A(B, L) \longrightarrow \mathrm{Der}_A(B', L) \tag{20.2.1.2}$$

as follows from (20.1.1.1); if $v' : B'' \to B'$ is a second A-homomorphism, one has $(v \circ v')^0 = v'^0 \circ v^0$. When A, B and B' are commutative and L a B-module, (20.2.1.2) is a homomorphism of B-modules.

Finally, let $u : A' \to A$ be a ring homomorphism making B into an A'-ring; every A-derivation $D \in \mathrm{Der}_A(B, L)$ is also an A'-derivation, whence a canonical injection of groups

$$u^0 : \mathrm{Der}_A(B, L) \longrightarrow \mathrm{Der}_{A'}(B, L) \tag{20.2.1.3}$$

and if $u' : A'' \to A'$ is a second ring homomorphism, one has $(u \circ u')^0 = u'^0 \circ u^0$; when A, A' and B are commutative and L a B-module, (20.2.1.3) is a homomorphism of B-modules.

One can also say that

$$(A, B, L) \rightsquigarrow \mathrm{Der}_A(B, L)$$

is a *covariant functor* from the category $\boldsymbol{K}$ defined in (18.3.5) into the category $\boldsymbol{Ab}$ of commutative groups, by associating to every triplet (u, v, w) constituting a morphism of $\boldsymbol{K}$ the homomorphism $w_0 \circ v^0 \circ u^0$; the verification of the functoriality follows from the commutativity of the diagrams

$$\begin{tikzcd} \mathrm{Der}_A(B, L) \arrow[r, "v^0"] \arrow[d, "w_0"'] & \mathrm{Der}_A(B', L) \arrow[d, "w_0"] \\ \mathrm{Der}_A(B, L') \arrow[r, "v^0"] & \mathrm{Der}_A(B', L') \end{tikzcd} \qquad \begin{tikzcd} \mathrm{Der}_A(B, L) \arrow[r, "u^0"] \arrow[d, "w_0"'] & \mathrm{Der}_{A'}(B, L) \arrow[d, "w_0"] \\ \mathrm{Der}_A(B, L') \arrow[r, "u^0"] & \mathrm{Der}_{A'}(B, L') \end{tikzcd}$$

for every homomorphism $w : L \to L'$ of B-bimodules.

$\mathbf{0_{IV\text{-}1}}$ | 120

Theorem (20.2.2). — *Let $u : A \to B$, $v : B \to C$ be two ring homomorphisms, L a C-bimodule. There is a canonical exact sequence of commutative groups*

(20.2.2.1)
$$0 \longrightarrow \mathrm{Der}_B(C, L) \xrightarrow{u^0} \mathrm{Der}_A(C, L) \xrightarrow{v^0} \mathrm{Der}_A(B, L) \xrightarrow{\partial}$$
$$\longrightarrow \mathrm{Exan}_B(C, L) \xrightarrow{u^1} \mathrm{Exan}_A(C, L) \xrightarrow{v^1} \mathrm{Exan}_A(B, L)$$

where u^0, v^0 are the homomorphisms (20.2.1.3) and (20.2.1.2) respectively, u^1, v^1 are the homomorphisms defined in (18.3.4.1) and (18.3.3.1) respectively, and where ∂ is defined as follows: for every A-derivation D of B into L, $\partial(D)$ is the class of the B-extension of C by L defined by the A-homomorphism $\alpha : x \mapsto (v(x), D(x))$ (*cf.* (20.1.5)). *Moreover, the exact sequence* (20.2.2.1) *is functorial in L* (*for the homomorphisms defined in* (20.2.1.1) *and* (18.3.1.1) *respectively*).

Proof. As D is an A-derivation (and *a fortiori* a $\mathbf{Z}$-derivation) of B into L, the A-homomorphism $\alpha : x \mapsto (v(x), D(x))$ indeed defines on $D_C(L)$ a structure of B-extension, hence $\partial(D)$ is well defined (20.1.5). We must verify the exactness at the 5 places:

1) The exactness at $\mathrm{Der}_B(C, L)$ is trivial (cf. (20.2.1)).

2) By definition (20.2.1) the kernel of v^0 is the set of A-derivations of C which vanish on $v(B)$, that is, those which are also B-derivations; whence the exactness at $\mathrm{Der}_A(C, L)$.

3) The kernel of ∂ is formed of the derivations $D \in \mathrm{Der}_A(B, L)$ for which the B-extension defined by $\alpha : x \mapsto (v(x), D(x))$ is B-trivial; this means (18.2.3) that there exists a B-homomorphism $z \mapsto (z, w(z))$ of C into $D_C(L)$ (the structure of B-ring of $D_C(L)$ being defined by α); but such a homomorphism, being *a fortiori* an A-homomorphism, is of the form $z \mapsto (z, D'(z))$ where $D' \in \mathrm{Der}_A(C, L)$ (20.1.6); and writing that this is a B-homomorphism, we get

$$D(x)z + v(x)D'(z) = D'(v(x)z) = v(x)D'(z) + D'(v(x))z$$

for $x \in B$, $z \in C$, which gives $D'(v(x)) = D(x)$; the kernel of ∂ is therefore the image of v^0.

4) The kernel of u^1 is the set of classes of B-extensions of C by L which are A-trivial, hence (up to equivalence) of the form $D_C(L)$, where the structure of A-ring of $D_C(L)$ is defined by the homomorphism $t \mapsto (u(t), 0)$. Now, every structure of B-extension on $D_C(L)$ is defined by a homomorphism $\alpha : x \mapsto (v(x), D(x))$, where D is a $\mathbf{Z}$-derivation of B into L (20.1.5); to say that the structure of A-ring of this B-extension is deduced from its structure of B-ring by means of $u : A \to B$ means that $D(u(t)) = 0$ for $t \in A$, hence that D is an A-derivation, or equivalently that the class of the B-extension considered is of the form $\partial(D)$; whence the exactness at $\mathrm{Exan}_B(C, L)$.

5) The kernel of v^1 is the set of classes of A-extensions E of C by L which trivialise on $v(B)$, that is, for which there is an A-homomorphism $w : B \to E$ such that v factors as $B \xrightarrow{w} E \to C$; now such an A-homomorphism defines on E a structure of B-extension whose class has as its image under u^1 the class of the given A-extension; the converse being trivially true, this proves the exactness at $\mathrm{Exan}_A(C, L)$.

Finally, the functoriality in L follows trivially from the definitions. □

$\mathbf{0_{IV\text{-}1}}$ | 121

Corollary (20.2.3). — *Let A, B, C be three commutative rings, $u : A \to B$, $v : B \to C$ two ring homomorphisms, L a C-module. There is a canonical exact sequence of A-modules*

(20.2.3.1)
$$0 \longrightarrow \mathrm{Der}_B(C, L) \xrightarrow{u^0} \mathrm{Der}_A(C, L) \xrightarrow{v^0} \mathrm{Der}_A(B, L) \xrightarrow{\partial}$$
$$\longrightarrow \mathrm{Exalcom}_B(C, L) \xrightarrow{u^1} \mathrm{Exalcom}_A(C, L) \xrightarrow{v^1} \mathrm{Exalcom}_A(B, L)$$

functorial in L.

Proof. The reasoning is the same as in (20.2.2) once one has verified that for every derivation $D \in \mathrm{Der}_A(B, L)$, $\partial(D)$ is indeed the class of a B-extension of C by L which is a commutative B-algebra; but this follows immediately from the commutativity of C and from the fact that L is a C-module. □

Corollary (20.2.4). — *Under the hypotheses of* (20.2.2) (*resp.* (20.2.3)), *there is a canonical exact sequence, functorial in L,*

$$0 \longrightarrow \mathrm{Der}_B(C, L) \xrightarrow{u^0} \mathrm{Der}_A(C, L) \xrightarrow{v^0} \mathrm{Der}_A(B, L) \xrightarrow{\partial} \mathrm{Exan}_{B/A}(C, L) \longrightarrow 0 \tag{20.2.4.1}$$

(*resp.*

$$0 \longrightarrow \mathrm{Der}_B(C, L) \xrightarrow{u^0} \mathrm{Der}_A(C, L) \xrightarrow{v^0} \mathrm{Der}_A(B, L) \xrightarrow{\partial} \mathrm{Exalcom}_{B/A}(C, L) \longrightarrow 0). \tag{20.2.4.2}$$

This follows from the definition of $\mathrm{Exan}_{B/A}(C, L)$ (*resp.* $\mathrm{Exalcom}_{B/A}(C, L)$) *((18.3.7) and (18.4.2)).*

Remark (20.2.5). — Suppose that one has a commutative diagram of ring homomorphisms

$$\begin{tikzcd}
A \arrow[r] & B \arrow[r] & C \\
A' \arrow[r] \arrow[u] & B' \arrow[r] \arrow[u] & C' \arrow[u]
\end{tikzcd}$$

Then there is a commutative diagram

$$\begin{tikzcd}
0 \arrow[r] & \mathrm{Der}_B(C, L) \arrow[r] \arrow[d] & \mathrm{Der}_A(C, L) \arrow[r] \arrow[d] & \mathrm{Der}_A(B, L) \arrow[r, "\partial"] \arrow[d] & \mathrm{Exan}_B(C, L) \arrow[r] \arrow[d] & \mathrm{Exan}_A(C, L) \arrow[r] \arrow[d] & \mathrm{Exan}_A(B, L) \arrow[d] \\
0 \arrow[r] & \mathrm{Der}_{B'}(C', L) \arrow[r] & \mathrm{Der}_{A'}(C', L) \arrow[r] & \mathrm{Der}_{A'}(B', L) \arrow[r, "\partial"] & \mathrm{Exan}_{B'}(C', L) \arrow[r] & \mathrm{Exan}_{A'}(C', L) \arrow[r] & \mathrm{Exan}_{A'}(B', L)
\end{tikzcd}$$

and similarly for the exact sequences (20.2.3.1), (20.2.4.1) and (20.2.4.2).

20.3. Continuous derivations in topological rings

(20.3.1). Given two topological rings A, B (linearly topologised, as always), we will denote by $\mathrm{Hom.\ cont}(A, B)$ the set of continuous homomorphisms from A to B. Given a topological ring A, the category of topological A-rings is defined as that of A-rings (18.1.4) by replacing throughout "ring" by "topological ring" and "homomorphism" by "continuous homomorphism"; if B and C are two topological A-rings, we denote $\mathrm{Hom.\ cont}_A(B, C)$ the set of continuous A- **$\mathbf{0_{IV\text{-}1}}$** | 122
homomorphisms from B to C.

Let A be a topological ring, B a topological A-ring, L a topological B-bimodule; we denote $\mathrm{Dér.\ cont}_A(B, L)$ the set of *continuous* A-derivations of B into L; it is clear that this is a *subgroup* of $\mathrm{Der}_A(B, L)$ (and a sub-A-module when A and B are commutative and L a B-module).

(20.3.2). It is immediate that the proposition (20.1.1) remains valid when one replaces "ring" by "topological ring" and "homomorphism" by "continuous homomorphism". Similarly, (20.1.3) and (20.1.4) remain valid by replacing Der by Dér. cont, "ring" (resp. "bimodule") by "topological ring" (resp. "topological bimodule"), "homomorphism" by "continuous homomorphism"; one must naturally suppose in (20.1.4) that p is continuous, and replace "A-equivalences" by "continuous A-equivalences". One has the same results for (20.1.5) and (20.1.6), provided one takes as topology on $D_C(L)$ (resp. $D_B(L)$) the product topology (on $C \times L$, resp. $B \times L$).

Proposition (20.3.3). — *Let A be a topological ring, B a topological A-ring, L a discrete topological B-bimodule annihilated by an open bilateral ideal of B. If in B the square of every open bilateral ideal is open, one has* $\mathrm{Dér.\ cont}_A(B, L) = \mathrm{Der}_A(B, L)$.

Proof. Indeed, if $\mathfrak{R}$ is an open bilateral ideal of B annihilating L, and D an A-derivation of B into L, one has $D(\mathfrak{R}^2) \subset \mathfrak{R}.D(\mathfrak{R}) + D(\mathfrak{R}).\mathfrak{R} = 0$ (20.1.1.1), hence D is continuous. □

(20.3.4). All the results of (20.2.1) remain valid when one replaces "ring" by "topological ring", "bimodule" by "topological bimodule", "homomorphism" by "continuous homomorphism" and Der by Dér. cont.

Proposition (20.3.5). — *Let A be a topological ring, B a topological A-ring, L a discrete topological B-bimodule annihilated by an open bilateral ideal of B. There is then a canonical isomorphism*

$$\varinjlim \mathrm{Der}_{A/\mathfrak{J}}(B/\mathfrak{R}, L) \xrightarrow{\sim} \mathrm{Dér.\ cont}_A(B, L) \tag{20.3.5.1}$$

where in the first member the inductive limit is taken over the ordered filtered set of pairs $(\mathfrak{J}, \mathfrak{R})$ of bilateral ideals such that $\mathfrak{R}.L = L.\mathfrak{R} = 0$, $\mathfrak{J}.B \subset \mathfrak{R}$, $B.\mathfrak{J} \subset \mathfrak{R}$.

Proof. As $A/\mathfrak{J}$ and $B/\mathfrak{R}$ are discrete, one has canonical homomorphisms $w_{\mathfrak{J},\mathfrak{R}} : \mathrm{Der}_{A/\mathfrak{J}}(B/\mathfrak{R}, L) \to \mathrm{Dér.\ cont}_A(B, L)$ forming an inductive system (20.3.4), whence the homomorphism (20.3.5.1) by passage to the inductive limit. As the homomorphism $B/\mathfrak{R}' \to B/\mathfrak{R}$ is surjective for $\mathfrak{R} \supset \mathfrak{R}'$, it follows immediately from the definition that the homomorphism $\mathrm{Der}_{A/\mathfrak{J}}(B/\mathfrak{R}, L) \to \mathrm{Der}_{A/\mathfrak{J}}(B/\mathfrak{R}', L)$ (with $\mathfrak{R}.L = L.\mathfrak{R} = 0$, $\mathfrak{J}.B \subset \mathfrak{R}'$, $B.\mathfrak{J} \subset \mathfrak{R}'$) is injective, and it follows similarly that the homomorphism $\mathrm{Der}_{A/\mathfrak{J}}(B/\mathfrak{R}, L) \to \mathrm{Der}_{A/\mathfrak{J}'}(B/\mathfrak{R}, L)$ for $\mathfrak{J}' \subset \mathfrak{J}$ (20.2.1) is injective; one concludes that the homomorphism (20.3.5.1) is injective. On the other hand, if D is a continuous A-derivation of B into L, its kernel contains an open bilateral ideal $\mathfrak{R}_0$ of B, and if $\mathfrak{J}_0$ is an open bilateral ideal of A such that $\mathfrak{J}_0 B \subset \mathfrak{R}_0$ and $B\mathfrak{J}_0 \subset \mathfrak{R}_0$, it is clear that D is the canonical image of an $(A/\mathfrak{J}_0)$-derivation of $B/\mathfrak{R}_0$ into L, hence (20.3.5.1) is surjective. □

$\mathbf{0_{IV\text{-}1}}$ | 123

Proposition (20.3.6). — *Let $u : A \to B$, $v : B \to C$ be two continuous homomorphisms of topological rings, L a discrete C-bimodule annihilated by an open bilateral ideal of C. There is a canonical exact sequence*

$$\begin{aligned}(20.3.6.1)\quad 0 \longrightarrow \mathrm{Dér.\ cont}_B(C, L) \xrightarrow{u^0} \mathrm{Dér.\ cont}_A(C, L) \xrightarrow{v^0} \mathrm{Dér.\ cont}_A(B, L) \xrightarrow{\partial} \\ \longrightarrow \mathrm{Exantop}_B(C, L) \xrightarrow{u^1} \mathrm{Exantop}_A(C, L) \xrightarrow{v^1} \mathrm{Exantop}_A(B, L)\end{aligned}$$

where ∂ is defined by passage to the inductive limit from the homomorphism ∂ of (20.2.2.1); this exact sequence is functorial in L (in the category of discrete C-bimodules annihilated by open bilateral ideals).

Proof. This follows from the exactness of the functor $\varinjlim$, from (20.2.2). □

Corollary (20.3.7). — *Let A, B, C be three commutative topological rings, $u : A \to B$, $v : B \to C$ two continuous homomorphisms, L a discrete C-module annihilated by an open ideal of C. There is a canonical exact sequence of A-modules, functorial in L,*

(20.3.7.1)

$$\begin{aligned}0 \longrightarrow \mathrm{Dér.\ cont}_B(C, L) \xrightarrow{u^0} \mathrm{Dér.\ cont}_A(C, L) \xrightarrow{v^0} \mathrm{Dér.\ cont}_A(B, L) \xrightarrow{\partial} \\ \longrightarrow \mathrm{Exalcotop}_B(C, L) \xrightarrow{u^1} \mathrm{Exalcotop}_A(C, L) \xrightarrow{v^1} \mathrm{Exalcotop}_A(B, L).\end{aligned}$$

Corollary (20.3.8). — *Under the hypotheses of* (20.3.5) (*resp.* (20.3.6)) *there is a canonical exact sequence, functorial in L*

(20.3.8.1)

$$0 \longrightarrow \mathrm{Dér.\ cont}_B(C, L) \xrightarrow{u^0} \mathrm{Dér.\ cont}_A(C, L) \xrightarrow{v^0} \mathrm{Dér.\ cont}_A(B, L) \longrightarrow \mathrm{Exantop}_{B/A}(C, L) \longrightarrow 0$$

(*resp.*

(20.3.8.2)

$$0 \longrightarrow \mathrm{Dér.\ cont}_B(C, L) \xrightarrow{u^0} \mathrm{Dér.\ cont}_A(C, L) \xrightarrow{v^0} \mathrm{Dér.\ cont}_A(B, L) \longrightarrow \mathrm{Exalcotop}_{B/A}(C, L) \longrightarrow 0).$$

We leave to the reader the task of writing the diagrams analogous to those of (20.2.5).

20.4. Principal parts and differentials In the remainder of this section and in the three following sections, all rings are assumed *commutative*.

(20.4.1). Let A be a topological ring, B a topological A-algebra; the A-algebra $B \otimes_A B$ will be equipped with the *tensor product* topology, which in fact makes it into a topological A-algebra; we denote by p (or $p_{B/A}$) the surjective continuous A-homomorphism

$$p : B \otimes_A B \longrightarrow B \tag{20.4.1.1}$$

such that $p(b \otimes b') = bb'$; it is immediate that p is continuous. The *kernel* of p will be denoted $\mathfrak{J}_{B/A}$ (or simply $\mathfrak{J}$ if there is no risk of confusion). We denote by $j_1 : B \to B \otimes_A B$ and $j_2 : B \to B \otimes_A B$ the two canonical A-homomorphisms, such that

$$j_1(b) = b \otimes 1, \qquad j_2(b) = 1 \otimes b$$

which are continuous.

$\mathbf{0_{IV\text{-}1}}$ | 124

Definition (20.4.2). — The *augmented B-algebra of principal parts of order* 1 of B over A is the topological A-algebra quotient

$$\mathrm{P}^1_{B/A} = (B \otimes_A B)/\mathfrak{J}^2 \tag{20.4.2.1}$$

equipped with the structure of B-algebra defined by the homomorphism $\bar{j}_1 : B \to \mathrm{P}^1_{B/A}$ (deduced from j_1 by composition with the canonical map $B \otimes_A B \to \mathrm{P}^1_{B/A}$), and with the augmentation of B-algebra $\varepsilon : \mathrm{P}^1_{B/A} \to B$ (also denoted $\varepsilon_{B/A}$) deduced from p by passage to the quotient. As $p(b \otimes 1) = b$ by definition, it is clear that ε is indeed an augmentation of B-algebra.

Definition (20.4.3). — The kernel of the augmentation $\varepsilon : \mathrm{P}^1_{B/A} \to B$,

$$\Omega^1_{B/A} = \mathfrak{J}_{B/A}/(\mathfrak{J}_{B/A})^2 \tag{20.4.3.1}$$

equipped with the topology induced by that of $\mathrm{P}^1_{B/A}$, which in fact makes it into a topological B-module, is called the B-module of 1-*differentials* (or simply *differentials*) of B over A.

We note that the topology of $\Omega^1_{B/A}$ is also the quotient topology of the topology induced on $\mathfrak{J}_{B/A}$ by that of $B \otimes_A B$ (Bourbaki, *Top. gén.*, chap. III, 3e éd., § 2, n° 7, prop. 20). If B is discrete it follows that so is $\Omega^1_{B/A}$. We denote $\widehat{\Omega}^1_{B/A}$ the *separated completion* of the topological B-module $\Omega^1_{B/A}$.

Every topological ring B can be considered as a topological $\mathbf{Z}$-algebra (where $\mathbf{Z}$ is equipped with the discrete topology), so one can define the topological B-module $\Omega^1_{B/\mathbf{Z}}$, which is sometimes also called the B-module of *absolute differentials* over B and which one denotes Ω^1_B. If B is a topological algebra over a prime field P (discrete), one has $B \otimes_P B = B \otimes_{\mathbf{Z}} B$, hence $\Omega^1_{B/P} = \Omega^1_B$.

Lemma (20.4.4). — *Let A be a ring, B an A-algebra. The ideal $\mathfrak{J}_{B/A}$ of $B \otimes_A B$ is generated by the elements $1 \otimes s - s \otimes 1$, where s runs through a set of generators of the A-algebra B.*

Proof. It is clear that for every $x \in B$, one has $x \otimes 1 - 1 \otimes x \in \mathfrak{J}$; on the other hand, for all x, y in B, one has $x \otimes y = xy \otimes 1 + (x \otimes 1)(1 \otimes y - y \otimes 1)$. If $\sum_i (x_i \otimes y_i) \in \mathfrak{J}$, one has by definition $\sum_i x_i y_i = 0$, hence

$$\sum_i (x_i \otimes y_i) = \sum_i (x_i \otimes 1)(1 \otimes y_i - y_i \otimes 1) \tag{20.4.4.1}$$

which proves that $\mathfrak{J}$ is generated by the elements $1 \otimes x - x \otimes 1$. Moreover, if $x = st$, one has

$$x \otimes 1 - 1 \otimes x = (s \otimes 1)(t \otimes 1 - 1 \otimes t) + (s \otimes 1 - 1 \otimes s)(1 \otimes t) \tag{20.4.4.2}$$

which immediately completes the proof by induction. □

Proposition (20.4.5). — *Let A be a topological ring, B a topological A-algebra. The topology of $\Omega^1_{B/A}$ is less fine than the topology deduced from that of B (19.0.2); if in B the square of every open ideal is open, these two topologies are identical.*

Proof. The first assertion is trivial, the tensor product topology on $B \otimes_A B$ being less fine than the topology deduced from that of B; *a fortiori* the topology induced on $\mathfrak{J} = \mathfrak{J}_{B/A}$ by that of $B \otimes_A B$ is less fine than the topology on $\mathfrak{J}$ deduced from that of B. To prove the second assertion, write, by abuse of notation, $M \otimes N$ for the submodule $\operatorname{Im}(M \otimes_A N)$ for two sub-A-modules M, N of B. Using the relation $\mathbf{0}_{\mathbf{IV\text{-}1}}$ | 125

$$\begin{aligned}(xy) \otimes z - x \otimes (yz) &= (x \otimes 1)(1 \otimes z)(y \otimes 1 - 1 \otimes y) \\ &= xz \cdot (y \otimes 1 - 1 \otimes y) \\ &\quad - x \cdot (z \otimes 1 - 1 \otimes z)(y \otimes 1 - 1 \otimes y)\end{aligned}$$

in the B-module $B \otimes_A B$ (defined by j_1), and taking into account (20.4.4), one sees immediately that, if $\mathfrak{R}$ is an ideal of B, one has

$$((\mathfrak{R}^2 \otimes B) + (B \otimes \mathfrak{R}^2)) \cap \mathfrak{J} \subset (\mathfrak{R} \otimes \mathfrak{R}) \cap \mathfrak{J} + \mathfrak{R}\mathfrak{J} + \mathfrak{J}^2.$$

On the other hand, if x_i, y_i are elements of $\mathfrak{R}$ such that $\sum_i (x_i \otimes y_i) \in \mathfrak{J}$, it follows from (20.4.4.1) that $\sum_i (x_i \otimes y_i) \in \mathfrak{R}\mathfrak{J}$, and hence finally

$$(\mathfrak{R}^2 \otimes B + B \otimes \mathfrak{R}^2) \cap \mathfrak{J} \subset \mathfrak{R}\mathfrak{J} + \mathfrak{J}^2. \tag{20.4.5.1}$$

Now, there is a fundamental system of neighbourhoods of 0 in $\mathfrak{J}$ (for the topology induced by that of $B \otimes_A B$) obtained by taking for neighbourhoods of 0 the sets $(\mathfrak{R} \otimes B + B \otimes \mathfrak{R}) \cap \mathfrak{J}$, where $\mathfrak{R}$ runs through the set of open ideals. As the topology of $\Omega^1_{B/A}$ deduced from that of B is also the quotient by $\mathfrak{J}^2$ of the topology of $\mathfrak{J}$ deduced from that of B, the hypothesis on the open ideals of B and the relation (20.4.5.1) complete the proof of the second assertion. □

Definition (20.4.6). — Let p_1 and p_2 be the composite maps $B \xrightarrow{j_1} B \otimes_A B \to \mathrm{P}^1_{B/A}$, $B \xrightarrow{j_2} B \otimes_A B \to \mathrm{P}^1_{B/A}$, which are continuous A-homomorphisms such that $\varepsilon \circ p_1 = \varepsilon \circ p_2 = \mathrm{I}_B$. The continuous A-module homomorphism

$$d_{B/A} = p_1 - p_2 : B \longrightarrow \Omega^1_{B/A} \tag{20.4.6.1}$$

is called the *exterior differential* of B relative to A; for every $x \in B$, $d_{B/A}(x)$ (also denoted $d(x)$ or dx) is called the *differential* of x (relative to A).

When $A = \mathbf{Z}$, one writes d_B instead of $d_{B/\mathbf{Z}}$; if B is an algebra over a prime field P, one has $d_B = d_{B/P}$.

Proposition (20.4.7). — *The B-module $\Omega^1_{B/A}$ is generated by the elements $d_{B/A}(x)$, where x runs through a system of generators of the A-algebra B.*

Proof. As $d_{B/A}(x)$ is the canonical image of $x \otimes 1 - 1 \otimes x$ in $\Omega^1_{B/A}$, the proposition is an immediate consequence of (20.4.4). □

Theorem (20.4.8). — *Let A be a topological ring, B a topological A-algebra.*

(i) *There exists a unique isomorphism of augmented topological B-algebras*

$$\varphi : \mathrm{P}^1_{B/A} \xrightarrow{\sim} D_B(\Omega^1_{B/A}) \tag{20.4.8.1}$$

which reduces to the identity on $\Omega^1_{B/A}$.

(ii) *The homomorphism $d_{B/A}$ is an A-derivation of B into $\Omega^1_{B/A}$, having the following universal property: for every topological B-module L, the map $u \mapsto u \circ d_{B/A}$ is an isomorphism of A-modules*

$$\operatorname{Hom.\,cont}_B(\Omega^1_{B/A}, L) \xrightarrow{\sim} \operatorname{Dér.\,cont}_A(B, L). \tag{20.4.8.2}$$

Proof. (i) It is immediate that φ (using the notation of (20.4.6)) is necessarily the map $z \mapsto (\varepsilon(z), z - p_1(\varepsilon(z)))$, and the inverse isomorphism the map $(b, x) \mapsto p_1(b) + x$; these two maps being continuous, this proves the first assertion. We note that the topology of B identifies (by p_1) with the *quotient* of the topology of $B \otimes_A B$ by $\mathfrak{J}_{B/A}$. $\mathbf{0}_{\mathbf{IV\text{-}1}}$ | 126

(ii) The fact that $d_{B/A}$ is an A-derivation of B follows from the definition (20.4.6) and from (20.1.1).

To prove the universal property, recall that $\operatorname{Dér.\,cont}_A(B, L)$ identifies canonically with the set of continuous A-algebra homomorphisms $u : B \to D_B(L)$ such that the composite $B \xrightarrow{u} D_B(L) \xrightarrow{q} B$

is the identity (where $q(b,0) = b$ is the projection; cf. (20.1.6) and (20.3.2)). On the other hand, by virtue of the isomorphism φ, Hom. $\mathrm{cont}_B(\Omega^1_{B/A}, L)$ identifies canonically with the set of continuous B-algebra homomorphisms $v : \mathrm{P}^1_{B/A} \to D_B(L)$ such that the composite $\mathrm{P}^1_{B/A} \xrightarrow{v} D_B(L) \xrightarrow{q} B$ is the augmentation ε. As $p_2 = p_1 - d_{B/A}$ by definition, it suffices to prove that every $u \in G$ factors as

$$\begin{tikzcd} B \arrow[r, "u"] \arrow[d, "p_2"'] & D_B(L) \\ \mathrm{P}^1_{B/A} \arrow[ur, "v"'] & \end{tikzcd}$$

where v is a continuous B-homomorphism. Now, one already has a continuous A-algebra homomorphism $j : b \mapsto (b,0)$ from B into $D_B(L)$, which belongs to G; by definition of the topological tensor product of topological algebras ($\mathbf{0_I}$, 7.7.6), there therefore exists a continuous A-algebra homomorphism $w : B \otimes_A B \to D_B(L)$ making the diagram

$$\begin{tikzcd} B \otimes_A B \arrow[dr, "w"] & B \arrow[l, "j_1"'] \arrow[d, "j"] \\ B \arrow[u, "j_2"] \arrow[r, "u"'] & D_B(L) \end{tikzcd}$$

commutative. One therefore has by definition $w(b \otimes 1 - 1 \otimes b) = j(b) - u(b) \in L$, and by virtue of (20.4.4), this implies $w(\mathfrak{J}) \subset L$, hence $w(\mathfrak{J}^2) = 0$; w therefore factors as $B \otimes_A B \to \mathrm{P}^1_{B/A} \xrightarrow{v} D_B(L)$, where v is a continuous A-algebra homomorphism; moreover, as $v \circ p_1 = j$ is a homomorphism of B-algebras, v is a B-algebra homomorphism by the definition of the B-algebra structure of $\mathrm{P}^1_{B/A}$; as one has by definition $u = v \circ p_2$, this completes the proof. □

Theorem (20.4.9). — *Suppose that B is a topological A-algebra formally smooth. Then the topological B-module $\Omega^1_{B/A}$ is* formally projective.

Proof. Indeed, the hypothesis implies that $B \otimes_A B$ (equipped with the B-algebra structure defined by j_1) is a topological B-algebra formally smooth (19.3.5), (iii), and therefore also a topological A-algebra formally smooth (19.3.5), (ii); as B is topologically isomorphic to the A-algebra quotient $(B \otimes_A B)/\mathfrak{J}$ and is a formally smooth A-algebra, the conclusion follows from (19.5.3). □

$\mathbf{0_{IV\text{-}1}}$ | 127

Corollary (20.4.10). — *Suppose moreover that in B the square of every open ideal is open; then, for every open ideal $\mathfrak{R}$ of B, $\Omega^1_{B/A} \otimes_B (B/\mathfrak{R}) = \Omega^1_{B/A}/\mathfrak{R}.\Omega^1_{B/A}$ is a projective $(B/\mathfrak{R})$-module.*

Proof. Indeed, the topology of $\Omega^1_{B/A}$ is then deduced from that of B (20.4.5), and it suffices to apply (19.2.4). □

Corollary (20.4.11). — *Let A, B be two local Noetherian rings, $\rho : A \to B$ a local homomorphism, making B a topological A-algebra formally smooth (for the preadic topologies). Then, for every ideal of definition $\mathfrak{b}$ of B, $\Omega^1_{B/A} \otimes_B (B/\mathfrak{b})$ is a* free *$(B/\mathfrak{b})$-module.*

Proof. Indeed, it follows from (20.4.10) that this module is projective, and as $B/\mathfrak{b}$ is an Artinian ring, every projective $(B/\mathfrak{b})$-module is free ($\mathbf{0_{III}}$, 10.1.3). □

Proposition (20.4.12). — *Let A be a topological ring, B a topological A-algebra. If the structural homomorphism $A \to B$ is surjective, one has $\Omega^1_{B/A} = 0$.*

Proof. Indeed, one has $\mathrm{Der}_A(B, L) = 0$ for every B-module L by virtue of (20.1.1), and the proposition follows immediately from (20.4.8). □

Examples (20.4.13). — (i) Let A be a ring, $B = A[X_\alpha]_{\alpha \in I}$ a polynomial algebra over A. Then $\Omega^1_{B/A}$ is a free B-module, of which the dX_α form a *basis*. Indeed, the dX_α generate this B-module (20.4.7). On the other hand, if L is a free B-module with basis $(z_\alpha)_{\alpha \in I}$ whose index set I is the same, there exists an A-homomorphism u of B into $D_B(L)$ such that $u(X_\alpha) = (X_\alpha, z_\alpha)$

for every $\alpha \in I$, hence (20.1.5) a derivation D of B into L such that $D(X_\alpha) = z_\alpha$ for every α; by virtue of (20.4.8.1), this proves that the dX_α are linearly independent.

(ii) Let A be a ring, L an A-module, B the A-algebra $D_A(L)$; then the canonical homomorphism $x \mapsto d_{B/A}x$ of L into $\Omega^1_{B/A}$ is *bijective*, for it is immediate that the B-derivations of $B = D_A(L)$ into a B-module M are the maps of the form $(b, x) \mapsto u(x)$, where $u \in \mathrm{Hom}_A(L, M)$; one concludes by (20.4.8), (ii).

(iii) Suppose that B is the product of two topological A-algebras B_1, B_2 (identified with ideals of B). Then the images of $B_1 \otimes_A B_2$ and $B_2 \otimes_A B_1$ by the homomorphism p (20.4.1.1) are zero, whence it follows immediately that $\mathrm{P}^1_{B/A}$ identifies with the *product* (topological) $\mathrm{P}^1_{B_1/A} \times \mathrm{P}^1_{B_2/A}$, and that the B-module $\Omega^1_{B/A}$ is the *direct sum* (topological) of the B-modules $\Omega^1_{B_1/A}$ and $\Omega^1_{B_2/A}$ (annihilated by B_2 and B_1 respectively).

(iv) Let A, B be two integral domains such that $A \subset B$, B integral over A, and the field of fractions of B a *separable* extension of that of A. Then the B-module $\Omega^1_{B/A}$ is a *torsion* module. Indeed, for every $x \in B$, let f be the minimal polynomial of x over the field of fractions K of A; there exists a nonzero $a \in A$ such that $af[T] \in A[T]$; as x is separable over K, one has $f'(x) \neq 0$, and on the other hand from the relation $af(x) = 0$ one deduces that $af'(x)d_{B/A}x = 0$, whence our assertion by virtue of (20.4.7).

Remarks (20.4.14). — (i) We note that the B-module $\Omega^1_{B/A}$, stripped of its topology, is independent of the topologies of A and of B.

(ii) We will introduce later the "algebra of principal parts of order n" of B over A, $\mathrm{P}^n_{B/A} = (B \otimes_A B)/(\mathfrak{J}_{B/A})^{n+1}$, which is the basis of the "differential calculus of order n".

20.5. Fundamental functorial properties of $\Omega^1_{B/A}$ $\mathbf{0_{IV\text{-}1}}$ | 128

(20.5.1). In this section and the following, unless expressly stated otherwise, all rings and modules considered are assumed equipped with the *discrete* topology.

(20.5.2). Let A be a ring, B, C two A-algebras, $u : B \to C$ an A-homomorphism; there is a commutative diagram

(20.5.2.1)
$$\begin{tikzcd} B \otimes_A B \arrow[r, "u\otimes u"] \arrow[d, "p_{B/A}"'] & C \otimes_A C \arrow[d, "p_{C/A}"] \\ B \arrow[r, "u"] & C \end{tikzcd}$$

whence by passage to quotients, an A-homomorphism of algebras

(20.5.2.2)
$$u' : \mathrm{P}^1_{B/A} \longrightarrow \mathrm{P}^1_{C/A}$$

such that the diagram

$$\begin{tikzcd} \mathrm{P}^1_{B/A} \arrow[r, "u'"] & \mathrm{P}^1_{C/A} \\ B \arrow[u, "p_1"] \arrow[r, "u"] & C \arrow[u, "p_1"'] \end{tikzcd}$$

is commutative; as $u \otimes u$ maps $\mathfrak{J}_{B/A}$ into $\mathfrak{J}_{C/A}$, one obtains, by restricting u' to $\Omega^1_{B/A}$, a map

(20.5.2.3)
$$u'' : \Omega^1_{B/A} \longrightarrow \Omega^1_{C/A}$$

such that the pair (u'', u) is a *di-homomorphism* for the B-module structure of $\Omega^1_{B/A}$ and the C-module structure of $\Omega^1_{C/A}$; this last fact allows one to deduce canonically a *homomorphism of C-modules*

(20.5.2.4)
$$u_{C/B/A} : \Omega^1_{B/A} \otimes_B C \longrightarrow \Omega^1_{C/A}.$$

$\mathbf{0_{IV\text{-}1}}$ | 129

Moreover, as the diagram

$$\begin{tikzcd} \mathrm{P}^1_{B/A} \arrow[r, "u'"] & \mathrm{P}^1_{C/A} \\ B \arrow[u, "p_2"] \arrow[r, "u"] & C \arrow[u, "p_2"'] \end{tikzcd} \tag{20.5.2.5}$$

is also commutative, one deduces that the diagram

$$\begin{tikzcd} \Omega^1_{B/A} \arrow[r, "u''"] & \Omega^1_{C/A} \\ B \arrow[u, "d_{B/A}"] \arrow[r, "u"] & C \arrow[u, "d_{C/A}"'] \end{tikzcd} \tag{20.5.2.6}$$

is commutative. Finally, if $w : C \to D$ is a second homomorphism of A-algebras, one has the transitivity property

$$(w \circ u)_{D/B/A} = w_{D/C/A} \circ (u_{C/B/A} \otimes \mathrm{I}_D) \tag{20.5.2.7}$$

as follows from the definition.

(20.5.3). Let now A, B be two rings, $v : A \to B$ a homomorphism of rings, C a B-algebra which becomes an A-algebra by means of v; then the canonical map $v_0 : C \otimes_A C \to C \otimes_B C$ is a surjective *di-homomorphism* of algebras (relative to $v : A \to B$) such that the diagram

$$\begin{tikzcd} C \otimes_A C \arrow[r, "v_0"] \arrow[d, "p_{C/A}"'] & C \otimes_B C \arrow[d, "p_{C/B}"] \\ C \arrow[r, "\mathrm{I}_C"] & C \end{tikzcd} \tag{20.5.3.1}$$

is commutative; by passage to quotients, one deduces a di-homomorphism of algebras

$$v' : \mathrm{P}^1_{C/A} \longrightarrow \mathrm{P}^1_{C/B} \tag{20.5.3.2}$$

such that the diagram

$$\begin{tikzcd} \mathrm{P}^1_{C/A} \arrow[r, "v'"] & \mathrm{P}^1_{C/B} \\ C \arrow[u, "p_1"] \arrow[r, "\mathrm{I}_C"] & C \arrow[u, "p_1"'] \end{tikzcd}$$

is commutative. As v_0 maps $\mathfrak{J}_{C/A}$ into $\mathfrak{J}_{C/B}$, one obtains, by restricting v' to $\Omega^1_{C/A}$, a map

$$v_{C/B/A} : \Omega^1_{C/A} \longrightarrow \Omega^1_{C/B} \tag{20.5.3.3}$$

which is a *homomorphism of C-modules*. Moreover, since the diagram **$0_{\text{IV-1}}$** | 130

$$\begin{tikzcd} \mathrm{P}^1_{C/A} \arrow[r, "v'"] & \mathrm{P}^1_{C/B} \\ C \arrow[u, "p_2"] \arrow[r, "\mathrm{I}_C"] & C \arrow[u, "p_2"'] \end{tikzcd} \tag{20.5.3.4}$$

is commutative, it follows that the diagram

$$\begin{tikzcd} \Omega^1_{C/A} \arrow[r, "v_{C/B/A}"] & \Omega^1_{C/B} \\ C \arrow[u, "d_{C/A}"] \arrow[r, "\mathrm{I}_C"] & C \arrow[u, "d_{C/B}"'] \end{tikzcd} \tag{20.5.3.5}$$

is commutative. Finally, if $s : A' \to A$ is a second ring homomorphism, one has the transitivity property

$$(v \circ s)_{C/B/A'} = v_{C/B/A} \circ s_{C/A/A'}. \tag{20.5.3.6}$$

(20.5.4). If now one has a commutative diagram of ring homomorphisms

$$\begin{tikzcd} B \arrow[r, "v"] & B' \\ A \arrow[u, "f"] \arrow[r, "u"] & A' \arrow[u, "g"'] \end{tikzcd}$$

one deduces from (20.5.2.4) and (20.5.3.3), by composition, a homomorphism of B'-modules

(20.5.4.1) $$\Omega^1_{B/A} \otimes_B B' \xrightarrow{v_{B'/B/A}} \Omega^1_{B'/A} \xrightarrow{u_{B'/A'/A}} \Omega^1_{B'/A'}$$

such that the diagram of A'-homomorphisms

(20.5.4.2) $$\begin{tikzcd} \Omega^1_{B/A} \otimes_B B' \arrow[r] & \Omega^1_{B'/A'} \\ B' \arrow[u, "d_{B/A} \otimes 1"] \arrow[r, "\mathrm{I}_{B'}"] & B' \arrow[u, "d_{B'/A'}"'] \end{tikzcd}$$

is commutative. The homomorphism (20.5.4.1) corresponds moreover to a di-homomorphism of B-modules

(20.5.4.3) $$\Omega^1_{B/A} \longrightarrow \Omega^1_{B'/A'}.$$

Proposition (20.5.5). — *If A', B are two A-algebras and $B' = B \otimes_A A'$, the canonical homomorphism* (20.5.4.1)

(20.5.5.1) $$\Omega^1_{B/A} \otimes_B B' \longrightarrow \Omega^1_{B'/A'}$$

is bijective.

Proof. The first member of (20.5.5.1) is none other than $\Omega^1_{B/A} \otimes_A A'$. One can write $B' \otimes_{A'} B' =$ $(B \otimes_A B) \otimes_A A'$ up to canonical isomorphism, and $p_{B'/A'}$ then identifies with $p_{B/A} \otimes \mathrm{I}_{A'}$; hence (as $p_{B/A}$ is surjective) $\mathfrak{J}_{B'/A'} = \mathrm{Im}(\mathfrak{J}_{B/A} \otimes_A A')$ and $\mathfrak{J}^2_{B'/A'} = \mathrm{Im}(\mathfrak{J}^2_{B/A} \otimes_A A')$, whence $\mathrm{P}^1_{B'/A'} =$ $\mathrm{P}^1_{B/A} \otimes_A A'$ up to canonical isomorphism, which transforms the augmentation ideals into each other; as the A-module $\mathrm{P}^1_{B/A}$ identifies canonically with the direct sum of B and $\Omega^1_{B/A}$, one has $\mathbf{0_{IV\text{-}1}}$ | 131

(20.5.5.2) $$\Omega^1_{B/A} \otimes_A A' = \Omega^1_{B'/A'}$$

by the same isomorphism, and one verifies immediately that the composite of this isomorphism and the canonical isomorphism $\Omega^1_{B/A} \otimes_B B' \xrightarrow{\sim} \Omega^1_{B/A} \otimes_A A'$ is none other than (20.5.5.1). □

(20.5.6). The canonical homomorphisms (20.5.2.4) and (20.5.3.3) give, by functoriality, for every C-module L, canonical homomorphisms

(20.5.6.1) $$\mathrm{Hom}_C(\Omega^1_{C/A}, L) \longrightarrow \mathrm{Hom}_C(\Omega^1_{B/A} \otimes_B C, L) = \mathrm{Hom}_B(\Omega^1_{B/A}, L)$$

(20.5.6.2) $$\mathrm{Hom}_C(\Omega^1_{C/B}, L) \longrightarrow \mathrm{Hom}_C(\Omega^1_{C/A}, L).$$

In view of (20.4.8.2) and of the commutative diagrams (20.5.2.6) and (20.5.3.5), these homomorphisms are none other (up to canonical identification) than the homomorphisms (20.2.1.2) and (20.2.1.3) respectively.

Theorem (20.5.7). — *Let $u : A \to B$, $v : B \to C$ be two ring homomorphisms.*

(i) *The sequence of C-modules*

(20.5.7.1) $$\Omega^1_{B/A} \otimes_B C \xrightarrow{v_{C/B/A}} \Omega^1_{C/A} \xrightarrow{u_{C/B/A}} \Omega^1_{C/B} \longrightarrow 0$$

is exact.

(ii) *For $v_{C/B/A}$ to be left-invertible, it is necessary and sufficient that C be a B-algebra formally smooth relative to A (for the discrete topologies (cf.* (19.9.1)*)); in particular, it suffices that C be a B-algebra formally smooth (for the discrete topologies).*

Proof. (i) The exactness of the sequence (20.2.4.2) shows, taking into account (20.5.6), that the sequence

$$0 \longrightarrow \mathrm{Hom}_C(\Omega^1_{C/B}, L) \longrightarrow \mathrm{Hom}_C(\Omega^1_{C/A}, L) \longrightarrow \mathrm{Hom}_C(\Omega^1_{B/A} \otimes_B C, L)$$

is exact for every C-module L. It is known that this implies the exactness of the sequence (20.5.7.1) (Bourbaki, *Alg.*, chap. II, 3^e^ éd., § 2, n° 1, th. 1).

(ii) By virtue of the exactness of (20.5.7.1), to say that $v_{C/B/A}$ is left-invertible means that the sequence

(20.5.7.2) $$0 \longrightarrow \Omega^1_{B/A} \otimes_B C \xrightarrow{v_{C/B/A}} \Omega^1_{C/A} \xrightarrow{u_{C/B/A}} \Omega^1_{C/B} \longrightarrow 0$$

is *exact and split*; it is known (Bourbaki, *loc. cit.*, n° 1, prop. 1) that this is equivalent to saying that for every C-module L, the sequence

$$0 \longrightarrow \mathrm{Hom}_C(\Omega^1_{C/B}, L) \longrightarrow \mathrm{Hom}_C(\Omega^1_{C/A}, L) \longrightarrow \mathrm{Hom}_C(\Omega^1_{B/A} \otimes_B C, L) \longrightarrow 0$$

is exact; taking into account (20.5.6) and (20.2.4.2), this condition is equivalent to

$$\mathrm{Exalcom}_{B/A}(C, L) = 0$$

for every C-module L, and the conclusion follows from (19.9.8.1). □

We note moreover that if one has a commutative diagram of ring homomorphisms $\mathbf{0_{IV\text{-}1}}$ | 132

$$\begin{tikzcd} A' \arrow[r] & B' \arrow[r] & C' \\ A \arrow[u] \arrow[r] & B \arrow[u] \arrow[r] & C \arrow[u] \end{tikzcd}$$

one deduces a commutative diagram

(20.5.7.3) $$\begin{tikzcd} \Omega^1_{B/A} \otimes_B C \arrow[r] \arrow[d] & \Omega^1_{C/A} \arrow[r] \arrow[d] & \Omega^1_{C/B} \arrow[r] \arrow[d] & 0 \\ \Omega^1_{B'/A'} \otimes_{B'} C' \arrow[r] & \Omega^1_{C'/A'} \arrow[r] & \Omega^1_{C'/B'} \arrow[r] & 0 \end{tikzcd}$$

where the vertical arrows come from the di-homomorphisms (20.5.4.3).

Corollary (20.5.8). — *Suppose that the homomorphism $v : B \to C$ makes C into a B-algebra formally étale* (*for the discrete topologies* (19.10.2)); *then the homomorphism* (20.5.2.4)

$$v_{C/B/A} : \Omega^1_{B/A} \otimes_B C \longrightarrow \Omega^1_{C/A}$$

is bijective.

Proof. Indeed, if C is a B-algebra formally unramified for the discrete topologies, it follows from (19.10.4), (20.4.8) and (20.1.1) that one has $\mathrm{Hom}_C(\Omega^1_{C/B}, L) = 0$ for *every* C-module L, hence $\Omega^1_{C/B} = 0$ (cf. (20.7.4)); on the other hand, if C is a B-algebra formally smooth for the discrete topologies, the sequence (20.5.7.2) is exact; whence the corollary. □

Corollary (20.5.9). — *Let A be a ring, B an A-algebra, S a multiplicative subset of B; then the canonical homomorphism*

(20.5.9.1) $$S^{-1}\Omega^1_{B/A} \longrightarrow \Omega^1_{S^{-1}B/A}$$

is bijective.

Proof. It suffices to apply (20.5.8) to $C = S^{-1}B$, which is a B-algebra formally étale for the discrete topologies (19.10.3), (ii). □

Taking into account (20.5.5), one can therefore write

(20.5.9.2) $$\Omega^1_{S^{-1}B/S^{-1}A} = S^{-1}\Omega^1_{B/A} = \Omega^1_{S^{-1}B/A},$$

up to canonical isomorphisms.

Corollary (20.5.10). — *If k is a field and $K = k(X_\alpha)_{\alpha \in I}$ a pure transcendental extension of k, the dX_α form a basis of the K-vector space $\Omega^1_{K/k}$.*

Proof. As K is the field of fractions of the polynomial ring $k[X_\alpha]_{\alpha \in I}$, this follows from (20.4.13), (i) and (20.5.9). □

$\mathbf{0_{IV\text{-}1}}$ | 133

(20.5.11). Let A be a ring, B an A-algebra, $\mathfrak{R}$ an ideal of B, C the A-algebra quotient $B/\mathfrak{R}$, and consider the composite homomorphism of A-modules

(20.5.11.1) $$\delta : \mathfrak{R} \longrightarrow B \xrightarrow{d_{B/A}} \Omega^1_{B/A}$$

where the first arrow is the canonical injection; as $d(xy) = xdy + ydx$, we see that $\delta(\mathfrak{R}^2) \subset \mathfrak{R}.\Omega^1_{B/A}$, whence, by passing to quotients, a homomorphism of A-modules

(20.5.11.2) $$\delta_{C/B/A} : \mathfrak{R}/\mathfrak{R}^2 \longrightarrow \Omega^1_{B/A} \otimes_B C = \Omega^1_{B/A}/(\mathfrak{R}.\Omega^1_{B/A}).$$

But in fact, $\delta_{C/B/A}$ is a homomorphism of C-*modules*, since for $x \in B$ and $y \in \mathfrak{R}$, we have $ydx \in \mathfrak{R}.\Omega^1_{B/A}$, hence $d(xy) \equiv xdy \pmod{\mathfrak{R}.\Omega^1_{B/A}}$, which proves first that (20.5.11.2) is a homomorphism of B-modules, and as $\mathfrak{R}$ annihilates both members, this establishes our assertion.

If B' is a second A-algebra, $u : B \to B'$ an A-homomorphism, $\mathfrak{R}'$ an ideal of B' such that $u(\mathfrak{R}) \subset \mathfrak{R}'$ and $C' = B'/\mathfrak{R}'$ the quotient algebra, one has a commutative diagram

(20.5.11.3)
$$\begin{tikzcd} \mathfrak{R}/\mathfrak{R}^2 \arrow[r, "\delta_{C/B/A}"] \arrow[d] & \Omega^1_{B/A} \otimes_B C \arrow[d] \\ \mathfrak{R}'/\mathfrak{R}'^2 \arrow[r, "\delta_{C'/B'/A}"] & \Omega^1_{B'/A} \otimes_{B'} C' \end{tikzcd}$$

where the vertical arrows come from u (20.5.2.4).

Theorem (20.5.12). — *Let A be a ring, B an A-algebra, C the A-algebra quotient $B/\mathfrak{R}$, $u : B \to C$ the canonical homomorphism.*

(i) *One has an exact sequence of C-modules*

(20.5.12.1) $$\mathfrak{R}/\mathfrak{R}^2 \xrightarrow{\delta_{C/B/A}} \Omega^1_{B/A} \otimes_B C \xrightarrow{u_{C/B/A}} \Omega^1_{C/A} \longrightarrow 0$$

where $u_{C/B/A}$ and $\delta_{C/B/A}$ are defined by (20.5.2.4) *and* (20.5.11.2) *respectively.*

(ii) *If one sets $E = B/\mathfrak{R}^2$, the canonical homomorphism* (20.5.2.4)

$$\Omega^1_{B/A} \otimes_B C \longrightarrow \Omega^1_{E/A} \otimes_E C$$

is bijective.

(iii) *The three following conditions are equivalent:*

a) *$\delta_{C/B/A}$ is left-invertible.*

b) *Every A-extension of C by a C-module L, whose inverse image by $u : B \to C$ is A-trivial, is itself A-trivial.*

c) *The A-algebra $E = B/\mathfrak{R}^2$ is an A-trivial extension of C by $\mathfrak{R}/\mathfrak{R}^2$.*

(iv) *There is a canonical bijective correspondence between the left inverses of $\delta_{C/B/A}$ and the right inverses of the canonical homomorphism $E \to C$.*

Proof. (i) As u is surjective, one has $\mathrm{Der}_B(C, L) = 0$ for every C-module L by virtue of (20.1.1). The exact sequence (20.2.3.1) therefore becomes $\mathbf{0_{IV\text{-}1}}$ | 134

(20.5.12.2)
$$0 \longrightarrow \mathrm{Der}_A(C, L) \xrightarrow{v^0} \mathrm{Der}_A(B, L) \xrightarrow{\partial} \mathrm{Exalcom}_B(C, L) \xrightarrow{v^1} \mathrm{Exalcom}_A(C, L) \xrightarrow{u^1} \mathrm{Exalcom}_A(B, L)$$

where v denotes the homomorphism $A \to B$. Recall on the other hand that $\mathrm{Exalcom}_B(C, L)$ is canonically identified with $\mathrm{Hom}_C(\mathfrak{R}/\mathfrak{R}^2, L)$ (18.3.8); one deduces therefore from (20.5.12.2) and (20.4.8) the exact sequence

(20.5.12.3)
$$0 \longrightarrow \mathrm{Hom}_C(\Omega^1_{C/A}, L) \longrightarrow \mathrm{Hom}_C(\Omega^1_{B/A} \otimes_B C, L) \xrightarrow{\varphi} \mathrm{Hom}_C(\mathfrak{R}/\mathfrak{R}^2, L) \xrightarrow{\psi} \mathrm{Ker}(u^1) \longrightarrow 0$$

with $\varphi = \partial \circ \eta^{-1}$ and $\psi = v^1 \circ \eta$. Returning to the definitions of ∂ (20.2.2) and of η (18.3.8), one verifies immediately that φ is precisely the homomorphism $\mathrm{Hom}(\delta_{C/B/A}, 1_L)$. The existence of the exact sequence formed by the first 4 terms of (20.5.12.3) shows therefore that the sequence (20.5.12.1) is exact (Bourbaki, *Alg.*, chap. II, 3e éd., § 2, n° 1, th. 1).

(ii) Apply to B and the ideal $\mathfrak{R}^2$ the exact sequence (20.5.12.1), which gives

(20.5.12.4)
$$\mathfrak{R}^2/\mathfrak{R}^4 \longrightarrow \Omega^1_{B/A} \otimes_B E \longrightarrow \Omega^1_{E/A} \longrightarrow 0$$

whence, by tensoring with C (considered as an E-algebra), the exact sequence

$$\mathfrak{R}^2/\mathfrak{R}^4 \otimes_E C \longrightarrow \Omega^1_{B/A} \otimes_B C \longrightarrow \Omega^1_{E/A} \otimes_E C \longrightarrow 0.$$

But if x, y are two elements of $\mathfrak{R}$ and ζ the class of xy modulo $\mathfrak{R}^4$, the image $\delta'(\zeta \otimes 1)$ is $(x d_{B/A}(y) + y d_{B/A}(x)) \otimes 1$; but as the images of x and of y in C are zero, one has also $d_{B/A}(xy) \otimes 1 = 0$ in $\Omega^1_{B/A} \otimes_B C$, which proves our assertion.

(iii) To say that $\delta_{C/B/A}$ is left-invertible amounts, taking into account the exactness of (20.5.12.1), to saying that the sequence

(20.5.12.5)
$$0 \longrightarrow \mathfrak{R}/\mathfrak{R}^2 \xrightarrow{\delta_{C/B/A}} \Omega^1_{B/A} \otimes_B C \xrightarrow{u_{C/B/A}} \Omega^1_{C/A} \longrightarrow 0$$

is *exact and split*, and it is known (Bourbaki, *loc. cit.*) that to say that $\mathrm{Ker}(u^1) = 0$ in the exact sequence (20.5.12.3) for every L, which shows the equivalence of the conditions a) and b) (cf. (18.3.6.2)).

The fact that b) implies c) comes from the fact that the inverse image by $u : B \to C$ of the A-extension E of C by $\mathfrak{R}/\mathfrak{R}^2$ is A-trivial, u being composed of the canonical homomorphisms $B \to E \to C$ (18.1.6). Conversely, c) implies b), since every B-extension of C by L is B-equivalent to $E \otimes_{\mathfrak{R}/\mathfrak{R}^2} L$ (18.3.8), in other words its class is the image of the class of E (considered as B-extension) by the homomorphism $w_* : \mathrm{Exan}_B(C, \mathfrak{R}/\mathfrak{R}^2) \to \mathrm{Exan}_B(C, L)$ corresponding to a B-homomorphism $w : \mathfrak{R}/\mathfrak{R}^2 \to L$. The fact that c) implies b) then follows from the commutativity of the diagram (18.3.6.5) **0_IV-1** | 135

$$\begin{tikzcd} \mathrm{Exan}_B(C, \mathfrak{R}/\mathfrak{R}^2) \arrow[r, "w_*"] \arrow[d, "u^*"'] & \mathrm{Exan}_B(C, L) \arrow[d, "u^*"] \\ \mathrm{Exan}_A(C, \mathfrak{R}/\mathfrak{R}^2) \arrow[r, "w_*"'] & \mathrm{Exan}_A(C, L) \end{tikzcd}$$

(iv) We have seen (20.1.7) that the right inverses of $E \to C$ correspond bijectively, in a canonical fashion, to the set of elements $D \in \mathrm{Der}_A(E, \mathfrak{R}/\mathfrak{R}^2)$ such that $D(x) = x$ in $\mathfrak{R}/\mathfrak{R}^2$, hence also, by (20.4.8), to the set of E-homomorphisms $h : \Omega^1_{E/A} \to \mathfrak{R}/\mathfrak{R}^2$ such that the composite $\mathfrak{R}/\mathfrak{R}^2 \xrightarrow{d_{E/A}} \Omega^1_{E/A} \xrightarrow{h} \mathfrak{R}/\mathfrak{R}^2$ is the identity. By tensorization with C, one deduces that the composite

$$\mathfrak{R}/\mathfrak{R}^2 \xrightarrow{\delta_{C/B/A}} \Omega^1_{B/A} \otimes_B C \xrightarrow{h \otimes 1} \mathfrak{R}/\mathfrak{R}^2$$

is the identity; or, since $\mathfrak{R}/\mathfrak{R}^2$ is a C-module, $h \mapsto h \otimes 1$ is an isomorphism of the set $\mathrm{Hom}_E(\Omega^1_{E/A}, \mathfrak{R}/\mathfrak{R}^2)$ onto $\mathrm{Hom}_C(\Omega^1_{E/A} \otimes_E C, \mathfrak{R}/\mathfrak{R}^2)$; and by (ii) elsewhere one can canonically identify $\Omega^1_{E/A} \otimes_E C$ and $\Omega^1_{B/A} \otimes_B C$, $\delta_{C/E/A}$ being identified with $\delta_{C/B/A}$. □

Example (20.5.13). — Let $B = A[X_\alpha]_{\alpha \in I}$ be a polynomial algebra over A, $\mathfrak{R}$ an ideal of B and $C = B/\mathfrak{R}$; we know that $\Omega^1_{B/A}$ is a free B-module whose dX_α form a basis (20.4.13), (i), hence the dX_α also form a basis of the free C-module $\Omega^1_{B/A} \otimes_B C$. On the other hand, from the definition it follows immediately that the image of $\mathfrak{R}/\mathfrak{R}^2$ by $\delta_{C/B/A}$ is the sub-C-module generated by the

$$dP_\lambda = \sum_\alpha \frac{\partial P_\lambda}{\partial X_\alpha} dX_\alpha.$$

One concludes that $\Omega^1_{C/A}$ is isomorphic to the quotient of the free C-module with basis the dX_α by the sub-C-module generated by the dP_λ, which gives a description of the module of differentials of an *arbitrary* A-algebra C that can always be obtained in the above manner.

Corollary (20.5.14). — *If C is an A-algebra formally smooth (for the discrete topologies), the sequence*

(20.5.14.1) $$0 \longrightarrow \mathfrak{N}/\mathfrak{N}^2 \xrightarrow{\delta_{C/B/A}} \Omega^1_{B/A} \otimes_B C \xrightarrow{u_{C/B/A}} \Omega^1_{C/A} \longrightarrow 0$$

is exact and split.

Proof. Indeed, every A-extension of C by a C-module is then trivial (19.4.1). □

$\mathbf{0_{IV\text{-}1}}$ | 136

Remark (20.5.15). — Let $u : A \to B$ be a *surjective* homomorphism of rings; then, for every homomorphism of rings $v : B \to C$, the canonical homomorphism

(20.5.15.1) $$u_{C/B/A} : \Omega^1_{C/A} \longrightarrow \Omega^1_{C/B}$$

is *bijective*; this indeed follows from the exact sequence (20.5.7.1), since $\Omega^1_{B/A} = 0$ (20.4.12).

20.6. Modules of imperfection and characteristic homomorphisms

Definition (20.6.1). — Given two ring homomorphisms $u : A \to B$, $v : B \to C$, one calls the *module of imperfection* of the B-algebra C relative to A, and one denotes by $\Upsilon_{C/B/A}$, the kernel of the C-module homomorphism $v_{C/B/A} : \Omega^1_{B/A} \otimes_B C \to \Omega^1_{C/A}$. One therefore has by definition (cf. (20.5.7)) the exact sequence

(20.6.1.1) $$0 \longrightarrow \Upsilon_{C/B/A} \longrightarrow \Omega^1_{B/A} \otimes_B C \xrightarrow{v_{C/B/A}} \Omega^1_{C/A} \xrightarrow{u_{C/B/A}} \Omega^1_{C/B} \longrightarrow 0.$$

When $A = \mathbf{Z}$ (so that $\Omega^1_{B/A}$ and $\Omega^1_{C/A}$ are the modules of "absolute" differentials), one writes $\Upsilon_{C/B}$ instead of $\Upsilon_{C/B/\mathbf{Z}}$; when B and C are algebras over a prime field P, one has $\Upsilon_{C/B/P} = \Upsilon_{C/B}$.

Let R, S be multiplicative subsets of B and C respectively, such that the image of R is contained in S. It then follows from the exact sequence (20.6.1.1) and (20.5.9) that one has

(20.6.1.2) $$\Upsilon_{S^{-1}C/R^{-1}B/A} = S^{-1}\Upsilon_{C/B/A}.$$

Proposition (20.6.2). — *If C is a B-algebra formally smooth relative to A (and in particular if C is a B-algebra formally smooth), one has $\Upsilon_{C/B/A} = 0$.*

Proof. This follows from (20.5.7), (ii). □

Proposition (20.6.3). — *Let k be a field, K an extension of k. For K to be a separable extension of k, it is necessary and sufficient that $\Upsilon_{K/k} = 0$ (or equivalently, the canonical homomorphism $\Omega^1_k \otimes_k K \to \Omega^1_K$ is injective, or again (20.4.8), every derivation of k in K extends to a derivation of K in K).*

Proof. Indeed, it is equivalent to saying that K is separable over k or that K is a k-algebra formally smooth (19.6.1); on the other hand, if P is the prime field of k, K is separable over P, hence also a P-algebra formally smooth, and it follows that K is a k-algebra formally smooth relative to P. Finally, to say that K is a k-algebra formally smooth relative to P amounts, by (20.5.7), (ii), to saying that the homomorphism $v_{K/k/P} : \Omega^1_k \otimes_k K \to \Omega^1_K$ is left-invertible; but as K is a field, this last condition is equivalent to saying that the kernel of $v_{K/k/P}$, that is to say $\Upsilon_{K/k/P}$, is zero. □

(20.6.4). Consider a commutative diagram of ring homomorphisms

(20.6.4.1) $$\begin{tikzcd} A' \arrow[r, "u'"] & B' \arrow[r, "v'"] & C' \\ A \arrow[u, "f"] \arrow[r, "u"] & B \arrow[u, "g"] \arrow[r, "v"] & C \arrow[u, "h"] \end{tikzcd}$$

The commutativity of the diagram corresponding to (20.5.7.3) implies the existence of a unique C-homomorphism

(20.6.4.2) $$\Upsilon_{C/B/A} \longrightarrow \Upsilon_{C'/B'/A'}$$

deduced canonically from (20.6.4.1) and rendering commutative the diagram

(20.6.4.3)
$$\begin{tikzcd}
0 \arrow[r] & \mathrm{Y}_{C/B/A} \arrow[r] \arrow[d] & \Omega^1_{B/A} \otimes_B C \arrow[r, "v_{C/B/A}"] \arrow[d] & \Omega^1_{C/A} \arrow[r, "u_{C/B/A}"] \arrow[d] & \Omega^1_{C/B} \arrow[r] \arrow[d] & 0 \\
0 \arrow[r] & \mathrm{Y}_{C'/B'/A'} \arrow[r] & \Omega^1_{B'/A'} \otimes_{B'} C' \arrow[r, "v_{C'/B'/A'}"'] & \Omega^1_{C'/A'} \arrow[r, "u_{C'/B'/A'}"'] & \Omega^1_{C'/B'} \arrow[r] & 0
\end{tikzcd}$$

where the vertical arrows come from the di-homomorphisms (20.5.4.3).

The definition of (20.6.4.2) is also equivalent to that of a C'-homomorphism

(20.6.4.4)
$$\mathrm{Y}_{C/B/A} \otimes_C C' \longrightarrow \mathrm{Y}_{C'/B'/A'}$$

which, composed with the canonical homomorphism $\mathrm{Y}_{C/B/A} \to \mathrm{Y}_{C/B/A} \otimes_C C'$, gives back (20.6.4.2). It is clear that (20.6.4.2) enjoys an evident transitivity property, allowing us to say that $\mathrm{Y}_{C/B/A}$ is a *functor* in the triple (A, B, C).

(20.6.5). It will be convenient for us in what follows, under the conditions of (20.6.1), to introduce a *complex* (of chains) *of C-modules* $\mathrm{K}_\bullet(C/B/A)$ whose terms are zero except in degrees 0 and 1, where one takes

(20.6.5.1)
$$\begin{cases} \mathrm{K}_0(C/B/A) = \Omega^1_{C/A} \\ \mathrm{K}_1(C/B/A) = \Omega^1_{B/A} \otimes_B C \end{cases}$$

the differential operator being $v_{C/B/A} : \mathrm{K}_1 \to \mathrm{K}_0$. This allows writing (up to canonical isomorphisms) $\Omega^1_{C/B}$ and $\mathrm{Y}_{C/B/A}$ as the *homology modules* of this complex

(20.6.5.2)
$$\mathrm{H}_0(\mathrm{K}_\bullet(C/B/A)) = \Omega^1_{C/B}, \qquad \mathrm{H}_1(\mathrm{K}_\bullet(C/B/A)) = \mathrm{Y}_{C/B/A}.$$

Similarly:

Proposition (20.6.6). — *Under the hypotheses of (20.6.1), for every C-module L, one has canonical C-isomorphisms*

(20.6.6.1)
$$\mathrm{H}^0(\mathrm{K}_\bullet(C/B/A), L) \simeq \mathrm{Der}_B(C, L)$$

(20.6.6.2)
$$\mathrm{H}^1(\mathrm{K}_\bullet(C/B/A), L) \simeq \mathrm{Exalcom}_{B/A}(C, L).$$

Proof. Indeed, the complex of cochains $\mathrm{Hom}_C(\mathrm{K}_\bullet(C/B/A), L)$ is none other, by virtue of (20.4.8) and (20.5.6), than the complex

$$\cdots \longrightarrow 0 \longrightarrow \mathrm{Der}_A(C, L) \longrightarrow \mathrm{Der}_A(B, L) \longrightarrow 0 \longrightarrow \cdots$$

where the differential operator is v^0 (with the notations of (20.2.1)). The proposition follows from **$0_{\text{IV-1}}$** | 138
the exact sequence (20.2.4.2) and from the definition of the cohomology modules

(20.6.6.3)
$$\mathrm{H}^i(\mathrm{K}_\bullet, L) = \mathrm{H}^i(\mathrm{Hom}_C(\mathrm{K}_\bullet, L)).$$

□

If one has a commutative diagram of ring homomorphisms

$$\begin{tikzcd}
A' \arrow[r] & B' \arrow[r] & C' \\
A \arrow[r] \arrow[u] & B \arrow[r] \arrow[u] & C \arrow[u]
\end{tikzcd}$$

the di-homomorphisms (20.5.4.3) define a di-homomorphism of complexes of modules

(20.6.6.4)
$$\mathrm{K}_\bullet(C/B/A) \longrightarrow \mathrm{K}_\bullet(C'/B'/A')$$

and the di-homomorphisms that one deduces for the homology or the cohomology are identified, by the formulas (20.6.5.2), (20.6.6.1) and (20.6.6.2), with the di-homomorphisms already defined in (20.5.4.3), (20.6.4.2), (20.2.1) and (18.3.7.2) (taking into account, for the last, the definition of the operator ∂ in the exact sequence (20.2.4.2)).

(20.6.7). One knows that for a complex $\mathrm{K}_\bullet$ of C-modules and a C-module L, one has canonical homomorphisms

$$\alpha_i : \mathrm{H}^i(\mathrm{K}_\bullet, L) \longrightarrow \mathrm{Hom}_C(\mathrm{H}_i(\mathrm{K}_\bullet), L)$$

(M, IV, 6). Here, the canonical homomorphism

$$\alpha_1 : \mathrm{H}^1(\mathrm{K}_\bullet(C/B/A), L) \longrightarrow \mathrm{Hom}_C(\mathrm{H}_1(\mathrm{K}_\bullet(C/B/A)), L)$$

is defined immediately as obtained by passing to the quotient by the image of $\mathrm{Hom}_C(\mathrm{K}_0, L)$ of the restriction homomorphism

$$\mathrm{Hom}_C(\mathrm{K}_1(C/B/A), L) \longrightarrow \mathrm{Hom}_C(\mathrm{H}_1(\mathrm{K}_\bullet(C/B/A)), L)$$

since $\mathrm{H}_1(\mathrm{K}_\bullet(C/B/A))$ is none other than the kernel of $\mathrm{K}_1 \to \mathrm{K}_0$; taking into account (20.6.6.2) and (20.6.5.2), one obtains therefore a canonical C-homomorphism

$$\mathrm{Exalcom}_{B/A}(C, L) \longrightarrow \mathrm{Hom}_C(\Upsilon_{C/B/A}, L) \tag{20.6.7.1}$$

which can be described explicitly as follows: by virtue of (20.2.4.2), every B-extension of C by L which is A-trivial comes from the datum of an A-derivation D of B in L, hence (20.4.8) of a C-homomorphism f of $\Omega^1_{B/A} \otimes_B C$ in L; one associates to this extension the *restriction* of f to $\Upsilon_{C/B/A}$, which in fact depends only on the class of this extension and not on the choice of D.

Definition (20.6.8). — Let $u : A \to B$, $v : B \to C$ be two ring homomorphisms. For every B-extension E of C by a C-module L, which is A-trivial (18.3.7), one calls the *characteristic homomorphism* of E, and one denotes by χ_E, the C-homomorphism $\Upsilon_{C/B/A} \to L$, image of the class of E by the canonical homomorphism (20.6.7.1).

One can define the homomorphism χ_E in another way: $\mathbf{0}_{\mathbf{IV\text{-}1}}$ | 139

Proposition (20.6.9). — *Let E be a B-extension of C by a C-module L, which is A-trivial (18.3.7); then the diagram*

$$\begin{tikzcd} 0 \arrow[r] & \Upsilon_{C/B/A} \arrow[r] \arrow[d, "\chi_E"] & \Omega^1_{B/A} \otimes_B C \arrow[r, "v_{C/B/A}"] \arrow[d, "q_{E/B/A} \otimes 1_C"] & \Omega^1_{C/A} \arrow[d, "1"] & \\ 0 \arrow[r] & L \arrow[r, "\delta_{C/E/A}"'] & \Omega^1_{E/A} \otimes_E C \arrow[r, "p_{C/E/A}"'] & \Omega^1_{C/A} \arrow[r] & 0 \end{tikzcd} \tag{20.6.9.1}$$

where $q : B \to E$ defines the structure of B-extension of E and $p : E \to C$ is the augmentation, is commutative and its rows are exact.

Proof. The bottom row of the diagram is the sequence (20.5.12.5) relative to the two homomorphisms $A \xrightarrow{q \circ u} E$ and $p : E \to C = E/L$; as p is surjective and E is an A-trivial extension, this sequence is exact and split by virtue of (20.5.12), (iii). The commutativity of the right-hand square of (20.6.9.1) follows from the relation $v = p \circ q$ (20.5.2.7); the image by $q_{E/B/A} \otimes 1_C$ of the kernel $\Upsilon_{C/B/A}$ of $v_{C/B/A}$ is therefore contained in the kernel L of $p_{C/E/A}$. On the other hand, let $h : C \to E$ be an A-homomorphism that is a right inverse of p, and let $j : L \to E$ be the canonical injection, so that one has $q(b) = h(v(b)) + j(D(b))$ for $b \in B$, where D is the A-derivation of B in L defining the B-extension E; one can write $D = f \circ d_{B/A}$, where $f : \Omega^1_{B/A} \to L$ is a B-homomorphism. By virtue of (20.5.2.6), one has $q_{E/B/A}(d_{B/A}(b)) = d_{E/A}(q(b)) = d_{E/A}(h(v(b))) + d_{E/A}(j(f(d_{B/A}(b))))$ for $b \in B$. Let then $z = \sum_i d_{B/A}(b_i) \otimes c_i$, where $b_i \in B$ and $c_i \in C$, be an element of $\Omega^1_{B/A} \otimes_B C$; one has

$$(q_{E/B/A} \otimes 1_C)(z) = \sum_i d_{E/A}(h(v(b_i))) \otimes c_i + \sum_i d_{E/A}(j(f(d_{B/A}(b_i)))) \otimes c_i.$$

In the first sum, one has $d_{E/A}(h(v(b_i))) = h_{E/C/A}(d_{C/A}(v(b_i)))$, hence this sum equals $(h_{E/C/A} \otimes 1_C)(v_{C/B/A}(z))$. So if one takes $z \in \Upsilon_{C/B/A}$, this sum is zero, and it remains, by definition of $\delta_{C/E/A}$,

$$(q_{E/B/A} \otimes 1_C)(z) = \sum_i \delta_{C/E/A}(c_i f(d_{B/A}(b_i))) = \delta_{C/E/A}(f(z))$$

which proves the commutativity of the left-hand square in (20.6.9.1). □

One notes that when one only assumes that $\delta_{C/E/A}$ is *injective* (and not necessarily left-invertible), this interpretation would still allow one to *define* χ_E as the restriction of $q_{E/B/A} \otimes 1_C$ to $\Upsilon_{C/B/A}$.

Corollary (20.6.10). — *If $\mathfrak{N}$ is an ideal of B, $C = B/\mathfrak{N}$, $E = B/\mathfrak{N}^2$, and if E is a B-extension A-trivial (18.3.7) of C by $\mathfrak{N}/\mathfrak{N}^2$, then the characteristic homomorphism $\chi_E : \Upsilon_{C/B/A} \to \mathfrak{N}/\mathfrak{N}^2$ is bijective.*

Proof. Indeed, in the diagram (20.6.9.1), the two right-hand vertical arrows are bijective (20.5.12), (ii). □ $\mathbf{0_{IV\text{-}1}}$ | 140

Theorem (20.6.11). — *Let $u : A \to B$, $v : B \to C$ be two ring homomorphisms, L a C-module. Suppose one of the following conditions satisfied:*

(i) *L is an injective C-module.*
(ii) *$\Upsilon_{C/B/A}$ is a direct factor of $\Omega^1_{B/A} \otimes_B C$ and $u_{C/B/A} : \Omega^1_{C/A} \to \Omega^1_{C/B}$ is right-invertible.*

Then the canonical homomorphism (20.6.7.1)

$$\mathrm{Exalcom}_{B/A}(C, L) \longrightarrow \mathrm{Hom}_C(\Upsilon_{C/B/A}, L)$$

is bijective.

In particular, if $\Omega^1_{C/B}$ and $\Omega^1_{C/A}$ are projective C-modules, the canonical homomorphism (20.6.7.1) is bijective.

Proof. The fact that each of the conditions (i), (ii) implies that (20.6.7.1) is bijective follows in both cases from the definition of α_1. We note moreover that condition (ii) is *necessary and sufficient* for the homomorphism (20.6.7.1) to be bijective for *every* C-module L (Bourbaki, *Alg.*, chap. II, 3ᵉ éd., § 2, n° 1, prop. 1). If one assumes that $\Omega^1_{C/B}$ and $\Omega^1_{C/A}$ are projective C-modules, then, in the exact sequence (20.6.1.1), $\mathrm{Ker}(u_{C/B/A})$ is a projective C-module, since the sequence

$$0 \longrightarrow \mathrm{Ker}(u_{C/B/A}) \longrightarrow \Omega^1_{C/A} \longrightarrow \Omega^1_{C/B} \longrightarrow 0$$

is split, $\Omega^1_{C/B}$ being projective; as $\mathrm{Ker}(u_{C/B/A}) = \mathrm{Im}(v_{C/B/A})$, the sequence

$$0 \longrightarrow \Upsilon_{C/B/A} \longrightarrow \Omega^1_{B/A} \otimes_B C \longrightarrow \mathrm{Im}(v_{C/B/A}) \longrightarrow 0$$

is split. □

Corollary (20.6.12). — *Suppose that C is an A-algebra formally smooth. Then there exists a canonical homomorphism*

$$\mathrm{Exalcom}_B(C, L) \longrightarrow \mathrm{Hom}_C(\Upsilon_{C/B/A}, L). \tag{20.6.12.1}$$

Moreover, this homomorphism is bijective if one of the conditions (i), (ii) *of (20.6.11) is verified.*

Proof. Indeed, it follows from the hypothesis on C that $\mathrm{Exalcom}_B(C, L) = \mathrm{Exalcom}_{B/A}(C, L)$, and the homomorphism (20.6.12.1) is none other than (20.6.7.1). □

Corollary (20.6.13). — *If C is an A-algebra formally smooth and if $\Omega^1_{C/B}$ is a projective C-module, the homomorphism (20.6.12.1) is bijective.*

Proof. Indeed, one knows then that $\Omega^1_{C/A}$ is a projective C-module (20.4.9), the discrete topologies being considered. □

(20.6.14). The notations remaining the same, suppose now in addition that A, B, C are Λ-algebras and u, v are Λ-homomorphisms, which amounts to giving three ring homomorphisms $\Lambda \xrightarrow{s} A \xrightarrow{u} B \xrightarrow{v} C$.

One has therefore, apart from the module of imperfection $\Upsilon_{C/B/A}$, the modules of imperfection $\Upsilon_{B/A/\Lambda}$, $\Upsilon_{C/A/\Lambda}$ and $\Upsilon_{C/B/\Lambda}$, and one has already defined canonical C-module homomorphisms (20.6.4.2) $\mathbf{0_{IV\text{-}1}}$ | 141

$$u' : \Upsilon_{C/A/\Lambda} \longrightarrow \Upsilon_{C/B/\Lambda} \tag{20.6.14.1}$$

$$s' : \Upsilon_{C/B/\Lambda} \longrightarrow \Upsilon_{C/B/A}. \tag{20.6.14.2}$$

As in the commutative diagram (20.5.7.3)

(20.6.14.3)
$$\begin{tikzcd}
\Omega^1_{A/\Lambda} \otimes_A B \arrow[r] \arrow[d] & \Omega^1_{B/\Lambda} \arrow[r] \arrow[d] & \Omega^1_{B/A} \arrow[r] \arrow[d] & 0 \\
\Omega^1_{A/\Lambda} \otimes_A C \arrow[r] & \Omega^1_{C/\Lambda} \arrow[r] & \Omega^1_{C/A} \arrow[r] & 0
\end{tikzcd}$$

the bottom row is formed of C-modules, one deduces by tensorization a commutative diagram

(20.6.14.4)
$$\begin{tikzcd}
\Omega^1_{A/\Lambda} \otimes_A C \arrow[r] \arrow[d, equal] & \Omega^1_{B/\Lambda} \otimes_B C \arrow[r] \arrow[d] & \Omega^1_{B/A} \otimes_B C \arrow[r] \arrow[d] & 0 \\
\Omega^1_{A/\Lambda} \otimes_A C \arrow[r] & \Omega^1_{C/\Lambda} \arrow[r] & \Omega^1_{C/A} \arrow[r] & 0
\end{tikzcd}$$

where the first row is still exact and the left vertical arrow is the identity; if one puts

(20.6.14.5)
$$\Upsilon^C_{B/A/\Lambda} = \operatorname{Ker}(u_{B/A/\Lambda} \otimes 1_C) = \operatorname{Ker}(\Omega^1_{A/\Lambda} \otimes_A C \longrightarrow \Omega^1_{B/\Lambda} \otimes_B C)$$

one sees, taking into account the definition of $\Upsilon_{C/A/\Lambda}$, that one has a unique C-homomorphism

(20.6.14.6)
$$v' : \Upsilon^C_{B/A/\Lambda} \longrightarrow \Upsilon_{C/A/\Lambda}$$

rendering commutative the diagram

(20.6.14.7)
$$\begin{tikzcd}
0 \arrow[r] & \Upsilon^C_{B/A/\Lambda} \arrow[r] \arrow[d, "v'"] & \Omega^1_{A/\Lambda} \otimes_A C \arrow[r] \arrow[d, equal] & \Omega^1_{B/\Lambda} \otimes_B C \arrow[r] \arrow[d] & \Omega^1_{B/A} \otimes_B C \arrow[r] \arrow[d] & 0 \\
0 \arrow[r] & \Upsilon_{C/A/\Lambda} \arrow[r] & \Omega^1_{A/\Lambda} \otimes_A C \arrow[r] & \Omega^1_{C/\Lambda} \arrow[r] & \Omega^1_{C/A} \arrow[r] & 0
\end{tikzcd}$$

whose rows are exact.

When $\Lambda = \mathbf{Z}$, one writes $\Upsilon^C_{B/A}$ instead of $\Upsilon^C_{B/A/\mathbf{Z}}$. If Λ is a prime field, one has $\Upsilon^C_{B/A} = \Upsilon^C_{B/A/\Lambda}$.

(20.6.15). To study the relations between the preceding modules, we introduce on the one hand the complex of B-modules $\mathrm{K}_\bullet(B/A/\Lambda)$ (20.6.5), and on the other hand the complexes of C-modules $\mathbf{0}_{\textbf{IV-1}}$ | 142
$\mathrm{K}_\bullet(C/A/\Lambda)$ and $\mathrm{K}_\bullet(C/B/\Lambda)$. We shall also set

(20.6.15.1)
$$\mathrm{K}^C_\bullet(B/A/\Lambda) = \mathrm{K}_\bullet(B/A/\Lambda) \otimes_B C.$$

On the other hand, we denote by $\mathrm{T}_\bullet(C/B/\Lambda)$ the complex of C-modules whose terms are zero except in degrees 0 and 1, and where

(20.6.15.2)
$$\mathrm{T}_0(C/B/\Lambda) = \mathrm{T}_1(C/B/\Lambda) = \Omega^1_{B/\Lambda} \otimes_B C$$

the differential operator being the identity, so that this complex is homotopic to 0; finally let us set

(20.6.15.3)
$$\mathrm{K}'_\bullet(C/A/\Lambda) = \mathrm{K}_\bullet(C/A/\Lambda) \oplus \mathrm{T}_\bullet(C/B/\Lambda).$$

By virtue of the trivial character of $\mathrm{T}_\bullet$, it is clear that one has

(20.6.15.4)
$$\mathrm{H}^i(\mathrm{K}'_\bullet, L) = \mathrm{H}^i(\mathrm{K}_\bullet, L) \quad \text{and} \quad \mathrm{H}_i(\mathrm{K}'_\bullet, L) = \mathrm{H}_i(\mathrm{K}_\bullet, L)$$

for every C-module L and every i.

(20.6.16). Let us now define an exact sequence of complexes, *split* in each degree

(20.6.16.1)
$$0 \longrightarrow \mathrm{K}^C_\bullet(B/A/\Lambda) \xrightarrow{j} \mathrm{K}'_\bullet(C/A/\Lambda) \xrightarrow{p} \mathrm{K}_\bullet(C/B/\Lambda) \longrightarrow 0$$

in the following way: let us denote temporarily by

$$f : \Omega^1_{A/\Lambda} \otimes_A C \longrightarrow \Omega^1_{B/\Lambda} \otimes_B C, \quad g : \Omega^1_{B/\Lambda} \otimes_B C \longrightarrow \Omega^1_{C/\Lambda}$$

the canonical homomorphisms $u_{B/A/\Lambda} \otimes 1_C$ and $v_{C/B/\Lambda}$ respectively, whose composite is $g \circ f = (v \circ u)_{C/A/\Lambda}$ (cf. (20.6.14.4)). One will take $j_1(x) = (x, f(x))$, $p_1(y,z) = z - f(y)$, $j_0(x) = (g(x), x)$, $p_0(y,z) = g(z) - y$ so that $\operatorname{Im}(j_1) = \operatorname{Ker}(p_1)$ is the graph of f, and $\operatorname{Im}(j_0) = \operatorname{Ker}(p_0)$ is the graph of g, complementary to $\{0\} \oplus \mathrm{T}_1$ and $\mathrm{K}_1(C/A/\Lambda) \oplus \{0\}$ respectively; the verification of the commutativity of the diagram

$$\begin{tikzcd} 0 \arrow[r] & \mathrm{K}_1^C(B/A/\Lambda) \arrow[r, "j_1"] \arrow[d] & \mathrm{K}_1'(C/A/\Lambda) \arrow[r, "p_1"] \arrow[d] & \mathrm{K}_1(C/B/\Lambda) \arrow[r] \arrow[d] & 0 \\ 0 \arrow[r] & \mathrm{K}_0^C(B/A/\Lambda) \arrow[r, "j_0"'] & \mathrm{K}_0'(C/A/\Lambda) \arrow[r, "p_0"'] & \mathrm{K}_0(C/B/\Lambda) \arrow[r] & 0 \end{tikzcd}$$

where the vertical arrows are the differential operators, is immediate.

Theorem (20.6.17). — *One has an exact sequence of C-modules*

(20.6.17.1)
$$0 \longrightarrow \Upsilon^C_{B/A/\Lambda} \xrightarrow{v'} \Upsilon_{C/A/\Lambda} \xrightarrow{u'} \Upsilon_{C/B/\Lambda} \xrightarrow{\partial} \Omega^1_{B/A} \otimes_B C \xrightarrow{v_{C/B/A}} \Omega^1_{C/A} \xrightarrow{u_{C/B/A}} \Omega^1_{C/B} \longrightarrow 0$$

where the boundary operator ∂ is the composite **$0_{\text{IV-1}}$ | 143**

(20.6.17.2)
$$\Upsilon_{C/B/\Lambda} \xrightarrow{s'} \Upsilon_{C/B/A} \longrightarrow \Omega^1_{B/A} \otimes_B C$$

the second arrow being the canonical injection.

Proof. Writing the long exact homology sequence for the exact sequence of complexes (20.6.16.1), one obtains (20.6.17.1), the homology being zero in degrees distinct from 0 and 1; the fact that the homomorphisms of this exact sequence come from the functoriality of j and p is immediate. It remains to verify that ∂ is equal to (20.6.17.2); but an element $z \in \Upsilon_{C/B/\Lambda}$ is the image by p_1 of $(0, z)$, whence one deduces immediately that $\partial(z)$ is the image of z by the canonical homomorphism $s_{B/A/\Lambda} \otimes 1_C : \Omega^1_{B/\Lambda} \otimes_B C \to \Omega^1_{B/A} \otimes_B C$. Our assertion follows from the commutativity of the diagram

(20.6.17.3)
$$\begin{tikzcd} \Upsilon_{C/B/\Lambda} \arrow[r, "s'"] \arrow[d] & \Upsilon_{C/B/A} \arrow[d] \\ \Omega^1_{B/\Lambda} \otimes_B C \arrow[r] & \Omega^1_{B/A} \otimes_B C \end{tikzcd}$$

(cf. (20.6.4.3)). □

Corollary (20.6.18). — (i) *The sequence of C-modules*

(20.6.18.1)
$$0 \longrightarrow \Upsilon^C_{B/A/\Lambda} \xrightarrow{v'} \Upsilon_{C/A/\Lambda} \xrightarrow{u'} \Upsilon_{C/B/\Lambda} \xrightarrow{s'} \Upsilon_{C/B/A} \longrightarrow 0$$

is exact.

(ii) *If B is an A-algebra formally smooth relative to Λ, one has $\Upsilon^C_{B/A/\Lambda} = 0$.*

Proof. (i) In (20.6.17.1), the image of $\Upsilon_{C/B/\Lambda}$ by ∂ is the kernel of $v_{C/B/A}$, hence $\Upsilon_{C/B/A}$ by definition.

(ii) The hypothesis implies that the sequence

$$0 \longrightarrow \Omega^1_{A/\Lambda} \otimes_A B \longrightarrow \Omega^1_{B/\Lambda} \longrightarrow \Omega^1_{B/A} \longrightarrow 0$$

is exact and split (20.5.7); by tensorization with C, the sequence

$$0 \longrightarrow \Omega^1_{A/\Lambda} \otimes_A C \longrightarrow \Omega^1_{B/\Lambda} \otimes_B C \longrightarrow \Omega^1_{B/A} \otimes_B C \longrightarrow 0$$

remains therefore exact, whence our assertion. □

Corollary (20.6.19). — *Let K be a field, E, F two extensions of K such that $K \subset E \subset F$.*

(i) *If F is a separable extension of E, one has $\Upsilon_{F/E/K} = 0$ (or equivalently, the canonical homomorphism $\Omega^1_{E/K} \otimes_E F \to \Omega^1_{F/K}$ is injective).*

(ii) *Conversely, if F is a separable extension of K and if $\Upsilon_{F/E/K} = 0$, then F is a separable extension of E.*

Proof. If P is the prime field of K, one has the exact sequence (20.6.18)

$$\Upsilon_{F/K/P} \longrightarrow \Upsilon_{F/E/P} \longrightarrow \Upsilon_{F/E/K} \longrightarrow 0.$$

If $\Upsilon_{F/E/P} = \Upsilon_{F/E} = 0$, one therefore has $\Upsilon_{F/E/K} = 0$, whence (i) by virtue of (20.6.3); conversely, if $\Upsilon_{F/E/K} = 0$ and $\Upsilon_{F/K/P} = \Upsilon_{F/K} = 0$, one has $\Upsilon_{F/E/P} = \Upsilon_{F/E} = 0$, whence (ii) by virtue of (20.6.3). □

$\mathbf{0}_{\mathbf{IV}\text{-}\mathbf{1}}$ | 144

Corollary (20.6.20). — (i) *If K is an algebraic separable extension of k, one has $\Omega^1_{K/k} = 0$.*

(ii) *Let k be a field of characteristic 0, K an extension of k. For $\Omega^1_{K/k} = 0$, it is necessary and sufficient that K be an algebraic extension of k. In particular, for a field K of characteristic 0 to satisfy $\Omega^1_K = 0$, it is necessary and sufficient that K be an algebraic extension of* $\mathbf{Q}$ *(cf.* (21.4.4) *and* (21.7.5)*).*

Proof. (i) For every $x \in K$, let f be the minimal polynomial of x over k; as $f'(x) \neq 0$ and $d_{K/k}(f(x)) = f'(x)d_{K/k}(x) = 0$, one has $d_{K/k}(x) = 0$ and our assertion follows from (20.4.7).

(ii) There exists a pure extension L of k such that $k \subset L \subset K$ and K is an algebraic extension of L. As K is separable over L, it follows from (20.6.19), (i) that the sequence

$$0 \longrightarrow \Omega^1_{L/k} \otimes_L K \longrightarrow \Omega^1_{K/k} \longrightarrow \Omega^1_{K/L} \longrightarrow 0$$

is exact, and from (i) that $\Omega^1_{K/L} = 0$. The relation $\Omega^1_{K/k} = 0$ is therefore equivalent to $\Omega^1_{L/k} = 0$, and as L is a pure extension of k, it follows from (20.5.10) that the relation $\Omega^1_{L/k} = 0$ is equivalent to $L = k$. □

Remarks (20.6.21). — (i) As $\Upsilon_{B/A/\Lambda}$ is the kernel of $u_{B/A/\Lambda} : \Omega^1_{A/\Lambda} \otimes_A B \to \Omega^1_{B/\Lambda}$ and $\Upsilon^C_{B/A/\Lambda}$ the kernel of $u_{B/A/\Lambda} \otimes 1_C$, one has a canonical homomorphism

(20.6.21.1) $$\Upsilon_{B/A/\Lambda} \otimes_B C \longrightarrow \Upsilon^C_{B/A/\Lambda}.$$

This homomorphism is bijective when the sequence

(20.6.21.2) $$0 \longrightarrow \Upsilon_{B/A/\Lambda} \otimes_B C \longrightarrow \Omega^1_{A/\Lambda} \otimes_A C \longrightarrow \Omega^1_{B/\Lambda} \otimes_B C \longrightarrow \Omega^1_{B/A} \otimes_B C \longrightarrow 0$$

is exact, which occurs in the following cases:

1° C is a flat B-module.

2° The B-modules $\Omega^1_{B/\Lambda}$ and $\Omega^1_{B/A}$ are *flat*: indeed, the kernel of $\Omega^1_{B/\Lambda} \to \Omega^1_{B/A}$ is then also flat ($\mathbf{0}_{\mathbf{I}}$, 6.1.2), and the sequence (20.6.21.2) is then exact by virtue of ($\mathbf{0}_{\mathbf{I}}$, 6.1.2).

(ii) Consider a commutative diagram of ring homomorphisms

$$\begin{tikzcd}
\Lambda' \arrow[r] & A' \arrow[r] & B' \arrow[r] & C' \\
\Lambda \arrow[r] \arrow[u] & A \arrow[r] \arrow[u] & B \arrow[r] \arrow[u] & C \arrow[u]
\end{tikzcd}$$

Then the definitions of (20.6.16) show that one has a commutative diagram (where the vertical arrows come from (20.6.6.4))

$$\begin{tikzcd}
0 \arrow[r] & \mathrm{K}^C_\bullet(B/A/\Lambda) \arrow[r] \arrow[d] & \mathrm{K}'_\bullet(C/A/\Lambda) \arrow[r] \arrow[d] & \mathrm{K}_\bullet(C/B/\Lambda) \arrow[r] \arrow[d] & 0 \\
0 \arrow[r] & \mathrm{K}^{C'}_\bullet(B'/A'/\Lambda') \arrow[r] & \mathrm{K}'_\bullet(C'/A'/\Lambda') \arrow[r] & \mathrm{K}_\bullet(C'/B'/\Lambda') \arrow[r] & 0
\end{tikzcd}$$

whence, by passage to homology, a *commutative diagram* $\mathbf{0}_{\mathbf{IV}\text{-}\mathbf{1}}$ | 145

(20.6.21.3)
$$\begin{tikzcd}
0 \arrow[r] & \Upsilon^C_{B/A/\Lambda} \arrow[r] \arrow[d] & \Upsilon_{C/A/\Lambda} \arrow[r] \arrow[d] & \Upsilon_{C/B/\Lambda} \arrow[r] \arrow[d] & \Omega^1_{B/A} \otimes_B C \arrow[r] \arrow[d] & \Omega^1_{C/A} \arrow[r] \arrow[d] & \Omega^1_{C/B} \arrow[r] \arrow[d] & 0 \\
0 \arrow[r] & \Upsilon^{C'}_{B'/A'/\Lambda'} \arrow[r] & \Upsilon_{C'/A'/\Lambda'} \arrow[r] & \Upsilon_{C'/B'/\Lambda'} \arrow[r] & \Omega^1_{B'/A'} \otimes_{B'} C' \arrow[r] & \Omega^1_{C'/A'} \arrow[r] & \Omega^1_{C'/B'} \arrow[r] & 0
\end{tikzcd}$$

One has an analogous commutative diagram for (20.6.18.1).

Proposition (20.6.22). — *Let $s : \Lambda \to A$, $u : A \to B$ be two ring homomorphisms, $\mathfrak{N}$ an ideal of B, C the quotient ring $B/\mathfrak{N}$. Suppose that $E = B/\mathfrak{N}^2$ is a B-extension Λ-trivial of C by $\mathfrak{N}/\mathfrak{N}^2$. One then has an exact sequence*

(20.6.22.1) $$0 \longrightarrow \Upsilon^{C}_{B/A/\Lambda} \xrightarrow{v'} \Upsilon_{C/A/\Lambda} \xrightarrow{\chi_E} \mathfrak{N}/\mathfrak{N}^2 \xrightarrow{\delta_{C/B/A}} \Omega^1_{B/A} \otimes_B C \xrightarrow{v_{C/B/A}} \Omega^1_{C/A} \longrightarrow 0.$$

Proof. Indeed, as $v : B \to C$ is surjective, one has $\Omega^1_{C/B} = 0$ (20.4.12). Moreover, it follows from (20.6.10) that $\Upsilon_{C/B/\Lambda}$ is canonically identified with $\mathfrak{N}/\mathfrak{N}^2$. It suffices then to apply the exact sequences (20.6.17.1) and (20.6.18.1), noting that one has a commutative diagram

$$\begin{tikzcd}
\Upsilon_{C/A/\Lambda} \arrow[rr] \arrow[d, "\chi_E"'] & & \Omega^1_{A/\Lambda} \otimes_A C \arrow[d] \\
\Upsilon_{C/B/\Lambda} = \Upsilon_{C/B/A} = \mathfrak{N}/\mathfrak{N}^2 \arrow[r, "\delta_{C/B/A}"] \arrow[d, "\ell"'] & \Omega^1_{B/A} \otimes_B C = \Omega^1_{E/A} \otimes_E C \arrow[r, phantom] & {} \arrow[d] \\
\mathfrak{N}/\mathfrak{N}^2 \arrow[rr, "\delta_{C/B/A}"] & & \Omega^1_{B/A} \otimes_B C
\end{tikzcd}$$

and using the commutativity of the diagram (20.6.17.3). □

One has thus determined the *kernel* of $\delta_{C/B/A}$ in the case where there exists a ring Λ such that A is a Λ-algebra and $B/\mathfrak{N}^2$ is Λ-trivial; one observes that this is the case in particular when C is a Λ-*algebra formally smooth* (for the discrete topology).

Suppose in addition that one has a commutative diagram of ring homomorphisms

$$\begin{tikzcd}
\Lambda' \arrow[r] & A' \arrow[r] & B' \\
\Lambda \arrow[r] \arrow[u] & A \arrow[r] \arrow[u] & B \arrow[u, "f"']
\end{tikzcd}$$

that $\mathfrak{N}'$ is an ideal of B' such that $f(\mathfrak{N}) \subset \mathfrak{N}'$, and that $E' = B'/\mathfrak{N}'^2$ is a B'-extension Λ'-trivial of $C' = B'/\mathfrak{N}'$ by $\mathfrak{N}'/\mathfrak{N}'^2$. One then has a commutative diagram **$0_{\text{IV-1}}$** | 146

(20.6.22.2)
$$\begin{tikzcd}
0 \arrow[r] & \Upsilon^{C'}_{B'/A'/\Lambda'} \arrow[r] & \Upsilon_{C'/A'/\Lambda'} \arrow[r] & \mathfrak{N}'/\mathfrak{N}'^2 \arrow[r] & \Omega^1_{B'/A'} \otimes_{B'} C' \arrow[r] & \Omega^1_{C'/A'} \arrow[r] & 0 \\
0 \arrow[r] & \Upsilon^{C}_{B/A/\Lambda} \arrow[r] \arrow[u] & \Upsilon_{C/A/\Lambda} \arrow[r] \arrow[u] & \mathfrak{N}/\mathfrak{N}^2 \arrow[r] \arrow[u] & \Omega^1_{B/A} \otimes_B C \arrow[r] \arrow[u] & \Omega^1_{C/A} \arrow[r] \arrow[u] & 0
\end{tikzcd}$$

as follows from (20.6.21.3) and (20.5.11.3).

Corollary (20.6.23). — *Under the hypotheses of (20.6.22), suppose in addition that B is an A-algebra formally smooth. Then one has an exact sequence*

(20.6.23.1) $$0 \longrightarrow \Upsilon_{C/A/\Lambda} \xrightarrow{\chi_E} \mathfrak{N}/\mathfrak{N}^2 \xrightarrow{\delta_{C/B/A}} \Omega^1_{B/A} \otimes_B C \longrightarrow \Omega^1_{C/A} \longrightarrow 0.$$

Proof. This follows from (20.6.18), (ii). □

(20.6.24). When the hypotheses of (20.6.22) are satisfied, we also say that the characteristic homomorphism χ_E is the *characteristic homomorphism of the A-algebra B, relative to Λ and to the ideal $\mathfrak{N}$* (suppressing these last details when there is no danger of confusion); it is sometimes denoted by χ_B or $\chi_{B/A}$.

Proposition (20.6.25). — *Let $s : \Lambda \to A$, $u : A \to B$, $v : B \to C$ be three ring homomorphisms, L a C-module. One then has an exact sequence*

(20.6.25.1)
$$\begin{aligned} 0 \longrightarrow \operatorname{Der}_B(C,L) \xrightarrow{u^1} \operatorname{Der}_A(C,L) \xrightarrow{v^1} \operatorname{Der}_A(B,L) \xrightarrow{\partial} \\ \longrightarrow \operatorname{Exalcom}_{B/\Lambda}(C,L) \xrightarrow{u^1} \operatorname{Exalcom}_{A/\Lambda}(C,L) \xrightarrow{v^1} \operatorname{Exalcom}_{A/\Lambda}(B,L) \longrightarrow 0 \end{aligned}$$

where u^1, v^1 are homomorphisms defined in (18.3.6.4) and (18.3.6.2), and ∂ is defined as in (20.2.2).

Proof. Indeed, as the exact sequence (20.6.16.1) is split, one deduces from it an exact sequence

$$0 \longrightarrow \mathrm{Hom}_C(\mathrm{K}_\bullet(C/B/\Lambda), L) \longrightarrow \mathrm{Hom}_C(\mathrm{K}'_\bullet(C/A/\Lambda), L) \longrightarrow \mathrm{Hom}_C(\mathrm{K}^C_\bullet(B/A/\Lambda), L) \longrightarrow 0.$$

If one applies to this complex the long exact cohomology sequence, taking into account (20.6.15.4) and (20.6.6), one obtains (20.6.25.1) since one has

$$\mathrm{Hom}_C(\mathrm{K}^C_\bullet(B/A/\Lambda), L) = \mathrm{Hom}_B(\mathrm{K}_\bullet(B/A/\Lambda), L)$$

by definition; the identification of u^1 and v^1 with the homomorphisms (18.3.6.4) and (18.3.6.2), respectively, follows from (20.6.6.4).[22] □

Remark (20.6.26). — In this section, the complexes $\mathrm{K}_\bullet(C/B/A)$ have appeared as a technical device intended to simplify the exposition of certain functorial behaviours. In reality, these complexes, considered as objects of the category of complexes of C-modules "up to homotopy" (that is to say where the morphisms are the classes of homotopic homomorphisms) are remarkable invariants, finer than the pair formed by $\Omega^1_{C/B}$ and $\Upsilon_{C/B/A}$. When k is a prime field, and C a k-algebra formally smooth (for example a regular ring of finite type over an extension of k) (cf. (**IV**, 6.8.6)), one can show that the complex $\mathrm{K}_\bullet(C/A/k)$ can be described solely by making intervene C and A (to the exclusion of k): one expresses C as a quotient of a polynomial algebra B over A by an ideal $\mathfrak{Q}$, and one considers the complex $\mathrm{F}_\bullet(C/A)$ with 2 nonzero terms **$0_{\text{IV-1}}$ | 147**

$$\cdots \longrightarrow 0 \longrightarrow \mathfrak{Q}/\mathfrak{Q}^2 \longrightarrow \Omega^1_{B/A} \otimes_B C \longrightarrow 0 \longrightarrow \cdots$$

(whose homology coincides with that of $\mathrm{K}_\bullet(C/A/k)$ by virtue of (20.6.23.1)). These complexes $\mathrm{F}_\bullet(C/A)$, from the point of view of homological algebra, play the role of a conormal bundle for $\mathrm{Spec}(C)$ over $\mathrm{Spec}(A)$, and will be of great importance in the chapters of this work devoted to the duality of coherent sheaves and to the theorem of Riemann-Roch.

20.7. Generalizations to topological rings

(20.7.1). It follows immediately from the definitions that if, in (20.5.2) and (20.5.3), the rings A, B, C are assumed to be topological rings and the ring homomorphisms u, v continuous, then the homomorphisms $u_{C/B/A}$ and $v_{C/B/A}$ are *continuous* (one must naturally take on $\Omega^1_{B/A} \otimes_B C$ the tensor product topology).

Moreover, $u_{C/B/A} : \Omega^1_{C/A} \to \Omega^1_{C/B}$ is a *strict surjective morphism* of topological C-modules; indeed, it is also so of the canonical homomorphism $C \otimes_A C \to C \otimes_B C$, taking into account the definition of the tensor product topology; by passing to quotients one deduces that the corresponding homomorphism $\mathrm{P}^1_{C/A} \to \mathrm{P}^1_{C/B}$ is a strict surjective morphism, and $u_{C/B/A}$ is the restriction of this last to $\Omega^1_{C/A}$.

In (20.5.5), if A' and B are topological A-algebras, and if $B' = \Omega^1_{B/A} \otimes_B B'$ are equipped with the tensor product topologies, the homomorphism (20.5.5.1) is a topological isomorphism, taking into account that $\mathrm{P}^1_{B/A}$ is the same as the direct topological sum of B and $\Omega^1_{B/A}$.

Proposition (20.7.2). — *Let $u : A \to B$, $v : B \to C$ be two continuous homomorphisms of topological rings. For the continuous homomorphism $v_{C/B/A} : \Omega^1_{B/A} \otimes_B C \to \Omega^1_{C/A}$ to be formally left-invertible* (*cf.* (19.1.5)), *it is necessary and sufficient that C be a B-algebra formally smooth relative to A* (19.9.1) (*and a* fortiori *it suffices that C be a B-algebra formally smooth*).

Proof. To say that $v_{C/B/A}$ is formally left-invertible means, given that the topologies of $\Omega^1_{C/A}$ and $\Omega^1_{B/A} \otimes_B C$ are less fine than those deduced from the topology of C (20.4.5), that for every discrete C-module L, annihilated by an open ideal of C, the canonical homomorphism

$$\mathrm{Hom.cont}_C(\Omega^1_{C/A}, L) \longrightarrow \mathrm{Hom.cont}_C(\Omega^1_{B/A} \otimes_B C, L)$$

is *surjective* (19.1.5); as $\mathrm{Hom.cont}_C(\Omega^1_{B/A} \otimes_B C, L) = \mathrm{Hom.cont}_C(\Omega^1_{B/A}, L)$ by definition of the tensor product topology, it amounts to the same, by virtue of (20.4.8), to say that the canonical homomorphism **$0_{\text{IV-1}}$ | 148**

$$\mathrm{D\acute{e}r.\ cont}_A(C, L) \longrightarrow \mathrm{D\acute{e}r.\ cont}_A(B, L)$$

[22] The French source prints the nonexistent locator "(18.3.4.2)"; the two homomorphisms are defined in (18.3.6.4) and (18.3.6.2).

is surjective. But the exact sequence (20.3.8.2) shows that this condition is equivalent to $\mathrm{Exalcotop}_{B/A}(C, L) = 0$, that is to say precisely that C is formally smooth relative to A (19.9.8). ☐

Corollary (20.7.3). — *Suppose that in B and in C, the square of every open ideal is also open. For C to be a B-algebra formally smooth relative to A, it is necessary and sufficient that, if one denotes by $(\mathfrak{R}_\lambda)$ a fundamental system of neighbourhoods of 0 formed of ideals of C, then for every λ, the homomorphism*

(20.7.3.1) $$v_{C/B/A} \otimes 1_{C/\mathfrak{R}_\lambda} : \Omega^1_{B/A} \otimes_B (C/\mathfrak{R}_\lambda) \longrightarrow \Omega^1_{C/A} \otimes_C (C/\mathfrak{R}_\lambda)$$

is left-invertible.

Proof. Indeed, one then knows that the topology of $\Omega^1_{B/A}$ (respectively $\Omega^1_{C/A}$) is deduced from that of B (respectively C) (20.4.5); it follows immediately that the topology of $\Omega^1_{B/A} \otimes_B C$ is also deduced from that of C. The corollary then follows from (20.7.2) and (19.1.7). ☐

Proposition (20.7.4). — *Let A be a topological ring, B a topological A-algebra. For B to be formally non-ramified (19.10.2), it is necessary and sufficient that the separated completion $\widehat{\Omega}^1_{B/A}$ is zero.*

Proof. Indeed, it follows immediately from (19.10.4) and (20.1.1) that, for B to be formally non-ramified, it is necessary and sufficient that for every open ideal $\mathfrak{R}$ of B, every open ideal $\mathfrak{H}$ of A such that $\mathfrak{H}.B \subset \mathfrak{R}$ and every $(B/\mathfrak{R})$-module L, one has $\mathrm{Der}_{A/\mathfrak{H}}(B/\mathfrak{R}, L) = 0$, that is to say $\mathrm{Dér.\ cont}_A(B, L) = 0$ for every discrete B-module L annihilated by an open ideal; by virtue of (20.4.8), this is equivalent to $\mathrm{Hom.cont}_B(\Omega^1_{B/A}, L) = 0$ for every such B-module, whence the proposition.

When B is discrete, the condition of (20.7.4) is equivalent to $\Omega^1_{B/A} = 0$. ☐

Corollary (20.7.5). — *Let A be a ring, $\mathfrak{m}$ an ideal of A, and B an A-algebra; equip A with the $\mathfrak{m}$-preadic topology and B with the topology deduced from that of A, and set $A_0 = A/\mathfrak{m}$, $B_0 = B/\mathfrak{m}B = B \otimes_A A_0$. Then, for B to be an A-algebra formally non-ramified, it is necessary and sufficient that $\Omega^1_{B_0/A_0} = 0$ (or equivalently that B_0 is an A_0-algebra formally non-ramified).*

Proof. Indeed, one has $\Omega^1_{B/A} \otimes_B B_0 = \Omega^1_{B/A}/\mathfrak{m}.\Omega^1_{B/A} = \Omega^1_{B_0/A_0}$ by virtue of (20.5.5); to say that every open submodule of $\Omega^1_{B/A}$ is equal to $\Omega^1_{B/A}$ is equivalent by (20.4.5) to writing that $\mathfrak{m}.\Omega^1_{B/A} = \Omega^1_{B/A}$, whence the conclusion. ☐

Proposition (20.7.6). — *Let $u : A \to B$, $v : B \to C$ be two continuous homomorphisms of topological rings, and suppose that v makes C into a B-algebra formally étale; then $v_{C/B/A} : \Omega^1_{B/A} \otimes_B C \to \Omega^1_{C/A}$ is a formal bimorphism (19.1.2).*

Proof. Indeed, for every discrete C-module L annihilated by an open ideal of C, one has then (20.7.4) $\mathrm{Dér.\ cont}_B(C, L) = 0$ and by virtue of (20.3.6.1) the canonical homomorphism $\mathrm{Dér.\ cont}_A(C, L) \to$ $\mathbf{0_{IV\text{-}1}}$ | 149
$\mathrm{Dér.\ cont}_A(B, L)$ is injective; it is moreover surjective by virtue of (20.7.2), hence it is bijective. It follows that the image of $v_{C/B/A}$ is necessarily dense in $\Omega^1_{C/A}$, otherwise the quotient of $\Omega^1_{C/A}$ by the closure of $\mathrm{Im}(v_{C/B/A})$ would be separated and nonzero and would therefore have a nonzero discrete quotient L, contrary to what has just been seen (taking into account (20.4.8)). Consequently $v_{C/B/A}$, which is a formal monomorphism by virtue of (20.7.2), is also a formal epimorphism (19.1.2), hence a formal bimorphism. ☐

Corollary (20.7.7). — *Suppose that in B and in C, the square of every open ideal is also open. If C is a B-algebra formally étale, then, for every open ideal $\mathfrak{R}_\lambda$ of C, the homomorphism (20.7.3.1) is bijective.*

Proof. Indeed, by virtue of (19.1.1), this homomorphism is surjective, and it is injective by (20.7.3). ☐

Proposition (20.7.8). — *Let $u : A \to B$ be a continuous homomorphism of topological rings, $\mathfrak{R}$ an ideal of B, C the topological quotient $B/\mathfrak{R}$, $v : B \to C$ the canonical homomorphism.*

(i) *In the exact sequence (20.5.12.1)*

$$\mathfrak{R}/\mathfrak{R}^2 \xrightarrow{\delta_{C/B/A}} \Omega^1_{B/A} \otimes_B C \xrightarrow{v_{C/B/A}} \Omega^1_{C/A} \longrightarrow 0$$

the homomorphism $\delta_{C/B/A}$ is continuous and the homomorphism $v_{C/B/A}$ is a strict morphism of topological C-modules.

(ii) *For $\delta_{C/B/A}$ to be formally left-invertible (19.1.5), it is necessary and sufficient that for every discrete C-module L annihilated by an open ideal of C, the canonical homomorphism*

(20.7.8.1) $$\mathrm{Exalcotop}_A(C, L) \longrightarrow \mathrm{Exalcotop}_A(B, L)$$

is injective.

Proof. (i) The first assertion is evident. On the other hand, the canonical homomorphism $v \otimes v : B \otimes_A B \to C \otimes_A C$ is a strict morphism by definition of the tensor product topology, and one deduces immediately that it is the same for $v_{C/B/A}$.

(ii) To say that $\delta_{C/B/A}$ is formally left-invertible means that for every discrete C-module L annihilated by an open ideal of C, the canonical homomorphism

$$\mathrm{Hom.cont}_C(\Omega^1_{B/A} \otimes_B C, L) \longrightarrow \mathrm{Hom.cont}_C(\mathfrak{R}/\mathfrak{R}^2, L)$$

is surjective. But, taking into account (18.4.3) and (20.4.8), this amounts to saying that the canonical homomorphism

$$\mathrm{Dér.\ cont}_A(B, L) \longrightarrow \mathrm{Exalcotop}_B(C, L)$$

is surjective, and the conclusion follows from the exact sequence (20.3.6.1).

The injectivity of (20.7.8.1) can also be expressed as follows, taking into account the definition of its two members (18.4.1): for every open ideal $\mathfrak{M}$ of A, every open ideal $\mathfrak{N}$ of B such that $\mathfrak{M}B \subset \mathfrak{N}$, and every $(A/\mathfrak{M})$-extension E of $B/(\mathfrak{R} + \mathfrak{N})$ by a $(B/(\mathfrak{R} + \mathfrak{N}))$-module L, such that the inverse image of E under the canonical homomorphism $B/\mathfrak{N} \to B/(\mathfrak{R} + \mathfrak{N})$ is $(A/\mathfrak{M})$-trivial, there exists an open ideal $\mathfrak{M}' \subset \mathfrak{M}$ of A, an open ideal $\mathfrak{N}' \subset \mathfrak{N}$ of B such that $\mathfrak{M}'B \subset \mathfrak{N}'$ and such that the inverse $\mathbf{0_{IV\text{-}1}}$ | 150
image of E under the canonical homomorphism $B/(\mathfrak{R} + \mathfrak{N}') \to B/(\mathfrak{R} + \mathfrak{N})$ is $(A/\mathfrak{M}')$-trivial. □

Corollary (20.7.9). — *If the topological A-algebra $C = B/\mathfrak{R}$ is formally smooth, the canonical homomorphism $\delta_{C/B/A}$ is formally left-invertible.*

(20.7.10). In (20.6.1), when A, B, C are topological rings and u and v continuous homomorphisms, one equips $\Upsilon_{C/B/A}$ with the topology induced by that of $\Omega^1_{B/A} \otimes_B C$; the homomorphisms (20.6.4.2) and (20.6.4.4) are then continuous provided the same is true of those in diagram (20.6.4.1). Moreover, if in (20.6.7) one assumes that L is a discrete C-module annihilated by an open ideal of C, one deduces, by passage to the inductive limit, the canonical C-homomorphism

(20.7.10.1) $$\mathrm{Exalcotop}_{B/A}(C, L) \longrightarrow \mathrm{Hom.cont}_C(\Upsilon_{C/B/A}, L)$$

which can be described explicitly as follows (taking into account (18.5.3.1)): for every open ideal $\mathfrak{M}$ of A, every open ideal $\mathfrak{R}$ of B such that $\mathfrak{M}B \subset \mathfrak{R}$, every open ideal $\mathfrak{P}$ of C such that $\mathfrak{R}C \subset \mathfrak{P}$ and $\mathfrak{P}.L = 0$, every $(B/\mathfrak{R})$-extension E of $C/\mathfrak{P}$ by L which is $(A/\mathfrak{M})$-trivial comes from the datum of a continuous C-homomorphism f of $\Omega^1_{B/A} \otimes_B C$ in L, and the homomorphism (20.7.10.1) associates to the class of E the restriction of f to $\Upsilon_{C/B/A}$, called the *characteristic homomorphism of E* and again denoted χ_E.

Proposition (20.7.11). — *Suppose that the topology of C is such that the square of every open ideal is also open. If C is a topological A-algebra formally smooth and if $\Omega^1_{C/B}$ is a formally projective C-module, one has a canonical isomorphism*

(20.7.11.1) $$\mathrm{Exalcotop}_B(C, L) \xrightarrow{\sim} \mathrm{Hom.cont}_C(\Upsilon_{C/B/A}, L)$$

for every discrete C-module L annihilated by an open ideal of C.

Proof. One has indeed, in the exact sequence (20.3.7.1), $\mathrm{Exalcotop}_A(C, L) = 0$ (19.4.4), hence $\mathrm{Exalcotop}_B(C, L) = \mathrm{Exalcotop}_{B/A}(C, L)$ and the homomorphism (20.7.10.1) is none other than (20.7.8.1); the fact that it is bijective is deduced from (20.6.13) by passage to the inductive limit by (20.4.5) and (19.2.4). □

(20.7.12). In (20.6.14) one also equips $\Upsilon^C_{B/A/\Lambda}$ with the topology induced by that of $\Omega^1_{A/\Lambda} \otimes_A C$ and the homomorphism (20.6.14.6) is continuous, when the considered rings are topological and the homomorphisms of rings are continuous.

(20.7.13). If, in (20.6.23), one assumes that the rings Λ, A, B, C are topological, the homomorphisms s, u, v continuous and L a discrete C-module annihilated by an open ideal of C, one can pass to the inductive limit as in (20.3.6), and one obtains an exact sequence

$$\begin{aligned} 0 \longrightarrow \mathrm{Dér.\ cont}_B(C,L) \longrightarrow \mathrm{Dér.\ cont}_A(C,L) \longrightarrow \mathrm{Dér.\ cont}_A(B,L) \longrightarrow \\ \longrightarrow \mathrm{Exalcotop}_{B/\Lambda}(C,L) \longrightarrow \mathrm{Exalcotop}_{A/\Lambda}(C,L) \longrightarrow \mathrm{Exalcotop}_{A/\Lambda}(B,L) \longrightarrow 0. \end{aligned} \tag{20.7.13.1}$$

(20.7.14). Let A be a topological ring, B a topological A-algebra, $\mathfrak{M}'$ an open ideal of A, $\mathfrak{R}'$ an open ideal of B such that $\mathfrak{M}'B \subset \mathfrak{R}'$; set $A' = A/\mathfrak{M}'$, $B' = B/\mathfrak{R}'$; the kernel of the homomorphism $B \otimes_A B \to B' \otimes_{A'} B'$ is $\mathfrak{U} = \mathrm{Im}(\mathfrak{R}' \otimes B + B \otimes \mathfrak{R}')$, whence it follows immediately that the kernel of the homomorphism **$0_{IV\text{-}1}$** | 151

$$\varphi_{(\mathfrak{M}',\mathfrak{R}')} : \Omega^1_{B/A} \longrightarrow \Omega^1_{B'/A'} \tag{20.7.14.1}$$

is $((\mathfrak{J} \cap \mathfrak{U}) + \mathfrak{J}^2)/\mathfrak{J}^2$; moreover, the homomorphism (20.7.14.1) is *surjective*, as it follows from (20.4.7). If $\mathfrak{M}''$ (resp. $\mathfrak{R}''$) is a second open ideal of A (resp. B) such that $\mathfrak{M}'' \subset \mathfrak{M}'$, $\mathfrak{R}'' \subset \mathfrak{R}'$ and $\mathfrak{M}''B \subset \mathfrak{R}''$, and if one sets $A'' = A/\mathfrak{M}''$, $B'' = B/\mathfrak{R}''$, one has a surjective homomorphism

$$\varphi_{(\mathfrak{M}'',\mathfrak{R}''),(\mathfrak{M}',\mathfrak{R}')} : \Omega^1_{B''/A''} \longrightarrow \Omega^1_{B'/A'}$$

and these homomorphisms form a *projective system*. If one notices that the $((\mathfrak{J} \cap \mathfrak{U}') + \mathfrak{J}^2)/\mathfrak{J}^2$ form a fundamental system of neighbourhoods of 0 in $\Omega^1_{B/A'}$, one sees therefore that the *separated completion* $\widehat{\Omega}^1_{B/A}$ of the topological B-module $\Omega^1_{B/A}$ is given, up to a canonical isomorphism, by

$$\widehat{\Omega}^1_{B/A} = \varprojlim(\Omega^1_{B'/A'}). \tag{20.7.14.2}$$

Moreover, the canonical homomorphism $j : \Omega^1_{B/A} \to \widehat{\Omega}^1_{B/A}$ is the projective limit of the $\varphi_{(\mathfrak{M}',\mathfrak{R}')}$, hence $\varphi_{(\mathfrak{M}',\mathfrak{R}')}$ factors as $\Omega^1_{B/A} \xrightarrow{j} \widehat{\Omega}^1_{B/A} \to \Omega^1_{B'/A'}$, and as it is surjective one concludes that the canonical homomorphism

$$\widehat{\Omega}^1_{B/A} \longrightarrow \Omega^1_{B'/A'} \tag{20.7.14.3}$$

is *surjective* for every pair $(\mathfrak{M}',\mathfrak{R}')$. One can moreover replace A' by A everywhere in the above.

Finally, if L is a separated and *complete* topological B-module, every continuous B-homomorphism from $\Omega^1_{B/A}$ to L extends uniquely to a continuous $\widehat{B}$-homomorphism from $\widehat{\Omega}^1_{B/A}$ to L and conversely such a homomorphism gives by composition with $\Omega^1_{B/A} \to \widehat{\Omega}^1_{B/A}$ a continuous B-homomorphism, so that one has a canonical isomorphism

$$\mathrm{Hom\,.\,cont}_B(\Omega^1_{B/A}, L) \xrightarrow{\sim} \mathrm{Hom\,.\,cont}_{\widehat{B}}(\widehat{\Omega}^1_{B/A}, L).$$

More particularly, if L is a discrete B-module annihilated by an open ideal of B, one sees that the canonical isomorphism (20.4.8.2) can also be written

$$\mathrm{Hom\,.\,cont}_{\widehat{B}}(\widehat{\Omega}^1_{B/A}, L) \xrightarrow{\sim} \mathrm{Dér.\ cont}_A(B,L). \tag{20.7.14.4}$$

Proposition (20.7.15). — *Let A be a discrete ring, B a topological adic A-algebra ($\mathbf{0_I}$, 7.1.9), $\mathfrak{n}$ an ideal of definition of B, $B_0 = B/\mathfrak{n}$. Suppose that $\Omega^1_{B_0/A}$ and $\mathfrak{n}/\mathfrak{n}^2$ are B_0-modules of finite type. Then $\widehat{\Omega}^1_{B/A}$ is a $\widehat{B}$-module of finite type.*

Proof. As the square of every open ideal of B is open, the topology of $\Omega^1_{B/A}$ is the $\mathfrak{n}$-preadic topology (20.4.5). Taking into account the hypothesis that B is an adic ring, it therefore suffices, by virtue of ($\mathbf{0_I}$, 7.2.7 and 7.2.9), to prove that $\Omega^1_{B/A}/\mathfrak{n}\Omega^1_{B/A} = \Omega^1_{B/A} \otimes_B B_0$ is a B_0-module of finite type. But this follows from the hypothesis and from the exact sequence **$0_{IV\text{-}1}$** | 152

$$\mathfrak{n}/\mathfrak{n}^2 \longrightarrow \Omega^1_{B/A} \otimes_B B_0 \longrightarrow \Omega^1_{B_0/A} \longrightarrow 0.$$

□

(20.7.16). Proposition (20.7.15) applies, for example, when A is a field k, $B = k'[[T_1, \dots, T_n]]$ is a formal power series algebra equipped with its usual topology, and k' is a finite extension of k (cf. (21.9.2)). One will note that the field of fractions K of B has infinite transcendence degree over k; when k has characteristic 0, it follows immediately (with the aid, in particular, of (20.4.13), (i), and (20.5.9), also using the fact that every derivation of a field of characteristic 0 extends to every extension) that $\Omega^1_{B/k}$ is *not* a B-module of finite type.

(20.7.17). Let A, B, C be three topological rings, and let $u : A \to B$, $v : B \to C$ be two continuous homomorphisms. Replacing A, B, C by quotients by open ideals $A' = A/\mathfrak{M}'$, $B' = B/\mathfrak{N}'$, $C' = C/\mathfrak{P}'$, with $u(\mathfrak{M}') \subset \mathfrak{N}'$ and $v(\mathfrak{N}') \subset \mathfrak{P}'$, so that one has homomorphisms $u' : A' \to B'$, $v' : B' \to C'$, one obtains canonical homomorphisms $u_{C'/B'/A'}$ and $v_{C'/B'/A'}$ which, by virtue of (20.5.4), form projective systems and consequently give, by passage to the limit, canonical homomorphisms extending to the separated completions the homomorphisms of the exact sequence (20.5.7.1)

$$\Omega^1_{B/A} \otimes_B C \xrightarrow{v_{C/B/A}} \Omega^1_{C/A} \xrightarrow{u_{C/B/A}} \Omega^1_{C/B} \longrightarrow 0 :$$

(20.7.17.1) $$\widehat{v}_{C/B/A} : \widehat{\Omega}^1_{B/A} \widehat{\otimes}_{\widehat{B}} \widehat{C} \longrightarrow \widehat{\Omega}^1_{C/A},$$

(20.7.17.2) $$\widehat{u}_{C/B/A} : \widehat{\Omega}^1_{C/A} \longrightarrow \widehat{\Omega}^1_{C/B}.$$

In the sequence

(20.7.17.3) $$\widehat{\Omega}^1_{B/A} \widehat{\otimes}_{\widehat{B}} \widehat{C} \xrightarrow{\widehat{v}_{C/B/A}} \widehat{\Omega}^1_{C/A} \xrightarrow{\widehat{u}_{C/B/A}} \widehat{\Omega}^1_{C/B} \longrightarrow 0,$$

the composite of two consecutive homomorphisms is 0, but the sequence is *not necessarily exact*. However, if B and C are metrizable, the homomorphism $\widehat{u}_{C/B/A}$ is *surjective*, and $\operatorname{Im}(\widehat{v}_{C/B/A})$ is *dense* in $\ker(\widehat{u}_{C/B/A})$: this follows immediately (cf. $\mathbf{0_I}$, 7.3.1) from the fact that, if $(\mathfrak{M}_k)$ (resp. $(\mathfrak{N}_k)$) is a decreasing sequence of ideals of B (resp. C) forming a fundamental system of neighbourhoods of 0, and if one sets $B_k = B/\mathfrak{M}_k$, $C_k = C/\mathfrak{N}_k$, the transition homomorphisms $\Omega^1_{C_{k+1}/B_{k+1}} \to \Omega^1_{C_k/B_k}$, $\Omega^1_{C_{k+1}/A} \to \Omega^1_{C_k/A}$ and $\Omega^1_{B_{k+1}/A} \to \Omega^1_{B_k/A}$ are surjective (20.7.14).

Proposition (20.7.18). — *Let A, B, C be three topological rings, and let $u : A \to B$, $v : B \to C$ be two continuous homomorphisms. Suppose that B and C are admissible ($\mathbf{0_I}$, 7.1.2) and metrizable. For the canonical homomorphism*

$$\widehat{v}_{C/B/A} : \widehat{\Omega}^1_{B/A} \widehat{\otimes}_{\widehat{B}} \widehat{C} \longrightarrow \widehat{\Omega}^1_{C/A}$$

to admit a left inverse which is a continuous C-homomorphism, it is necessary and sufficient that C be a B-algebra formally smooth relative to A.

Proof. The condition is necessary by virtue of (20.7.2) and (19.1.6). To see that it is sufficient, note that the topological C-module

$$L = \widehat{\Omega}^1_{B/A} \widehat{\otimes}_{\widehat{B}} \widehat{C}$$

is metrizable and complete by virtue of the hypotheses, hence $E = D_C(L)$, equipped with the product topology, is metrizable and complete; it is moreover admissible, for if $\mathfrak{N}$ is an ideal of definition in C, the sequence $(\mathfrak{N} \oplus L)^n = \mathfrak{N}^n \oplus \mathfrak{N}^{n-1}L$ tends to 0. Since the composite map $\mathbf{0_{IV\text{-}1}}$ | 153

$$D : B \xrightarrow{d_{B/A}} \Omega^1_{B/A} \longrightarrow \widehat{\Omega}^1_{B/A} \widehat{\otimes}_{\widehat{B}} \widehat{C} = L$$

is a continuous A-derivation of B into L, the continuous A-homomorphism

$$f : x \longmapsto (v(x), D(x))$$

from B into E defines on E a structure of B-extension. Since L is a closed ideal in E, it follows from (19.9.5) and from the hypothesis that the identity map $C \to E/L$ (which is a B-homomorphism) factors as $C \xrightarrow{g} E \to E/L$, where g is a continuous homomorphism such that $g \circ v = f$; consequently (20.1.3), g is of the form $y \mapsto (y, D'(y))$, where D' is a continuous B-derivation of C into L, in other words $D' \circ v = D$. Taking into account (20.7.14.4), one has $D' = h \circ \widehat{d}_{C/A}$, where $h : \widehat{\Omega}^1_{C/A} \to L$ is a continuous C-homomorphism; but one has $\widehat{d}_{C/A} \circ v = \widehat{v}_{C/B/A} \circ D$ by definition, and since the image of B under D generates topologically the C-module L (20.4.7), the relation $D' \circ v = D$ gives $h \circ \widehat{v}_{C/B/A} = 1_L$. □

Corollary (20.7.19). — *Under the hypotheses of (20.7.18), if one supposes in addition that in B and C the square of every open ideal is open, then, for C to be a B-algebra formally smooth relative to A, it is necessary and sufficient that $\widehat{v}_{C/B/A}$ be left-invertible.*

Proof. Indeed, the topologies of $\widehat{\Omega}^1_{B/A}\widehat{\otimes}_{\widehat{B}}\widehat{C}$ and $\widehat{\Omega}^1_{C/A}$ are then deduced from that of C (20.4.5), and every C-homomorphism from one to the other is necessarily continuous. □

(20.7.20). Let A be a topological ring, B a topological A-algebra, metrizable and complete, $\mathfrak{R}$ a closed ideal of B, and $C = B/\mathfrak{R}$ the quotient topological ring, which is metrizable and complete. Let $(\mathfrak{M}_k)$ be a decreasing fundamental system of neighbourhoods of 0 in B formed of ideals, and set $B_k = B/\mathfrak{M}_k$, $\mathfrak{R}_k = (\mathfrak{R} + \mathfrak{M}_k)/\mathfrak{M}_k$, $C_k = B_k/\mathfrak{R}_k$. One has a projective system of homomorphisms

$$\delta_{C_k/B_k/A} : \mathfrak{R}_k/\mathfrak{R}_k^2 \longrightarrow \Omega^1_{B_k/A} \otimes_{B_k} C_k$$

(20.5.11.3), from which one obtains by passage to the limit a canonical homomorphism

$$\widehat{\delta}_{C/B/A} : \mathfrak{R}/\mathfrak{R}^2 \longrightarrow \widehat{\Omega}^1_{B/A}\widehat{\otimes}_{\widehat{B}}\widehat{C};$$

and, reasoning as in (20.7.17), one sees that the canonical homomorphism

$$\widehat{u}_{C/B/A} : \widehat{\Omega}^1_{B/A}\widehat{\otimes}_{\widehat{B}}\widehat{C}longrightarrow\widehat{\Omega}^1_{C/A}$$

is *surjective* and that $\mathrm{Im}(\widehat{\delta}_{C/B/A})$ is *dense* in $\ker(\widehat{u}_{C/B/A})$.

§21. Differentials in rings of characteristic p

The results of the present section, of a more specialized and technical nature than those of §§ 19, 20 and 22, will only serve occasionally in chapter IV. Their principal role here is in the proofs of three theorems of § 22 (22.3.3, 22.5.8 and 22.7.3), the first and last of which intervene in an essential way in the "fine" theory of Noetherian local rings of chapter IV, § 7.

$\mathbf{0}_{\textbf{IV-1}}$ | 154

21.1. Systems of p-generators and p-bases

(21.1.1). Given a number p which is either 0, or a prime number, we say that a ring A is *of characteristic* p if there exists a ring homomorphism $P \to A$, where P is the *prime field* of characteristic p; we note that this homomorphism is then unique, the composite $\mathbf{Z} \to P \to A$ being the unique homomorphism of $\mathbf{Z}$ into A. If $A \neq 0$, this amounts to saying that A *contains a field of characteristic* p, the image of P being necessarily the only subfield of A isomorphic to P (and moreover the only subfield of A isomorphic to P).

(21.1.2). If $p > 0$, to say that A is of characteristic p is equivalent to saying that, in A, $p.1 = 0$, or equivalently $pA = 0$. If $p = 0$, to say that A is of characteristic p is equivalent to saying that for every integer $n \neq 0$, $n.1$ is *invertible* in A. If $A \neq 0$, there can exist only one p (prime or 0) such that A is of characteristic p; this follows from the identity of Bezout $ap + bq = 1$ for two distinct primes p, q. On the other hand, the reduced ring 0 is of characteristic p for *every* p.

(21.1.3). If A is of characteristic p, then so is every *algebra* over A. In particular, for every prime ideal $\mathfrak{p}$ of A, the *residue field* of A at $\mathfrak{p}$ is of characteristic p. Conversely, if $p = 0$ and if for every *maximal* ideal $\mathfrak{m}$ of A, the residue field of A at $\mathfrak{m}$ is of characteristic 0, then so is A, since for every integer $n \neq 0$, $n.1$ is then invertible in all the $A_{\mathfrak{m}}$, hence also in A. On the other hand, if $p > 0$, a local ring can have its residue field of characteristic p without being itself of characteristic p, as shown by the example of the *prime integer ring* $\mathbf{Z}_{p\mathbf{Z}}$ (19.8.3) or of the local Artinian ring $\mathbf{Z}/p^n\mathbf{Z}$ for $n \geqslant 2$, which do not contain a field.

We note finally that for a ring (even reduced), the residue fields at its prime ideals can have different characteristics, as shown by the example of $\mathbf{Z}$.

(21.1.4). In all the rest of this section, we fix a *prime number* p and all rings will be assumed *of characteristic* p, unless express mention to the contrary. For such a ring A, the map $x \mapsto x^p$ is an *endomorphism* of A, which we denote F_A; if A is *reduced*, F_A is *injective*. We set $A^p = \mathrm{F}_A(A)$ (subring of A formed by the x^p for $x \in A$); one can naturally consider A as an A^p-algebra.

One can also consider A as an A-algebra *by means of the homomorphism* $\mathrm{F}_A : x \mapsto x^p$ of A into A; in other words, this is the A-algebra $A_{[\mathrm{F}_A]}$, for which the product $\lambda.x$ of $x \in A$ by a scalar $\lambda \in A$ is the product $\lambda^p x$ in the ring A; we denote this A-algebra $A^{(p)}$. It is clear that for every ring homomorphism $u : A \to B$ the pair (u, u) is a *di-homomorphism* of A-algebras $A^{(p)} \to B^{(p)}$. For every

A-module E, we set $E^{(p)} = E \otimes_A A^{(p)}$ where $A^{(p)}$ is considered as an (A, A)-bimodule, the structure of A-module on the left being that which one has just defined, and the structure of A-module on the right coming from the structure of A-module of $A^{(p)}$ provenant of the ring structure, so that for $x \in E$, α, β in A, one has

$$\alpha(x \otimes \beta) = x \otimes (\alpha\beta) \quad \text{and} \quad (\alpha x) \otimes \beta = x \otimes \alpha^p \beta.$$

Setting $x^{(p)} = x \otimes 1$, one therefore has $(\alpha x)^{(p)} = \alpha^p x^{(p)}$. When F_A is *injective*, one can identify $A^{(p)}$ as an algebra over its *subring* A^p. $\mathbf{0_{IV\text{-}1}}$ | 155

Proposition (21.1.5). — *Let A, B be two rings, $u : A \to B$ a homomorphism.*

(i) *Every A-derivation of B in a B-module L is zero in $A[B^p]$ (hence is an $A[B^p]$-derivation).*

(ii) *For every sub-A-algebra A' of $A[B^p]$, if $j : A' \to B$ is the canonical injection, the canonical homomorphism*

$$j_{B/A'/A} : \Omega^1_{B/A} \longrightarrow \Omega^1_{B/A'}$$

is bijective.

(iii) *Suppose that there exists an integer $s \geqslant 0$ such that $u(A) \supset B^{p^s}$. Then, in the ring $B \otimes_A B$, $\mathfrak{J}_{B/A}$ is a nilideal.*

Proof. (i) By induction from (20.1.1), one deduces, for every A-derivation $D : B \to L$, that $D(x^k) = kx^{k-1}D(x)$, whence in particular $D(x^p) = 0$.

(ii) In view of (20.4.8), the assertion (ii) is only a translation of (i), this last being written $\mathrm{Der}_{A[B^p]}(B, L) = \mathrm{Der}_A(B, L)$ for every B-module L.

(iii) For every $x \in B$, one has $(x \otimes 1 - 1 \otimes x)^{p^s} = x^{p^s} \otimes 1 - 1 \otimes x^{p^s} = 0$, since $x^{p^s} \in u(A)$. The conclusion follows from the fact that the elements $1 \otimes x - x \otimes 1$ generate $\mathfrak{J}_{B/A}$ (20.4.4). ☐

It follows immediately from (21.1.5) that one has, for every pair of ring homomorphisms $A \to B \to C$,

(21.1.5.1) $$\Upsilon_{C/B/A} = \Upsilon_{C/B/A'}$$

for every sub-A-algebra A' of $A[B^p]$.

On the other hand, (21.1.5) also shows in particular that for the modules of "absolute" differentials

(21.1.5.2) $$\Omega^1_A = \Omega^1_{A/A^p}$$

Corollary (21.1.6). — *Suppose that B is an A-algebra of finite type and that there exists an integer $s \geqslant 0$ such that $u(A) \supset B^{p^s}$. If $\Omega^1_{B/A} = 0$, u is surjective.*

Proof. By (21.1.5), (iii), $\mathfrak{J}_{B/A}$ is a nilideal; moreover, by virtue of (20.4.4) and the hypothesis $\Omega^1_{B/A} = 0$, $\mathbf{0_{IV\text{-}1}}$ | 156
the relation $\Omega^1_{B/A} = 0$ signifies that $\mathfrak{J}_{B/A} = \mathfrak{J}^2_{B/A}$, whence one concludes that $\mathfrak{J}_{B/A} = 0$, or equivalently that $\pi : B \otimes_A B \to B$ is bijective. But every element of B has its p^s-th power in $u(A)$, B is *integral* over A, and being of finite type over A, B is thus reduced to proving the following lemma (where one *does not assume* that the rings considered are of characteristic p): ☐

Lemma (21.1.6.1). — *Let R be a ring, S a finite R-algebra; if the canonical homomorphism $\pi : S \otimes_R S \to S$ is bijective, then the structural homomorphism $u : R \to S$ is surjective.*

Proof. It suffices to show that for every maximal ideal $\mathfrak{m}$ of R, if one sets $T = R - \mathfrak{m}$, the homomorphism $u_\mathfrak{m} : R_\mathfrak{m} \to T^{-1}S$ is surjective (Bourbaki, *Alg. comm.*, chap. II, §3, n° 3, th. 1); or the hypothesis implies that the homomorphism $(T^{-1}S) \otimes_{R_\mathfrak{m}} (S/\mathfrak{m}S) \to T^{-1}S$ is bijective, and as $T^{-1}S$ is a finite $R_\mathfrak{m}$-algebra, one sees that one can reduce to the case where R is a local ring. Denoting again by $\mathfrak{m}$ its maximal ideal, it suffices to prove that $u \otimes 1 : R/\mathfrak{m} \to S/\mathfrak{m}S$ is surjective, by virtue of the lemma of Nakayama; as the canonical homomorphism $(S/\mathfrak{m}S) \otimes_{R/\mathfrak{m}} (S/\mathfrak{m}S) \to S/\mathfrak{m}S$ is bijective and $S/\mathfrak{m}S$ is a finite $(R/\mathfrak{m})$-algebra, one is finally reduced to the case where R is a *field*; but then the ranks of $S \otimes_R S$ and of S over R must be equal, which is possible only if S is of rank 0 or 1, hence $u : R \to S$ is surjective. ☐

Proposition (21.1.7). — *Let A be a ring, B an A-algebra, $(x_\alpha)_{\alpha \in I}$ a family of elements of B. Consider the following properties:*

a) $B = A[B^p, (x_\alpha)]$, *or equivalently the* $A[B^p]$*-algebra* B *is generated by the family* $(x_\alpha)_{\alpha\in I}$.
b) *The* $A[B^p]$*-module* B *is generated by the monomials* $\prod_\alpha x_\alpha^{n(\alpha)}$, *where* $(n(\alpha))_{\alpha\in I}$ *is a family of integers with finite support such that* $0 \leqslant n(\alpha) < p$ *for all* $\alpha \in I$.
c) *The* B*-module* $\Omega^1_{B/A}$ *is generated by the* $d_{B/A}(x_\alpha)$ $(\alpha \in I)$.

Then the properties a) *and* b) *are equivalent and imply* c)*; if in addition* B *is an* $A[B^p]$*-algebra of finite type,* c) *is equivalent to* a) *and* b).

Proof. It is clear that b) implies a), and conversely a) implies b), since every monomial $\prod_\alpha x_\alpha^{m(\alpha)}$, where the $m(\alpha)$ are integers $\geqslant 0$ (forming a family with finite support), can be written $(\prod_\alpha x_\alpha^{q(\alpha)})^p \prod_\alpha x_\alpha^{r(\alpha)}$, by dividing each $m(\alpha)$ by p, which gives $m(\alpha) = p.q(\alpha) + r(\alpha)$ with $0 \leqslant r(\alpha) < p$. The fact that a) implies c) follows from (21.1.5), (ii) and (20.4.7).

Suppose conversely c) satisfied and that B is an $A[B^p]$-algebra of finite type; let B' be the sub-$A[B^p]$-algebra of B generated by the x_α; in the exact sequence (20.5.7.1)

$$\Omega^1_{B'/A[B^p]} \otimes_{B'} B \longrightarrow \Omega^1_{B/A[B^p]} \longrightarrow \Omega^1_{B/B'} \longrightarrow 0$$

the hypothesis implies that the left arrow is surjective (taking into account (21.1.5), (ii)); one therefore has $\Omega^1_{B/B'} = 0$, and as $B^p \subset B' \subset B$ and B is a B'-algebra of finite type, one necessarily has $B' = B$ by (21.1.6). □

Remark (21.1.8). — When B is a *field*, we will demonstrate the equivalence of properties a), b) and c) without hypothesis of finiteness (21.4.5).

Definition (21.1.9). — Let A be a ring (of characteristic p), B an A-algebra. One says that a family $(x_\alpha)_{\alpha\in I}$ of elements of B is *p-free over* A (resp. a *system of p-generators* of B over A, resp. a *p-base* of B over A) if the family of monomials $\prod_\alpha x_\alpha^{n(\alpha)}$ $(0 \leqslant n(\alpha) < p$, $(n(\alpha))_{\alpha\in I}$ with finite support) is a free family (resp. a system of generators, resp. a base) in the $A[B^p]$-module B.

One has corresponding definitions for a *subset* M of elements of B, by considering the family defined by the canonical injection $M \to B$. When one takes for A the *prime field* $\mathbf{F}_p$ (in which case $A[B^p] = B^p$), one omits the mention of A in the preceding definition (or also says that a family is "absolutely" p-free, resp. an absolute system of p-generators, resp. an absolute p-base).

$\mathbf{0_{IV\text{-}1}}$ | 157

Lemma (21.1.10). — *Let* C *be a sub-*A*-algebra of* B *such that* $B^p \subset C$, M *a subset of* C, N *a subset of* B.
(i) *If* M *is a system of p-generators of* C *over* A *and* N *a system of p-generators of* B *over* C, *then* $M \cup N$ *is a system of p-generators of* B *over* A.
(ii) *Suppose that* M *is a p-base of* C *over* A*; then, for* N *to be p-free over* C, *it is necessary and sufficient that* $M \cup N$ *is p-free over* A.

Proof. One can reduce to the case where $B^p \subset A \subset C \subset B$. Then (i) is a particular case from the fact that if P (resp. Q) is a system of generators of the A-module C (resp. the C-module B), the set of products xy, $x \in P$ and $y \in Q$, is a system of generators of the A-module B. Preserving the same notations, if P is a base of the A-module C, to say that Q is a free family on C signifies that the relation $\sum_{\lambda,\mu} a_{\lambda\mu} x_\lambda y_\mu = 0$, where $a_{\lambda\mu} \in A$, $x_\lambda \in P$, $y_\mu \in Q$ (with x_λ (resp. y_μ) pairwise distinct) is equivalent to $a_{\lambda\mu} = 0$ for every pair (λ, μ), or equivalently $\sum_\lambda a_{\lambda\mu} x_\lambda = 0$ for every μ, whence the assertion (ii). □

21.2. p-bases and formal smoothness

Theorem (21.2.1). — *Let B be a ring, A a subring of B such that $B^p \subset A \subset B$. Let E be an A-algebra, $u : A \to E$ the structural homomorphism, $q : E \to B$ a surjective A-homomorphism, $\mathfrak{N}$ its kernel, and suppose that $\mathfrak{N}^p = 0$. Then:*

(i) *For there to exist an A-homomorphism right inverse $v : B \to E$ of the homomorphism $q : E \to B$, it is necessary and sufficient that $u(q(z)^p) = z^p$ for every $z \in E$.*

(ii) *When the condition of* (i) *is satisfied, for every family $(z_\alpha)_{\alpha\in I}$ of elements of E such that $q(z_\alpha) = x_\alpha$ for all $\alpha \in I$, there exists an A-homomorphism $v : B \to E$ and* a unique one *such that $v(x_\alpha) = z_\alpha$ for all $\alpha \in I$, and v is right inverse to q.*

Proof. If there exists an A-homomorphism $v : B \to E$, one must have $v(a) = u(a)$ for all $a \in A \subset B$, hence $v(q(z)^p) = u(q(z)^p)$ for all $z \in E$, since $B^p \subset A$. But one has $v(q(z)^p) = (v(q(z)))^p$ and by definition $v(q(z)) \equiv z \pmod{\mathfrak{N}}$ so $q \circ v = 1_B$, hence $(v(q(z)))^p = z^p$ since $\mathfrak{N}^p = 0$; whence the necessity of (i). The sufficiency of condition (i) will follow from (ii). $\mathbf{0_{IV\text{-}1}}$ | 158

Under the hypotheses of (ii), the uniqueness of v is evident since the monomials $\prod_\alpha x_\alpha^{n(\alpha)}$ generate the A-module B; as these monomials also form a *base* of the A-module B, there exists an A-*linear* map v of B into E such that $v\big(\prod_\alpha x_\alpha^{n(\alpha)}\big) = \prod_\alpha z_\alpha^{n(\alpha)}$ for every family $(n(\alpha))_{\alpha\in I}$ with finite support with $0 \leqslant n(\alpha) < p$. It remains to see that v is a ring homomorphism. But, one can write $(\prod_\alpha x_\alpha^{m(\alpha)})(\prod_\alpha x_\alpha^{n(\alpha)}) = a.\prod_\alpha x_\alpha^{r(\alpha)}$, where $r(\alpha) = m(\alpha) + n(\alpha)$ if $m(\alpha) + n(\alpha) < p$, $r(\alpha) = m(\alpha) + n(\alpha) - p$ in the opposite case, and $a \in A$ is the product of the x_α^p for the $\alpha \in I$ such that $m(\alpha) + n(\alpha) \geqslant p$; it suffices to see that v is a ring homomorphism, and by construction, one has $f(q(z)^p) = z^p$ for every $z \in E$, the condition (i) of (21.2.1) is therefore satisfied by construction, and by the application of (21.2.1), one is therefore in the conditions of application of the theorem in this case.

For the general case, consider a fundamental system $(\mathfrak{J}_\lambda)$ of open ideals, and let $E_\lambda = E/\mathfrak{J}_\lambda$, $\mathfrak{N}_\lambda = (\mathfrak{N} + \mathfrak{J}_\lambda)/\mathfrak{J}_\lambda$, $C_\lambda = E_\lambda/\mathfrak{N}_\lambda = E/(\mathfrak{N} + \mathfrak{J}_\lambda)$; as $E = \varprojlim E_\lambda$ ($\mathbf{0_I}$, 7.2.2). For every pair (α, λ), denote by $z_{\alpha\lambda}$ the canonical image of z_α in E_λ, and by $p_\lambda : C_\lambda \to C_\lambda$ the canonical homomorphism and by $q_\lambda : E_\lambda \to C_\lambda$ the canonical homomorphism. As by hypothesis $\mathfrak{N}_\lambda$ is nilpotent, the first part of the proof shows the existence and uniqueness of an A-homomorphism $w_\lambda : B \to E_\lambda$ such that $p_\lambda \circ v = q_\lambda \circ w_\lambda$ and $w_\lambda(x_\alpha) = z_{\alpha\lambda}$ for all α. The uniqueness of the w_λ shows immediately that (w_λ) is a projective system of homomorphisms, and $w = \varprojlim w_\lambda$ answers the question. □

Corollary (21.2.2). — *If there exists a p-base of B over A, B is an A-algebra formally smooth relative to B^p* (*for the discrete topologies*).

Proof. Indeed, let E be an A-extension of B by a B-module L, $q : E \to B$ the augmentation, $u : A \to E$ the structural homomorphism. To say that E is B^p-trivial means that there exists an A-homomorphism $v : B \to E$ such that $q(v(b)) = b$ and $v(b^p) = u(b^p)$ for all $b \in B$. But one has $u(q(z)^p) = v(q(z)^p) = (v(q(z)))^p$; but by the relation $L^2 = 0$, one also has $L^p = 0$, and as $v(q(z)) - z \in L$, one has $(v(q(z)))^p = z^p$; the condition of (21.2.1), (i) is therefore satisfied, and E is B-trivial. □

Corollary (21.2.3). — *Let B be a ring, A a subring of B such that $B^p \subset A \subset B$, L a B-module. Then:*

(i) *For a derivation D of A in L to extend to a derivation of B in L, it is necessary and sufficient that D annihilate B^p.*

(ii) *If D annihilates B^p, then, for every family $(y_\alpha)_{\alpha\in I}$ of elements of L, there exists a unique derivation D' of B in L extending D and such that $D'(x_\alpha) = y_\alpha$ for all $\alpha \in I$.*

Proof. Given a derivation D of A in L, consider the ring $E = \mathrm{D}_B(L)$ and the homomorphism $u : A \to E$ defined by $u(a) = (a, D(a))$; an A-homomorphism right inverse $v : B \to E$ is then of the form $x \mapsto (x, D'(x))$, where D' is a derivation of B in L extending D (20.1.5); as $u(q(z)^p) = (q(z)^p, D(q(z)^p))$ for $z \in E$, the corollary follows immediately from (21.2.1) applied to E. □

It follows from (21.2.3) that the sequence

(21.2.3.1) $$0 \longrightarrow \mathrm{Der}_A(B, L) \longrightarrow \mathrm{Der}_{B^p}(B, L) \longrightarrow \mathrm{Der}_{B^p}(A, L) \longrightarrow 0$$

(cf. (20.2.2.1)) is *exact*, and that the map

(21.2.3.2) $$D' \longmapsto (D'(x_\alpha))_{\alpha\in I}$$

is an isomorphism of the B-module $\mathrm{Der}_A(B, L)$ onto the B-module product L^I (by taking $D = 0$ in (21.2.3)).

Corollary (21.2.4). — *Under the hypotheses of* (21.2.3), *the sequence*

(21.2.4.1) $$0 \longrightarrow \Omega^1_{A/B^p} \otimes_A B \longrightarrow \Omega^1_{B/B^p} \longrightarrow \Omega^1_{B/A} \longrightarrow 0$$

is exact and split, and the family $(d_{B/A}(x_\alpha))_{\alpha\in I}$ *is a base of the B-module* $\Omega^1_{B/A}$.

Proof. This follows immediately from (21.2.3) and from the formula $\mathrm{Der}_A(B, L) = \mathrm{Hom}_B(\Omega^1_{B/A}, L)$. □

Corollary (21.2.5). — *Let A be a ring, B an A-algebra, $(x_\alpha)_{\alpha\in I}$ a p-base of B over A. Then $(d_{B/A}(x_\alpha))_{\alpha\in I}$ is a base of the B-module $\Omega^1_{B/A}$.*

Proof. By using (21.1.5), (ii), one reduces to the case where $A = A[B^p]$ and it suffices then to apply (21.2.4). □

$\mathbf{0}_{\mathbf{IV\text{-}1}}$ | 159

(21.2.6). Let A, B be two rings, $u : A \to B$ a ring homomorphism; one has (with the notations of (21.1.4)) a commutative diagram

(21.2.6.1) $$\begin{tikzcd} A^{(p)} \arrow[r, "u"] & B^{(p)} \\ A \arrow[u, "\mathrm{F}_A"] \arrow[r, "u"] & B \arrow[u, "\mathrm{F}_B"'] \end{tikzcd}$$

One deduces therefore canonically a homomorphism of B-algebras

(21.2.6.2) $$u \otimes 1 : A^{(p)} \otimes_A B \longrightarrow B^{(p)}$$

whose image is the ring $A[B^p]$ (which is a B-algebra for the homomorphism $\mathrm{F}_B : B \to B^p$).

Theorem (21.2.7). — *Let A be a ring, B an A-algebra, $u : A \to B$ the structural homomorphism. One assumes the following conditions satisfied:*

(i) *The homomorphism* (21.2.6.2) *deduced from u is injective.*

(ii) *B admits a p-base $(x_\alpha)_{\alpha\in I}$ relative to A.*

Then B is an A-algebra formally smooth (for the discrete topologies). More precisely, let E be a topological A-algebra admissible ($\mathbf{0}_\mathbf{I}$, 7.1.2), *$\mathfrak{N}$ an ideal of definition of E, $C = E/\mathfrak{N}$, $v : B \to C$ an A-homomorphism, $q : E \to C$ the augmentation. Then, for every family $(z_\alpha)_{\alpha\in I}$ of elements of E such that $q(z_\alpha) = v(x_\alpha)$ for all $\alpha \in I$, there exists an A-homomorphism $w : B \to E$ and* a unique one *such that $v = q \circ w$ and $w(x_\alpha) = z_\alpha$ for all $\alpha \in I$.*

Proof. Consider first the case where E is *discrete*, hence $\mathfrak{N}$ is nilpotent; moreover, the reasoning of $\mathbf{0}_{\mathbf{IV\text{-}1}}$ | 160
(19.4.3) allows one to suppose $\mathfrak{N}^2 = 0$ and by consequence $\mathfrak{N}^p = 0$. Finally, by considering the inverse image of the extension E of C by $\mathfrak{N}$, one can reduce to the case where $C = B$ and v is the identity (19.4.4). As the ring homomorphism $\mathrm{F}_B : z \mapsto z^p$ annihilates $\mathfrak{N}$, it factors as $E \xrightarrow{q} B \xrightarrow{\mathrm{F}'} E$, and F', considered as a homomorphism of B into $E^{(p)}$, is an *A-homomorphism* defining the structure of A-algebra on $E^{(p)}$ with the help of the composite homomorphism $A \xrightarrow{r} E \xrightarrow{\mathrm{F}_E} E^{(p)}$, where $r : A \to E$ is the structural homomorphism of the A-algebra E; moreover $r : A^{(p)} \to E^{(p)}$ is also an A-homomorphism. There is therefore a unique A-homomorphism $f : A^{(p)} \otimes_A B \to E^{(p)}$ such that the composites of f with the canonical homomorphisms $A^{(p)} \to A^{(p)} \otimes_A B$ and $B \to A^{(p)} \otimes_A B$ are respectively r and F'. But, by hypothesis, one can identify $A^{(p)} \otimes_A B$ with $A[B^p]$, the canonical homomorphisms $A^{(p)} \to A^{(p)} \otimes_A B$ and $B \to A^{(p)} \otimes_A B$ becoming identified respectively with u and F_B. One can therefore now consider E as an $A[B^p]$-algebra by means of the homomorphism f, and, by construction, one has $f(q(z)^p) = z^p$ for every $z \in E$; one is therefore in the conditions of application of (21.2.1), whence the theorem in this case.

For the general case, consider a fundamental system $(\mathfrak{J}_\lambda)$ of open ideals, and let $E_\lambda = E/\mathfrak{J}_\lambda$, $\mathfrak{N}_\lambda = (\mathfrak{N} + \mathfrak{J}_\lambda)/\mathfrak{J}_\lambda$, $C_\lambda = E_\lambda/\mathfrak{N}_\lambda$; as $E = \varprojlim E_\lambda$ ($\mathbf{0_I}$, 7.2.2). For every pair (α, λ), denote by $z_{\alpha\lambda}$ the canonical image of z_α in E_λ; the first part of the proof shows the existence and uniqueness of an A-homomorphism $w_\lambda : B \to E_\lambda$ such that $p_\lambda \circ v = q_\lambda \circ w_\lambda$ and $w_\lambda(x_\alpha) = z_{\alpha\lambda}$ for all α. The uniqueness of the w_λ shows immediately that (w_λ) is a projective system of homomorphisms, and $w = \varprojlim w_\lambda$ answers the question. □

Remark (21.2.8). — The verification of the existence and uniqueness of the homomorphism $w : B \to E$ such that $w(x_\alpha) = z_\alpha$ for all α can also be deduced directly from the fact that B is an A-algebra formally smooth and from the fact that the $d_{B/A}(x_\alpha)$ form a base of the B-module $\Omega^1_{B/A}$ (21.2.4), without invoking the existence of a p-base (so that the result is valid without supposing the rings of characteristic p). Indeed, one can reduce to the case where $\mathfrak{N}^2 = 0$; as $\mathrm{Der}_A(B, \mathfrak{N}) = \mathrm{Hom}_B(\Omega^1_{B/A}, \mathfrak{N})$ by (20.4.8), there exists an A-derivation D of B in $\mathfrak{N}$ and a unique one such that $D(x_\alpha) = z'_\alpha$ for every family (z'_α) of elements of $\mathfrak{N}$; the conclusion follows from (20.1.1).

21.3. p-bases and modules of imperfection

(21.3.1). Let A, B be two rings (of characteristic p), $i : A \to B$, $j : B \to A$ two ring homomorphisms such that one has

(21.3.1.1) $$j(i(a)) = a^p \quad \text{for all } a \in A,$$

(21.3.1.2) $$i(j(b)) = b^p \quad \text{for all } b \in B.$$

Most often, i will be *injective*, so that A is identified with a subring of B; once this identification is made, the existence of j implies that $B^p \subset A$, and j is then identified with F_B.

(21.3.2). If $h : A^p \to A$ is the canonical injection, one has, by (21.3.1.2) and (21.3.1.1), a commutative diagram

(21.3.2.1) $$\begin{tikzcd} B \arrow[r, "j"] & A \\ A \arrow[u, "i"] \arrow[r, "\mathrm{F}_A"] & A^p \arrow[u, "h"'] \end{tikzcd}$$

so that the pair (j, F_A) can be considered as a *di-homomorphism* of the A-algebra B (for i) in the A^p-algebra A (for h). One deduces a *canonical homomorphism of A-modules*

(21.3.2.2) $$\pi_{B/A} : \Omega^1_{B/A} \otimes_B A_{[j]} \longrightarrow \Omega^1_{A/A^p} = \Omega^1_A$$

(cf. (20.5.4); the identification of Ω^1_{A/A^p} and of the module of absolute differentials Ω^1_A comes from (21.1.5), (ii)).

One will set

(21.3.2.3) $$\Theta_{B/A} = \Omega^1_{B/A} \otimes_B A_{[j]}$$

(21.3.2.4) $$\Xi_{B/A} = \mathrm{Ker}(\pi_{B/A})$$

so that one has the exact sequence $\mathbf{0_{IV\text{-}1}}$ | 161

(21.3.2.5) $$0 \longrightarrow \Xi_{B/A} \longrightarrow \Theta_{B/A} \xrightarrow{\pi_{B/A}} \Omega^1_A$$

(one notes that these notations can be confusing since $\Theta_{B/A}$ and $\pi_{B/A}$ depend not only on A and B, but also on i and j).

(21.3.3). As by (21.3.1.2), one has $\mathrm{F}_B = i \circ j$, one can write for every B-module M (cf. (21.1.4))

(21.3.3.1) $$M^{(p)} = M \otimes_B B^{(p)} = (M \otimes_B A_{[j]}) \otimes_A B_{[i]}$$

whence in particular

(21.3.3.2) $$(\Omega^1_{B/A})^{(p)} = \Theta_{B/A} \otimes_A B_{[i]}$$

and one deduces therefore from (21.3.2.2) a *canonical homomorphism of B-modules*

(21.3.3.3) $$\pi_{B/A} \otimes 1_B : (\Omega^1_{B/A})^{(p)} \longrightarrow \Omega^1_A \otimes_A B_{[i]}.$$

Taking into account (20.5.4.2), the image of this homomorphism is the B-module generated by the elements $d_A(j(b)) \otimes 1$ for $b \in B$. Their image by the canonical homomorphism $i_{B/A} : \Omega^1_A \otimes_A B \to \Omega^1_B$ deduced from i (20.5.2) is therefore contained in the sub-B-module of Ω^1_B generated by the $d_B(i(j(b)))$ for $b \in B$; by virtue of (21.3.1.2), this image is *zero*. In other words, one has a sequence of homomorphisms

(21.3.3.4)
$$0 \longrightarrow \Xi_{B/A} \otimes_A B_{[i]} \longrightarrow (\Omega^1_{B/A})^{(p)} \longrightarrow \Upsilon_{B/A}$$

which is not necessarily exact, but where the composite of two consecutive homomorphisms is zero.

Proposition (21.3.4). — *If B is a flat A-module* (*for i*), *the sequence* (21.3.3.4) *is exact.*

Proof. This follows from the definition of flatness. The proposition (21.3.4) applies in particular when $B^p \subset A \subset B$, i and j being respectively the canonical injection and F_B (so that B is then a free A-module). But even in this case the kernel $\Xi_{B/A}$ is not necessarily zero. However: □

Proposition (21.3.5). — *Let B be a* reduced *ring, A a subring of B such that $B^p \subset A \subset B$. Suppose that there exists a p-base $(x_\lambda)_{\lambda \in L}$ of B over A and a p-base $(y_\mu)_{\mu \in M}$ of A over B^p; then the canonical homomorphism* (21.3.3.4)

(21.3.5.1)
$$(\Omega^1_{B/A})^{(p)} \longrightarrow \Upsilon_{B/A}$$

is bijective, and the elements $d_A(x^p_\lambda) \otimes 1$ form a base of the B-module $\Upsilon_{B/A}$.

Proof. As B is reduced, $x \mapsto x^p$ is an isomorphism of structure of B onto B^p, and by transport of structure via this isomorphism, one sees that (x^p_λ) and the y_μ form a p-base of B^p over A^p (21.1.10); $\mathbf{0_{IV\text{-}1}}$ | 162
by consequence (21.1.5), (ii) and (21.2.5) the $d_A(x^p_\lambda)$ and the $d_A(y_\mu)$ form a *base* of the A-module Ω^1_A. But, the image of $d_A(x_\lambda) \otimes 1$ by $i_{B/A}$ is $d_B(x^p_\lambda) = 0$; on the other hand, the image of $d_A(y_\mu)$ by $i_{B/A}$ is $d_B(i(y_\mu))$, and as the y_μ and the x_λ form a p-base of B over B^p (21.1.10), the $d_B(y_\mu)$ are part of a base of Ω^1_B (21.2.5), and are thus linearly independent over B. Hence the kernel of $i_{B/A}$ has a base formed by the $d_A(x^p_\lambda) \otimes 1$, and as these are the images by (21.3.5.1), these last form a base of the B-module $\Omega^1_{B/A} \otimes_B B^{(p)}$ (21.2.5), the homomorphism (21.3.5.1) of B-modules is bijective. □

Remarks (21.3.6). — (i) Let A', B' be two rings of characteristic p, and suppose one has two homomorphisms $i' : A' \to B'$, $j' : B' \to A'$ verifying (21.3.1.1) and (21.3.1.2), and ring homomorphisms $f : A \to A'$, $g : B \to B'$ rendering commutative the diagram

$$\begin{tikzcd} A' \arrow[r, "i'"] & B' \arrow[r, "j'"] & A' \\ A \arrow[u, "f"] \arrow[r, "i"] & B \arrow[u, "g"] \arrow[r, "j"] & A \arrow[u, "f"] \end{tikzcd}$$

Then the canonical homomorphism $\Omega^1_{B/A} \to \Omega^1_{B'/A'}$ (20.5.4.3) gives a di-homomorphism $\Theta_{B/A} \to \Theta_{B'/A'}$ rendering commutative the diagram

$$\begin{tikzcd} 0 \arrow[r] & \Xi_{B/A} \arrow[r] \arrow[d] & \Theta_{B/A} \arrow[r, "\pi_{B/A}"] \arrow[d] & \Omega^1_A \arrow[d] \\ 0 \arrow[r] & \Xi_{B'/A'} \arrow[r] & \Theta_{B'/A'} \arrow[r, "\pi_{B'/A'}"] & \Omega^1_{A'} \end{tikzcd}$$

(ii) Let A' be any A-algebra, and set $B' = B \otimes_A A'$; then $i' = i \otimes 1 : A' \to B'$ and $j' = j \otimes 1 : B' \to A'$ verify (21.3.1.1) and (21.3.1.2), and one has

$$\Omega^1_{B'/A'} = \Omega^1_{B/A} \otimes_A A' = \Omega^1_{B/A} \otimes_B B'$$

(20.5.5); one deduces a canonical A'-isomorphism

(21.3.6.1)
$$\Theta_{B/A} \otimes_A A' \xrightarrow{\sim} \Theta_{B'/A'}$$

and also a canonical B'-homomorphism

(21.3.6.2)
$$(\Omega^1_{B/A})^{(p)} \otimes_B B' \xrightarrow{\sim} (\Omega^1_{B'/A'})^{(p)}.$$

21.4. The case of field extensions

(21.4.0). Let K be a field of characteristic $p > 0$, k a subfield of K; then the ring $k[K^p]$ is equal to the field $k(K^p)$ since k is algebraic over K^p. One can therefore apply the results of the preceding sections everywhere replacing A, B and $A[B^p]$ by k, K and $k(K^p)$.

Lemma (21.4.1). — *Let k be a field of characteristic $p > 0$, K an extension of k. For an element $x \in K$ to be p-free over k, it is necessary and sufficient that $x \notin k(K^p)$.*

Proof. Indeed, x is a root of the polynomial $X^p - x^p$ of $k(K^p)[X]$, and one knows (Bourbaki, *Alg.*, chap. V, § 8, n° 1, prop. 1) that if $x \notin k(K^p)$ this polynomial is irreducible, so that the elements $1, x, \ldots, x^{p-1}$ form a base of the $k(K^p)$-module $k(K^p)(x)$. □

Theorem (21.4.2). — *Let k be a field of characteristic $p > 0$, K an extension of k, S a system of p-generators of K over k, $L \subset S$ a p-free subset over k. There exists then a p-base B of K over k such that $L \subset B \subset S$. In particular, every extension of k admits a p-base over k.*

Proof. One can reduce to the case where $K^p \subset k$. By virtue of Zorn's theorem, there exists in K a subset B such that $L \subset B \subset S$, p-free over k and *maximal* amongst the subsets of S having these properties. It suffices to see that the subfield K' of K generated by k and B is equal to K. In the opposite case, there would exist $x \in S$ not in K'; as $K^p \subset k$, one has $K' = K'(K^p)$; hence x would be p-free over K' (21.4.1), and hence $B \cup \{x\}$ would be p-free over k (21.1.10), contradicting the maximality of B. The last assertion of (21.4.2) is obtained by taking $L = \emptyset$, $S = K$. □ □

Corollary (21.4.3). — *Let k be a field of characteristic $p > 0$, K an extension of k. For a family (x_α) of elements of K to be p-free over k, it is necessary and sufficient that, for all α, x_α does not belong to the field K_α generated by $k(K^p)$ and the x_β of index $\beta \neq \alpha$.*

Proof. The condition is necessary by virtue of (21.1.10). Conversely, suppose it is satisfied; one can reduce to the case where (x_α) is a system of p-generators of K. There exists then a sub-family of (x_α) which is a p-base of K (21.4.2), but this sub-family cannot be distinct from (x_α), since by hypothesis it would not be a family of p-generators of K. □

0_IV-1 | 163

Corollary (21.4.4). — *Let k be a field of characteristic $p > 0$, K an extension of k. For $\Omega^1_{K/k} = 0$, it is necessary and sufficient that $K = k(K^p)$. In particular, for $\Omega^1_K = 0$, it is necessary and sufficient that K be a* perfect field.

Proof. Indeed, if (x_α) is a p-base of K over k, the $d_{K/k}(x_\alpha)$ form a base of the K-vector space $\Omega^1_{K/k}$ (21.2.5). □

Theorem (21.4.5). — *Let k be a field of characteristic $p > 0$, K an extension of k, (x_α) a family of elements of K. For (x_α) to be p-free over k (resp. a family of p-generators of K over k, resp. a p-base of K over k), it is necessary and sufficient that the family $(d_{K/k}(x_\alpha))$ be a free family (resp. a system of generators, resp. a base) in the K-vector space $\Omega^1_{K/k}$.*

Proof. Let K' be the subfield (equal to the subring) of K generated by $k(K^p)$ and the x_α; taking into **0_IV-1** | 164
account (21.4.3), it suffices to see that, for each α, x_α does not belong to K_α. But, in the exact sequence

$$\Omega^1_{K_\alpha/k(K^p)} \otimes_{K_\alpha} K \longrightarrow \Omega^1_{K/k(K^p)} \longrightarrow \Omega^1_{K/K_\alpha} \longrightarrow 0$$

the images by the left arrow of the $d_{K_\alpha/k}(x_\beta)$ for $\beta \neq \alpha$ are the $d_{K/k}(x_\beta)$, hence generate a sub-vector space of $\Omega^1_{K/k(K^p)}$ not containing $d_{K/k}(x_\alpha)$, and as this sub-vector space is the kernel of the right arrow, we see that $d_{K/K_\alpha}(x_\alpha) \neq 0$, hence $x_\alpha \notin K_\alpha$.

If now (x_α) is a p-free family, it is a sub-family of a p-base of K over k (21.4.2), hence the $d_{K/k}(x_\alpha)$ are part of a base of $\Omega^1_{K/k}$ (21.2.5), and are thus linearly independent over K. Let us prove conversely that if the $d_{K/k}(x_\alpha)$ are linearly independent over K, the family (x_α) is p-free over k. □

Corollary (21.4.6). — *Let k be a field of characteristic $p > 0$, K an extension of k, x an element of K. The three following conditions are equivalent:*

a) $x \notin k(K^p)$.

b) $d_{K/k}(x) \neq 0$.
c) *The element x is p-free over k.*

Proposition (21.4.7). — *Let L be a field of characteristic $p > 0$, K a subfield of L such that $L^p \subset K \subset L$. Then the sequence of L-vector spaces*

$$0 \longrightarrow \Omega^1_{K/L^p} \otimes_K L \longrightarrow \Omega^1_{L/L^p} \longrightarrow \Omega^1_{L/K} \longrightarrow 0 \tag{21.4.7.1}$$

is exact; in other words, one has $\Upsilon_{L/K/L^p} = 0$.

Proof. This is a particular case of (21.2.4), taking into account (21.4.2). □

Proposition (21.4.8). — *Under the hypotheses of (21.4.7), the canonical homomorphism*

$$(\Omega^1_{L/K})^{(p)} \longrightarrow \Upsilon_{L/K} \tag{21.4.8.1}$$

is bijective; if (x_λ) is a p-base of L over K, the elements $d_K(x_\lambda^p) \otimes 1$ form a base of the L-vector space $\Upsilon_{L/K}$.

Proof. This is a particular case of (21.3.5). □

21.5. Application: criteria for separability In this and the following numbers, *we no longer assume* that the rings considered are of characteristic $p > 0$.

(21.5.1). Let us first note that the criterion (21.2.7) allows us to prove one part of the Cohen theorem on separable extensions (19.6.1), namely that if k is a field of characteristic $p > 0$ and if K is a separable extension of k, then K is a formally smooth k-algebra. Indeed, K admits a p-base over k (21.4.2), and on the other hand, it follows from the criterion of MacLane (Bourbaki, *Alg.*, chap. V, § 8, no. 2, prop. 3) that in an algebraic closure of K, $k^{p^{-1}}$ and K are linearly disjoint over k, and consequently the canonical homomorphism $k^{p^{-1}} \otimes_k K \to k^{p^{-1}}(K)$ is bijective, which is precisely the condition (i) of (21.2.7), after transport of structure by the isomorphism $x \mapsto x^p$.

Proposition (21.5.2). — (MacLane). *Let A, B be two complete discrete valuation rings, $\mathfrak{m}$, $\mathfrak{n}$ their respective maximal ideals, $K = A/\mathfrak{m}$ and $L = B/\mathfrak{n}$ their residue fields, $u : A \to B$ a homomorphism such that $Bu(\mathfrak{m}) = \mathfrak{n}$, $u_0 = u \otimes 1 : K \to L$ the corresponding homomorphism for the residue fields. Consider the following conditions:*

a) *L is a separable extension of K (for u_0).*
b) *For every complete discrete valuation ring B' with maximal ideal $\mathfrak{n}'$ and residue field L', every homomorphism $u' : A \to B'$ such that $B'u'(\mathfrak{m}) = \mathfrak{n}'$ and every K-isomorphism $\sigma : L \to L'$ (relative to u_0 and $u'_0 = u' \otimes 1 : K \to L'$), there exists an isomorphism $w : B \to B'$ such that $u' = w \circ u$ and that $w_0 = w \otimes 1 : L \to L'$ is equal to σ.*
b′) *For every homomorphism $u' : A \to B$ such that $Bu'(\mathfrak{m}) = \mathfrak{n}$ and such that $u'_0 = u' \otimes 1 : K \to L$ is equal to u_0, there exists an automorphism w of B such that $u' = w \circ u$ and that $w_0 = w \otimes 1 : L \to L$ is the identity.*
c) *Denoting by $u_1 : A/\mathfrak{m}^2 \to B/\mathfrak{n}^2$ the homomorphism deduced from u by passage to quotients, then for every local homomorphism $u'_1 : A/\mathfrak{m}^2 \to B/\mathfrak{n}^2$ such that $\mathrm{gr}_0(u'_1) = \mathrm{gr}_0(u_1) (= u_0)$, there exists an automorphism w_1 of $B/\mathfrak{n}^2$ such that $\mathrm{gr}_0(w_1)$ is the identity and that $u'_1 = w_1 \circ u_1$.*
c′) *For every local homomorphism $u'_1 : A/\mathfrak{m}^2 \to B/\mathfrak{n}^2$ such that $\mathrm{gr}_0(u'_1) = \mathrm{gr}_0(u_1)$ and $\mathrm{gr}_1(u'_1) = \mathrm{gr}_1(u_1)$ (homomorphism of $\mathfrak{m}/\mathfrak{m}^2$ into $\mathfrak{n}/\mathfrak{n}^2$), there exists an automorphism w_1 of $B/\mathfrak{n}^2$ such that $\mathrm{gr}_0(w_1)$ is the identity and that $u'_1 = w_1 \circ u_1$.*

Then one has the implications c) ⇔ c′) ⇔ a) ⇒ b) ⇒ b′).

If moreover A is a Cohen ring, the five conditions are equivalent.

Proof. The implications $b) \Rightarrow b')$ and $c) \Rightarrow c')$ are trivial. Let us show that $a)$ implies $b)$. The homomorphism u makes B into a torsion-free A-module, since it transforms a uniformizer of A into a uniformizer of B; it follows that B is a *flat* A-module ($\mathbf{0_I}$, 6.3.4), hence a *Cohen A-algebra* (19.8.1); the fact that $a)$ implies $b)$ is then a consequence of (19.8.2), (i) applied to $C = B'$, $\mathfrak{J} = \mathfrak{n}'$, B' being considered as an A-algebra for u' and the homomorphism $B \to B'/\mathfrak{n}'$ being the composite $B \to B/\mathfrak{n} \xrightarrow{\sigma} B'/\mathfrak{n}'$, which is an A-homomorphism by virtue of the hypothesis $u'_0 = \sigma \circ u_0$. The same reasoning proves that $a)$ implies $c)$, taking $C = B/\mathfrak{n}^2$, $\mathfrak{J} = \mathfrak{n}/\mathfrak{n}^2$, C being considered as an A-algebra for u'_1.

Let us prove next that c') implies a). The two homomorphisms u_1 and u_1' are such that $u_1' = u_1 + D$, where D is a derivation of $A/\mathfrak{m}^2$ into $\mathfrak{n}/\mathfrak{n}^2$ (20.1.1); moreover, the hypothesis $\mathrm{gr}_1(u_1') = \mathrm{gr}_1(u_1)$ means that D is zero in $\mathfrak{m}/\mathfrak{m}^2$, and can thus be considered as a derivation of $K = A/\mathfrak{m}$ into $\mathfrak{n}/\mathfrak{n}^2$, and $\mathfrak{n}/\mathfrak{n}^2$ identifies (by choice of a uniformizer of B) with the K-module L (for u_0). On the other hand, the conditions imposed on w_1 imply that $\mathrm{gr}_1(w_1)$ is also the identity (since $u_1(\mathfrak{m}/\mathfrak{m}^2)$ generates $\mathfrak{n}/\mathfrak{n}^2$); w_1 is thus of the form $z \mapsto z + D'(z)$, where D' is this time a derivation of $B/\mathfrak{n}^2$ in the $(B/\mathfrak{n}^2)$-module $\mathfrak{n}/\mathfrak{n}^2$; as w_1 is the identity on $\mathfrak{n}/\mathfrak{n}^2$, D' can again (by the preceding identification of $\mathfrak{n}/\mathfrak{n}^2$ and of L) be considered as a derivation *of L into L*; finally, the relation $u_1' = w_1 \circ u_1$ means that *D' extends D*. Let us note, on the other hand, that every derivation D of K into L corresponds to a homomorphism u_1' satisfying the conditions of c') (20.1.1); condition c') therefore means that every derivation of K into L extends to a derivation of L into itself, that is to say (20.6.5), that L is separable over K.

Let us prove finally that, when A is a Cohen ring, b') implies c'). Let us show first that under the hypotheses of c'), there exists a homomorphism $u' : A \to B$ satisfying the hypotheses of b') and that, by passage to quotients, gives $u_1' : A/\mathfrak{m}^2 \to B/\mathfrak{n}^2$. Indeed, this follows from (19.8.6), (i) applied to the composite homomorphism $v' : A \to A/\mathfrak{m}^2 \xrightarrow{u_1'} B/\mathfrak{n}^2$; this last thus factors as $A \xrightarrow{u'} B \to B/\mathfrak{n}^2$ $\mathbf{0}_{\text{IV-1}}$ | 166
and the hypotheses on $\mathrm{gr}_0(u_1')$ and $\mathrm{gr}_1(u_1')$ imply $\mathrm{gr}_0(u') = \mathrm{gr}_0(u) = u_0$ and $\mathrm{gr}_1(u') = \mathrm{gr}_1(u)$, hence the image by u' of a uniformizer of A is a uniformizer of B, and therefore $Bu'(\mathfrak{m}) = \mathfrak{n}$. It then suffices, to obtain an automorphism w_1 satisfying the question, to take the automorphism deduced by passage to quotients from the automorphism w of B provided by the application of b') to the homomorphism u'. □

Remarks (21.5.3). — (i) The differential properties of fields allow us to solve the question of the *uniqueness* of the representative field in a complete local Noetherian ring C (19.8.7), (ii). Let $\mathfrak{J}$ be the maximal ideal of C, $K = C/\mathfrak{J}$ the residue field of C; we can restrict to the case $\mathfrak{J} \neq 0$. Suppose there exists a homomorphism $u : K \to C$ that, composed with the augmentation $C \to K$, gives the identity; then, *for this homomorphism to be unique, it is necessary and sufficient that* $\Omega^1_K = 0$. Indeed, the condition $\Omega^1_K = 0$ implies that K is formally unramified on its prime field (20.7.4); if there existed a second homomorphism $v \neq u$ satisfying the question, there would exist a largest integer n such that $\mathfrak{J}^n$ contains the set of the $u(x) - v(x)$ for $x \in K$; by passage to the quotient, u and v would give two distinct homomorphisms u', v' of K into $C/\mathfrak{J}^{n+1}$, whose composites with $C/\mathfrak{J}^{n+1} \to C/\mathfrak{J}^n$ would be equal, which contradicts the definition (19.10.2). Conversely, suppose $\Omega^1_K \neq 0$; then there exists a derivation $D \neq 0$ of K into $\mathfrak{J}/\mathfrak{J}^2$ (20.4.8), hence a homomorphism $v_1 : K \to C/\mathfrak{J}^2$ such that, if $u_1 : K \to C/\mathfrak{J}^2$ is obtained by passage to quotients from u, one has $v_1 = u_1 + D$ (20.1.1). If k is the prime field of K, C is a k-algebra and K a formally smooth k-algebra (19.6.1), and the restrictions of u_1 and v_1 to k coincide, hence v_1 factors as $K \xrightarrow{v} C \to C/\mathfrak{J}^2$ and one has $v \neq u$.

Let us recall (20.6.20) and (21.4.4) that the condition $\Omega^1_K = 0$ means that K is *perfect* if it is of characteristic $\neq 0$, and an algebraic extension of $\mathbf{Q}$ if it is of characteristic 0.

(ii) In the same way, let W be a Cohen ring, C a complete local Noetherian ring, $\mathfrak{J}$ a nonzero ideal of C contained in the maximal ideal; for the factorization $W \xrightarrow{v} C \to C/\mathfrak{J}$ in (19.8.6), (i) to be *unique*, it is necessary and sufficient that the residue field K of the Cohen ring W is such that $\Omega^1_K = 0$. Indeed, if $\Omega^1_K \neq 0$ and if $\mathfrak{m}$ denotes the maximal ideal of W, it suffices to compose a derivation $D \neq 0$ of K into $\mathfrak{J}/\mathfrak{m}\mathfrak{J}$ to obtain a derivation $D' \neq 0$ of W into $\mathfrak{J}/\mathfrak{m}\mathfrak{J}$ and one finishes the reasoning as in (i) by forming the homomorphism $v_1 : W \to C/\mathfrak{m}\mathfrak{J}$ distinct from the homomorphism $u_1 : W \to C/\mathfrak{m}\mathfrak{J}$ deduced from u by passage to quotients; one finishes by invoking (19.8.6), (i). If on the contrary $\Omega^1_K = 0$, the uniqueness of v already follows from (i) when W is a field of characteristic 0. In the opposite case, one has $\widehat{\Omega}^1_W = 0$; in fact, one then has $\mathfrak{m} = pW$, p being the characteristic of K (19.8.5), and the canonical homomorphism $\mathfrak{m}/\mathfrak{m}^2 \to \Omega^1_W/\mathfrak{m}\Omega^1_W$ (20.5.11.2) is consequently zero. The exact sequence (20.5.12.1) applied to W and to $K = W/\mathfrak{m}$ then implies that $\Omega^1_W = \mathfrak{m}\Omega^1_W$, whence our assertion. But then (20.7.4) W is formally unramified (for its adic topology) over $\mathbf{Z}$, and the uniqueness of v is proved as in (i).

21.6. Admissible fields for an extension

(21.6.1). Given four fields $k_0 \subset k \subset K \subset L$, it follows from (20.6.16) and (20.6.17) that one has an exact sequence

$$0 \longrightarrow \Upsilon_{K/k/k_0} \otimes_K L \xrightarrow{v} \Upsilon_{L/k/k_0} \xrightarrow{u} \Upsilon_{L/K/k_0} \xrightarrow{s} \Upsilon_{L/K/k} \longrightarrow 0. \tag{21.6.1.1}$$

When one fixes k_0, K, and L and one lets the intermediate field k between k_0 and K "vary", one evidently has $\Upsilon_{L/K/k_0} = \Upsilon_{L/K/k}$ when $k = k_0$. When the canonical homomorphism s of (21.6.1.1) is still *bijective*, one says that k is a *k_0-admissible field for the extension L of K*. The interest of the existence, under certain conditions, of such fields k, which are however "sufficiently close" to K (for example such that $[K : k]$ is finite) is that they allow us to replace in certain questions the modules of differentials Ω^1_{K/k_0} and Ω^1_{L/k_0} (which can be "too large", for example when k_0 is the prime field) by $\Omega^1_{K/k}$ and $\Omega^1_{L/k}$, which are more easily handled.

When k_0 is the *prime field*, one says "admissible field" instead of "k_0-admissible field".

We set

(21.6.1.2).

$$\Delta(L/K, k/k_0) = \operatorname{Coker}(\Upsilon_{K/k/k_0} \otimes_K L \longrightarrow \Upsilon_{L/k/k_0}) \simeq \operatorname{Ker}(\Upsilon_{L/K/k_0} \longrightarrow \Upsilon_{L/K/k})$$

(vector space over L); its rank will be denoted $d(L/K, k/k_0)$ and called the *defect of k_0-admissibility of k for the extension L of K* (it is evidently zero if and only if k is k_0-admissible for this extension). When k_0 is the prime field, one writes $\Delta(L/K, k)$ and $d(L/K, k)$ instead of $\Delta(L/K, k/k_0)$ and $d(L/K, k/k_0)$.

Proposition (21.6.2). — *Let $k_0 \subset k \subset K \subset L$ be four fields.*

(i) *The following conditions are equivalent:*
  a) *The field k is k_0-admissible for the extension L of K (in other words, the homomorphism $\Upsilon_{L/K/k_0} \to \Upsilon_{L/K/k}$ is injective, hence bijective).*
  b) *The canonical homomorphism $u : \Upsilon_{K/k/k_0} \to \Upsilon_{L/k/k_0}$ is zero.*
  c) *The canonical homomorphism $v : \Upsilon_{K/k/k_0} \otimes_K L \to \Upsilon_{L/k/k_0}$ is surjective (hence bijective).*
  d) *One has $d(L/K, k/k_0) = 0$ (or $\Delta(L/K, k/k_0) = 0$).*

(ii) *The equivalent conditions of* (i) *are satisfied when one is in one of the following cases: α) L is separable over k; β) L is separable over K; γ) one has $k \subset k_0(K^p)$, where p denotes the characteristic exponent of k_0.*

Proof. (i) The assertions follow trivially from the exactness of the sequence (21.6.1.1).

(ii) If L is separable over k, one has $\Upsilon_{L/K/k_0} = 0$ (20.6.19), hence condition b) of (i) is satisfied; if L is separable over K, one has $\Upsilon_{L/K/k_0} = 0$ (20.6.19), hence condition a) of (i) is satisfied; finally, if $k \subset k_0(K^p)$, it follows that $\Upsilon_{L/K/k_0} = \Upsilon_{L/K/k}$ by virtue of (21.1.5.1), and the condition a) of (i) is satisfied.

□

(21.6.3). Suppose that one has a commutative diagram of monomorphisms of fields

$$\begin{tikzcd} k'_0 \arrow[r] & k' \arrow[r] & K' \arrow[r] & L' \\ k_0 \arrow[r] \arrow[u] & k \arrow[r] \arrow[u] & K \arrow[r] \arrow[u] & L \arrow[u] \end{tikzcd}$$

It then follows from (20.6.17), (ii) that one has a canonical homomorphism

$$\Delta(L/K, k/k_0) \longrightarrow \Delta(L'/K', k'/k'_0) \tag{21.6.3.1}$$

with an evident transitivity property, so that one can say that $\Delta(L/K, k/k_0)$ is a *functor* in the quadruplet (k_0, k, K, L).

Proposition (21.6.4). — (i) *Let $k \subset k' \subset k'' \subset K \subset L$ be five fields. One has an exact sequence of canonical homomorphisms*

$$0 \longrightarrow \Delta(L/K, k'/k) \longrightarrow \Delta(L/K, k''/k) \longrightarrow \Delta(L/K, k''/k') \longrightarrow 0 \tag{21.6.4.1}$$

and consequently the equality

$$d(L/K, k''/k) = d(L/K, k''/k') + d(L/K, k'/k). \tag{21.6.4.2}$$

(ii) *Let $k_0 \subset k \subset K \subset L \subset M$ be five fields. One has an exact sequence of canonical homomorphisms*

$$0 \longrightarrow \Delta(L/K, k/k_0) \otimes_L M \longrightarrow \Delta(M/K, k/k_0) \longrightarrow \Delta(M/L, k/k_0) \longrightarrow 0 \tag{21.6.4.3}$$

and consequently the equality

$$d(M/K, k/k_0) = d(M/L, k/k_0) + d(L/K, k/k_0). \tag{21.6.4.4}$$

Proof. (i) Consider the commutative diagram

$$\begin{tikzcd}
0 \arrow[r] & \Upsilon_{K/k'/k} \otimes_K L \arrow[r] \arrow[d] & \Upsilon_{K/k''/k} \otimes_K L \arrow[r] \arrow[d] & \Upsilon_{K/k''/k'} \otimes_K L \arrow[r] \arrow[d] & 0 \\
0 \arrow[r] & \Upsilon_{L/k'/k} \arrow[r] \arrow[d] & \Upsilon_{L/k''/k} \arrow[r] \arrow[d] & \Upsilon_{L/k''/k'} \arrow[r] \arrow[d] & 0 \\
0 \arrow[r] & \Delta(L/K, k'/k) \arrow[r] & \Delta(L/K, k''/k) \arrow[r] & \Delta(L/K, k''/k') \arrow[r] & 0
\end{tikzcd}$$

where one can consider the three rows as *complexes* $T_1^\bullet$, $T_2^\bullet$, $T_3^\bullet$ respectively; the exact sequence (21.6.1.1) and the definition of Δ (21.6.1.2) show that one has an exact sequence of complexes $0 \to T_1^\bullet \to T_2^\bullet \to T_3^\bullet \to 0$; applying the exact cohomology sequence to it, and noting that, by virtue of the exactness of (21.6.1.1), the cohomology of $T_1^\bullet$ and that of $T_2^\bullet$ are zero except in a single degree, for which the cohomology modules are both equal to $\Upsilon_{k''/k'/k} \otimes_{k''} L$; as $T_1^\bullet$ and $T_2^\bullet$ have the same cohomology, that of $T_3^\bullet$ is necessarily zero, which proves (i).

(ii) Consider similarly the commutative diagram

$$\begin{tikzcd}
0 \arrow[r] & \Delta(L/K, k/k_0) \otimes_L M \arrow[r] \arrow[d] & \Delta(M/K, k/k_0) \arrow[r] \arrow[d] & \Delta(M/L, k/k_0) \arrow[r] & 0 \\
0 \arrow[r] & \Upsilon_{L/K/k_0} \otimes_L M \arrow[r] \arrow[d] & \Upsilon_{M/K/k_0} \arrow[r] \arrow[d] & \Upsilon_{M/L/k_0} \arrow[r] & 0 \\
0 \arrow[r] & \Upsilon_{L/K/k} \otimes_L M \arrow[r] & \Upsilon_{M/K/k} \arrow[r] & \Upsilon_{M/L/k} \arrow[r] & 0
\end{tikzcd}$$

where again one considers the three rows as *complexes* $T_1'^\bullet$, $T_2'^\bullet$, and $T_3'^\bullet$; the exact sequence (21.6.1.1) and the definition of Δ (21.6.1.2) give here a short exact sequence of complexes $0 \to T_1'^\bullet \to T_2'^\bullet \to T_3'^\bullet \to 0$; applying the exact cohomology sequence to it again, this time, by virtue of the exactness of (21.6.1.1), the cohomology of $T_2'^\bullet$ and that of $T_3'^\bullet$ are zero except in a single degree, for which the cohomology modules are both equal to $\Upsilon_{M/L/k_0}$; one concludes therefore that the cohomology of $T_1'^\bullet$ is zero, which establishes (ii). □

Corollary (21.6.5). — (i) *Given five fields $k \subset k' \subset k'' \subset K \subset L$, for k'' to be k-admissible for the extension L of K, it is necessary and sufficient that k' be k-admissible and that k'' be k'-admissible for the extension L of K.*

(ii) *Given five fields $k_0 \subset k \subset K \subset L \subset M$, for k to be k_0-admissible for the extension M of K, it is necessary and sufficient that it be so for the extension L of K and for the extension M of L.*

This follows immediately from the relations (21.6.4.2) and (21.6.4.4), the values of d being $\geqslant 0$.

Corollary (21.6.6). — *Let $k_0 \subset k \subset K \subset L$ be four fields, and suppose that k is k_0-admissible for the extension L of K. Then, if k_0', k', K', L' are four fields such that $k_0 \subset k_0' \subset k' \subset k \subset K \subset K' \subset L' \subset L$, k' is k_0'-admissible for the extension L' of K'.*

21.7. Cartier's equality The following result translates in terms of differentials a theorem of MacLane on derivations:

Theorem (21.7.1). — (Cartier). *Let K be a field, L a finite type extension of K. Then $\Omega^1_{L/K}$ and $\Upsilon_{L/K}$ are L-vector spaces of finite rank, and one has*

(21.7.1.1) $$\operatorname{rg}\Omega^1_{L/K} - \operatorname{rg}\Upsilon_{L/K} = \deg.\operatorname{tr}_K L.$$

Proof. If L' is a field such that $K \subset L' \subset L$, one has the exact sequence (20.6.15.1) (applied to $\Lambda = P$, $A = K$, $B = L'$, $C = L$)

$$0 \longrightarrow \Upsilon_{L'/K} \otimes_{L'} L \longrightarrow \Upsilon_{L/K} \longrightarrow \Omega^1_{L'/K} \otimes_{L'} L \longrightarrow \Omega^1_{L/K} \longrightarrow \Omega^1_{L/L'} \longrightarrow 0$$

hence ($\mathbf{0}_{\mathbf{III}}$, 11.10.2)

$$\operatorname{rg}_L \Omega^1_{L/K} - \operatorname{rg}_L \Upsilon_{L/K} = (\operatorname{rg}_{L'} \Omega^1_{L/L'} - \operatorname{rg}_{L'} \Upsilon_{L/L'}) + (\operatorname{rg}_{L'} \Omega^1_{L'/K} - \operatorname{rg}_{L'} \Upsilon_{L'/K}).$$

Since moreover $\deg.\operatorname{tr}_K L = \deg.\operatorname{tr}_K L' + \deg.\operatorname{tr}_{L'} L$, one sees, by induction on the number of generators of the extension L, that one is reduced to proving (21.7.1.1) when $L = K(x)$. We then distinguish three cases:

a) x is transcendent over K; as L is separable over K, one has $\Upsilon_{L/K} = 0$ (20.6.3); on the other hand, (20.5.9) and (20.4.13) show that $\Omega^1_{L/K}$ is of rank 1, hence (21.7.1.1) in this case.

b) L is a finite algebraic separable extension of K, so that one has again $\Upsilon_{L/K} = 0$ (20.6.3). On the other hand, one has $\Omega^1_{L/K} = 0$ by (20.6.20), hence again (21.7.1.1).

c) L is a finite algebraic inseparable extension of K; the reasoning at the beginning shows that one can restrict to the case where $L^p \subset K$; it then follows from (21.4.8) that one has $\operatorname{rg}_L \Upsilon_{L/K} = \operatorname{rg}_L \Omega^1_{L/K}$, hence again (21.7.1.1). □

Corollary (21.7.2). — *Let K be a field, L a finite type extension of K, k a subfield of K. Then $\Omega^1_{L/K}$ and $\Upsilon_{L/K/k}$ are vector spaces of finite rank over L, and one has*

(21.7.2.1) $$\operatorname{rg}\Omega^1_{L/K} - \operatorname{rg}\Upsilon_{L/K/k} = \deg.\operatorname{tr}_K L + d(L/K,k).$$

Moreover, one has the inequality

(21.7.2.2) $$\operatorname{rg}\Omega^1_{L/K} - \operatorname{rg}\Upsilon_{L/K/k} \geqslant \deg.\operatorname{tr}_K L.$$

Furthermore, for the two members of (21.7.2.2) to be equal, it is necessary and sufficient that k be an admissible field for the extension L of K.

Proof. Indeed, as the homomorphism $\Upsilon_{L/K} \to \Upsilon_{L/K/k}$ is surjective, one has by definition (21.6.1.2) $\operatorname{rg}\Upsilon_{L/K} - \operatorname{rg}\Upsilon_{L/K/k} = d(L/K,k)$, and the corollary follows immediately from (21.7.1) and from (21.6.2). □

Corollary (21.7.3). — *Let $k \subset K \subset L$ be three fields such that L is a finite type extension of k. Then one has*

(21.7.3.1) $$\operatorname{rg}_L \Omega^1_{L/k} - \operatorname{rg}_K \Omega^1_{K/k} = \deg.\operatorname{tr}_K L + d(L/K,k).$$

Moreover, one has the inequality $\mathbf{0}_{\mathbf{IV\text{-}1}}$ | 171

(21.7.3.2) $$\operatorname{rg}_L \Omega^1_{L/k} - \operatorname{rg}_K \Omega^1_{K/k} \geqslant \deg.\operatorname{tr}_K L$$

the equality being attained if and only if k is an admissible field for the extension L of K.

Proof. One has the exact sequence (20.6.1.1)

$$0 \longrightarrow \Upsilon_{L/K/k} \longrightarrow \Omega^1_{K/k} \otimes_K L \longrightarrow \Omega^1_{L/k} \longrightarrow \Omega^1_{L/K} \longrightarrow 0$$

hence the first member of (21.7.3.1) is equal to

$$\operatorname{rg}_L \Omega^1_{L/k} - \operatorname{rg}_L \Upsilon_{L/K/k}$$

and it suffices to apply (21.7.2). □

The interest of this last corollary is that it only involves modules of differentials, to the exclusion of modules of imperfection. We shall see moreover below (21.8.6) that for every finite type extension L of K, there exists a subfield k of K such that $[K : k]$ is finite, and which is admissible for the extension L of K, so that the two members of (21.7.3.2) are then equal.

Corollary (21.7.4). — *Let K be a finite type extension of a field k. The following conditions are equivalent:*

a) *K is a finite separable extension of k.*
b) *K is a formally unramified k-algebra (19.10.2).*
c) *K is a formally étale k-algebra (19.10.2).*
d) *One has $\Omega^1_{K/k} = 0$.*

Proof. Indeed, one knows (the topologies being discrete) that the conditions b) and d) are equivalent (20.7.4) and that a) implies that K is a formally smooth k-algebra (19.6.1), hence the conjunction of a) and b) is equivalent to c). The whole thing reduces to seeing that d) implies a). Now, by virtue of (21.7.1.1), the relation $\Omega^1_{K/k} = 0$ implies that K is algebraic (hence finite) over k and that $\Upsilon_{K/k} = 0$, that is to say (20.6.3) that K is separable over k. □

Remark (21.7.5). — By virtue of (20.6.5.2) and ($\mathbf{0_{III}}$, 11.10.2) the first member of (21.7.1.1) is none other than the *Euler-Poincaré characteristic* of the complex $\mathrm{K}_\bullet(C/B/A)$ introduced in (20.6.5), for $C = L$, $B = K$ and $A = P$ (prime field of K).[23] In the chapter devoted to intersection theory and to the theorem of Riemann-Roch, an important role will be played equally by generalized Euler-Poincaré characteristics (with values in groups of classes of $\mathscr{O}_X$-Modules) of complexes generalizing the complexes $\mathrm{F}_\bullet(C/A)$ considered in (20.6.22).

21.8. Criteria for admissibility We return to our previous conventions and suppose therefore that all fields considered in this number are of characteristic $p > 0$.

Lemma (21.8.1). — *Let K be a field, k a subfield of K, $(k_\alpha)_{\alpha \in I}$ a decreasing filtering family of subfields of K such that $k = \bigcap_\alpha k_\alpha$. Let V be a vector space over K, $(a_i)_{1 \leqslant i \leqslant n}$ a finite family of vectors of V; if the family (a_i) is free over k, there exists an index γ such that it is also free over k_γ.*

Proof. Let r be the rank of the family $(a_i)_{1 \leqslant i \leqslant n}$ over K, and let us reason by induction on $n - r$; $\mathbf{0_{IV\text{-}1}}$ | 172
the proposition is evident for $n = r$, for the family $(a_i)_{1 \leqslant i \leqslant r}$ is then free over K, hence over every subfield of K. Suppose for example that $(a_i)_{1 \leqslant i \leqslant r}$ is free over K, and write $a_{r+1} = \sum_{i=1}^r \lambda_i a_i$ with $\lambda_i \in K$; the family $(a_i)_{1 \leqslant i \leqslant r+1}$ being free over k, the λ_i cannot all belong to k; suppose for example that $\lambda_{i_0} \notin k$. Then there is an index β such that $\lambda_{i_0} \notin k_\beta$; one concludes that the family $(a_i)_{1 \leqslant i \leqslant r+1}$ is *free over k_β*; indeed, if the family $(a_i)_{1 \leqslant i \leqslant r+1}$ were not free over k_β, a_{r+1} would be equal to a linear combination of the a_i with coefficients in k_β, and as these coefficients are necessarily the λ_i, one would arrive at a contradiction. It now suffices to apply the induction hypothesis by replacing K by k_β and the family $(k_\alpha)_{\alpha \in I}$ by the sub-family of the k_α contained in k_β. □

Lemma (21.8.2). — *Let K be a field, p its exponential characteristic, k_0 a subfield of K, $(k_\alpha)_{\alpha \in I}$ a decreasing filtering family of subfields of K such that $\bigcap_\alpha k_\alpha(K^p) = k_0(K^p)$. If $(x_i)_{1 \leqslant i \leqslant n}$ is a finite family of elements of K that is p-free over k_0, there exists an index α such that (x_i) is also p-free over k_α.*

Proof. Indeed, to say that the family (x_i) is p-free over a subfield k of K means that the finite family of monomials $\prod_{i=0}^n x_i^{m(i)}$ with $0 \leqslant m(i) < p$ is free over $k(K^p)$; it suffices therefore to apply the lemma (21.8.1) to this family of monomials in the vector space $V = K$, and to the subfields $k_\alpha(K^p)$ and $k_0(K^p)$ of K. □

Theorem (21.8.3). — *Let K be a field of characteristic $p > 0$, k_0 a subfield of K, $(k_\alpha)_{\alpha \in I}$ a decreasing filtering family of subfields of K containing k_0. The following conditions are equivalent:*

a) $\bigcap_\alpha k_\alpha(K^p) = k_0(K^p)$.
b) *For every extension L of K such that $\Upsilon_{L/K/k_\alpha}$ is an L-vector space of finite rank (which holds in particular if L is a finite type extension by virtue of (21.7.2)), there exists $\alpha \in I$ such that k_α is k_0-admissible for the extension L of K.*
b′) *For every extension $L = K(x)$ of K, with $x^p \in K$, there exists $\alpha \in I$ such that k_α is k_0-admissible for the extension L of K.*
c) *The canonical map*

(21.8.3.1) $$\Omega^1_{K/k_0} \longrightarrow \varprojlim_\alpha \Omega^1_{K/k_\alpha}$$

is injective.

[23] The French source prints "(20.6.3.2)", which does not exist; the homology identities used here are (20.6.5.2).

Proof. The canonical map (21.8.3.1) is understood as passage to the projective limit in the projective system of homomorphisms $\Omega^1_{K/k_0} \to \Omega^1_{K/k_\alpha}$ (20.5.3.3). We shall prove the logical scheme $c) \Rightarrow b) \Rightarrow b') \Rightarrow a) \Rightarrow c)$.

To say that k_α is k_0-admissible for the extension L of K means that the canonical homomorphism $\Upsilon_{L/K/k_0} \to \Upsilon_{L/K/k_\alpha}$ is injective; or, if N_α is the kernel of this homomorphism, the N_α form a decreasing filtering system of sub-vector spaces of $\Upsilon_{L/K/k_0}$, and as $\Upsilon_{L/K/k_0}$ is by hypothesis of *finite* rank, it amounts to the same to say that one of the N_α is 0 or that their *intersection* is 0. But this intersection is none other than the kernel of the projective limit homomorphism $\Upsilon_{L/K/k_0} \to \varprojlim_\alpha \Upsilon_{L/K/k_\alpha}$. Now, one has the commutative diagram

$$\begin{tikzcd} \Upsilon_{L/K/k_0} \arrow[r] \arrow[d] & \varprojlim \Upsilon_{L/K/k_\alpha} \arrow[d] \\ \Omega^1_{K/k_0} \otimes_K L \arrow[r] & \varprojlim(\Omega^1_{K/k_\alpha} \otimes_K L) \end{tikzcd}$$

where the left vertical arrow is injective by definition. To prove that $c)$ implies $b)$, it suffices therefore to show that the canonical map

$$\Omega^1_{K/k_0} \otimes_K V \longrightarrow \varprojlim_\alpha(\Omega^1_{K/k_\alpha} \otimes_K V) \tag{21.8.3.2}$$

is injective for every vector space V over K (and in particular for $V = L$). Now this is evident if $V = K^n$ since then $W \otimes_K V = W^n$ for every vector space W over K and projective limits and products commute. On the other hand, for every element z of the first member of (21.8.3.2) there exists a subspace V' of V of finite rank containing z (identified canonically with a subspace of $\Omega^1_{K/k_0} \otimes_K V'$); if $z \neq 0$, its image $\varprojlim(\Omega^1_{K/k_\alpha} \otimes_K V')$ is also non-zero; as the $\varprojlim$ functor is exact on the left, the image of z in the second member of (21.8.3.2) is therefore also $\neq 0$, which finishes the proof that $c)$ implies $b)$.

It is trivial that $b)$ implies $b')$; let us show that $b')$ implies $a)$. Using the notations of $b')$, one can suppose $L \neq K$. It then follows from (21.4.7) that one has $\operatorname{rg} \Upsilon_{L/K} \leqslant 1$. If $\Upsilon_{L/K/k_\alpha} = 0$ there is nothing to prove by virtue of (21.6.1.1). Otherwise, $\Upsilon_{L/K/k_\alpha}$ is identified canonically with $\Upsilon_{L/K}$, and if one sets $a = x^p$, $\Upsilon_{L/K}$ is a one-dimensional space generated by the single element $d_K(a) \otimes 1$ (21.4.7); $\Upsilon_{L/K/k_\alpha}$ is thus a one-dimensional space generated by the single element $d_{K/k_\alpha}(a) \otimes 1$, i.e., to say that a subfield k_α is k_0-admissible for the extension L of K means that one has $d_{K/k_\alpha}(a) \neq 0$, or equivalently (21.4.6) that $a \notin k_\alpha(K^p)$. Now, for every $a \notin k_0(K^p)$, one has $d_{K/k_0}(a) \neq 0$ and $K(a^{1/p}) \neq K$, hence one can apply $b')$, which proves the existence of an α such that $a \notin k_\alpha(K^p)$; as this holds for every $a \notin k_0(K^p)$, we have shown $b') \Rightarrow a)$.

It remains to show that $a)$ implies $c)$. Let $(x_\mu)_{\mu \in M}$ be a p-base of K over k_0; then the $d_{K/k_0}(x_\mu)$ form a base of the K-vector space Ω^1_{K/k_0} (21.4.5), and the condition $c)$ means that for every finite subset J of the set of indices M, there exists $\alpha \in I$ such that the $d_{K/k_\alpha}(x_\mu)$ for $\mu \in J$ are linearly independent in Ω^1_{K/k_α}; but this means also (21.4.5) that the x_μ for $\mu \in J$ form a p-free family *over* k_α, and the existence of an α having this property follows from (21.8.2) and from the hypothesis $a)$. □

$\mathbf{0_{IV\text{-}1}}$ | 174

Corollary (21.8.4). — *Let K be a field of characteristic $p > 0$, k_0 a subfield of K, $(k_\alpha)_{\alpha \in I}$ a decreasing filtering family of subfields of K, containing k_0, such that*

$$\bigcap_\alpha k_\alpha(K^p) = k_0(K^p).$$

Let L be an extension of K such that $\Upsilon_{L/K/k_0}$ is an L-vector space of finite rank; then, for every field K' such that $K \subset K' \subset L$, there exists $\alpha \in I$ such that k_α is k_0-admissible for the extension L of K'.

Proof. It suffices to apply (21.8.3) and (21.6.6). □

Corollary (21.8.5). — *Let K be a field of characteristic $p > 0$, k_0 a subfield of K, $(k_\alpha)_{\alpha\in I}$ a decreasing filtering family of subfields of K containing k_0, such that*

$$\bigcap_\alpha k_\alpha(K^p) = k_0(K^p).$$

Then, for every extension L of K such that $\Upsilon_{L/K/k_0}$ is an L-vector space of finite rank, one has $\bigcap_\alpha k_\alpha(L^p) = k_0(L^p)$.

Proof. Suppose indeed that M is an extension of L such that $\Upsilon_{M/L/k_0}$ is an M-vector space of finite rank. The exact sequence (21.6.1.1)

$$0 \longrightarrow \Upsilon_{L/K/k_0} \otimes_L M \longrightarrow \Upsilon_{M/K/k_0} \longrightarrow \Upsilon_{M/L/k_0}$$

and the hypothesis show that $\Upsilon_{M/K/k_0}$ is also an M-vector space of finite rank. There exists therefore an index α such that k_α is k_0-admissible for the extension M of K (21.8.3); this holding also for the extension M of L (21.6.6); the equivalence of a) and b) in (21.8.3) gives the corollary. □

Corollary (21.8.6). — *Let K be a field of characteristic $p > 0$, k_0 a subfield of K, $(k_\alpha)_{\alpha\in I}$ a decreasing filtering family of subfields of K containing k_0, such that*

$$\bigcap_\alpha k_\alpha(K^p) = k_0(K^p).$$

Let L be an extension of K such that $\Upsilon_{L/K/k_0}$ is an L-vector space of finite rank; then there exists a subfield k of K, containing $k_0(K^p)$, such that $[K : k]$ is finite, and which is k_0-admissible for the extension L of K.

Proof. It suffices indeed, by virtue of (21.8.3), to construct a decreasing filtering family $(k_\alpha)_{\alpha\in I}$ of subfields of K, containing K^p and k_0, for which $[K : k_\alpha] < +\infty$ and $\bigcap_\alpha k_\alpha = k_0(K^p)$. For this one considers a p-base $(x_\lambda)_{\lambda\in J}$ of K over k_0 and, for every finite subset H of J, one considers the subfield k_H of K generated by $k_0(K^p)$ and the x_λ for $\lambda \in J - H$; it follows from this definition that $(x_\lambda)_{\lambda\in H}$ is a p-base of K over k_H, and one concludes immediately that the k_H satisfy the required conditions. □

Remarks (21.8.7). —

(i) One has already seen (21.7.2) that if L is a *finite type* extension of K, $\Upsilon_{L/K/k_0}$ is of finite rank for every subfield k_0 of K. It is the same if L is a *separable* extension of K, for by virtue of (20.6.19), one has $\Upsilon_{L/K/k_0} = 0$. Finally, if L is a *finite type extension of a separable extension L_0 of K*, the same reasoning as in (21.8.5) shows that $\Upsilon_{L/K/k_0}$ is still of finite rank (and in fact is isomorphic to a subspace of $\Upsilon_{L/L_0/k_0}$). **$0_{\text{IV-1}}$** | 175

(ii) In the statement of (21.8.5), and consequently in that of (21.8.3), b)), one cannot omit the hypothesis that $\Upsilon_{L/K/k_0}$ is of finite rank over L. Let us take for k_0 the prime field $\mathbf{F}_p$, for K a field such that $[K : K^p]$ is countably infinite (for example the field of rational functions $\mathbf{F}_p(X_1, \ldots, X_n, \ldots)$ with a countable infinity of indeterminates); the construction procedure of (21.8.6) then shows that there exists an infinite strictly decreasing sequence (K_n) of subfields of K such that $K_0 = K$ and $\bigcap_n K_n = K^p$. We shall construct increasing finite extensions M_n of K, such that if M is the union of the M_n, the extension $L = M^{1/p}$ of K gives (21.8.5) a counterexample. Namely, take an element x of $K - K^p$, set $M_0 = K^p$, and $M_n = K^p(a_1x, a_2x, \ldots, a_nx)$ for $n \geqslant 1$, where the a_n are constructed by induction so that $a_n \in K_n$ and $a_{n+1} \notin M_n(x)$ for all n: this is possible, since $M_n(x)$ is of finite degree over K^p, while K_n is not of finite degree over K^p. One concludes also that $x \notin M = L^p$, but as $x = (a_nx)a_n^{-1}$, one has $x \in K_n(M) = K_n(L^p)$ for all n, hence $x \in \bigcap_n K_n(L^p)$, which proves our assertion.

Proposition (21.8.8). — *Let k be a field of characteristic $p > 0$, and let $A = k[[T_1, \ldots, T_r]]$ be the ring of formal power series in r indeterminates over k, $K = k((T_1, \ldots, T_r))$ its field of fractions. Then there exists a decreasing filtering family (A_α) of subrings Noetherian of A such that A is an A_α-module* free of finite type *for all α and that, if K_α is the field of fractions of A_α, one has $\bigcap_\alpha K_\alpha = K^p$.*

Proof. One can write $K^p = k^p((T_1^p, \ldots, T_r^p))$; as one has seen in the proof of (21.8.6), there exists a decreasing family (k_α) of subfields of k such that $[k : k_\alpha]$ is finite for all α and $\bigcap_\alpha k_\alpha = k^p$; it is clear that if one sets $A_\alpha = k_\alpha[[T_1^p, \dots, T_r^p]]$, A is an A_α-module *free of finite type*; the whole thing therefore reduces to proving the relation

(21.8.8.1) $$\bigcap_\alpha k_\alpha((T_1^p, \dots, T_r^p)) = k^p((T_1^p, \dots, T_r^p)).$$

Since $\bigcap_\alpha k_\alpha = k^p$, this will follow from the following two lemmas: □

Lemma (21.8.8.2). — *If k' is an extension of a field k, one has*

$$k'[[T_1, \dots, T_r]] \cap k((T_1, \dots, T_r)) = k[[T_1, \dots, T_r]].$$

Proof. Indeed, set $C = k[[T_1, \dots, T_r]]$, $D = k'[[T_1, \dots, T_r]]$; as $k((T_1, \dots, T_r))$ is the field of fractions of C, it will suffice to prove that D is a C-module *faithfully flat* (Bourbaki, *Alg. comm.*, chap. I, § 3, no. 5, prop. 10). Now, C and D are local rings Noetherian, and if $\mathfrak{m}$ is the maximal ideal of C, one has $D/\mathfrak{m}^j D = (C/\mathfrak{m}^j) \otimes_k k'$, hence $D/\mathfrak{m}^j D$ is a flat $(C/\mathfrak{m}^j)$-module; it suffices to apply $(\mathbf{0_{III}}, 10.2.1)$ and $(\mathbf{0_I}, 6.6.2)$. □

Lemma (21.8.8.3). — *Let k be a field, (k_α) a decreasing filtering family of subfields of k, and set $k_0 = \bigcap_\alpha k_\alpha$. Suppose there exists a power q of the characteristic exponent of k such that $k^q \subset k_0$. Then one has*

(21.8.8.4) $$\bigcap_\alpha k_\alpha((T_1, \dots, T_r)) = k_0((T_1, \dots, T_r)).$$

Proof. It suffices to prove that a nonzero element f of the first member of (21.8.8.4) belongs to the second member. Let γ be an index, $g \in k_\gamma[[T_1, \dots, T_r]]$ such that $gf \in k_\gamma[[T_1, \dots, T_r]]$; replacing g by g^q, one can suppose that $g \in k_0[[T_1, \dots, T_r]]$. Then, for all $\alpha \geqslant \gamma$, one has $\mathbf{0_{IV\text{-}1}}$ | 176

$$gf \in k_\gamma[[T_1, \dots, T_r]] \cap k_\alpha((T_1, \dots, T_r)) = k_\alpha[[T_1, \dots, T_r]]$$

by virtue of the lemma (21.8.8.2). But it is clear that the intersection of the rings $k_\alpha[[T_1, \dots, T_r]]$ is $k_0[[T_1, \dots, T_r]]$, and one has thus $gf \in k_0((T_1, \dots, T_r))$. □

21.9. Completed modules of differentials in formal power series rings In this number, the fields are no longer necessarily supposed to be of characteristic > 0.

Lemma (21.9.1). — *Let k be a field, A a local Noetherian complete ring that is a k-algebra, K the residue field of A. If K is a finite type extension of k, the A-module $\widehat{\Omega}^1_{A/k}$ is of finite type.*

Proof. By virtue of (20.7.15), it suffices to prove that $\Omega^1_{K/k}$ is a K-vector space of finite rank. Now, by hypothesis, K is the field of fractions of a k-algebra of finite type B; as $\Omega^1_{B/k}$ is a B-module of finite type by virtue of (20.4.7), the conclusion follows from (20.5.9). □

Proposition (21.9.2). — *Let k_0 be a field, A a local Noetherian complete ring that is a k_0-algebra formally smooth, $\mathfrak{m}$ its maximal ideal, $K = A/\mathfrak{m}$ its residue field (so that in particular A is isomorphic to a formal power series ring $K[[T_1, \dots, T_r]]$ (19.6.5)). If K is a finite type extension of k_0, then $\widehat{\Omega}^1_{A/k_0}$ is an A-module* free *of rank equal to* $\dim(A) + \deg.\mathrm{tr}_{k_0} K$. *Furthermore, for every subfield k of k_0 such that $\Omega^1_{k_0/k}$ is of finite rank, $\widehat{\Omega}^1_{A/k}$ is an A-free module of rank equal to* $\dim(A) + \deg.\mathrm{tr}_{k_0} K + \mathrm{rg}_{k_0}(\Omega^1_{k_0/k})$.

Proof. It is clear that, if P is the prime subfield of k_0, K is a formally smooth P-algebra (19.6.1). Let us note, on the other hand, that $\Upsilon^K_{A/k_0/P} = 0$: indeed, this amounts to seeing that the homomorphism

$$u_{A/k_0/P} \otimes 1_K : \Omega^1_{k_0/P} \otimes_{k_0} K \longrightarrow \Omega^1_{A/P} \otimes_A K$$

is injective (20.6.14.5), where u denotes the structural homomorphism $k_0 \to A$. But since A is a formally smooth k_0-algebra by hypothesis, it follows from (20.7.2) that $u_{A/k_0/P}$ is formally left invertible; hence (19.1.7), $u_{A/k_0/P} \otimes 1_K$ is left invertible and *a fortiori* injective, proving our assertion. Applying the exact sequence (20.6.22.1), with Λ, A, B, C replaced by P, k_0, A, K, gives the exact sequence

$$0 \longrightarrow \Upsilon^K_{A/k_0} \longrightarrow \mathfrak{m}/\mathfrak{m}^2 \longrightarrow \Omega^1_{A/k_0} \otimes_A K \longrightarrow \Omega^1_{K/k_0} \longrightarrow 0,$$

so that

$$\begin{aligned}\mathrm{rg}_K(\Omega^1_{A/k_0} \otimes_A K) &= \mathrm{rg}_K(\mathfrak{m}/\mathfrak{m}^2) + \big(\mathrm{rg}_K(\Omega^1_{K/k_0}) - \mathrm{rg}_K(\Upsilon_{K/k_0})\big) \\ &= \mathrm{rg}_K(\mathfrak{m}/\mathfrak{m}^2) + \deg.\mathrm{tr}_{k_0} K\end{aligned}$$

by virtue of (21.7.1). On the other hand, $\widehat{\Omega}^1_{A/k_0}$ is a formally projective A-module (20.4.9); since its topology is the $\mathfrak{m}$-preadic topology (20.4.5), $\widehat{\Omega}^1_{A/k_0}/\mathfrak{m}^{j+1}\widehat{\Omega}^1_{A/k_0}$ is a projective $(A/\mathfrak{m}^{j+1})$-module for every j (19.2.4), hence free ($\mathbf{0_{III}}$, 10.1.2) and of rank $n = \mathrm{rg}_K(\Omega^1_{A/k_0} \otimes_A K)$. By virtue of (21.9.1), $\mathbf{0_{IV\text{-}1}}$ | 177
$\widehat{\Omega}^1_{A/k_0}$ is an A-module of finite type; moreover this A-module is flat by virtue of ($\mathbf{0_{III}}$, 10.2.1), and is therefore free ($\mathbf{0_{III}}$, 10.1.3) of rank n, proving the first assertion.

Since, by hypothesis, $\Omega^1_{k_0/k}$ has finite rank over k_0, the completed tensor product $\Omega^1_{k_0/k}\widehat{\otimes}_{k_0}A$ identifies with $\Omega^1_{k_0/k}\otimes_{k_0} A$. As A is a formally smooth k_0-algebra, it follows from (20.7.18) that the homomorphism

$$\widehat{u}_{A/k_0/k} : \Omega^1_{k_0/k} \otimes_{k_0} A \longrightarrow \widehat{\Omega}^1_{A/k}$$

has a left inverse which is a continuous A-homomorphism; in particular, its image is closed in $\widehat{\Omega}^1_{A/k}$. Consequently the exact sequence

$$0 \longrightarrow \Omega^1_{k_0/k} \otimes_{k_0} A \xrightarrow{\widehat{u}_{A/k_0/k}} \widehat{\Omega}^1_{A/k} \longrightarrow \widehat{\Omega}^1_{A/k_0} \longrightarrow 0$$

is exact and split by virtue of (20.7.17) and what precedes; this completes the proof. □

Corollary (21.9.3). — *Let k be a field, A the ring of formal power series $k[[T_1, \dots, T_r]]$, equipped with its usual structure as a k-algebra. Then $\widehat{\Omega}^1_{A/k}$ is an A-free module of rank $r = \dim(A)$.*

Proof. It suffices to note that A is a k-algebra formally smooth (19.3.4), and to apply (21.9.2) with $k_0 = k = K$. □

Lemma (21.9.4). — *Let k be a field of characteristic $p > 0$, A a k-algebra that is a local Noetherian complete ring, B a sub-k-algebra of A isomorphic to a topological algebra of the form $k[[T_1, \dots, T_r]]$ and such that A is a B-algebra of finite type. If B_1 is the subalgebra $k[[T_1^p, \dots, T_r^p]]$ of B, $\widehat{\Omega}^1_{A/k}$ identifies canonically with Ω^1_{A/B_1}.*

Proof. Every continuous derivation of B_1 into a topological A-module P, which is the restriction of a continuous k-derivation of A into P, is *zero*, for it is zero in the subring $k[T_1^p, \dots, T_r^p]$ of polynomials, and this last is dense in B_1. The exact sequence (20.3.7.1) then shows that the canonical homomorphism

$$\text{Dér. cont}_{B_1}(A, P) \longrightarrow \text{Dér. cont}_k(A, P)$$

is bijective; the conclusion follows from (20.7.14.4), taking into account that Ω^1_{A/B_1} is an A-module of finite type (20.4.7), hence separated and complete since A is a local Noetherian complete ring. □

Proposition (21.9.5). — *Let A be a local Noetherian complete integral ring, A_0 a subring of A isomorphic to a formal power series ring $k[[T_1, \dots, T_r]]$ over a field k, such that A is a finite A_0-algebra and that the field of fractions E of A is a separable extension of the field of fractions L_0 of A_0. Then one has*

(21.9.5.1) $$\mathrm{rg}_A\, \widehat{\Omega}^1_{A/k} = \mathrm{rg}_E(\widehat{\Omega}^1_{A/k} \otimes_A E) = \dim(A).$$

Proof. Let us note that if $\mathfrak{m}_0$ is the maximal ideal of A_0, the topology of A is the $\mathfrak{m}_0$-adic topology since A is a finite A_0-algebra (Bourbaki, *Alg. comm.*, chap. IV, § 2, no. 5, cor. 3 of prop. 9) and it induces on A_0 the $\mathfrak{m}_0$-adic topology (Bourbaki, *Alg. comm.*, chap. III, § 3, no. 4, th. 3). One knows (21.9.1) that $\widehat{\Omega}^1_{A/k}$ is an A-module of finite type. By virtue of (21.9.3), $\widehat{\Omega}^1_{A_0/k}$ is a free A_0-module of $\mathbf{0_{IV\text{-}1}}$ | 178
rank $r = \dim(A_0) = \dim(A)$ (16.1.5); the tensor product $\widehat{\Omega}^1_{A_0/k} \otimes_{A_0} A$ is therefore a free A-module of rank r, identical with its separated completion. Finally, $\widehat{\Omega}^1_{A/k}$ is an A-module of finite type (20.4.7), hence identical with its separated completion (7.3.6). This being so, in the sequence of homomorphisms

(21.9.5.2) $$\widehat{\Omega}^1_{A_0/k} \otimes_{A_0} A \xrightarrow{u} \widehat{\Omega}^1_{A/k} \xrightarrow{v} \widehat{\Omega}^1_{A/A_0} \longrightarrow 0,$$

one knows that v is surjective and that $\mathrm{Im}(u)$ is dense in $\ker(v)$ (20.7.17); but every sub-A_0-module of $\widehat{\Omega}^1_{A/k}$ is closed for the $\mathfrak{m}_0$-adic topology (7.3.5), so the sequence (21.9.5.2) is exact. On the other hand, since A is integral over A_0, A_0 is integrally closed, and E is separable over L_0, $\widehat{\Omega}^1_{A/A_0}$ is a torsion A-module (20.4.13), (iv). Tensoring the exact sequence (21.9.5.2) by E, one obtains an exact sequence

$$\widehat{\Omega}^1_{A_0/k} \otimes_{A_0} E \longrightarrow \widehat{\Omega}^1_{A/k} \otimes_A E \longrightarrow 0,$$

whence $\mathrm{rg}_E(\widehat{\Omega}^1_{A/k} \otimes_A E) \leqslant r$.

It remains to show that there exist in $\widehat{\Omega}^1_{A/k} \otimes_A E$ r elements linearly independent over E. Let $D_i = \partial/\partial T_i$ be the canonical derivations of A_0 into itself ($1 \leqslant i \leqslant r$). They extend uniquely to derivations (still denoted D_i) of E into itself, since E is a finite separable extension of L_0. By restriction to A, these derivations give derivations of A into E, and it is immediate that they take their values in one and the same finite type sub-A-module of E. Since they are continuous on A_0 and the topology of A is the $\mathfrak{m}_0$-adic topology, one has thus obtained r continuous derivations of A into a topological A-module; they are evidently linearly independent, since $D_i(T_j) = \delta_{ij}$. This completes the proof. □

Proposition (21.9.6). — *Let $k_0 \subset k \subset K_0$ be three fields of characteristic $p > 0$, such that $[K_0 : k] < +\infty$; set*

$$L_0 = K_0((T_1, \ldots, T_r)), \quad M_0 = K_0((T_1^p, \ldots, T_r^p))$$

$$L = k((T_1, \ldots, T_r)), \quad M = k((T_1^p, \ldots, T_r^p)), \quad N = k((T_1^{p^2}, \ldots, T_r^{p^2})).$$

Let E be a finite type extension of L_0.

(i) *If Υ_{K_0/k_0} is of finite rank, one has*

(21.9.6.1) $$\mathrm{rg}_E\, \Omega^1_{E/M} - \mathrm{rg}_{K_0}\, \Omega^1_{K_0/k} = (r + \mathrm{deg.tr}_{L_0} E) + d(E/K_0, k_0) + d(E/M_0, N/k_0)$$

(*notations of* (21.6.1)), *and in particular one has*

(21.9.6.2) $$\mathrm{rg}_E\, \Omega^1_{E/M} - \mathrm{rg}_{K_0}\, \Omega^1_{K_0/k} \geqslant r + \mathrm{deg.tr}_{L_0} E + d(E/K_0, k_0).$$

Furthermore, if the two members of (21.9.6.2) *are equal, they remain so when one replaces k by a subfield k' such that $k_0 \subset k' \subset k$.*

(ii) *Suppose moreover that $[k_0 : k_0^p] < +\infty$. Let (k_α) be a decreasing filtering family of subfields of K_0 containing k_0, such that $[K_0 : k_\alpha] < +\infty$ for all α and that $\bigcap_\alpha k_\alpha(K_0^p) = k_0(K_0^p)$; then there exists α such that, for $k = k_\alpha$, the two members of* (21.9.6.2) *are equal.*

Proof. $\mathbf{0_{IV\text{-}1}}$ | 179

One knows (21.1.5), (ii) that $\mathrm{rg}_E\, \Omega^1_{E/M}$ does not change when one replaces M by $M(L_0^p)$; as $L_0^p = K_0^p((T_1^p, \ldots, T_r^p))$ and that $[k(K_0^p) : k] < +\infty$, one has $M(L_0^p) = k(K_0^p)((T_1^p, \ldots, T_r^p))$; similarly $\Omega^1_{K_0/k}$ does not change when one replaces k by $k(K_0^p)$, so that one can *suppose that* $K_0^p \subset k$, which we shall do in what follows. We introduce also the fields

$$k_0' = k_0(K_0^p), \quad N' = k_0'((T_1^{p^2}, \ldots, T_r^{p^2}))$$

so that one has the diagram of fields

$$\begin{tikzcd}
K_0 \arrow[r] & M_0 \arrow[r] & L_0 \arrow[r] & E \\
k \arrow[u] \arrow[r] & N \arrow[u] \arrow[r] & M \arrow[u] & \\
k_0 \arrow[u] \arrow[r] & k_0' \arrow[u] \arrow[r] & N' \arrow[u] &
\end{tikzcd}$$

We propose to evaluate the difference δ of the first and second members of (21.9.6.2). It follows from (21.7.3) that one has

$$\mathrm{rg}_E\, \Omega^1_{E/M} - \mathrm{rg}_{M_0}\, \Omega^1_{M_0/M} = \mathrm{deg.tr}_{M_0} E + d(E/M_0, M)$$

and as L_0 is a finite extension of M_0, one has $\mathrm{deg.tr}_{L_0} E = \mathrm{deg.tr}_{M_0} E$. On the other hand, a p-base of K_0 over $k = k(K_0^p)$ is also a p-base of M_0 over M, hence (21.4.5), one has

$$\mathrm{rg}_{M_0}\, \Omega^1_{M_0/M} = \mathrm{rg}_{K_0}\, \Omega^1_{K_0/k},$$

so that

(21.9.6.3) $$\delta = d(E/M_0, M) - d(E/K_0, k_0) - r.$$

Let us now note the following classical lemma.

Lemma (21.9.6.4). — *For every field k, the formal power series field $K = k((T_1, \dots, T_r))$ is a separable extension of k.*

(i) *Proof.* Let us briefly recall the proof for completeness. It suffices (Bourbaki, *Alg.*, chap. VIII, § 7, no. 3, proof of th. 1) to prove that for every finite extension k' of k, $K \otimes_k k'$ has no nilpotent element. Set $A = k[[T_1, \dots, T_r]]$ and $S = A - \{0\}$. Then $K \otimes_k k' = S^{-1}(A \otimes_k k')$, while $A \otimes_k k'$ identifies canonically with the integral ring $A' = k'[[T_1, \dots, T_r]]$ and A with a subring of A'; the conclusion follows. □

Using this lemma and (21.6.2), (ii), one has $d(L_0/K_0, k_0) = 0$, and formula (21.6.4.4) therefore gives

$$d(E/K_0, k_0) = d(E/L_0, k_0).$$

Formulas (21.6.4.4) and (21.6.4.2) give, on the other hand, $\mathbf{0_{IV\text{-}1}}$ | 180

$$d(E/M_0, M) = d(E/L_0, M) + d(L_0/M_0, M),$$

$$d(L_0/M_0, M) = d(L_0/M_0, M/N) + d(L_0/M_0, N),$$

whence

$$\delta = d(E/L_0, M) + d(L_0/M_0, N) - d(E/L_0, k_0) + d(L_0/M_0, M/N) - r.$$

We shall show that

(21.9.6.5) $$d(L_0/M_0, M/N) = r.$$

Indeed, by definition,

$$d(L_0/M_0, M/N) = \mathrm{rg}_{L_0} \Upsilon_{L_0/M/N} - \mathrm{rg}_{M_0} \Upsilon_{M_0/M/N}.$$

Taking account of the two exact sequences

$$0 \longrightarrow \Upsilon_{L_0/M/N} \longrightarrow \Omega^1_{M/N} \otimes_M L_0 \longrightarrow \Omega^1_{L_0/N} \longrightarrow \Omega^1_{L_0/M} \longrightarrow 0,$$

$$0 \longrightarrow \Upsilon_{M_0/M/N} \longrightarrow \Omega^1_{M/N} \otimes_M M_0 \longrightarrow \Omega^1_{M_0/N} \longrightarrow \Omega^1_{M_0/M} \longrightarrow 0,$$

one obtains

$$\begin{aligned} d(L_0/M_0, M/N) = {} & \mathrm{rg}_{L_0} \Omega^1_{L_0/M} - \mathrm{rg}_{L_0} \Omega^1_{L_0/N} \\ & - \mathrm{rg}_{M_0} \Omega^1_{M_0/M} + \mathrm{rg}_{M_0} \Omega^1_{M_0/N}. \end{aligned}$$

Now $N(L_0^p) \supset M$, hence $\Omega^1_{L_0/N} = \Omega^1_{L_0/M}$ (21.1.5), (ii). On the other hand, the T_i^p $(1 \leqslant i \leqslant r)$ form a p-basis of M over N, and a p-basis of K_0 over k is also a p-basis of M_0 over M. Since $M_0^p \subset N$, it follows from (21.4.5) and (21.1.10) that

$$\mathrm{rg}_{M_0} \Omega^1_{M_0/N} = r + \mathrm{rg}_{M_0} \Omega^1_{M_0/M} = r + \mathrm{rg}_{K_0} \Omega^1_{K_0/k},$$

proving (21.9.6.5).

One has again, by (21.6.4.2),

$$d(E/L_0, M) = d(E/L_0, k_0) + d(E/L_0, M/k_0)$$

and

$$d(L_0/M_0, N) = d(L_0/M_0, N/k) + d(L_0/M_0, k).$$

Since L_0 is separable over K_0 (21.9.6.4), one has $d(L_0/K_0, k) = 0$, and consequently also $d(L_0/M_0, k) = 0$ by (21.6.2) and (21.6.4). Thus

$$\delta = d(E/L_0, M/k_0) + d(L_0/M_0, N/k).$$

Applying (21.6.4.2) twice more to the first term on the right gives

$$d(E/L_0, M/k_0) = d(E/L_0, M/N) + d(E/L_0, N/k) + d(E/L_0, k/k_0).$$

Since $M \subset N(L_0^p)$, one has $d(E/L_0, M/N) = 0$ (21.6.2); hence, by (21.6.4.4),

$$\delta = d(E/L_0, k/k_0) + d(E/M_0, N/k).$$

But M_0 and L_0 are separable extensions of K_0 (21.9.6.4), so

$$d(L_0/K_0, k/k_0) = d(M_0/K_0, k/k_0) = 0$$

by (21.6.2). Applying (21.6.4.4) twice more, one has **$0_{\text{IV-1}}$** | 181

$$d(E/L_0, k/k_0) = d(E/K_0, k/k_0) = d(E/M_0, k/k_0),$$

and a final application of (21.6.4.2) gives

$$\delta = d(E/M_0, N/k_0),$$

which proves (21.9.6.1).

Furthermore, when k is replaced by an intermediate field k' with $k_0 \subset k' \subset k$, N is replaced by a subextension N', and therefore $d(E/M_0, N'/k_0) \leqslant d(E/M_0, N/k_0)$ (21.6.4.2). This proves the last assertion of (i).

(ii) For all α, set $N_\alpha = k_\alpha((T_1^{p^2}, \ldots, T_r^{p^2}))$. By virtue of (21.9.6.1) and of (21.8.3), it suffices to show (taking into account the fact that E is a finite type extension of M_0) that one has

$$\bigcap_\alpha N_\alpha = k_0(M_0^p).$$

Or, one has

$$\bigcap_\alpha N_\alpha = N' = (k_0(K_0^p))((T_1^{p^2}, \ldots, T_r^{p^2})) \tag{21.9.6.6}$$

by virtue of (21.8.8.3) and of the relation $\bigcap_\alpha k_\alpha = k_0(K_0^p)$ (21.8.6). On the other hand, one has $k_0(M_0^p) = k_0(K_0^p((T_1^{p^2}, \ldots, T_r^{p^2})))$. To finish the proof of (21.9.6), (ii), it therefore remains to prove the following lemma.

Lemma (21.9.6.7). — *Let k_0 be a field of characteristic $p > 0$ such that $[k_0 : k_0^p] < +\infty$, and let K_0 be an extension of k_0. Then*

$$(k_0(K_0^p))((T_1, \ldots, T_r)) = k_0\big(K_0^p((T_1, \ldots, T_r))\big). \tag{21.9.6.8}$$

Proof. Since $k_0^p \subset K_0^p$, one has

$$k_0^p\big(K_0^p((T_1, \ldots, T_r))\big) = K_0^p((T_1, \ldots, T_r)).$$

If $(c_i)_{1\leqslant i\leqslant n}$ is a basis of k_0 over k_0^p, it is immediate that (c_i) is also a system of generators of each side of (21.9.6.8) over $K_0^p((T_1, \ldots, T_r))$. □

□

Remark (21.9.7). — The assertion of (21.9.6), (ii) *does not extend* to the case where $[k_0 : k_0^p]$ is infinite. Take for k_0 the field $\mathbf{F}_p(X_n)_{n\geqslant 0}$ of rational functions in infinitely many indeterminates, so that the X_n form a p-basis of k_0 over $\mathbf{F}_p$, and consequently $[k_0 : k_0^p] = +\infty$. In the statement of (21.9.6), take $K_0 = k_0$ (hence necessarily $k = k_0$), $L_0 = k_0((T))$, and let $E = L_0(y)$, where y is a root of

$$Y^p - \sum_{n=0}^{\infty} X_n T^{np} \in L_0[Y].$$

Then the difference δ between the two sides of (21.9.6.2) is nonzero. Indeed, E is separable over k_0; otherwise y^p would belong to $k_0(L_0^p)$, which is plainly impossible because the X_n are infinitely many algebraically independent elements. Thus $d(E/K_0, k_0) = 0$, formula (21.9.6.3) reduces to $\delta = d(E/M_0, M_0) - 1$, and it is clear that $d(E/M_0, M_0) = \operatorname{rg}_E \Upsilon_{E/M_0}$. It remains to check that this rank is 2. Now $E^p \subset M_0$; a p-basis of E over L_0 consists of the single element y, and L_0 has the single-element p-basis T over M_0. Since E is algebraic over M_0, the assertion follows from (21.7.1) and (21.4.5).

Proposition (21.9.8). — *Let k_0 be a field (of arbitrary characteristic), K_0 a separable extension of k_0, A a local Noetherian complete ring, which is a k_0-algebra and whose residue field is a finite extension of K_0. For every prime ideal $\mathfrak{p}$ of A, let $k(\mathfrak{p})$ be the residue field of A at $\mathfrak{p}$. Then, for every field k such that $k_0 \subset k \subset K_0$ and such that $[K_0 : k] < +\infty$, one has* $\mathbf{0_{IV\text{-}1}}$ | 182

(21.9.8.1)
$$\operatorname{rg}_{k(\mathfrak{p})}(\widehat{\Omega}^1_{(A/\mathfrak{p})/k} \otimes_{A/\mathfrak{p}} k(\mathfrak{p})) - \operatorname{rg}_{K_0} \Omega^1_{K_0/k} \geqslant \dim(A/\mathfrak{p}) + \operatorname{rg}_{k(\mathfrak{p})} \Upsilon_{k(\mathfrak{p})/k_0}.$$

Suppose moreover that $[k_0 : k_0^p] < +\infty$ (where p is the exponential characteristic of k_0). Then one can find a field k such that $k_0(K_0^p) \subset k \subset K_0$ and $[K_0 : k] < +\infty$, for which the two members of (21.9.8.1) are equal.

Proof. As $A/\mathfrak{p}$ has the same residue field K as A and is complete, one can restrict to the case where A is integral and $\mathfrak{p} = 0$; one will then set $E = k(\mathfrak{p})$, field of fractions of A. As K_0 is formally smooth over k_0 (19.6.1), there exists a k_0-monomorphism $K_0 \to A$ making A into a K_0-algebra; one knows in particular that there exists a sub-K_0-algebra A_0 of A, K_0-isomorphic to a formal power series algebra $K_0[[T_1, \dots, T_r]]$ and such that A is an A_0-algebra *finite* (19.8.9), which implies that E is a finite extension of the field of fractions $L_0 = K_0((T_1, \dots, T_r))$ of A_0. One has $\Upsilon_{K_0/k_0} = 0$ since K_0 is separable over k_0, and $\deg.\operatorname{tr}_{L_0} E = 0$; moreover, as A is a finite A_0-algebra, $\dim(A) = \dim(A_0)$ (16.1.5).

If $p = 1$, one has $\operatorname{rg}_E(\widehat{\Omega}^1_{A/k} \otimes_A E) = r$ by (21.9.5) and (17.1.4), (iii), and $\Omega^1_{K_0/k} = 0$ since K_0 being a separable finite extension of k (21.7.4); on the other hand $\Upsilon_{E/k_0} = 0$, E being a separable extension of k_0; the two members of (21.9.8.1) are therefore equal in this case.

Suppose now $p > 1$; if $B = k[[T_1, \dots, T_r]]$, A is a finite B-algebra. Setting $B_1 = k[[T_1^p, \dots, T_r^p]]$, $\widehat{\Omega}^1_{A/k}$ identifies with Ω^1_{A/B_1} (21.9.4); and if M denotes the field of fractions $k((T_1^p, \dots, T_r^p))$, it follows from (20.5.9) that $\widehat{\Omega}^1_{A/k} \otimes_A E$ identifies with $\Omega^1_{E/M}$. The inequality (21.9.8.1) is then none other than (21.9.6.2), and the last assertion follows from (21.9.6), (ii). □

§22. Differential criteria for smoothness and regularity

The main results of this section are: $\mathbf{0_{IV\text{-}1}}$ | 182

a) The criteria (22.2.2) and (22.5.8), which give necessary and sufficient conditions for a complete Noetherian local ring A containing a field k to be formally smooth over k; the criterion (22.5.8) is stated without involving differential notions, and completes (19.6.6); the statement (22.2.2), of a slightly more technical nature, permits giving a *classification*, for fixed k, of the local rings A in question (22.2.5): they are determined by their dimension n and their residue field K, under the sole condition $n \geqslant \operatorname{rg}_{\mathrm{K}} \Upsilon_{\mathrm{K}/k}$.
b) The theorem (22.3.3), and the corollary (22.7.6) of the Jacobian criterion of Nagata (22.7.3), which give conditions allowing one to assert that a *localized* ring of a complete Noetherian local ring A containing a field k is geometrically regular over k; they will play an important role in the study of the "fine" properties of local rings carried out in chap. IV, § 7. We do not possess for the moment any proof of (22.7.6) independent of the Jacobian criterion of Nagata.
c) The Jacobian criterion of Zariski (22.6.7) and its variants, which are easy consequences of (20.7.8).

22.1. Lifting of formal smoothness $\mathbf{0_{IV\text{-}1}}$ | 183

Theorem (22.1.1). — *Let $s : \Lambda \to \mathrm{A}$, $u : \mathrm{A} \to \mathrm{B}$ be two ring homomorphisms, $\mathfrak{J}$ an ideal of* B, C *the quotient ring* $\mathrm{B}/\mathfrak{J}$. *Suppose that* C *is a Λ-algebra formally smooth for the discrete topology.*

(i) Suppose the following conditions are satisfied:
   α) $\mathfrak{J}/\mathfrak{J}^2$ is a projective C-module.
   β) The canonical homomorphism $\mathbf{S}^*_{\mathrm{C}}(\mathfrak{J}/\mathfrak{J}^2) \to \operatorname{gr}^*_{\mathfrak{J}}(\mathrm{B})$ (19.5.2) is bijective.
   γ) The characteristic homomorphism $\chi : \Upsilon_{\mathrm{C}/\mathrm{B}/\Lambda} \to \mathfrak{J}/\mathfrak{J}^2$ (20.6.20) is injective.
   δ) The C-module $\Omega^1_{\mathrm{B}/\mathrm{A}} \otimes_{\mathrm{B}} \mathrm{C}$ is projective.

   Then B, equipped with the $\mathfrak{J}$-preadic topology, is a formally smooth Λ-algebra.
(ii) Conversely, suppose that B is a Λ-algebra formally smooth for the $\mathfrak{J}$-preadic topology, and that A is a Λ-algebra formally smooth for the discrete topology. Then the conditions *α*), *β*), *γ*), *δ*) of (i) are satisfied.

Proof. By virtue of the exact sequence (20.6.22.1) (which is applicable, since $B/\mathfrak{J}^2$ is a Λ-trivial extension of C by $\mathfrak{J}/\mathfrak{J}^2$, C being assumed to be a formally smooth Λ-algebra (19.4.4)), the condition γ) is equivalent to $Y^C_{B/A/\Lambda} = 0$, or equivalently to the following:

γ') *The homomorphism* $u_{B/A/\Lambda} \otimes 1_C : \Omega^1_{A/\Lambda} \otimes_A C \to \Omega^1_{B/\Lambda} \otimes_B C$ *is injective.*

(i) The conditions α) and β) imply that B is a Λ-algebra formally smooth for the $\mathfrak{J}$-preadic topology (19.5.4). It amounts to the same thing to say that B is an A-algebra formally smooth, or an A-algebra formally smooth *relative to* Λ, for the $\mathfrak{J}$-preadic topology. To see that B is an A-algebra formally smooth, it suffices therefore, by virtue of (20.7.2), to prove that the continuous homomorphism of topological B-modules $u_{B/A/\Lambda} : \Omega^1_{A/\Lambda} \otimes_A B \to \Omega^1_{B/\Lambda}$ is *formally invertible on the left*. But since B is a Λ-algebra formally smooth, the topological B-module $\Omega^1_{B/\Lambda}$ is formally projective (20.4.9), and its topology is deduced from that of B (20.4.5). By virtue of (19.1.9), it suffices therefore, for $u_{B/A/\Lambda}$ to be formally invertible on the left, that $u_{B/A/\Lambda} \otimes 1_C$ be invertible on the left. But by virtue of γ'), this last map is injective, and one therefore has the exact sequence (20.6.14.7)

$$0 \longrightarrow \Omega^1_{A/\Lambda} \otimes_A C \longrightarrow \Omega^1_{B/\Lambda} \otimes_B C \longrightarrow \Omega^1_{B/A} \otimes_B C \longrightarrow 0.$$

Finally, by virtue of δ), the C-module $\Omega^1_{B/A} \otimes_B C$ is projective, so the preceding exact sequence is split, which finishes proving (i).

(ii) If B is a Λ-algebra formally smooth for the $\mathfrak{J}$-preadic topology, and A is a Λ-algebra formally smooth for the discrete topology, then B is an A-algebra formally smooth for the $\mathfrak{J}$-preadic topology (19.3.5); the conditions α) and β) therefore follow from (19.5.6). Moreover, (20.7.2) shows that $u_{B/A/\Lambda}$ is formally invertible on the left, so $u_{B/A/\Lambda} \otimes 1_C$ is invertible on the left (19.1.7), and *a fortiori* injective. Finally, $\Omega^1_{B/A}$ is a formally projective B-module (20.4.9), and consequently $\Omega^1_{B/A} \otimes_B C$ is a projective C-module (19.2.4). ☐ $\mathbf{0_{IV\text{-}1}}$ | 184

Corollary (22.1.2). — *Let* $s : \Lambda \to A$, $u : A \to B$ *be two ring homomorphisms,* $\mathfrak{m}$ *a maximal ideal of* B, $K = B/\mathfrak{m}$ *the quotient field. Suppose that the* Λ*-algebras* A *and* K *are formally smooth for the discrete topology. Then the following conditions are equivalent:*

a) B *is an* A*-algebra formally smooth for the* $\mathfrak{m}$*-preadic topology.*

b) The canonical homomorphism

$$\mathbf{S}^*_K(\mathfrak{m}/\mathfrak{m}^2) \longrightarrow \mathrm{gr}^*_{\mathfrak{m}}(B) \tag{22.1.2.1}$$

is bijective, and the characteristic homomorphism

$$\chi : Y_{K/B/\Lambda} \longrightarrow \mathfrak{m}/\mathfrak{m}^2 \tag{22.1.2.2}$$

is injective.

Proof. This follows immediately from (22.1.1), the conditions α) and δ) being trivially satisfied here, since K is a field. ☐

Remark (22.1.3). — Suppose the hypotheses of (22.1.2) are satisfied, and suppose in addition that $\mathfrak{m}/\mathfrak{m}^2$ is a K-vector space of *finite* rank. Then, for B to be an A-algebra formally smooth for the $\mathfrak{m}$-preadic topology, it suffices that the following conditions be satisfied:

(22.1.3.1). Given a polynomial algebra $E = K[T_1, \ldots, T_n]$, the maximal ideal $\mathfrak{n}$ of E generated by the T_i $(1 \leqslant i \leqslant n)$, and an ideal $\mathfrak{b} \supset \mathfrak{n}^k$ in E, every Λ-homomorphism $v : B \to E/\mathfrak{b}$ which, by passing to quotients, gives the identity $K \to K$, factors as $B \xrightarrow{w} E/\mathfrak{n}^k \to E/\mathfrak{b}$, where w is a Λ-homomorphism.

(22.1.3.2). If F is the trivial extension $D_K(K)$ ("algebra of dual numbers over K"), $\rho : A \to F$ a ring homomorphism such that the composition $A \xrightarrow{\rho} F \to K$ is the canonical homomorphism, then every Λ-homomorphism $v : B \to K$ which, by passing to quotients, gives the identity $K \to K$, factors as $B \xrightarrow{w} F \to K$, where w is a Λ-homomorphism (for the A-algebra structure on F defined by ρ).

Indeed, it was seen (19.5.5) that the condition (22.1.3.1) implies that the canonical homomorphism (22.1.2.1) is bijective. By virtue of (22.1.2), it suffices then to see that $u_{B/A/\Lambda} \otimes 1_K : \Omega^1_{A/\Lambda} \otimes_A K \to \Omega^1_{B/\Lambda} \otimes_B K$ is injective, or equivalently (since these are vector spaces over K) that for every K-vector space L, the canonical homomorphism $\mathrm{Der}_\Lambda(B, L) \to \mathrm{Der}_\Lambda(A, L)$ *is surjective* (by virtue of

(20.4.8)); it is clear that for this, it is necessary and sufficient that the canonical homomorphism $\mathrm{Der}_\Lambda(B, K) \to \mathrm{Der}_\Lambda(A, K)$ be surjective, and our assertion follows, by virtue of (20.1.5).

Note that the two conditions (22.1.3.1) and (22.1.3.2) are implied by the following:

(22.1.3.3). For every local Artinian Λ-algebra E with residue field equal to K, and every nilpotent ideal $\mathfrak{r}$ of E, every Λ-homomorphism $B \to E/\mathfrak{r}$ which, by passing to quotients, gives the identity $K \to K$, factors as $B \xrightarrow{u} E \to E/\mathfrak{r}$, where u is a Λ-homomorphism.

$\mathbf{0}_{\mathbf{IV\text{-}1}}$ | 185

Proposition (22.1.4). — *Let $\varphi : A \to B$ be a local homomorphism of local Noetherian rings, k (resp. K) the residue field of A (resp. B). For B to be a formally smooth A-algebra (for the preadic topologies), it is necessary and sufficient that for every local Artinian ring C, with residue field isomorphic to K, every local homomorphism $A \to C$ (making C a topological A-algebra), and every nilpotent ideal $\mathfrak{J}$ of C, every local A-homomorphism $B \to C/\mathfrak{J}$ such that the homomorphism $K \to K$ obtained by passing to quotients is the identity, factors as $B \xrightarrow{f} C \to C/\mathfrak{J}$, where f is a local A-homomorphism.*

Proof. The condition being necessary by definition (19.3.1), let us show that it is sufficient. Since the local $\widehat{A}$-homomorphisms from $\widehat{B}$ into a discrete local $\widehat{A}$-algebra arise by extension from the local A-homomorphisms from B into that algebra, we may restrict ourselves to the case where A and B are *complete*, by virtue of (19.3.6). When A is a *field* k, the proposition follows from (22.1.3.3), where one takes Λ to be the prime subfield of k, and (19.6.1). In the general case, set $B_0 = B \otimes_A k = B/\mathfrak{m}B$ ($\mathfrak{m}$ the maximal ideal of A), which is complete. If C_0 is a local Artinian k-algebra with residue field isomorphic to K, $\mathfrak{J}_0$ a nilpotent ideal of C_0, every k-local homomorphism $g_0 : B_0 \to C_0/\mathfrak{J}_0$ giving the identity on K by passing to quotients, gives by composition an A-local homomorphism

$$g : B \longrightarrow B_0 \xrightarrow{g_0} C_0/\mathfrak{J}_0$$

which by hypothesis factors as $B \xrightarrow{f} C_0 \to C_0/\mathfrak{J}_0$, where f is a local A-homomorphism; but as C_0 is a k-algebra, f factors as $B \to B_0 \xrightarrow{f_0} C_0$, where f_0 is a local k-homomorphism. We thus see that the hypotheses of the statement are still fulfilled when one substitutes B_0 and k for B and A respectively; therefore B_0 is a k-algebra *formally smooth* from what we have just seen. Applying (19.7.2) and (19.7.1), we see that there exists a local Noetherian complete ring B', a local homomorphism $A \to B'$ making B' a flat A-module and an A-algebra *formally smooth*, and a k-isomorphism $u'_0 : B'_0 = B' \otimes_A k \xrightarrow{\sim} B_0$. Let v'_0 be the inverse isomorphism of u'_0; we now propose to show that there exists a local A-homomorphism $v : B \to B'$ such that v'_0 comes from v by passing to quotients. For this, let us denote by $\mathfrak{n}$ and $\mathfrak{n}'$ the maximal ideals of B and B' respectively, and for every j, let $w_j : B/(\mathfrak{n}^{j+1} + \mathfrak{m}B) \to B'/(\mathfrak{n}'^{j+1} + \mathfrak{m}B')$ be the A-local homomorphism deduced from v'_0 by passing to quotients; it will suffice to form for each j an A-local homomorphism $v_j : B/\mathfrak{n}^{j+1} \to B'/\mathfrak{n}'^{j+1}$ such that the diagrams

$$\begin{array}{ccc} B/\mathfrak{n}^{j+1} & \xrightarrow{v_j} & B'/\mathfrak{n}'^{j+1} \\ \downarrow & & \downarrow \\ B/\mathfrak{n}^{j} & \xrightarrow[v_{j-1}]{} & B'/\mathfrak{n}'^{j} \end{array} \qquad \begin{array}{ccc} B/\mathfrak{n}^{j+1} & \xrightarrow{v_j} & B'/\mathfrak{n}'^{j+1} \\ \downarrow & & \downarrow \\ B/(\mathfrak{n}^{j+1} + \mathfrak{m}B) & \xrightarrow[w_j]{} & B'/(\mathfrak{n}'^{j+1} + \mathfrak{m}B') \end{array}$$

are commutative; B and B' being complete, the homomorphism $v = \varprojlim v_j$ will give the answer. The inductive construction of v_j follows from the hypothesis on B and from

$\mathbf{0}_{\mathbf{IV\text{-}1}}$ | 186

the same reasoning as in (19.3.10.1), using the lemma (19.3.10.2), and the fact that $\mathfrak{n}'^j + (\mathfrak{n}'^{j+1} + \mathfrak{m}B') = \mathfrak{n}'^j + \mathfrak{m}B'$. It follows then from (19.7.1.4) that v is an A-*isomorphism*, for B' is a flat A-module, and B is complete for the $\mathfrak{m}$-preadic topology, the ideals $\mathfrak{m}^i B$ being closed in B for the $\mathfrak{n}$-adic topology ($\mathbf{0}_{\mathrm{I}}$, 7.3.5). Q.E.D. □

22.2. Differential characterization of local algebras formally smooth over a field

(22.2.1). Let k be a field, P its prime subfield, A a k-algebra that is a *local* ring, $\mathfrak{m}$ its maximal ideal, $\mathrm{K} = \mathrm{A}/\mathfrak{m}$ its residue field. As K is separable over P, K is a P-algebra formally smooth for the discrete topology (19.6.1), and consequently the P-extension $\mathrm{A}/\mathfrak{m}^2$ of K by $\mathfrak{m}/\mathfrak{m}^2$ is P-*trivial*, and the characteristic homomorphism

$$\chi_{\mathrm{A}/k} : \mathrm{Y}_{\mathrm{K}/k} \longrightarrow \mathfrak{m}/\mathfrak{m}^2 \tag{22.2.1.1}$$

is therefore defined (20.6.23).

Theorem (22.2.2). — *Under the conditions of (22.2.1), for* A *to be a k-algebra formally smooth for the* $\mathfrak{m}$*-preadic topology, it is necessary and sufficient that the following conditions be satisfied:*

(i) The canonical homomorphism $\mathbf{S}^*_{\mathrm{K}}(\mathfrak{m}/\mathfrak{m}^2) \to \mathrm{gr}^*_{\mathfrak{m}}(\mathrm{A})$ is bijective.
(ii) The characteristic homomorphism $\chi_{\mathrm{A}/k} : \mathrm{Y}_{\mathrm{K}/k} \to \mathfrak{m}/\mathfrak{m}^2$ is injective.

This is a particular case of (22.1.2), where one replaces Λ *by* P, A *by* k, *and* B *by* A; K *and* k, *being separable over* P, *are indeed formally smooth* P*-algebras (19.6.1).*

Remark (22.2.3). — The condition (ii) of (22.2.2) can be replaced by any one of the following:

a) The canonical homomorphism $\Omega^1_k \otimes_k \mathrm{K} \to \Omega^1_{\mathrm{A}} \otimes_{\mathrm{A}} \mathrm{K}$ is injective.
b) For every n, the canonical homomorphism $\Omega^1_k \otimes_k (\mathrm{A}/\mathfrak{m}^{n+1}) \to \Omega^1_{\mathrm{A}} \otimes_{\mathrm{A}} (\mathrm{A}/\mathfrak{m}^{n+1})$ is invertible on the left.
c) The canonical homomorphism $\Omega^1_k \widehat{\otimes}_k \mathrm{A} \to \widehat{\Omega}^1_{\mathrm{A}}$ is invertible on the left.
d) A is a k-algebra formally smooth (for the $\mathfrak{m}$-preadic topology) *relative to the prime field*.

Indeed, it was already noted in (22.1.1) that the injectivity of $\chi_{\mathrm{A}/k}$ is equivalent to *a*), and that the conjunction of *a*) and condition (i) of (22.2.2) is equivalent to that of (i) and *d*). Finally, we have also seen in (22.1.1) that *b*) and *d*) are equivalent, and the equivalence of *b*) and *c*) follows from (19.1.8).

(22.2.4). The main application of (22.2.2) concerns Noetherian local k-algebras that are *complete* (the case where $\mathfrak{m}/\mathfrak{m}^2$ is a K-vector space of *finite* rank). More precisely, let k be a field, K an extension of k, V a K-vector space of finite rank; we consider the triplets $(\mathrm{A}, \alpha, \beta)$, where A is a complete Noetherian **$0_{\text{IV-1}}$ | 187**
local k-algebra *formally smooth* with maximal ideal $\mathfrak{m}$, $\alpha : \mathrm{A}/\mathfrak{m} \xrightarrow{\sim} \mathrm{K}$ a k-algebra isomorphism, $\beta : \mathfrak{m}/\mathfrak{m}^2 \xrightarrow{\sim} \mathrm{V}$ a di-isomorphism of vector spaces (for the isomorphism α). Given two such triplets $(\mathrm{A}, \alpha, \beta)$, $(\mathrm{A}', \alpha', \beta')$, an *equivalence* from the first to the second is a k-isomorphism $u : \mathrm{A} \xrightarrow{\sim} \mathrm{A}'$ such that (if $\mathfrak{m}'$ is the maximal ideal of A'), the diagrams

$$\begin{array}{ccc} \mathrm{A}/\mathfrak{m} & \xrightarrow{\mathrm{gr}^0(u)} & \mathrm{A}'/\mathfrak{m}' \\ \downarrow{\scriptstyle\alpha} & & \downarrow{\scriptstyle\alpha'} \\ \mathrm{K} & \xrightarrow{1_{\mathrm{K}}} & \mathrm{K} \end{array} \qquad \begin{array}{ccc} \mathfrak{m}/\mathfrak{m}^2 & \xrightarrow{\mathrm{gr}^1(u)} & \mathfrak{m}'/\mathfrak{m}'^2 \\ \downarrow{\scriptstyle\beta} & & \downarrow{\scriptstyle\beta'} \\ \mathrm{V} & \xrightarrow{1_{\mathrm{V}}} & \mathrm{V} \end{array}$$

are commutative. It is immediate that the *equivalence classes* of triplets $(\mathrm{A}, \alpha, \beta)$ form a *set* that we shall denote $\mathrm{FL}(\mathrm{K}/k, \mathrm{V})$. We now note that to every triplet $(\mathrm{A}, \alpha, \beta)$ is associated the K-homomorphism composition of vector spaces $\mathrm{Y}_{\mathrm{K}/k} \xrightarrow{\chi_{\mathrm{A}/k}} \mathfrak{m}/\mathfrak{m}^2 \xrightarrow{\beta} \mathrm{V}$ (where $\chi_{\mathrm{A}/k}$ is considered as a di-homomorphism relative to α^{-1}); the preceding definition shows (by (20.6.22.2)) that this K-homomorphism *depends only on the equivalence class* of $(\mathrm{A}, \alpha, \beta)$ in $\mathrm{FL}(\mathrm{K}/k, \mathrm{V})$; in other words we have thus defined a canonical map

$$\mathrm{FL}(\mathrm{K}/k, \mathrm{V}) \longrightarrow \mathrm{Hom}_{\mathrm{K}}(\mathrm{Y}_{\mathrm{K}/k}, \mathrm{V}). \tag{22.2.4.1}$$

Proposition (22.2.5). — *Let k be a field,* K *an extension of k,* V *a* K*-vector space of finite rank. The canonical map (22.2.4.1) is a bijection from* $\mathrm{FL}(\mathrm{K}/k, \mathrm{V})$ *to the set of injective* K*-homomorphisms from* $\mathrm{Y}_{\mathrm{K}/k}$ *to* V.

Proof. (i) To show that (22.2.4.1) is injective, it must be proved that the following is true: let A, A′ be two complete Noetherian local k-algebras formally smooth, $\mathfrak{m}$, $\mathfrak{m}'$ their respective maximal ideals, $\alpha : \mathrm{A}/\mathfrak{m} \xrightarrow{\sim} \mathrm{K}$, $\alpha' : \mathrm{A}'/\mathfrak{m}' \xrightarrow{\sim} \mathrm{K}$ two k-isomorphisms; let us be given two k-isomorphisms

$v^0 : A/\mathfrak{m} \xrightarrow{\sim} A'/\mathfrak{m}'$, $v^1 : \mathfrak{m}/\mathfrak{m}^2 \xrightarrow{\sim} \mathfrak{m}'/\mathfrak{m}'^2$ such that the diagrams

(22.2.5.1)
$$\begin{tikzcd} A/\mathfrak{m} \arrow[r, "v^0"] \arrow[d, "\alpha"] & A'/\mathfrak{m}' \arrow[dl, "\alpha'"] \\ K & \end{tikzcd} \qquad \begin{tikzcd} \mathfrak{m}/\mathfrak{m}^2 \arrow[r, "v^1"] & \mathfrak{m}'/\mathfrak{m}'^2 \\ Y_{K/k} \arrow[u, "\chi_A"] \arrow[ur, "\chi_{A'}"'] & \end{tikzcd}$$

are commutative. One must prove that there exists a k-isomorphism $u : A \xrightarrow{\sim} A'$ such that $\mathrm{gr}^0(u) = v^0$ and $\mathrm{gr}^1(u) = v^1$. We note first that since K is a field, the canonical homomorphism (20.6.7.1) is *bijective* (20.6.11), so there already exists a k-isomorphism $v : A/\mathfrak{m}^2 \xrightarrow{\sim} A'/\mathfrak{m}'^2$ such that $\mathrm{gr}^0(v) = v^0$ and $\mathrm{gr}^1(v) = v^1$. We now note that since A′ is metrizable and complete, and A a k-algebra formally smooth, the composite homomorphism $A \to A/\mathfrak{m}^2 \xrightarrow{v} A'/\mathfrak{m}'^2$ factors as $A \xrightarrow{u} A' \to A'/\mathfrak{m}'^2$, where u is a k-homomorphism (19.3.11), and one has thus already $\mathrm{gr}^0(u) = v^0$ and $\mathrm{gr}^1(u) = v^1$. One has the commutative diagram $\mathbf{0_{IV\text{-}1}}$ | 188

$$\begin{tikzcd} \mathbf{S}^*_K(\mathfrak{m}/\mathfrak{m}^2) \arrow[r] \arrow[d, "w"'] & \mathrm{gr}^*_{\mathfrak{m}}(A) \arrow[d, "\mathrm{gr}^*(u)"] \\ \mathbf{S}^*_K(\mathfrak{m}'/\mathfrak{m}'^2) \arrow[r] & \mathrm{gr}^*_{\mathfrak{m}'}(A') \end{tikzcd}$$

where the horizontal arrows are the canonical homomorphisms and w is induced by v^0 and v^1. Since v^0 and v^1 are bijective, so is w; and since A and A′ are k-algebras formally smooth, one deduces from (22.2.2), (i) that $\mathrm{gr}(u)$ is *bijective*; but since A and A′ are separated and complete, this implies that u itself is *bijective* (Bourbaki, *Alg. comm.*, chap. III, § 2, nº 8, cor. 3 of th. 1).

(ii) It remains to show that the image of (22.2.4.1) is the set of *injective* homomorphisms of $Y_{K/k}$ in V; one already knows by (22.2.2), (ii) that it is contained in this set, so it remains to prove the □

Lemma (22.2.5.2). — *For every* K*-homomorphism* $h : Y_{K/k} \to V$, *there exists a* k*-algebra* A *that is a local Noetherian ring, regular and complete, with maximal ideal* $\mathfrak{m}$, *with residue field* K, *and a* K*-isomorphism* $\beta : \mathfrak{m}/\mathfrak{m}^2 \xrightarrow{\sim} V$ *such that* $h = \beta \circ \chi_{A/k}$.

Proof. Indeed, if this lemma is proved, the fact that A is regular implies that condition (i) of (22.2.2) is satisfied (17.1.1); if moreover h is injective, (22.2.2) will show that A is a k-algebra formally smooth whose equivalence class maps to h under (22.2.4.1) (while if h is not injective, the k-algebra A of which (22.2.5.2) proves the existence is not formally smooth).

To prove (22.2.5.2), let B be the K-algebra $\mathbf{S}^*_K(V)$, let $\mathfrak{n}$ be the augmentation ideal of B, and let $A = \widehat{B}$ be the completion of B for the $\mathfrak{n}$-preadic topology (so that A is isomorphic to a formal power series algebra $K[[T_1, \dots, T_n]]$ if $n = \mathrm{rg}_K V$). By virtue of (20.6.11), there exists on $A/\mathfrak{m}^2$ (where $\mathfrak{m} = \mathfrak{n}A$) a structure of k-extension of K by V, in general distinct from the k-trivial structure defined by the canonical injection $k \to K \to A$, such that h is the characteristic homomorphism of this extension. If $f : k \to A/\mathfrak{m}^2$ is the structural homomorphism, the fact that k is separable over the prime field permits (19.6.1) factoring f as $k \xrightarrow{g} A \to A/\mathfrak{m}^2$, and the k-algebra A thus defined answers the question (20.6.22.2). □

Theorem (22.2.6). — *Let k be a field,* K *an extension of k. For there to exist a k-algebra* A, *which is a local Noetherian ring, with maximal ideal* $\mathfrak{m}$, *such that* $A/\mathfrak{m} = K$ *and such that* A *is formally smooth (for the* $\mathfrak{m}$*-preadic topology), it is necessary and sufficient that* $Y_{K/k}$ *is a* K*-vector space of finite rank. The k-algebra* A *is then determined (up to k-isomorphism inducing the identity* $K \to K$ *on residue fields) by its dimension alone, which is subject to the sole condition of being* $\geqslant \mathrm{rg}_K Y_{K/k}$.

Proof. Since $\mathfrak{m}/\mathfrak{m}^2$ is of finite rank over K, the necessity of the condition follows from (22.2.2), (ii); conversely, (22.2.5) shows that the condition is sufficient and that one can take for $\mathfrak{m}/\mathfrak{m}^2$ a K-vector space of rank any $\geqslant \mathrm{rg}_K(Y_{K/k})$. □

In particular, the identity homomorphism of $Y_{K/k}$ associates *canonically* to K a complete Noetherian k-algebra, formally smooth, for which $Y_{K/k}$ is isomorphic to $\mathfrak{m}/\mathfrak{m}^2$. $\mathbf{0_{IV\text{-}1}}$ | 189

Remark (22.2.7). — (i) Let Λ be a local Noetherian ring, with residue field k; it follows from (19.7.1) and (19.7.2) that the determination of the Λ-algebras A that are complete Noetherian local rings and are formally smooth is *equivalent* to the same problem where Λ is replaced by k, and is thus in principle entirely solved by (22.2.5), which reduces the question to the structure of the *residue fields* of the k-algebras sought, as extensions of k.

(ii) The fact that $\mathrm{Y}_{\mathrm{K}/k}$ is of finite rank over K does *not imply* that K is of "finite radicial multiplicity" over k (cf. (19.6.6)). For example, let k_0 be a perfect field of characteristic $p > 0$, $k = k_0(\mathrm{T})$ the field of rational functions in one indeterminate over k_0, so that $\mathrm{K} = k^{p^{-\infty}}$ is the smallest perfect extension of k. Then $\Omega^1_{\mathrm{K}} = \Omega^1_{\mathrm{K}/k} = 0$ (21.4.4), therefore $\mathrm{Y}_{\mathrm{K}/k} = \Omega^1_k \otimes_k \mathrm{K}$, and since $k^p = k_0(\mathrm{T}^p)$, T is a p-base of k over k^p, therefore (21.4.5), Ω^1_k is of rank 1 over k, and hence $\mathrm{Y}_{\mathrm{K}/k}$ is of rank 1 over K. But for every n the residue field of the local ring $\mathrm{K} \otimes_k k^{p^{-n}}$ is isomorphic to K, which is therefore not separable over $k^{p^{-n}}$.

Proposition (22.2.8). — *Under the conditions of (22.2.1), suppose that the characteristic p of k is > 0; let (k_α) be a decreasing filtering family of subfields of k, such that $\bigcap k_\alpha(k^p) = k^p$. Then the condition (ii) of (22.2.2) can be replaced by any one of the following:*

a) There exists α_0 such that the canonical homomorphism

$$\Omega^1_{k/k_\alpha} \otimes_k \mathrm{K} \longrightarrow \Omega^1_{\mathrm{A}/k_\alpha} \otimes_{\mathrm{A}} \mathrm{K}$$

is injective for every $\alpha \geqslant \alpha_0$.

b) There exists α_0 such that A is a k-algebra formally smooth (for the $\mathfrak{m}$-preadic topology) relative to k_α, for every $\alpha \geqslant \alpha_0$.

c) For every α and every integer $n \geqslant 0$, the canonical homomorphism

$$\Omega^1_{k/k_\alpha} \otimes_k (\mathrm{A}/\mathfrak{m}^{n+1}) \longrightarrow \Omega^1_{\mathrm{A}/k_\alpha} \otimes_{\mathrm{A}} (\mathrm{A}/\mathfrak{m}^{n+1})$$

is invertible on the left.

Proof. Indeed, if A is a formally smooth k-algebra, it is so *a fortiori* relative to every subfield of k, which implies c) by virtue of (20.7.2) and (19.1.7); it is clear that c) implies b), and that b) implies a). Finally, taking into account (22.2.3), it remains to prove that a) implies that the canonical homomorphism $u : \Omega^1_k \otimes_k \mathrm{K} \to \Omega^1_{\mathrm{A}} \otimes_{\mathrm{A}} \mathrm{K}$ is *injective*. But for every α, one has a commutative diagram

$$\begin{tikzcd} \Omega^1_k \otimes_k \mathrm{K} \arrow[r, "u"] \arrow[d, "v_\alpha"'] & \Omega^1_{\mathrm{A}} \otimes_{\mathrm{A}} \mathrm{K} \arrow[d] \\ \Omega^1_{k/k_\alpha} \otimes_k \mathrm{K} \arrow[r, "u_\alpha"'] & \Omega^1_{\mathrm{A}/k_\alpha} \otimes_{\mathrm{A}} \mathrm{K} \end{tikzcd}$$

and the hypothesis that u_α is injective for $\alpha \geqslant \alpha_0$ implies that $\mathrm{Ker}(u)$ is contained in the intersection **0**$_{\textbf{IV-1}}$ | 190
of the $\mathrm{Ker}(v_\alpha)$. But one has seen (21.8.3) that this intersection is zero by virtue of the hypothesis $\bigcap k_\alpha(k^p) = k^p$, which finishes the proof. □

Proposition (22.2.9). — *Under the hypotheses of (22.2.1), the following conditions are equivalent:*

a) $\mathrm{A}/\mathfrak{m}^2$ is a k-extension k-trivial of K by $\mathfrak{m}/\mathfrak{m}^2$.

b) $\chi_{\mathrm{A}/k} = 0$.

c) The canonical homomorphism (20.5.11.2)

$$\delta_{\mathrm{K}/\mathrm{A}/k} : \mathfrak{m}/\mathfrak{m}^2 \longrightarrow \Omega^1_{\mathrm{A}/k} \otimes_{\mathrm{A}} \mathrm{K}$$

is injective (in other words, the sequence

(22.2.9.1) $$0 \longrightarrow \mathfrak{m}/\mathfrak{m}^2 \longrightarrow \Omega^1_{\mathrm{A}/k} \otimes_{\mathrm{A}} \mathrm{K} \longrightarrow \Omega^1_{\mathrm{K}/k} \longrightarrow 0$$

is exact*).*

Proof. The equivalence of b) and c) follows from the exact sequence (20.6.22.1); the equivalence of c) and a) follows from (20.5.12), this sequence being split if it is exact, since these are vector spaces.

Note that if K is *separable* over k, the equivalent conditions of (22.2.9) are satisfied, by virtue of the definition of $\chi_{\mathrm{A}/k}$ (22.2.1) and of (20.6.3). □

Corollary (22.2.10). — *Under the hypotheses of (22.2.1), consider a subfield k_0 of k. The following conditions are equivalent:*

a) $A/\mathfrak{m}^2$ *is a k_0-extension k_0-trivial of* K *by* $\mathfrak{m}/\mathfrak{m}^2$.

b) The composite homomorphism $Y_{K/k_0} \to Y_{K/k} \xrightarrow{\chi_{A/k}} \mathfrak{m}/\mathfrak{m}^2$ *is zero.*

c) The characteristic homomorphism $\chi_{A/k} : Y_{K/k} \to \mathfrak{m}/\mathfrak{m}^2$ *factors through* $Y_{K/k} \to Y_{K/k/k_0} \xrightarrow{\chi'} \mathfrak{m}/\mathfrak{m}^2$.

Moreover, when these conditions are satisfied, the homomorphism χ' is determined in a unique and canonical way, and coincides with the characteristic homomorphism of the k_0-extension k_0-trivial $A/\mathfrak{m}^2$ *of* K *by* $\mathfrak{m}/\mathfrak{m}^2$.

Proof. Since the composition in *b*) is nothing other than χ_{A/k_0}, the equivalence of *a*) and *b*) follows from (22.2.9); on the other hand, *b*) and *c*) are equivalent by virtue of the exact sequence (20.6.18.1)

$$Y_{K/k_0} \longrightarrow Y_{K/k} \longrightarrow Y_{K/k/k_0} \longrightarrow 0,$$

and since the canonical homomorphism $Y_{K/k} \to Y_{K/k/k_0}$ is surjective, this implies the uniqueness of χ'; the fact that χ' is the characteristic homomorphism of the k_0-extension $A/\mathfrak{m}^2$ follows from (20.6.22.2). ☐

Corollary (22.2.11). — *Under the hypotheses of (22.2.1), let p be the characteristic exponent of k, and let (k_α) be a decreasing filtering family of subfields of k such that $\bigcap k_\alpha(k^p) = k^p$. If $Y_{K/k}$ is of finite rank over* K, *there exists an index α such that* $A/\mathfrak{m}^2$ *is a k_α-extension k_α-trivial of* K *by* $\mathfrak{m}/\mathfrak{m}^2$.

Proof. It is known (21.8.3) that there exists then α such that the canonical homomorphism $Y_{K/k} \to Y_{K/k/k_\alpha}$ is bijective, so the condition *b*) of (22.2.10) (where k_α replaces k_0) is satisfied. ☐

22.3. Application to relations between certain local rings and their completions $\mathbf{0_{IV\text{-}1}}$ | 191

Lemma (22.3.1). — *Let* A_0 *be a semi-local Noetherian ring,* A *a finite* A_0*-algebra (which is thus a semi-local Noetherian ring, cf. Bourbaki,* Alg. comm.*, chap. IV, § 2, n° 5, cor. 3 of prop. 9). If* $\widehat{A}_0$ *and* $\widehat{A}$ *are the completions of* A_0 *and* A *for their preadic topologies respectively, then, when one equips* A_0, A *and* $\widehat{A}$ *with discrete topologies,* $\widehat{A}$ *is an* A*-algebra formally smooth relative to* A_0 *(19.9.1).*

Proof. It is known that $\widehat{A} = A \otimes_{A_0} \widehat{A}_0$ (Bourbaki, *Alg. comm.*, chap. IV, § 2, n° 5, cor. 3 of prop. 9 and chap. III, § 3, n° 4, th. 1), so the proposition follows from (19.9.3). ☐

Proposition (22.3.2). — *Let* A *be a local Noetherian regular ring,* K *its field of fractions, p the characteristic of* K. *Suppose that one of the following hypotheses is satisfied:*

(i) $p = 0$.

(ii) $p > 0$ *and there exists a filtering decreasing family* (A_α) *of Noetherian subrings of* A, *such that* A *is a finite* A_α*-algebra for every α, such that* $A^{p^{h(\alpha)}} \subset A_\alpha$ *for a suitable integer $h(\alpha)$, and such that, if* K_α *denotes the field of fractions of* A_α, *we have* $\bigcap K_\alpha(K^p) = K^p$.

Let then B *be a finite* A*-algebra that is an integral domain and contains* A, $\mathfrak{n}$ *a prime ideal of* B, C *the local ring* $B_\mathfrak{n}$, $\mathfrak{q}$ *a prime ideal of the completion* $\widehat{C}$, *such that* $\mathfrak{q} \cap C = 0$, *so that the local ring* $\widehat{C}_\mathfrak{q}$ *is an algebra over the field of fractions* L *of* B. *Then* $\widehat{C}_\mathfrak{q}$ *is an* L*-algebra formally smooth for its* $\mathfrak{q}$*-adic topology, and is therefore a geometrically regular ring over* L *(19.6.5).*

Proof. We distinguish two cases.

I) Suppose that $\mathfrak{n}$ contains the maximal ideal $\mathfrak{m}$ of A, so that $\mathfrak{n} \cap A = \mathfrak{m}$. Then $\mathfrak{n}$ is maximal (Bourbaki, *Alg. comm.*, chap. V, § 2, n° 1, prop. 1). If $\mathfrak{r}$ is the radical of the semi-local ring B, $\widehat{C}$ is the separated completion of B for the $\mathfrak{n}$-preadic topology, and a component of the semi-local ring $\widehat{B}$, the completion of B for the $\mathfrak{r}$-preadic topology (Bourbaki, *Alg. comm.*, chap. III, § 3, n° 4, prop. 8); one can thus write $\widehat{C}_\mathfrak{q} = \widehat{B}_{\mathfrak{q}'}$, where $\mathfrak{q}'$ is the prime ideal of $\widehat{B}$ that is the inverse image of $\mathfrak{q}$. Let us now note that B is a subring of $\widehat{B}$, and the hypothesis $\mathfrak{q} \cap C = 0$ implies $\mathfrak{q}' \cap B = 0$, so $\widehat{B}_{\mathfrak{q}'}$ is also a localization of $\widehat{B} \otimes_B L$ at one of its prime ideals $\mathfrak{q}''$, of which $\mathfrak{q}'$ is the inverse image in $\widehat{B}$; moreover we have $\widehat{B} = \widehat{A} \otimes_A B$ (Bourbaki, *Alg. comm.*, chap. IV, § 2, n° 5, cor. of prop. 9 and chap. III, § 3, n° 4, th. 1), so $\widehat{B} \otimes_B L = \widehat{A} \otimes_A L$; finally, if $\mathfrak{p}$ is the prime ideal of $\widehat{A}$ that is the inverse image of $\mathfrak{q}''$, the fact that $A \to B$ is injective and the commutativity of the diagram

$$\begin{array}{ccc} B & \longrightarrow & \widehat{B} \\ \uparrow & & \uparrow \\ A & \longrightarrow & \widehat{A} \end{array}$$

imply that $\mathfrak{p} \cap A = 0$, so $(\widehat{A} \otimes_A L)_{\mathfrak{q}''}$ is also a localization of the ring $\widehat{A}_{\mathfrak{p}} \otimes_A L = (\widehat{A}_{\mathfrak{p}} \otimes_A K) \otimes_K L$.

To show that this local ring is an L-algebra formally smooth, it suffices therefore to prove that $\widehat{A}_{\mathfrak{p}} \otimes_A K$ is a K-algebra formally smooth (19.3.5), (iii) and (iv); moreover $\widehat{A}_{\mathfrak{p}} \otimes_A K = \widehat{A}_{\mathfrak{p}}$ since $\mathfrak{p} \cap A = 0$. We shall apply the criteria (22.2.2) and (22.2.8). First of all, as A is regular, so is $\widehat{A}$ (17.1.5), and hence so is $\widehat{A}_{\mathfrak{p}}$ (17.3.2); condition (i) of (22.2.2) is therefore satisfied (17.1.1). It therefore suffices (when $p > 0$) to verify condition *b*) of (22.2.8). But (22.3.1) shows that, for every α, $\widehat{A}$ is an A-algebra formally smooth relative to A_α (for the discrete topologies); hence $\widehat{A} \otimes_{A_\alpha} K_\alpha = \widehat{A} \otimes_A (A \otimes_{A_\alpha} K_\alpha)$ is an $(A \otimes_{A_\alpha} K_\alpha)$-algebra formally smooth relative to K_α, for the discrete topologies (19.9.2), (iii). Since A is an A_α-algebra *finite*, we have $A \otimes_{A_\alpha} K_\alpha = K$; as $\widehat{A}_{\mathfrak{p}}$ is a ring of fractions of $\widehat{A} \otimes_A K$, we deduce (19.9.2), (iv) that $\widehat{A}_{\mathfrak{p}}$ is a K-algebra formally smooth *relative* to K_α, for the discrete topology, and *a fortiori* for its $\mathfrak{p}$-adic topology (19.3.8) and (19.9.5). But this is precisely condition *b*) of (22.2.8), so the proposition is proved in this case for $p > 0$. When $p = 0$, the residue field of $\widehat{A}_{\mathfrak{p}}$ is separable over K, and since $\widehat{A}_{\mathfrak{p}}$ is a regular ring, it is a K-algebra formally smooth by virtue of (19.6.4). **$0_{\text{IV-1}}$ | 192**

II) General case. Let $\mathfrak{s}$ be the prime ideal $\mathfrak{n} \cap A$ of A, and set $S = A - \mathfrak{s}$, so that $S^{-1}A = A_{\mathfrak{s}}$, and $C = (S^{-1}B)_{S^{-1}\mathfrak{n}}$, where this time $S^{-1}\mathfrak{n}$ contains the maximal ideal $\mathfrak{s}A_{\mathfrak{s}}$ of $A_{\mathfrak{s}}$. As $A_{\mathfrak{s}}$ is regular (17.3.2) and $S^{-1}B$ is a finite $A_{\mathfrak{s}}$-algebra that is an integral domain and contains $A_{\mathfrak{s}}$, it remains only to verify condition (ii) for $A_{\mathfrak{s}}$ when $p > 0$: set $\mathfrak{s}_\alpha = \mathfrak{s} \cap A_\alpha$ and consider the local ring $(A_\alpha)_{\mathfrak{s}_\alpha}$. For every $t \notin \mathfrak{s}$, one has by hypothesis, setting $q = p^{h(\alpha)}$, $t^q \in A_\alpha$ and $t^q \notin \mathfrak{s}$, hence $t^q \notin \mathfrak{s}_\alpha$; if one sets $S_\alpha = A_\alpha - \mathfrak{s}_\alpha$, one sees therefore that $A_{\mathfrak{s}} = S_\alpha^{-1}A$, and the hypothesis implies that $A_{\mathfrak{s}}$ is a finite $(A_\alpha)_{\mathfrak{s}_\alpha}$-algebra; moreover, K_α is also the field of fractions of $(A_\alpha)_{\mathfrak{s}_\alpha}$, which finishes the proof. □

Theorem (22.3.3). — *Let* A *be a local Noetherian complete ring,* $\mathfrak{p}$ *a prime ideal of* A, B *the localized ring* $A_{\mathfrak{p}}$, $\mathfrak{q}$ *a prime ideal of the completion* $\widehat{B}$, $\mathfrak{r} = \mathfrak{q} \cap B$. *Then the localized ring* $\widehat{B}_{\mathfrak{q}}$ *is a* $B_{\mathfrak{r}}$*-algebra formally smooth for the preadic topologies.*

Proof. The prime ideal $\mathfrak{r}$ of B is of the form $\mathfrak{n}_{\mathfrak{p}}$, where $\mathfrak{n} \subset \mathfrak{p}$ is a prime ideal of A, and $B_{\mathfrak{r}} = A_{\mathfrak{n}}$; let k be the residue field of $B_{\mathfrak{r}}$, which is also the field of fractions of the complete integral local ring $A' = A/\mathfrak{n}$. As $\widehat{B}$ is a flat B-module ($\mathbf{0}_{\text{I}}$, 7.3.5), $\widehat{B}_{\mathfrak{q}}$ is a flat $B_{\mathfrak{r}}$-module ($\mathbf{0}_{\text{I}}$, 6.3.2), and to prove that $\widehat{B}_{\mathfrak{q}}$ is a $B_{\mathfrak{r}}$-algebra formally smooth, it suffices to prove that

$$\widehat{B}_{\mathfrak{q}} \otimes_{B_{\mathfrak{r}}} k = \widehat{B}_{\mathfrak{q}}/\mathfrak{r}\widehat{B}_{\mathfrak{q}}$$

is a k-algebra formally smooth (19.7.1). But $\widehat{B}_{\mathfrak{q}}/\mathfrak{r}\widehat{B}_{\mathfrak{q}} = (\widehat{B}/\mathfrak{r}\widehat{B})_{\mathfrak{q}'}$, where $\mathfrak{q}'$ is the canonical image of $\mathfrak{q}$ in $\widehat{B}/\mathfrak{r}\widehat{B}$; one has by definition $\mathfrak{q}' \cap (B/\mathfrak{r}) = 0$ and $B/\mathfrak{r} = A_{\mathfrak{p}'}$, where $\mathfrak{p}' = \mathfrak{p}/\mathfrak{n}$; moreover $\widehat{B}/\mathfrak{r}\widehat{B}$ is the completion of $B/\mathfrak{r}$.

We are thus reduced to proving the following corollary: □

Corollary (22.3.4). — *Let* A *be a complete Noetherian local integral domain,* K *its field of fractions,* $\mathfrak{p}$ *a prime ideal of* A, B *the localized ring* $A_{\mathfrak{p}}$. *Then, for every prime ideal* $\mathfrak{q}$ *of the completion* $\widehat{B}$, *such that* $\mathfrak{q} \cap B = 0$, *the local ring* $\widehat{B}_{\mathfrak{q}}$ *is a* K*-algebra formally smooth for its* $\mathfrak{q}$*-adic topology, and is therefore a geometrically regular ring over* K. **$0_{\text{IV-1}}$ | 193**

Proof. Indeed, it follows from (19.8.9) that there exists a subring A_0 of A that is a power series ring over a field of characteristic $p > 0$ or over a Cohen ring (recall that Cohen rings have a field of fractions of characteristic 0), and such that A is a finite A_0-algebra. Now, we know that the ring A_0 is *regular* (17.3.8), and it satisfies one of the hypotheses (i), (ii) of (22.3.2), by virtue of (21.8.8); it suffices therefore to apply (22.3.2), replacing B by A and A by A_0. □

22.4. Preliminary results on finite extensions of local rings whose maximal ideal has square zero

Proposition (22.4.1). — *Let* A *be a local ring whose maximal ideal* $\mathfrak{m}$ *has square zero,* $\mathrm{K} = \mathrm{A}/\mathfrak{m}$ *its residue field; let us denote by* V *the ideal* $\mathfrak{m}$ *considered as a* K*-vector space. Let* T_i $(1 \leqslant i \leqslant r)$ *be indeterminates, and for each* i*, let* F_i *be a monic polynomial of* $\mathrm{A}[\mathrm{T}_i]$*, of degree* d_i*; let* A' *be the quotient of the polynomial ring* $\mathrm{A}[\mathrm{T}_1, \ldots, \mathrm{T}_r]$ *by the ideal* $\mathfrak{b}$ *generated by the* r *polynomials* F_i*. Suppose that* A' *is a local ring, and let* $\mathfrak{m}'$ *and* $\mathrm{K}' = \mathrm{A}'/\mathfrak{m}'$ *be its maximal ideal and residue field. Then:*

(i) *If one sets* $d = \prod_{i=1}^{r} d_i$*,* A' *is a free* A*-module of rank* d*, and we have* $[\mathrm{K}' : \mathrm{K}] \leqslant d$*.*

(ii) *For* $[\mathrm{K}' : \mathrm{K}] = d$*, it is necessary and sufficient that* $\mathrm{A}' \otimes_{\mathrm{A}} \mathrm{K} = \mathrm{A}'/\mathfrak{m}\mathrm{A}'$ *be a field (necessarily isomorphic to* K'*), in other words, that* $\mathfrak{m}' = \mathfrak{m}\mathrm{A}'$*. In this case,* $\mathfrak{m}'^2 = 0$*, and if* V' *denotes the ideal* $\mathfrak{m}'$ *considered as a* K'*-vector space, the canonical homomorphism* $\mathrm{V} \otimes_{\mathrm{K}} \mathrm{K}' \to \mathrm{V}'$ *is bijective (and consequently* $\mathrm{rg}_{\mathrm{K}'} \mathrm{V}' = \mathrm{rg}_{\mathrm{K}} \mathrm{V}$*).*

Proof. Without assuming A' local, it is evident by Euclidean division and induction on r that, if t_i is the class of T_i modulo $\mathfrak{b}$, the monomials $\mathrm{M}_\nu = t_1^{\nu_1} t_2^{\nu_2} \cdots t_r^{\nu_r}$, where $0 \leqslant \nu_i \leqslant d_i - 1$, form a basis of A' as an A-module. If A' is assumed local, K' is a quotient of $\mathrm{A}'/\mathfrak{m}\mathrm{A}' = \mathrm{A}' \otimes_{\mathrm{A}} \mathrm{K}$, so $[\mathrm{K}' : \mathrm{K}] \leqslant [\mathrm{A}' \otimes_{\mathrm{A}} \mathrm{K} : \mathrm{K}] = d$, and there cannot be equality unless $\mathfrak{m}' = \mathfrak{m}\mathrm{A}'$, which proves (i) and the first assertion of (ii). On the other hand, it is clear that when $\mathfrak{m}' = \mathfrak{m}\mathrm{A}'$, we have $\mathfrak{m}'^2 = 0$, and $\mathrm{V} \otimes_{\mathrm{K}} \mathrm{K}' = \mathfrak{m} \otimes_{\mathrm{A}} \mathrm{A}' = \mathfrak{m}\mathrm{A}' = \mathrm{V}'$ since A' is a free A-module. □

Remark (22.4.2). — When A is Artinian (that is to say $\mathrm{rg}_{\mathrm{K}}(\mathrm{V})$ is finite), the hypothesis that A' is local always implies $\mathrm{rg}_{\mathrm{K}'}(\mathfrak{m}'/\mathfrak{m}'^2) \geqslant \mathrm{rg}_{\mathrm{K}}(\mathrm{V})$, as we shall see further on (22.5.2). Note that these two ranks can be equal without having $\mathfrak{m}' = \mathfrak{m}\mathrm{A}'$.

Proposition (22.4.3). — *With the hypotheses and notations of* (22.4.1)*, suppose that the* F_i *are of the form*

(22.4.3.1)
$$\mathrm{F}_i(\mathrm{T}_i) = \mathrm{T}_i^{d_i} + \sum_{1 \leqslant k \leqslant d_i} c_{ik} \mathrm{T}_i^{d_i - k}$$

where $d_i \geqslant 2$ *for every* i *and* $c_{ik} \in \mathfrak{m}$ *("Eisenstein polynomials"). Then:*

(i) A' *is a local ring, and its residue field* $\mathrm{K}' = \mathrm{A}'/\mathfrak{m}'$ *is isomorphic to* K*.*

$\mathbf{0}_{\mathbf{IV\text{-}1}}$ | 194

(ii) *The kernel of the canonical homomorphism* $\mathrm{V} \to \mathrm{V}' = \mathfrak{m}'/\mathfrak{m}'^2$ *is the ideal* $\mathfrak{n}$ *of* A *generated by the elements* $\xi_i = c_{i,d_i}$*, and its cokernel has as a basis over* K' *the images of the* T_i*. In particular,*

(22.4.3.2)
$$\mathrm{rg}_{\mathrm{K}'}(\mathrm{V}') = \mathrm{rg}_{\mathrm{K}}(\mathrm{V}) + r - r',$$

where $r' = \mathrm{rg}_{\mathrm{K}}(\mathfrak{n})$*. When* $\mathrm{rg}_{\mathrm{K}}(\mathrm{V})$ *is finite, equivalently when* A *is Artinian, equality* $\mathrm{rg}_{\mathrm{K}'}(\mathrm{V}') = \mathrm{rg}_{\mathrm{K}}(\mathrm{V})$ *holds if and only if the* ξ_i *are linearly independent over* K*.*

Proof. (i) It is clear that $\mathrm{A}' \otimes_{\mathrm{A}} \mathrm{K} = \mathrm{A}'/\mathfrak{m}\mathrm{A}'$ is isomorphic to $\mathrm{K}[\mathrm{T}_1, \ldots, \mathrm{T}_r]/\mathfrak{b}'$, where $\mathfrak{b}'$ is the ideal generated by the r polynomials $\mathrm{T}_i^{d_i}$; this is therefore a local ring of residue field K, and it is the same for A', from which (i) follows.

(ii) Let t_i $(1 \leqslant i \leqslant r)$ be the class of T_i mod. $\mathfrak{b}$; it follows from (i) that the maximal ideal $\mathfrak{m}'$ of A' is given by

$$\mathfrak{m}' = \mathfrak{m}\mathrm{A}' + \sum_i t_i \mathrm{A}'$$

from which, taking into account that $\mathfrak{m}^2 = 0$,

$$\mathfrak{m}'^2 = \sum_{i,j} t_i t_j \mathrm{A}' + \sum_i t_i \mathfrak{m}\mathrm{A}'.$$

One deduces that $\mathrm{A}'/\mathfrak{m}'^2$ is isomorphic to the ring $\mathrm{A}[\mathrm{T}_1, \ldots, \mathrm{T}_r]/\mathfrak{c}$, where $\mathfrak{c}$ is the ideal generated by the elements

$$\mathrm{F}_i \ (1 \leqslant i \leqslant r), \quad \mathrm{T}_i\mathrm{T}_j \ (1 \leqslant i \leqslant r,\ 1 \leqslant j \leqslant r), \quad x\mathrm{T}_i \ (1 \leqslant i \leqslant r,\ x \in \mathfrak{m}).$$

Since $d_i \geqslant 2$ and $\mathrm{T}_i^2 \in \mathfrak{c}$, the hypotheses show that $\mathfrak{c}$ is also generated by

$$\xi_i \ (1 \leqslant i \leqslant r), \quad \mathrm{T}_i\mathrm{T}_j \ (1 \leqslant i \leqslant r,\ 1 \leqslant j \leqslant r), \quad \mathrm{T}_i x \ (1 \leqslant i \leqslant r,\ x \in \mathfrak{m}).$$

Let $\mathfrak{c}_1 = \sum_{i,j} \mathrm{T}_i\mathrm{T}_j \mathrm{A}[\mathrm{T}_1, \ldots, \mathrm{T}_r]$, $\mathfrak{c}_2 = \mathfrak{c}_1 + \sum_i \mathfrak{m}\mathrm{T}_i \mathrm{A}[\mathrm{T}_1, \ldots, \mathrm{T}_r]$, then $\mathfrak{c} = \mathfrak{c}_2 + \sum_i \xi_i \mathrm{A}[\mathrm{T}_1, \ldots, \mathrm{T}_r]$. It is clear that $\mathrm{A}[\mathrm{T}_1, \ldots, \mathrm{T}_r]/\mathfrak{c}_1$ is the A-module direct sum of A and of $\mathrm{A}t_i^{(1)}$, where $t_i^{(1)}$ is the class of T_i

mod. $\mathfrak{c}_1$. One deduces that $A[T_1, \ldots, T_r]/\mathfrak{c}_2$ is the direct sum of A and of the $Kt_i^{(2)}$, where $t_i^{(2)}$ is the class of T_i mod. $\mathfrak{c}_2$. Finally $A[T_1, \ldots, T_r]/\mathfrak{c}$ is the direct sum of $A/\mathfrak{n}$ and of the Kt'_i, where t'_i is the class of T_i mod. $\mathfrak{c}$, and $\mathfrak{n}$ is the ideal of A generated by the ξ_i; in the identification of $A'/\mathfrak{m}'^2$ with $A[T_1, \ldots, T_r]/\mathfrak{c}$, the image of V identifies with $\mathfrak{m}/\mathfrak{n}$, and this proves (ii). □

Proposition (22.4.4). — *With the hypotheses and notations of (22.4.1), suppose that* K *is of characteristic* $p > 0$ *(hence* $p.1 \in \mathfrak{m}$ *in* A*) and that the* F_i *are of the form*

(22.4.4.1) $$F_i(T_i) = T_i^p + p \sum_{k=1}^{p-1} c_{ik} T_i^{p-k} - f_i$$

with $c_{ik} \in A$ *and* $f_i \in A$ *for every* i *and every* k *such that* $1 \leqslant k \leqslant p-1$*; furthermore, if* a_i *is the class of* f_i *modulo* $\mathfrak{m}$*, suppose that the family* $(a_i)_{1 \leqslant i \leqslant r}$ *is* p*-free over* K^p *("absolutely* p*-free"). Then:*

(i) A' *is a local ring, with maximal ideal* $\mathfrak{m}A'$*, whose residue field* K' *is isomorphic to the extension of* K *obtained by adjunction of the* $a_i^{1/p}$ $(1 \leqslant i \leqslant r)$*.*

$\mathbf{0_{IV\text{-}1}}$ | 195

(ii) *The elements* $d_A f_i \otimes 1_{K'}$ *form a basis of the kernel* $N = \Upsilon^{K'}_{A'/A}$ *of the canonical homomorphism*

$$\Omega^1_A \otimes_A K' \longrightarrow \Omega^1_{A'} \otimes_{A'} K'.$$

Proof. (i) This time $A' \otimes_A K = A'/\mathfrak{m}A'$ is isomorphic to $K[T_1, \ldots, T_r]/\mathfrak{b}'$, where $\mathfrak{b}'$ is the ideal generated by the polynomials $T_i^p - a_i$ $(1 \leqslant i \leqslant r)$; the hypothesis made on the a_i implies that this quotient ring is a field (21.1.8), from which the assertions of (i) follow.

Before proving (ii), we shall establish the

Lemma (22.4.4.2). — *Let* Λ *be a ring,* A *a* Λ*-algebra,* $\mathfrak{J}$ *an ideal of* A *such that the ring* $C = A/\mathfrak{J}$ *is of characteristic* $p > 0$ *(which is equivalent to saying that* $p.1 \in \mathfrak{J}$ *in* A*). Let* π *be the canonical image of* $p.1$ *in* $\mathfrak{J}/\mathfrak{J}^2$*. If* C *is a* $(\Lambda/p\Lambda)$*-algebra formally smooth for the discrete topologies, one has a canonical exact sequence*

(22.4.4.3) $$0 \longrightarrow (\mathfrak{J}/\mathfrak{J}^2)/C \cdot \pi \longrightarrow \Omega^1_{A/\Lambda} \otimes_A C \longrightarrow \Omega^1_{C/\Lambda} \longrightarrow 0.$$

Proof of the lemma. Indeed, set $A' = A/pA$, $\mathfrak{J}' = \mathfrak{J}/pA$, so that $C = A'/\mathfrak{J}'$. As $A' = A \otimes_\Lambda (\Lambda/p\Lambda)$, we have $\Omega^1_{A/\Lambda} \otimes_A A' = \Omega^1_{A'/\Lambda'}$ up to canonical isomorphism, where Λ' denotes $\Lambda/p\Lambda$ (20.5.5). Applying the exact sequence (20.5.14.1) to the formally smooth Λ'-algebra $C = A'/\mathfrak{J}'$, one obtains the exact sequence

$$0 \longrightarrow \mathfrak{J}'/\mathfrak{J}'^2 \longrightarrow \Omega^1_{A'/\Lambda'} \otimes_{A'} C \longrightarrow \Omega^1_{C/\Lambda'} \longrightarrow 0.$$

Since the homomorphism $\Lambda \to \Lambda'$ is surjective, one has $\Omega^1_{C/\Lambda'} = \Omega^1_{C/\Lambda}$ up to canonical isomorphism (20.5.15); hence the exact sequence (22.4.4.3) follows from the preceding observations. □

(ii) As $\mathfrak{m}'^2 = 0$, we shall also denote by V' the ideal $\mathfrak{m}'$ considered as a K'-vector space, and we shall set

(22.4.4.4) $$V_0 = V/K \cdot p = \mathfrak{m}/(\mathfrak{m}^2 + pA), \qquad V'_0 = V'/K' \cdot p = \mathfrak{m}'/(\mathfrak{m}'^2 + pA').$$

Applying the exact sequence (22.4.4.3) in the case where $\Lambda = \mathbf{Z}$, to the $\mathbf{Z}$-algebra A (resp. A') and to its ideal $\mathfrak{m}$ (resp. $\mathfrak{m}'$), it follows, since K (resp. K') is separable over the prime field $\mathbf{Z}/p\mathbf{Z}$, hence a $(\mathbf{Z}/p\mathbf{Z})$-algebra formally smooth (19.6.1), that the following sequences are exact:

(22.4.4.5) $$0 \longrightarrow V_0 \longrightarrow \Omega^1_A \otimes_A K \longrightarrow \Omega^1_K \longrightarrow 0, \qquad 0 \longrightarrow V'_0 \longrightarrow \Omega^1_{A'} \otimes_{A'} K' \longrightarrow \Omega^1_{K'} \longrightarrow 0.$$

Consider then the diagram (22.4.4.6) in which the two middle columns are the second exact sequence (22.4.4.5) and the first exact sequence (22.4.4.5) tensorized by K'; as the first exact sequence (22.4.4.5) is formed of K-vector spaces, the two middle columns of (22.4.4.6) are exact; moreover, the diagram formed by these columns and the horizontal arrows connecting them is commutative, by virtue of the proof of (22.4.4.2) and the commutativity of the diagram (20.5.11.3). The last line of (22.4.4.6) is the exact sequence obtained from (20.6.1.1) by replacing A, B, C by $\mathbf{Z}$, K and K'; the middle line is obtained by tensorization with K' from the K-module exact sequence deduced from (20.6.1.1) by replacing A, B, C by $\mathbf{Z}$, A, K respectively. The diagram formed by these two lines and the vertical arrows connecting them is commutative by virtue of the commutativity of (20.6.4.3). We note moreover that we are in the conditions of application of (22.4.1), (ii), so the upper line of the diagram (22.4.4.6) is *exact*; the extreme columns of the diagram

$\mathbf{0}_{\mathbf{IV}\text{-}\mathbf{1}}$ | 196

(22.4.4.6)

$$\begin{tikzcd}
 & & 0 \arrow[d] & 0 \arrow[d] & & \\
 & 0 \arrow[r] & V_0 \otimes_K K' \arrow[r] \arrow[d] & V'_0 \arrow[rr] \arrow[d] & & 0 \\
0 \arrow[r] & N \arrow[r] \arrow[d] & \Omega^1_A \otimes_A K' \arrow[r] \arrow[d] & \Omega^1_{A'} \otimes_{A'} K' \arrow[r] \arrow[d] & \Omega^1_{A'/A} \otimes_{A'} K' \arrow[r] \arrow[d] & 0 \\
0 \arrow[r] & Y_{K'/K} \arrow[r] \arrow[d] & \Omega^1_K \otimes_K K' \arrow[r] \arrow[d] & \Omega^1_{K'} \arrow[r] \arrow[d] & \Omega^1_{K'/K} \arrow[r] \arrow[d] & 0 \\
 & 0 & 0 & 0 & 0 &
\end{tikzcd}$$

are therefore formed respectively of the *kernels* and the *cokernels* of the middle horizontal arrows, which finishes proving that the diagram is *commutative*. Furthermore:

Lemma (22.4.4.7). — *The homomorphisms*

$$N \longrightarrow Y_{K'/K} \qquad \text{and} \qquad \Omega^1_{A'/A} \otimes_{A'} K' \longrightarrow \Omega^1_{K'/K}$$

of diagram (22.4.4.6) *are bijective.*

Proof. Indeed, the snake diagram (Bourbaki, *Alg. comm.*, chap. I, § 1, nº 4, prop. 2) applied to the two middle columns of (22.4.4.6) gives an exact sequence

$$0 \longrightarrow N \longrightarrow Y_{K'/K} \longrightarrow 0 \longrightarrow \Omega^1_{A'/A} \otimes_{A'} K' \longrightarrow \Omega^1_{K'/K} \longrightarrow 0.$$

But, if t_i is the canonical image of T_i in A', the relation $F_i(t_i) = 0$, together with the fact that $p.1 \in \mathfrak{m}A' \subset \mathfrak{m}'$, shows immediately that $d_{A'}f_i \in \mathfrak{m}'\Omega^1_{A'}$, hence $d_{A'}f_i \otimes 1_{K'} = 0$; this proves that the $d_A f_i \otimes 1_{K'}$ belong to N. Moreover, their images in $Y_{K'/K}$ are the $d_K a_i \otimes 1_{K'}$, which form a basis of $Y_{K'/K}$ over K' (21.4.7); taking into account (22.4.4.7), this finishes proving (22.4.4). □

□

(22.4.5). Now consider two rings A, B of *characteristic* $p > 0$, and two homomorphisms

$$A \xrightarrow{i} B \xrightarrow{j} A$$

satisfying the conditions of (21.3.1). Let furthermore $\mathfrak{m}$ be an ideal *of square zero* in A; set $\mathbf{0}_{\mathbf{IV}\text{-}\mathbf{1}}$ | 197

$$K = A/\mathfrak{m}, \qquad B_{(K)} = B \otimes_A K = B/Bi(\mathfrak{m})$$

and let

$$\varphi : A \longrightarrow K, \qquad \psi : B \longrightarrow B_{(K)}$$

be the canonical homomorphisms. Since φ is surjective, $\Omega^1_{B_{(K)}/A}$ identifies canonically with $\Omega^1_{B_{(K)}/K}$ (20.5.15). We note that, since $p \geqslant 2$, for every $x \in \mathfrak{m}$, one has $j(i(x)) = x^p = 0$, in other words $j(i(\mathfrak{m})) = 0$; by passing to quotients, one deduces from j a homomorphism

$$j' : B_{(K)} \longrightarrow A$$

such that, if $i' = \psi \circ i : A \to B_{(K)}$, we have

$$j'(i'(x)) = x^p \quad \text{and} \quad i'(j'(y)) = y^p \quad \text{for} \quad x \in A \quad \text{and} \quad y \in B_{(K)}.$$

Setting, following the notations of (21.3.2)

$$\Theta_{B_{(K)}/A} = \Omega^1_{B_{(K)}/A} \otimes_{B_{(K)}} A_{[j']} = \Omega^1_{B_{(K)}/K} \otimes_{B_{(K)}} A_{[j']}$$

one has therefore (21.3.2.2) a canonical homomorphism

(22.4.5.1) $$\pi_{\mathrm{B}_{(\mathrm{K})}/\mathrm{A}} : \Theta_{\mathrm{B}_{(\mathrm{K})}/\mathrm{A}} \longrightarrow \Omega^1_{\mathrm{A}}.$$

On the other hand, one deduces from i and j, by passing to quotients (taking into account that $j(i(\mathfrak{m})) = 0$) homomorphisms

$$\mathrm{K} \xrightarrow{i_0} \mathrm{B}_{(\mathrm{K})} \xrightarrow{j_0} \mathrm{K}$$

so that one has the commutative diagram

$$\begin{tikzcd}
\mathrm{A} \arrow[r, "i"] \arrow[d, "\varphi"'] & \mathrm{B} \arrow[r, "j"] \arrow[d, "\psi"] & \mathrm{A} \arrow[d, "\varphi"] \\
\mathrm{K} \arrow[r, "i_0"'] & \mathrm{B}_{(\mathrm{K})} \arrow[r, "j_0"'] \arrow[ur, "j'"] & \mathrm{K}
\end{tikzcd}$$

It is clear furthermore that

$$j_0(i_0(s)) = s^p \quad \text{and} \quad i_0(j_0(t)) = t^p \quad \text{for} \quad s \in \mathrm{K} \quad \text{and} \quad t \in \mathrm{B}_{(\mathrm{K})}.$$

One therefore defines in the same way

$$\Theta_{\mathrm{B}_{(\mathrm{K})}/\mathrm{K}} = \Omega^1_{\mathrm{B}_{(\mathrm{K})}/\mathrm{K}} \otimes_{\mathrm{B}_{(\mathrm{K})}} \mathrm{K}_{[j_0]} = \Theta_{\mathrm{B}_{(\mathrm{K})}/\mathrm{A}} \otimes_{\mathrm{A}} \mathrm{K}$$

hence, tensorizing (22.4.5.1) by K, one obtains a *canonical* K-homomorphism

(22.4.5.2) $$\pi'_{\mathrm{B}_{(\mathrm{K})}/\mathrm{K}} = \pi_{\mathrm{B}_{(\mathrm{K})}/\mathrm{A}} \otimes 1_{\mathrm{K}} : \Theta_{\mathrm{B}_{(\mathrm{K})}/\mathrm{K}} \longrightarrow \Omega^1_{\mathrm{A}} \otimes_{\mathrm{A}} \mathrm{K}.$$

It follows immediately from the definitions that the diagram $\mathbf{0}_{\textbf{IV-1}}$ | 198

$$\begin{tikzcd}
\Theta_{\mathrm{B}_{(\mathrm{K})}/\mathrm{K}} \arrow[r, "\pi'_{\mathrm{B}_{(\mathrm{K})}/\mathrm{K}}"] \arrow[dr, "\pi_{\mathrm{B}_{(\mathrm{K})}/\mathrm{K}}"'] & \Omega^1_{\mathrm{A}} \otimes_{\mathrm{A}} \mathrm{K} \arrow[d, "\varphi_{\mathrm{K}/\mathrm{A}}"] \\
& \Omega^1_{\mathrm{K}}
\end{tikzcd}$$

is commutative, $\pi_{\mathrm{B}_{(\mathrm{K})}/\mathrm{K}}$ being the canonical homomorphism corresponding to i_0 and j_0 (21.3.2.2). By *restriction* to $\Xi_{\mathrm{B}_{(\mathrm{K})}/\mathrm{K}} = \mathrm{Ker}(\pi_{\mathrm{B}_{(\mathrm{K})}/\mathrm{K}})$, the homomorphism $\pi'_{\mathrm{B}_{(\mathrm{K})}/\mathrm{K}}$ therefore defines a canonical homomorphism

(22.4.5.3) $$\Xi_{\mathrm{B}_{(\mathrm{K})}/\mathrm{K}} \longrightarrow \mathrm{Ker}(\Omega^1_{\mathrm{A}} \otimes_{\mathrm{A}} \mathrm{K} \longrightarrow \Omega^1_{\mathrm{K}}) = \Upsilon_{\mathrm{K}/\mathrm{A}}.$$

(22.4.6). With the hypotheses and notations of (22.4.5), suppose in addition that $\mathfrak{m}$ be a *maximal* ideal of square zero, hence K a *field*, and let V denote the ideal $\mathfrak{m}$ considered as a K-vector space. As K is a formally smooth algebra over its prime field $\mathbf{F}_p$ (21.5.2) (so that A is an algebra over $\mathbf{F}_p$, in the sense that $\Omega^1_{\mathrm{A}} = \Omega^1_{\mathrm{A}/\mathbf{F}_p}$), one deduces from (20.5.14) that one has an *exact sequence*

(22.4.6.1) $$0 \longrightarrow \mathrm{V} \longrightarrow \Omega^1_{\mathrm{A}} \otimes_{\mathrm{A}} \mathrm{K} \longrightarrow \Omega^1_{\mathrm{K}} \longrightarrow 0.$$

One has therefore by (22.4.5.3) a homomorphism denoted

(22.4.6.2) $$\chi'_{\mathrm{B}/\mathrm{A}} : \Xi_{\mathrm{B}_{(\mathrm{K})}/\mathrm{K}} \longrightarrow \mathrm{V}$$

that we shall call the *characteristic homomorphism* of the A-algebra B (relative to i, j and $\mathfrak{m}$). It follows from the definitions that for $\chi'_{\mathrm{B}/\mathrm{A}}$ to be *injective*, it is necessary and sufficient that $\pi'_{\mathrm{B}_{(\mathrm{K})}/\mathrm{K}}$ is injective, the kernel of the latter being obviously contained in $\Xi_{\mathrm{B}_{(\mathrm{K})}/\mathrm{K}}$.

Proposition (22.4.7). — *Let* A *be a local Artinian ring whose maximal ideal* $\mathfrak{m}$ *is of square zero,* $\mathrm{K} = \mathrm{A}/\mathfrak{m}$ *its residue field,* V *the ideal* $\mathfrak{m}$ *considered as a* K*-vector space; we suppose that* A *is of characteristic* $p > 0$*; let*

(22.4.7.1) $$\mathrm{F}_i(\mathrm{T}_i) = \mathrm{T}_i^p - f_i \qquad \textit{with} \quad f_i \in \mathrm{A} \quad (1 \leqslant i \leqslant r)$$

and let B *be the quotient ring of* $\mathrm{A}[\mathrm{T}_1, \ldots, \mathrm{T}_r]$ *by the ideal generated by the* r *polynomials* F_i*. Then:*

(i) B *is a local ring.*

(ii) *If $\mathfrak{m}'$ is the maximal ideal of* B, $K' = B/\mathfrak{m}'$ *its residue field,* V′ *the* B*-module* $\mathfrak{m}'/\mathfrak{m}'^2$ *considered as a* K′*-vector space, then, for* $\mathrm{rg}_K(V) = \mathrm{rg}_{K'}(V')$*, it is necessary and sufficient that the characteristic homomorphism of* K*-vector spaces*

$$\chi'_{B/A} : \Xi_{B_{(K)}/K} \longrightarrow V \tag{22.4.7.2}$$

(cf. (22.4.6.2)) is injective.

Proof. Let us again denote by a_i $(1 \leqslant i \leqslant r)$ the class of f_i mod. $\mathfrak{m}$; the a_i are not necessarily p-independent over K^p, but one can always suppose that the subfamily $(a_i)_{s+1\leqslant i\leqslant r}$ is p-free over K^p $\mathbf{0}_{\textbf{IV-1}}$ | 199
and forms a p-base over K^p of the field $K^p(a_1, \ldots, a_r)$ so that

$$a_i \in K^p(a_{s+1}, \ldots, a_r) \qquad \text{for} \quad 1 \leqslant i \leqslant s.$$

Let us denote by A″ the quotient ring of $A[T_{s+1}, \ldots, T_r]$ by the ideal generated by the F_i of index $i \geqslant s+1$; then, by (22.4.4), A″ is a local ring whose maximal ideal is $\mathfrak{m}'' = \mathfrak{m}A''$ and the residue field is $K'' = K(a_{s+1}^{1/p}, \ldots, a_r^{1/p})$. One has thus $a_i \in K''^p$ for $1 \leqslant i \leqslant s$ and hence, in A″, the element f_i, for $1 \leqslant i \leqslant s$, can be written

$$f_i = g_i^p + h_i \tag{22.4.7.3}$$

where $g_i \in A''$ and $h_i \in \mathfrak{m}''$ (since $\mathfrak{m}''^2 = 0$ and $p\mathfrak{m}'' = 0$, it is immediate that h_i is uniquely determined by these conditions). Replacing T_i by $T_i + g_i$, one sees thus that if one sets

$$G_i(T_i) = T_i^p + \sum_{k=1}^{p-1} \binom{p}{k} g_i^{p-k} T_i^k - h_i \qquad (1 \leqslant i \leqslant s)$$

B is the quotient ring of $A''[T_1, \ldots, T_s]$ by the ideal generated by the G_i; but, all the coefficients of G_i except the leading coefficient belong to $\mathfrak{m}''$, we are in the situation of (22.4.3), which proves (i) (which indeed follows directly from the fact that $B^p \subset A$, and by consequence B has only a single ideal above $\mathfrak{m}$), and furthermore the residue field K′ is *isomorphic* to K″.

Now let us note that for (22.4.7.2) to be injective, it is necessary and sufficient that

$$\pi'_{B_{(K)}/K} : \Omega^1_{B_{(K)}/K} \otimes_{B_{(K)}} K \longrightarrow \Omega^1_A \otimes_A K$$

is injective (by (22.4.6)). But $B_{(K)} = B/\mathfrak{m}B$ is the quotient algebra $C = K[T_1, \ldots, T_r]$ by the ideal generated by the polynomials $\overline{F}_i = T_i^p - a_i$, and since $d_{C/K}\overline{F}_i = 0$ it follows from (20.5.13) that $\Omega^1_{B_{(K)}/K}$ is a free $B_{(K)}$-module with base $d_{B_{(K)}/K} t_i$, where t_i is the canonical image of T_i. But by definition (22.4.5), the canonical image under $j' : B_{(K)} \to A$ of the class modulo $\mathfrak{m}B$ of an element $x \in B$ is the element $x^p \in A$; one deduces immediately, since $t_i^p = f_i$, that the image of $d_{B_{(K)}/K} t_i \otimes 1$ under $\pi'_{B_{(K)}/K}$ is $d_A f_i \otimes 1$ in $\Omega^1_A \otimes_A K$; the condition that $\pi'_{B_{(K)}/K}$ is injective is thus equivalent to the fact that the $d_A f_i \otimes 1_K$ are *linearly independent over* K, or equivalently that their images $d_A f_i \otimes 1_{K'}$ are *linearly independent over* K′ in $\Omega^1_A \otimes_A K'$.

Now, if one applies (22.4.4) to the A-algebra A″, one sees that the kernel of the canonical homomorphism $\Omega^1_A \otimes_A K' \to \Omega^1_{A''} \otimes_{A''} K'$ has as its *basis* the $d_A f_i \otimes 1_{K'}$ for $s+1 \leqslant i \leqslant r$. The preceding condition thus also amounts to saying that the $d_{A''} f_i \otimes 1_{K'}$ for $1 \leqslant i \leqslant s$ are linearly independent in $\Omega^1_{A''} \otimes_{A''} K'$ (taking into account that $d_{A''} f_i = d_{A''} h_i$ by (22.4.7.3)); on the other hand, if V″ is the K′-vector space $\mathfrak{m}''$, one has $\mathrm{rg}_{K'}(V'') = \mathrm{rg}_K(V)$ (22.4.1), (ii), and the condition $\mathrm{rg}_{K'}(V') = \mathrm{rg}_K(V)$ is therefore equivalent to $\mathrm{rg}_{K'}(V'') = \mathrm{rg}_{K'}(V')$. But it follows from (22.4.3) that this last relation is equivalent to the classes h_i being linearly independent over K′ in V″. Now, in $\Omega^1_{A''} \otimes_{A''} K'$, the $\mathbf{0}_{\textbf{IV-1}}$ | 200
$d_{A''} h_i \otimes 1_{K'}$ are the canonical images (20.5.11.2) of the h_i under the injection $V'' \to \Omega^1_{A''} \otimes_{A''} K'$ (cf. (22.4.6.1)), and this finishes the proof of (22.4.7). □

Corollary (22.4.7.4). — *For* $\mathrm{rg}_K(V) = \mathrm{rg}_{K'}(V')$*, it is necessary and sufficient that the elements* $d_A f_i \otimes 1_K$ $(1 \leqslant i \leqslant r)$ *be linearly independent in the* K*-vector space* $\Omega^1_A \otimes_A K$.

Remark (22.4.8). — One can define the homomorphisms (22.4.5.2) and (22.4.6.2) in slightly different conditions. Let A be a ring, $\mathfrak{m}$ an ideal *of square zero* in A, $K = A/\mathfrak{m}$, p a prime number such that

$p.1 \in \mathfrak{m}$ (in other words, K is of characteristic p, but not necessarily A). Let furthermore B be an A-algebra that is an A-module *faithfully flat* (so that $A \subset B$), and suppose that we have

(22.4.8.1) $$y^p \in A + pB \subset A + \mathfrak{m}B$$

for every $y \in B$. If $y^p = x + pz$ with $x \in A$, $z \in B$, the *class modulo* $(A \cap pB)$ of x is well determined, and since $A \cap pB = pA$ as B is a faithfully flat A-module, one has thus defined a canonical map $j : B \to A/pA$, such that, for $x \in A$, $j(x)$ is the class of x^p mod. pA. Furthermore, if $y' \in B$ and $y'^p = x' + pz'$ with $x' \in A$, $z' \in B$, it is immediate that the elements $(y+y')^p - x - x'$ and $(yy')^p - xx'$ belong to pB by virtue of the fact that the binomial coefficients $\binom{p}{i}$ are multiples of p for $1 \leqslant i \leqslant p-1$. The map j is therefore a *ring homomorphism*. By composition, one deduces from j a homomorphism $j' : B \xrightarrow{j} A/pA \to A/\mathfrak{m} = K$ and hence a homomorphism $j_0 : B_{(K)} \to K$ such that j' is the composite $B \to B_{(K)} = B \otimes_A K \xrightarrow{j_0} K$; moreover, if $i_0 : K \to B_{(K)}$ is the canonical map, i_0 and j_0 satisfy the conditions of (21.3.1) for the rings *of characteristic* p, K and $B_{(K)}$. This being so, in order to define a K-homomorphism $\pi'_{B_{(K)}/K} : \Omega^1_{B_{(K)}/K} \otimes_{B_{(K)}} K_{[j_0]} \to \Omega^1_A \otimes_A K$, it suffices (20.4.8) to define a K-*derivation*

(22.4.8.2) $$D_0 : B_{(K)} \longrightarrow \Omega^1_A \otimes_A K$$

where the second member is considered as a $B_{(K)}$-module by means of j_0. For this, it suffices to define an A-*derivation*

(22.4.8.3) $$D : B \longrightarrow \Omega^1_A \otimes_A K$$

that *vanishes on* $\mathfrak{m}B$ (the second member being considered as a B-module by means of j'). Indeed, if $y^p = x + pz$ with $y \in B$, $x \in A$, $z \in B$, the element $d_A x \otimes 1_K$ of $\Omega^1_A \otimes_A K$ depends only on the *class* $j(y)$ mod. pA of x (for since $d_A(pt) = p d_A(t)$, hence $d_A(pt) \otimes 1 = 0$ in $\Omega^1_A \otimes_A K = \Omega^1_A/\mathfrak{m}\Omega^1_A$, since $p.1 \in \mathfrak{m}$). One can therefore take

$$D(y) = d_A x \otimes 1_K.$$

The fact that D is a derivation follows easily from the fact that j is a ring homomorphism; moreover, for $t \in A$, one has $d_A(t^p x) = t^p d_A(x) + pt^{p-1} x d_A(t)$ and one deduces that $D(ty) = tD(y)$, hence D is an A-derivation; finally, if in addition $t \in \mathfrak{m}$, one has $D(ty) = tD(y) = 0$ since $\Omega^1_A \otimes_A K$ is annihilated by $\mathfrak{m}$. We have thus defined the desired homomorphism (22.4.5.2), and it is immediate to verify that the composition **0_{IV-1}** | 201

$$\Theta_{B_{(K)}/K} \xrightarrow{\pi'_{B_{(K)}/K}} \Omega^1_A \otimes_A K \longrightarrow \Omega^1_K$$

is again the canonical homomorphism $\pi_{B_{(K)}/K}$ (relative to i_0 and j_0). One therefore also has a canonical homomorphism analogous to (22.4.5.3).

Now if K is a *field*, A/pA is an $\mathbf{F}_p$-algebra, and one has the exact sequence (20.5.14)

$$0 \longrightarrow V/pA \longrightarrow \Omega^1_{A/pA} \otimes_{A/pA} K \longrightarrow \Omega^1_K \longrightarrow 0$$

and, on the other hand, one has the exact sequence (20.5.12.1)

$$pA \longrightarrow \Omega^1_A \otimes_A (A/pA) \longrightarrow \Omega^1_{A/pA} \longrightarrow 0$$

which shows, tensorizing with K, that $\Omega^1_A \otimes_A K$ and $\Omega^1_{A/pA} \otimes_{A/pA} K$ are isomorphic. The analog of (22.4.6.2) is therefore a homomorphism

(22.4.8.4) $$\Xi_{B_{(K)}/K} \longrightarrow V/pA = \mathfrak{m}/(\mathfrak{m}^2 + pA).$$

That said, the *criterion* (22.4.7), in which one replaces V and V′ by V/pA and V'/pB respectively, *remains valid assuming only that* K *is of characteristic* $p > 0$ (in other words, that $p.1 \in \mathfrak{m}$ in A), *and that the* $F_i(T_i)$ *are of the more general form* (22.4.4.1): indeed, B is a free A-module (hence faithfully flat), and it suffices to redo the argument of (22.4.7), replacing (22.4.6.2) by (22.4.8.4) and V″ by V''/pA''.

22.5. Geometrically regular algebras and formally smooth algebras

Proposition (22.5.1). — *Let* A *be a regular local ring,* A' *a local ring containing* A *and being a finite* A*-algebra,* $\mathfrak{m}$ *(resp.* $\mathfrak{m}'$*) the maximal ideal of* A *(resp.* A'*),* $K = A/\mathfrak{m}$ *(resp.* $K' = A'/\mathfrak{m}'$*) its residue field. For* A' *to be a regular ring, it is necessary and sufficient that*

(22.5.1.1) $$\mathrm{rg}_K(\mathfrak{m}/\mathfrak{m}^2) = \mathrm{rg}_{K'}(\mathfrak{m}'/\mathfrak{m}'^2).$$

Proof. Indeed, the first member of (22.5.1.1) is $\dim(A)$ (17.1.1) and since $A' \supset A$ and A' is a finite A-algebra, $\dim(A') = \dim(A)$ (16.1.5); the equality (22.5.1.1) is therefore necessary and sufficient for A' to be regular (17.1.1). □

Remark (22.5.2). — (i) Let $A_1 = A/\mathfrak{m}^2$, $A'_1 = A' \otimes_A A_1 = A'/\mathfrak{m}^2A'$; as $\mathfrak{m}^2A' \subset \mathfrak{m}'^2$, $\mathfrak{m}'_1 = \mathfrak{m}'/\mathfrak{m}^2A'$ is the maximal ideal of A'_1 and $\mathfrak{m}'_1/\mathfrak{m}'^2_1$ is a K'-vector space isomorphic to $\mathfrak{m}'/\mathfrak{m}'^2$; the condition of regularity of A' depends therefore only on the structure of the A_1-*algebra* A'_1, which will allow us below to apply the preliminary results of (22.4) on algebras finite over Artinian rings.

(ii) It follows from the proof of (22.5.1) and from (16.2.6.1) that one has in all cases

(22.5.2.1) $$\mathrm{rg}_K(\mathfrak{m}/\mathfrak{m}^2) \leqslant \mathrm{rg}_{K'}(\mathfrak{m}'/\mathfrak{m}'^2).$$

$\mathbf{0_{IV\text{-}1}}$ | 202

(iii) Suppose that A and A' verify the general hypotheses of (22.4.1). It is known (19.8.10) that there exists a regular local ring B, with maximal ideal $\mathfrak{n}$, such that A is isomorphic to $B/\mathfrak{n}^2$; let us denote by $G_i \in B[T_i]$ a monic polynomial whose canonical image in $A[T_i]$ is F_i $(1 \leqslant i \leqslant r)$; then, if B' is the quotient ring of $B[T_1, \dots, T_r]$ by the ideal generated by the G_i, it is clear that B' is a free B-module of rank d and $A' = B' \otimes_B A = B'/\mathfrak{n}^2B'$; as A' is assumed to be a local ring, so is B', and if $\mathfrak{n}'$ is the maximal ideal of B', $B'/\mathfrak{n}'$ is isomorphic to K' and $\mathfrak{n}'/\mathfrak{n}'^2$ is isomorphic to $\mathfrak{m}'/\mathfrak{m}'^2$ as a K'-vector space; the inequality (22.5.2.1) shows thus that we have, under the hypotheses of (22.4.1)

(22.5.2.2) $$\mathrm{rg}_K(V) \leqslant \mathrm{rg}_{K'}(\mathfrak{m}'/\mathfrak{m}'^2).$$

Corollary (22.5.3). — *Let* A *be a regular local ring,* $\mathfrak{m}$ *its maximal ideal,* T_i $(1 \leqslant i \leqslant r)$ *indeterminates, and for each* i*, let*

(22.5.3.1) $$F_i(T_i) = T_i^{d_i} + \sum_{1 \leqslant k \leqslant d_i} c_{ik} T_i^{d_i - k}$$

be a unitary polynomial of $A[T_i]$*, with* $d_i \geqslant 2$ *for every* i *and* $c_{ik} \in \mathfrak{m}$*. Let* A' *be the quotient of the polynomial ring* $A[T_1, \dots, T_r]$ *by the ideal* $\mathfrak{b}$ *generated by the* r *polynomials* F_i*. Then:*

(i) A' *is a local ring, and its residue field* K' *is isomorphic to the residue field* K *of* A*.*

(ii) *For* A' *to be regular, it is necessary and sufficient that the classes* ξ_i *mod.* $\mathfrak{m}^2$ *of the elements* c_{i,d_i} $(1 \leqslant i \leqslant r)$ *be linearly independent over* K*.*

Proof. Indeed, with the notations of (22.5.2), (i), if $\overline{F}_i$ denotes the polynomial of $A_1[T_i]$ obtained by applying to the coefficients of F_i the homomorphism $A \to A_1$, A'_1 is defined from A_1 and the polynomials $\overline{F}_i$ as in (22.4.1), and the conclusion follows from (22.5.1) and (22.4.3). □

Theorem (22.5.4). — *Let* A *be a regular local ring,* K *its residue field; suppose that* K *is of characteristic* $p > 0$*; let*

(22.5.4.1) $$F_i(T_i) = T_i^p + p \sum_{k=1}^{p-1} c_{ik} T_i^{p-k} - f_i$$

with $c_{ik} \in A$ *and* $f_i \in A$ $(1 \leqslant i \leqslant r)$*; let* B *be the quotient ring of* $A[T_1, \dots, T_r]$ *by the ideal generated by the* r *polynomials* F_i*. Then* B *is a local ring, and the following conditions are equivalent:*

a) B *is regular;*

b) *the elements* $d_A f_i \otimes 1_K$ $(1 \leqslant i \leqslant r)$ *are linearly independent in the* K*-vector space* $\Omega^1_A \otimes_A K$*;*

c) *if* $B' = B/\mathfrak{m}^2B$ *and if one sets* $\Xi_{B_{(K)}/K} = \Xi_{B'_{(K)}/K}$ (22.4.5)*, the characteristic homomorphism* $\Xi_{B_{(K)}/K} \to \mathfrak{m}/\mathfrak{m}^2$ (22.4.6.2) *is injective.*

Proof. Indeed, B' is defined again from $A_1 = A/\mathfrak{m}^2$ and the polynomials $\overline{F}_i$ obtained by applying the homomorphism $A \to A_1$ to the coefficients. Taking into account that $\Omega^1_A \otimes_A K$ is canonically isomorphic to $\Omega^1_{A_1} \otimes_{A_1} K$ (20.5.12), (ii), the theorem follows from (22.5.1) and (22.4.7.4), using remark (22.4.8) when A_1 is not of characteristic p. □

$\mathbf{0_{IV\text{-}1}}$ | 203

(22.5.5). Let k be a field of characteristic $p > 0$, A a local ring, k' a *finite radicial* extension of k such that $k'^p \subset k$, $\mathfrak{m}$ the maximal ideal of A, $K = A/\mathfrak{m}$ its residue field; recall that $A' = A \otimes_k k'$ is a local ring whose residue field is the same as that of the local ring $K \otimes_k k'$ (Bourbaki, *Alg. comm.*, chap. V, § 2, No. 3, lemma 4). We note that one has $A'_{(K)} = A' \otimes_A K = K \otimes_k k'$, and hence (21.3.6)

(22.5.5.1) $$\Theta_{A'_{(K)}/K} = \Theta_{k'/k} \otimes_k K$$

to a canonical isomorphism. Furthermore, it is known (21.4.7) that one has $\Xi_{k'/k} = 0$, in other words the canonical homomorphism (21.3.2.2)

$$\pi_{k'/k} : \Theta_{k'/k} \longrightarrow \Omega^1_k$$

is injective, so that one has a canonical *injection*

(22.5.5.2) $$\Theta_{A'_{(K)}/K} \longrightarrow \Omega^1_k \otimes_k K$$

which can be described explicitly as follows (taking into account (22.5.5.1)): for every $x' \in k'$, to the element $d_{A'_{(K)}/K}(x' \otimes 1_K) \otimes 1_K$ of $\Omega^1_{A'_{(K)}/K} \otimes_{A'_{(K)}} K$, one associates the element $d_k(x'^p) \otimes 1_K$ of $\Omega^1_k \otimes_k K$.

Lemma (22.5.6). — *With the notations of (22.5.5):*

(i) *The kernel of the canonical homomorphism $\pi_{A'_{(K)}/K}$ (21.3.2.2) identifies by (22.5.5.2) with $(\Theta_{k'/k} \otimes_k K) \cap Y_{K/k}$.*

(ii) *Let $A_1 = A/\mathfrak{m}^2$, $A'_1 = A_1 \otimes_k k' = A'/\mathfrak{m}^2 A'$; then the characteristic homomorphism $\chi'_{A'_1/A_1}$ (22.4.6.2) identifies with the restriction of the characteristic homomorphism $\chi_{A/k} : Y_{K/k} \to V = \mathfrak{m}/\mathfrak{m}^2$ to $(\Theta_{k'/k} \otimes_k K) \cap Y_{K/k}$ (20.6.24).*

Proof. (i) By virtue of (20.6.9), applied by replacing A with the prime field, B with k, C with K and E with $A_1 = A/\mathfrak{m}^2$ (extension of K by $V = \mathfrak{m}/\mathfrak{m}^2$), it suffices (cf. (22.5.5)) to verify that if $x' \in k'$ and if $z \in A_1$ is an element whose class mod. $\mathfrak{m}/\mathfrak{m}^2$ is $x'^p \in k$, then the image of $d_k(x'^p) \otimes 1_K$ under the canonical homomorphism $\Omega^1_k \otimes_k K \to \Omega^1_{A_1} \otimes_{A_1} K$ is $d_{A_1} z \otimes 1_K$, which follows from the definitions.

(ii) As $A'_{(K)} = K \otimes_k k' = (A'_1)_{(K)}$ (by virtue of the relation $K = A_1/(\mathfrak{m}/\mathfrak{m}^2)$), $\Theta_{A'_{(K)}/K}$ identifies with $\Theta_{(A'_1)_{(K)}/K}$, and the verification follows from the same calculation as in (i) and from the definition of $\pi'_{(A'_1)_{(K)}/K}$. □

Proposition (22.5.7). — *Let k be a field of characteristic $p > 0$, A a k-algebra that is a regular local ring, $\mathfrak{m}$ its maximal ideal, $K = A/\mathfrak{m}$ its residue field; let $V = \mathfrak{m}/\mathfrak{m}^2$, considered as a K-vector space. Let k' be a finite extension of k such that $k'^p \subset k$, and $A' = A \otimes_k k'$; for A' to be a regular local ring, it is necessary and sufficient that the restriction of the characteristic homomorphism $\chi_{A/k} : Y_{K/k} \to V$ (20.6.24) to $(\Theta_{k'/k} \otimes_k K) \cap Y_{K/k}$ is injective.*

Proof. We must prove that the condition in the statement is equivalent to (22.5.1.1), denoting by $\mathfrak{m}'$ the maximal ideal of A' and by $K' = A'/\mathfrak{m}'$ its residue field. With the notations of remark (22.5.2), (i), one has $A'_1 = A_1 \otimes_k k'$. Now, let $(a_i)_{1 \leqslant i \leqslant r}$ be a p-basis of k' over k, so that $a_i^p = b_i \in k$, and k' is isomorphic to the quotient of the polynomial ring $k[T_1, \dots, T_r]$ by the ideal generated by $\mathbf{0_{IV\text{-}1}}$ | 204
the polynomials $F_i = T_i^p - b_i$ $(1 \leqslant i \leqslant r)$; it follows that A'_1 is isomorphic to the quotient of the polynomial ring $A_1[T_1, \dots, T_r]$ by the ideal generated by the F_i. One can then apply the criterion (22.4.7), and the condition in the statement is therefore equivalent to $\chi'_{A'_1/A_1}$ being injective; the conclusion follows from (22.5.6). □

Theorem (22.5.8). — *Let k be a field, p its characteristic exponent, A a local Noetherian k-algebra. The following conditions are equivalent:*

a) A *is a k-algebra formally smooth (for its preadic topology).*
b) A *is geometrically regular over k.*
b′) For every finite extension k' of k such that $k'^p \subset k$, $A' = A \otimes_k k'$ is a regular ring.

Proof. Taking into account (19.6.6), one can restrict oneself to the case $p > 1$.

The fact that *a*) implies *b*) is none other than (19.6.5), and *b*) trivially implies *b′*). Let us show that *b′*) implies the conditions of (22.2.2) are satisfied; it is evident for the first (17.1.1) since *b′*) implies first of all that A is regular. Next, let $(x_\alpha)_{\alpha\in I}$ be a p-base of $k^{1/p}$ over k; we know that the elements $d_k(x_\alpha^p)$ form a base of the k-vector space Ω^1_k (21.4.5), hence the elements $d_k(x_\alpha^p) \otimes 1_K$ form a base of the K-vector space $\Omega^1_k \otimes_k K$. One concludes (cf. (22.5.5)) that when k' ranges over the finite subextensions of $k^{1/p}$, the family of subspaces $\Theta_{k'/k} \otimes_k K$ is filtering increasing and has as union $\Omega^1_k \otimes_k K$. It follows then from (22.5.7) that the condition *b′*) implies that $\chi_{A/k}$ is injective, which is none other than condition (ii) of (22.2.2). □

Corollary (22.5.9). — *Let k be a field,* A *a local Noetherian k-algebra that is formally smooth. Then, for every prime ideal $\mathfrak{p}$ of* A*, the local ring $A_\mathfrak{p}$ is a k-algebra formally smooth (for the $\mathfrak{p}$-preadic topology).*

Proof. Indeed, with the notations of (22.5.8), *b′*), it suffices to show that the local ring $A_\mathfrak{p} \otimes_k k'$ is regular; but since this is a ring of fractions of the local ring $A \otimes_k k'$ and the latter is regular by hypothesis, it is the same by (17.3.6). □

Remark (22.5.10). — (i) The conclusion of (22.5.8) fails when, in condition *b′*), one restricts to *monogenic* extensions $k' = k(x)$ of k (with $x^p \in k$). It can indeed happen that for all these extensions k', one has $Y_{K/k} \cap (\Theta_{k'/k} \otimes_k K) = 0$, although $Y_{K/k} \neq 0$; this means that for every $x \in k^{1/p}$ such that $x \notin k$, one must have $d_k(x^p) \otimes 1_K \notin Y_{K/k}$, or equivalently $d_K(x^p) \neq 0$, that is, $x^p \notin K^p$; in other words, one must have $K^p \cap k = k^p$, even though K is an *inseparable* extension of k. Now, one easily constructs examples of such extensions: start from a perfect field k_0 of characteristic $p > 0$, let X, Y, Z be three indeterminates and set $k = k_0(X, Y)$ and $K = k(X^{1/p} + ZY^{1/p})$; one verifies easily that K satisfies the preceding conditions, hence $Y_{K/k} \neq 0$. Applying now the lemma (22.2.5.2) taking $V = K$ and for h the zero homomorphism; A is then a valuation ring of discrete valuation having K as residue field, with $\chi_{A/k} = 0$, and is not a k-algebra formally smooth by (22.2.2); however $A \otimes_k k'$ is a regular ring for every *monogenic* subextension $k' \subset k^{1/p}$ of k. $\mathbf{0_{IV\text{-}1}}$ | 205

(ii) The corollary (22.5.9) leads to the following question: if A is a Noetherian k-algebra, under what conditions is the set of prime ideals $\mathfrak{p} \in \operatorname{Spec}(A)$ such that $A_\mathfrak{p}$ is a k-algebra formally smooth an *open* set? We will address this later in certain particular cases.

22.6. Zariski's Jacobian criterion

Theorem (22.6.1). — (Jacobian criterion for formal smoothness.) *Let* A, B *be two topological rings, $u : A \to B$ a continuous homomorphism making* B *a formally smooth* A*-algebra, $\mathfrak{J}$ an ideal of* B *(not necessarily closed), $C = B/\mathfrak{J}$ the quotient topological algebra. For* C *to be a formally smooth* A*-algebra, it is necessary and sufficient that the canonical homomorphism (cf.* (20.5.11.2)*)*

(22.6.1.1)
$$\delta_{C/B/A} : \mathfrak{J}/\mathfrak{J}^2 \longrightarrow \Omega^1_{B/A} \otimes_B C$$

be formally invertible on the left *(cf.* (19.1.5)*).*

Proof. Indeed, saying that B (resp. C) is a formally smooth A-algebra signifies (19.4.4) that $\operatorname{Exalcotop}_A(B, L) = 0$ (resp. $\operatorname{Exalcotop}_A(C, L) = 0$) for every B-module (resp. C-module) discrete L annihilated by an open ideal of B (resp. C). By hypothesis $\operatorname{Exalcotop}_A(B, L) = 0$ for every such discrete C-module L annihilated by an open ideal of C, saying that C is a formally smooth A-algebra thus signifies that the canonical homomorphism $\operatorname{Exalcotop}_A(C, L) \to \operatorname{Exalcotop}_A(B, L)$ is *injective*, and the theorem follows from (20.7.8). □

Recall (19.5.3) that when B and C are formally smooth A-algebras, $\mathfrak{J}/\mathfrak{J}^2$ is a C-module topologically *formally projective*; moreover, the canonical homomorphisms $\varphi_n : \mathbf{S}^n_C(\mathfrak{J}/\mathfrak{J}^2) \to \mathfrak{J}^n/\mathfrak{J}^{n+1}$ are *formal bimorphisms* when B is assumed to be a preadmissible ring.

Corollary (22.6.2). — *With the hypotheses and notations of (22.6.1), suppose furthermore that the square of every open ideal of* B *is open, and that on* $\mathfrak{J}$ *the topology induced by that of* B *is identical to the topology deduced from that of* B *(19.0) (note that these two conditions are satisfied when* B *is Noetherian and its topology is preadic* ($\mathbf{0}_{\mathrm{I}}$, 7.3.2)*, or if the topology of* B *is the* $\mathfrak{J}$*-preadic topology). Let* $(\mathfrak{b}_\lambda)$ *be a fundamental system of open ideals of* B *and set* $\mathrm{B}_\lambda = \mathrm{B}/\mathfrak{b}_\lambda$ *for every* λ*. Then:*

(i) *The following conditions are equivalent:*

a) C *is a formally smooth* A*-algebra.*

b) For every λ*, the homomorphism of* B_λ*-modules*

$$(\mathfrak{J}/\mathfrak{J}^2) \otimes_{\mathrm{B}} \mathrm{B}_\lambda \longrightarrow \Omega^1_{\mathrm{B}/\mathrm{A}} \otimes_{\mathrm{B}} \mathrm{B}_\lambda \tag{22.6.2.1}$$

deduced from $\delta_{\mathrm{C}/\mathrm{B}/\mathrm{A}}$ *by tensorization, is invertible on the left (in other words, an isomorphism onto a direct factor of* $\Omega^1_{\mathrm{B}/\mathrm{A}} \otimes_{\mathrm{B}} \mathrm{B}_\lambda$*).*

(ii) *Suppose furthermore that the topological ring* C *is preadmissible* ($\mathbf{0}_{\mathrm{I}}$, 7.1.2) *and let* $\mathfrak{L}$ *be an ideal of definition of* C*; then conditions a) and b) of (i) are also equivalent to:* $\mathbf{0}_{\mathbf{IV\text{-}1}}$ | 206

c) The homomorphism of $(\mathrm{C}/\mathfrak{L})$*-modules*

$$(\mathfrak{J}/\mathfrak{J}^2) \otimes_{\mathrm{C}} (\mathrm{C}/\mathfrak{L}) \longrightarrow \Omega^1_{\mathrm{B}/\mathrm{A}} \otimes_{\mathrm{B}} (\mathrm{C}/\mathfrak{L})$$

is invertible on the left.

Proof. The hypotheses imply that on $\Omega^1_{\mathrm{B}/\mathrm{A}}$ the topology is deduced from that of B (20.4.5), hence (i) follows from (22.6.1) and (19.1.7). On the other hand, recall (20.4.9) that since B is a formally smooth A-algebra, $\Omega^1_{\mathrm{B}/\mathrm{A}}$ is a formally projective B-module, hence $\Omega^1_{\mathrm{B}/\mathrm{A}} \otimes_{\mathrm{B}} \mathrm{B}_\lambda$ is a projective B_λ-module for every λ (19.2.4); the equivalence of *c*) with *a*) and *b*), when C is preadmissible, then follows from (19.1.9). □

In particular:

Corollary (22.6.3). — *Let* A *be a ring,* B *an* A*-algebra,* $\mathfrak{J}$ *an ideal of* B, $\mathrm{C} = \mathrm{B}/\mathfrak{J}$*; we suppose* A, B, C *equipped with the discrete topologies and that* B *is a formally smooth* A*-algebra. For* C *to be a formally smooth* A*-algebra, it is necessary and sufficient that the canonical homomorphism (22.6.1.1) be invertible on the left.*

Note that since *every* A-algebra C is a quotient of a polynomial algebra $\mathrm{A}[\mathrm{T}_\alpha]_{\alpha \in \mathrm{I}}$, and the latter is formally smooth (19.3.3), the criterion (22.6.3) allows in principle to determine whether C is a formally smooth A-algebra.

Proposition (22.6.4). — *Let* A *be a ring,* B *a formally smooth* A*-algebra (for the discrete topologies),* $\mathfrak{J}$ *an ideal of* B, $\mathrm{C} = \mathrm{B}/\mathfrak{J}$*; suppose that* $\mathfrak{J}/\mathfrak{J}^2$ *is a* C*-module of finite type. Let* $\mathfrak{p}$ *be a prime ideal of* C, $k(\mathfrak{p})$ *the residue field of* $\mathrm{C}_\mathfrak{p}$, $\mathfrak{p}'$ *the inverse image of* $\mathfrak{p}$ *in* B*, and* $\mathfrak{q}$ *the prime ideal of* A *which is the inverse image of* $\mathfrak{p}'$*. The following conditions are equivalent:*

a) $\mathrm{C}_\mathfrak{p}$ *is a formally smooth* $\mathrm{A}_\mathfrak{q}$*-algebra (for the discrete topologies).*

a′) $\mathrm{C}_\mathfrak{p}$ *is a formally smooth* A*-algebra (for the discrete topologies).*

b) The canonical homomorphism

$$(\mathfrak{J}/\mathfrak{J}^2) \otimes_{\mathrm{C}} k(\mathfrak{p}) \longrightarrow \Omega^1_{\mathrm{B}/\mathrm{A}} \otimes_{\mathrm{B}} k(\mathfrak{p}) \tag{22.6.4.1}$$

is injective.

c) There exists $f \in \mathrm{C} - \mathfrak{p}$ *such that* C_f *is a formally smooth* A*-algebra.*

If furthermore B *is* Noetherian*, the preceding conditions are also equivalent to:*

d) $\mathrm{C}_\mathfrak{p}$ *is a formally smooth* $\mathrm{A}_\mathfrak{q}$*-algebra for the* $\mathfrak{p}$*-preadic topology on* $\mathrm{C}_\mathfrak{p}$ *and the discrete topology (or the* $\mathfrak{q}$*-preadic topology) on* $\mathrm{A}_\mathfrak{q}$*.*

Proof. Since $\mathrm{A}_\mathfrak{q}$ is a formally smooth A-algebra (19.3.5), (iv) and (ii), conditions *a*) and *a′*) are already known to be equivalent (19.3.5), (ii). We have $\mathrm{C}_\mathfrak{p} = \mathrm{B}_{\mathfrak{p}'}/\mathfrak{J}\mathrm{B}_{\mathfrak{p}'}$, and $\mathrm{B}_{\mathfrak{p}'}$ is a formally smooth A-algebra for the discrete topology (19.3.5), (iv); moreover, $\Omega^1_{\mathrm{B}_{\mathfrak{p}'}/\mathrm{A}} = (\Omega^1_{\mathrm{B}/\mathrm{A}})_{\mathfrak{p}'}$ (20.5.9). The equivalence of *a′*) and *b*) therefore follows by applying (22.6.3) to $\mathrm{B}_{\mathfrak{p}'}$ and $\mathrm{C}_\mathfrak{p}$, taking into account that $\Omega^1_{\mathrm{B}/\mathrm{A}}$ is a projective B-module (20.4.9), (19.2.11), that $\mathfrak{J}/\mathfrak{J}^2$ is a B-module of finite type, and using (19.1.12). Applying (19.1.12) also proves the equivalence of *b*) and *c*). Finally, since $\mathrm{B}_{\mathfrak{p}'}$ is a formally smooth $\mathrm{A}_\mathfrak{q}$-algebra for the discrete topologies (19.3.5), (iv), it remains formally smooth when $B_{\mathfrak{p}'}$ is given its $\mathfrak{p}'$-preadic topology and $A_{\mathfrak{q}}$ is given either the discrete or the $\mathfrak{q}$-preadic topology (19.3.8). To prove the equivalence of *b*) and *d*) when B is Noetherian, apply (22.6.2) to $A_{\mathfrak{q}}$ with the discrete (or $\mathfrak{q}$-preadic) topology and to $B_{\mathfrak{p}'}$ with the $\mathfrak{p}'$-preadic topology. Since $C_{\mathfrak{p}}$ is preadmissible and $\mathfrak{p}C_{\mathfrak{p}}$ is an ideal of definition for its topology, the equivalence of *c*) and *a*) in (22.6.2) applies. □ $\mathbf{0_{IV\text{-}1}}$ | 207

Corollary (22.6.5). — *Under the general hypotheses of (22.6.4), the set of* $\mathfrak{p} \in \mathrm{Spec}(C)$ *such that* $C_{\mathfrak{p}}$ *is a formally smooth* A*-algebra (or a formally smooth* $A_{\mathfrak{q}}$*-algebra, where* $\mathfrak{q}$ *denotes the inverse image of* $\mathfrak{p}$ *in* A*), for the discrete topologies, is open in* $\mathrm{Spec}(C)$*.*

Proof. This follows from form *c*) of (22.6.4). Note that when B is Noetherian, one can replace the discrete topologies by the preadic topologies. □

Corollary (22.6.6). — *Under the general hypotheses of (22.6.4), the following conditions are equivalent:*

a) C *is a formally smooth* A*-algebra (for the discrete topologies).*

b) For every $\mathfrak{p} \in \mathrm{Spec}(C)$ *(or only for every* maximal *ideal* $\mathfrak{p}$ *of* C*),* $C_{\mathfrak{p}}$ *is a formally smooth* A*-algebra (or a formally smooth* $A_{\mathfrak{q}}$*-algebra, where* $\mathfrak{q}$ *denotes the inverse image of* $\mathfrak{p}$ *in* A*)* for the discrete topologies.

Furthermore, when B *is Noetherian, one can replace in b) the discrete topologies by the preadic topologies on* $A_{\mathfrak{q}}$ *and* $C_{\mathfrak{p}}$.

Proof. The last assertion follows from (22.6.4). By virtue of (22.6.3), condition *a*) is equivalent to the fact that the homomorphism (22.6.1.1) is invertible on the left; the equivalence of *a*) and *b*) therefore follows from (19.1.14), taking into account that $\Omega^1_{B/A}$ is a projective B-module and $\mathfrak{J}/\mathfrak{J}^2$ a C-module of finite type. □

Proposition (22.6.7). — *Let* k_0 *be a field,* k *a separable extension of* k_0*,* C *a* k*-algebra of finite type.*

(i) *Let* $\mathfrak{p}$ *be a prime ideal of* C*. The following conditions are equivalent:*

a) $C_{\mathfrak{p}}$ *is a* k_0*-algebra formally smooth for the discrete topology.*

b) $C_{\mathfrak{p}}$ *is a* k_0*-algebra formally smooth for the* $\mathfrak{p}$*-preadic topology.*

c) There exists $f \in C - \mathfrak{p}$ *such that* C_f *is a* k_0*-algebra formally smooth for the discrete topology.*

d) $C_{\mathfrak{p}}$ *is a geometrically regular ring over* k_0 (19.6.5).

Furthermore the set of $\mathfrak{p} \in \mathrm{Spec}(C)$ *having any of these properties is open in* $\mathrm{Spec}(C)$*.*

(ii) *The following conditions are equivalent:*

a) C *is a* k_0*-algebra formally smooth for the discrete topology.*

b) Every $\mathfrak{p} \in \mathrm{Spec}(C)$ *satisfies the equivalent conditions of (i).*

c) Every maximal ideal $\mathfrak{m}$ *of* C *satisfies the equivalent conditions of (i).*

d) For every extension k' *of* k_0*,* $C \otimes_{k_0} k'$ *is a regular ring* (17.3.6)*; we also say that* C *is a geometrically regular ring over* k_0*.*

$\mathbf{0_{IV\text{-}1}}$ | 208

(iii) *Let* $B = k[T_1, \dots, T_r]$ *be a polynomial algebra and* $\mathfrak{J}$ *an ideal of* B *such that* C *is isomorphic to* $B/\mathfrak{J}$*. Let* $\mathfrak{q}$ *be a prime ideal of* B *containing* $\mathfrak{J}$ *and set* $\mathfrak{p} = \mathfrak{q}/\mathfrak{J}$*. The conditions of (i) are then also equivalent to the following (the "Jacobian criterion of Zariski"):*

e) There exists a system $(f_i)_{1 \leqslant i \leqslant m}$ *of elements of* $\mathfrak{J}$ *generating the ideal* $\mathfrak{J}_{\mathfrak{q}}$ *in* $B_{\mathfrak{q}}$*, and* k_0*-derivations* D_j *of* B *into itself* $(1 \leqslant j \leqslant m)$*, such that* $\det(D_j(f_i)) \notin \mathfrak{q}$.

Proof. One knows that C is always isomorphic to a k-algebra of the form $B/\mathfrak{J}$. Since B is a formally smooth k-algebra (19.3.3), and k, being separable over k_0, is a formally smooth k_0-algebra (19.6.1), B is a formally smooth k_0-algebra (19.3.5), (ii). The equivalence of conditions *a*), *b*), *c*) of (i) therefore follows from (22.6.4), and that of *a*), *b*), *c*) in (ii) follows from (22.6.6); the equivalence of *a*) and *d*) in (i) follows from (22.5.8). Since every localization of $C \otimes_{k_0} k'$ is also a localization of $C_{\mathfrak{p}} \otimes_{k_0} k'$ for a suitable prime ideal $\mathfrak{p} \in \mathrm{Spec}(C)$, the equivalence of *d*) and *b*) in (ii) follows from the equivalence of *d*) and *a*) in (i). Finally, since Ω^1_{B/k_0} is a projective B-module, the equivalence of the Zariski criterion *e*) and the other conditions in (i) follows from (19.1.12) and (22.6.3), taking (20.4.8) into account. □

Zariski was in fact interested in a differential criterion of regularity for the local rings $C_{\mathfrak{p}}$. Since saying that a Noetherian local ring containing a field is regular is equivalent to saying that it is formally smooth as an algebra over its prime subfield (19.6.4), such a criterion follows immediately by replacing k_0 by the prime subfield of k in (22.6.7). In particular, one obtains the following result, which will be recovered later in (IV, 6.12.5) as a special case of more general results of Nagata:

Corollary (22.6.8). — (Zariski.) *Let* C *be an algebra of finite type over a field. Then the set of* $\mathfrak{p} \in \operatorname{Spec}(\mathrm{C})$ *such that* $\mathrm{C}_{\mathfrak{p}}$ *is a regular local ring is open in* $\operatorname{Spec}(\mathrm{C})$.

Remark (22.6.9). — (i) The statements of (22.6.7) are still valid if instead of supposing k separable over k_0, one assumes only that it is of *finite radiciel multiplicity*, that is to say (19.6.6) that there exists a finite radiciel extension k'_0 of k_0 such that the residue field of the local Artinian ring $k \otimes_{k_0} k'_0$ is a *separable* extension k' of k'_0. There exists then a k'_0-monomorphism $k' \to k \otimes_{k_0} k'_0$ which, composed with the canonical homomorphism $k \otimes_{k_0} k'_0 \to k'$, gives the identity, since k' is a formally smooth k'_0-algebra (19.6.1). One concludes that $\mathrm{C} \otimes_{k_0} k'_0$ is equipped with the structure of a k'-algebra of finite type, and since k' is separable over k'_0, one can apply (22.6.7) to this k'-algebra; the assertion follows by applying (19.4.7). Since we shall not need this generalization, we leave the details to the reader. We do not know whether the results of (22.6.7) are valid without *any* hypothesis on the extension k of k_0.

(ii) Under the general hypotheses of (22.6.7), let (k_α) be a decreasing filtering family of subfields of k containing k_0 and such that $\bigcap k_\alpha(k^p) = k_0(k^p)$ (where p is the characteristic exponent of k_0). Using a dimension counting method due to Nagata, one can show that, in the Jacobian criterion (22.6.7), (iii), one may restrict the derivations D_j of B to be k_α-derivations for a suitable α.

The interest of this result is that there always exist such families (k_α) for which $[k : k_\alpha]$ is finite (21.8.6). We shall not prove this refinement of the Zariski criterion, which we shall not need. In (22.7), we give, for complete local rings, a variant (also due to Nagata) of the Zariski criterion, proved essentially by the same method (with somewhat greater technical difficulties). $\mathbf{0}_{\mathbf{IV\text{-}1}}$ | 209

22.7. Nagata's Jacobian criterion

(22.7.1). The Jacobian criterion of Nagata is the analog of the Jacobian criterion of Zariski, but for quotient rings of *formal power series* rings over a field. We shall give, as Nagata [Nag57], two versions, presented here as criteria of formal smoothness.

Proposition (22.7.2). — *Let* k *be a field,* $\mathrm{A} = k[[\mathrm{T}_1, \ldots, \mathrm{T}_r]]$ *a formal power series ring, equipped with its usual* k*-algebra structure,* $\mathfrak{q}$ *an ideal of* A, $\mathrm{B} = \mathrm{A}/\mathfrak{q}$. *Let* $\mathfrak{p}$ *be a prime ideal of* A *containing* $\mathfrak{q}$. *Suppose that there exists a sub-*k*-algebra* C' *of* $\mathrm{C} = \mathrm{A}/\mathfrak{p}$, *isomorphic to a formal power series ring* $k[[\mathrm{X}_1, \ldots, \mathrm{X}_s]]$, *such that* C *is finite over* C' *and that the field of fractions* L *of* C *is a separable extension of* $\mathrm{L}' = k((\mathrm{X}_1, \ldots, \mathrm{X}_s))$ *(this hypothesis is always satisfied if* k *is of characteristic* 0*). Then the following conditions are equivalent:*

- *a)* $\mathrm{B}_{\mathfrak{p}} = \mathrm{A}_{\mathfrak{p}}/\mathfrak{q}\mathrm{A}_{\mathfrak{p}}$ *is a* k*-algebra formally smooth for the* $\mathfrak{p}$*-preadic topology.*
- *b) There exist* k*-derivations* D_i *of* A *into itself* $(1 \leqslant i \leqslant m)$, *and elements* f_i *of* $\mathfrak{q}$ $(1 \leqslant i \leqslant m)$, *such that the images of the* f_i *in* $\mathfrak{q}\mathrm{A}_{\mathfrak{p}}$ *generate this ideal of* $\mathrm{A}_{\mathfrak{p}}$, *and that* $\det(\mathrm{D}_i f_j) \notin \mathfrak{p}$.
- *c)* $\mathrm{B}_{\mathfrak{p}}$ *is a regular ring.*

Proof. The residue field of $\mathrm{B}_{\mathfrak{p}}$ is $k(\mathfrak{p})$. Since $k((\mathrm{X}_1, \ldots, \mathrm{X}_s))$ is separable over k (21.9.6.4), the field $k(\mathfrak{p}) = \mathrm{L}$ is separable over k by hypothesis; hence conditions *a*) and *c*) are equivalent by (19.6.4). Furthermore, $\mathrm{A}_{\mathfrak{p}}$ is regular (17.1.4), (17.3.2), and therefore formally smooth over k for its $\mathfrak{p}$-preadic topology (19.6.4). By (22.6.2), (ii), condition *a*) is consequently equivalent to injectivity of

(22.7.2.1) $$j_0 : (\mathfrak{q}/\mathfrak{q}^2) \otimes_{\mathrm{A}} \mathrm{L} \longrightarrow \Omega^1_{\mathrm{A}_{\mathfrak{p}}/k} \otimes_{\mathrm{A}_{\mathfrak{p}}} \mathrm{L} = \widehat{\Omega}^1_{\mathrm{A}/k} \otimes_{\mathrm{A}} \mathrm{L}.$$

Consider also

(22.7.2.2) $$j : (\mathfrak{q}/\mathfrak{q}^2) \otimes_{\mathrm{A}} \mathrm{L} \xrightarrow{j_0} \Omega^1_{\mathrm{A}/k} \otimes_{\mathrm{A}} \mathrm{L} \longrightarrow \widehat{\Omega}^1_{\mathrm{A}/k} \otimes_{\mathrm{A}} \mathrm{L}.$$

We show first that *b*) is equivalent to injectivity of j. Indeed,

$$(\mathfrak{q}/\mathfrak{q}^2) \otimes_{\mathrm{A}} \mathrm{L} = (\mathfrak{q}\mathrm{A}_{\mathfrak{p}}/\mathfrak{q}^2\mathrm{A}_{\mathfrak{p}}) \otimes_{\mathrm{A}_{\mathfrak{p}}} \mathrm{L}.$$

If $F_i = j(f'_i \otimes 1)$, condition *b*) says that the matrix $(\langle F_i, \mathrm{D}_j \otimes 1\rangle)$ is invertible. Thus the F_i, and hence the generators $f'_i \otimes 1$, are linearly independent, so j is injective. Conversely, if j is injective, choose f_i so that the $f'_i \otimes 1$ form a basis of the source. Then the F_i are linearly independent. By (21.9.3), $\widehat{\Omega}^1_{A/k}$ is free of rank r, and the k-derivations of A into itself generate its dual; hence there exist derivations D_j for which $(\langle F_i, D_j \otimes 1\rangle)$ is invertible. This is condition b). **$0_{IV\text{-}1}$** | 210

These observations show already that b) implies a). Conversely, assume a), so that j_0 is injective, and consider

$$\begin{array}{ccc} (\mathfrak{q}/\mathfrak{q}^2)\otimes_A L & \xrightarrow{j} & \widehat{\Omega}^1_{A/k}\otimes_A L \\ {\scriptstyle\alpha}\downarrow & & \| \\ (\mathfrak{p}/\mathfrak{p}^2)\otimes_A L & \xrightarrow[i]{} & \widehat{\Omega}^1_{A/k}\otimes_A L. \end{array} \tag{22.7.2.3}$$

We shall use the following lemma. □

Lemma (22.7.2.4). — *Let* R *be a regular local ring,* $\mathfrak{m}$ *its maximal ideal,* $K = R/\mathfrak{m}$ *its residue field. If* $\mathfrak{n}$ *is an ideal of* R *such that* $R/\mathfrak{n}$ *is regular, then the canonical homomorphism*

$$\alpha : (\mathfrak{n}/\mathfrak{n}^2)\otimes_R K \longrightarrow (\mathfrak{m}/\mathfrak{m}^2)\otimes_R K \tag{22.7.2.5}$$

is injective.

Proof. Indeed, one knows (17.1.6) that $\mathfrak{n}$ is generated by a subset $(x_i)_{1\leqslant i\leqslant l}$ forming part of a regular system of parameters $(x_i)_{1\leqslant i\leqslant n}$ of R; the images of the x_i for $1\leqslant i\leqslant l$ form a base of $(\mathfrak{n}/\mathfrak{n}^2)\otimes_R K$, and their images by α form part of the base of $(\mathfrak{m}/\mathfrak{m}^2)\otimes_R K$ formed by the images of the x_i for $1\leqslant i\leqslant n$, from which the lemma. □

Continuation of the proof of Proposition (22.7.2). By the lemma and the diagram (22.7.2.3), it remains only to prove that i is injective. Consider the sequence

$$\mathfrak{p}/\mathfrak{p}^2 \xrightarrow{h} \widehat{\Omega}^1_{A/k}\widehat{\otimes}_A(A/\mathfrak{p}) \xrightarrow{g} \widehat{\Omega}^1_{(A/\mathfrak{p})/k} \longrightarrow 0. \tag{22.7.2.6}$$

By (20.7.20), g is surjective and the image of h is dense in $\operatorname{Ker}(g)$ for the $\mathfrak{m}$-adic topology. Since $\widehat{\Omega}^1_{A/k}$ is an A-module of finite type, every submodule of

$$\widehat{\Omega}^1_{A/k}\otimes_A(A/\mathfrak{p}) = \widehat{\Omega}^1_{A/k}\widehat{\otimes}_A(A/\mathfrak{p})$$

is closed for the $\mathfrak{m}$-adic topology (**I**, 7.3.5); therefore (22.7.2.6) is exact. After tensoring with L, one obtains the exact sequence

$$(\mathfrak{p}/\mathfrak{p}^2)\otimes_A L \xrightarrow{i} \widehat{\Omega}^1_{A/k}\otimes_A L \longrightarrow \widehat{\Omega}^1_{(A/\mathfrak{p})/k}\otimes_{A/\mathfrak{p}} L \longrightarrow 0.$$

The separability hypothesis and (21.9.5) show that the last module has rank s over L; the middle module has rank r by (21.9.3). Thus $\operatorname{rg}_L(\operatorname{Im} i) = r - s$. Since $A/\mathfrak{p}$ is finite over a subalgebra isomorphic to $k[[T_1,\ldots,T_s]]$, one has $\dim(A/\mathfrak{p}) = s$ by (17.1.4) and (16.1.5), and hence

$$r - s = \dim(A) - \dim(A/\mathfrak{p}) = \dim(A_\mathfrak{p})$$

by (16.5.11). Finally, $A_\mathfrak{p}$ is regular, so $\dim(A_\mathfrak{p})$ is the rank over L of $(\mathfrak{p}/\mathfrak{p}^2)\otimes_A L$ (17.1.1). The source and image of i therefore have the same rank, and i is injective. □ **$0_{IV\text{-}1}$** | 211

Theorem (22.7.3). — *Let k be a field,* A *a local Noetherian complete ring with residue field* K. *Suppose that:*

1° $[k : k^p] < +\infty$ *(where p is the characteristic exponent of k);*
2° K *is a finite extension of a separable extension* K_0 *of k;*
3° A *is equipped with a structure of* K_0*-algebra formally smooth (for the preadic topology).*

Let $\mathfrak{q}$ *be an ideal of* A, $B = A/\mathfrak{q}$, $\mathfrak{p}$ *a prime ideal of* A *containing* $\mathfrak{q}$. *The following conditions are equivalent:*

a) $B_\mathfrak{p}$ *is a k-algebra formally smooth for the* $\mathfrak{p}$*-preadic topology.*
b) *There exist k-derivations* D_i *of* A *into itself* $(1\leqslant i\leqslant m)$, *and elements* f_i $(1\leqslant i\leqslant m)$ *of* $\mathfrak{q}$, *such that the images of the* f_i *in* $\mathfrak{q}A_\mathfrak{p}$ *generate this ideal of* $A_\mathfrak{p}$, *and that* $\det(D_i f_j) \notin \mathfrak{p}$.
b') *There exists a sub-extension k' of* K_0, *containing* K_0^p, *such that* $[K_0 : k'] < +\infty$, *k'-derivations* D_i *of* A *into itself, and elements* f_i *of* $\mathfrak{q}$ $(1\leqslant i\leqslant m)$, *such that the images of the* f_i *in* $\mathfrak{q}A_\mathfrak{p}$ *generate this ideal of* $A_\mathfrak{p}$, *and that* $\det(D_i f_j) \notin \mathfrak{p}$.

Proof. We distinguish two cases, according to whether $p = 1$ or $p > 1$.

A) k is of characteristic 0. Since K is then a separable extension of K_0, (19.6.4) shows that A is K_0-isomorphic to a formal power series ring $K[[T_1, \ldots, T_r]]$ equipped with its usual K-algebra structure. Taking (19.8.8), (ii), applied to $A/\mathfrak{p}$ into account, the general hypotheses of (22.7.2) are satisfied after replacing k by K. Moreover, by (19.6.4), saying that $B_\mathfrak{p}$ is formally smooth as a k-algebra or as a K-algebra amounts to the same thing, both conditions being equivalent to regularity of $B_\mathfrak{p}$. We may therefore apply (22.7.2), which immediately proves the equivalence of *a*), *b*), and *b′*) (with $k' = K_0$ in *b′*)).

B) k is of characteristic $p > 0$. Since A is a formally smooth K_0-algebra and K_0 is separable over k, it follows from (19.3.5), (ii), and (19.6.1) that A is a formally smooth k-algebra; by (22.5.9), $A_\mathfrak{p}$ is also formally smooth over k for the $\mathfrak{p}$-preadic topology. It follows therefore from (22.6.2), (ii) that the condition *a*) is equivalent to the fact that the homomorphism j_0 defined in (22.7.2.1) (where $L = k(\mathfrak{p})$) is injective. Therefore (19.1.12), *c*) shows already that *b*) implies *a*); and since moreover *b′*) trivially implies *b*), it all amounts to showing that the hypothesis that j_0 is injective implies *b′*).

Let us first denote by k' a sub-extension of K_0 such that $[K_0 : k'] < +\infty$. Note that $\widehat{\Omega}^1_{A/k'}$ is a free A-module of finite type. By the argument of (22.7.2), it is enough to prove that (for a suitable choice of k') the composite homomorphism

(22.7.3.1) $$j' : (\mathfrak{q}/\mathfrak{q}^2) \otimes_A L \xrightarrow{j_0} \Omega^1_{A/k} \otimes_A L \longrightarrow \widehat{\Omega}^1_{A/k'} \otimes_A L$$

is injective. Consider again the commutative diagram **$0_{IV\text{-}1}$** | 212

(22.7.3.2) $$\begin{array}{ccccc} (\mathfrak{q}/\mathfrak{q}^2) \otimes_A L & \xrightarrow{j_0} & \Omega^1_{A/k} \otimes_A L & \longrightarrow & \widehat{\Omega}^1_{A/k'} \otimes_A L \\ {\scriptstyle\alpha}\big\downarrow & & \big\| & & \big\| \\ (\mathfrak{p}/\mathfrak{p}^2) \otimes_A L & \xrightarrow[i_0]{} & \Omega^1_{A/k} \otimes_A L & \longrightarrow & \widehat{\Omega}^1_{A/k'} \otimes_A L \end{array}$$

Since j_0 is injective, we have $\operatorname{Ker}(i_0 \circ \alpha) = 0$. But as $A_\mathfrak{p}$ is regular, and the hypothesis *a*) implies that $B_\mathfrak{p} = A_\mathfrak{p}/\mathfrak{q}A_\mathfrak{p}$ is also regular (19.6.5), the lemma (22.7.2.4) shows that α is injective, from which $\alpha^{-1}(\operatorname{Ker}(i_0)) = 0$. If i' is the composite homomorphism of the second line of (22.7.3.2), one likewise has $\operatorname{Ker}(j') = \alpha^{-1}(\operatorname{Ker}(i'))$; it therefore remains to prove that, for a suitable choice of k',

(22.7.3.3) $$\operatorname{Ker}(i') = \operatorname{Ker}(i).$$

But the same argument as in (22.7.2) gives an exact sequence

$$(\mathfrak{p}/\mathfrak{p}^2) \otimes_A L \xrightarrow{i'} \widehat{\Omega}^1_{A/k'} \otimes_A L \longrightarrow \widehat{\Omega}^1_{(A/\mathfrak{p})/k'} \otimes_{A/\mathfrak{p}} L \longrightarrow 0.$$

The hypotheses allow us to apply (21.9.8); hence there exists a sub-extension k' of K_0 containing K_0^p, with $[K_0 : k'] < +\infty$, for which

$$\operatorname{rg}_L\big(\widehat{\Omega}^1_{(A/\mathfrak{p})/k'} \otimes_{A/\mathfrak{p}} L\big) = \dim(A/\mathfrak{p}) + \operatorname{rg}_L Y_{L/k} + \operatorname{rg}_{K_0} \Omega^1_{K_0/k'}.$$

But

$$\dim(A/\mathfrak{p}) = \dim(A) - \dim(A_\mathfrak{p})$$

by (16.5.11),

$$\dim(A_\mathfrak{p}) = \operatorname{rg}_L\big((\mathfrak{p}/\mathfrak{p}^2) \otimes_A L\big)$$

because $A_\mathfrak{p}$ is regular (17.1.1), and

$$\dim(A) + \operatorname{rg}_{K_0} \Omega^1_{K_0/k'} = \operatorname{rg}_L\big(\widehat{\Omega}^1_{A/k'} \otimes_A L\big)$$

by (21.9.2). Consequently

(22.7.3.4) $$\operatorname{rg}_L(\operatorname{Ker}(i')) = \operatorname{rg}_L Y_{L/k}.$$

On the other hand, since the residue field of $A_\mathfrak{p}$ is formally smooth over the prime field of k, there is an exact sequence (20.6.22.1)

$$Y_{L/k} \xrightarrow{\chi_{A_\mathfrak{p}/k}} (\mathfrak{p}A_\mathfrak{p})/(\mathfrak{p}A_\mathfrak{p})^2 \xrightarrow{i} \Omega^1_{A_\mathfrak{p}/k} \otimes_{A_\mathfrak{p}} L.$$

Since $A_{\mathfrak{p}}$ is a formally smooth k-algebra for the $\mathfrak{p}$-preadic topology, (22.2.2) shows that $\chi_{A_{\mathfrak{p}}/k}$ is injective. Thus $\mathrm{Ker}(i)$ is isomorphic to $Y_{L/k}$; taking (22.7.3.4) and $\mathrm{Ker}(i) \subset \mathrm{Ker}(i')$ into account proves (22.7.3.3), and hence the theorem. □

$\mathbf{0}_{\mathbf{IV}\text{-}\mathbf{1}}$ | 213

Remark (22.7.4). — It was shown in fact (using (21.9.6)) that condition b') is even equivalent to the other conditions of (22.7.3) when one subjects k' to be one of the fields of a decreasing filtering family (k_α) of subfields of K_0, containing K_0^p, such that $[K_0 : k_\alpha] < +\infty$ for every α and that $\bigcap k_\alpha = K_0^p$.

Corollary (22.7.5). — *Under the general hypotheses of (22.7.3), the set of prime ideals* $\mathfrak{n} \in \mathrm{Spec}(B)$ *such that* $B_{\mathfrak{n}}$ *is a k-algebra formally smooth (for the* $\mathfrak{n}$*-preadic topology) is open in* $\mathrm{Spec}(B)$.

Proof. With the notations of (22.7.3), it suffices to see that if $B_{\mathfrak{p}}$ is formally smooth over k, then the same is true of $B_{\mathfrak{p}'}$ for every $\mathfrak{p}' \in V(\mathfrak{q})$ sufficiently near to $\mathfrak{p}$ in $\mathrm{Spec}(A)$. But, if the k-derivations D_i and the elements f_i of $\mathfrak{q}$ satisfy criterion b) of (22.7.3), one has also $f = \det(D_i f_j) \notin \mathfrak{p}'$ for every $\mathfrak{p}' \in D(f)$; on the other hand, there exists $g \notin \mathfrak{p}$ such that the images of f_i in $\mathfrak{q}A_{\mathfrak{p}'}$ generate this ideal of $A_{\mathfrak{p}'}$ for every $\mathfrak{p}' \in D(g)$, which finishes the proof of the corollary. □

Corollary (22.7.6). — (Nagata.) *Let* B *be a local Noetherian complete ring containing a field. Then the set of* $\mathfrak{n} \in \mathrm{Spec}(B)$ *such that* $B_{\mathfrak{n}}$ *is regular is open in* $\mathrm{Spec}(B)$.

Proof. Indeed, B is an algebra over a *prime* field k, hence by (19.8.8, ii) it is of the form $A/\mathfrak{q}$, where $A = K_0[[T_1, \ldots, T_n]]$ is a formal power series ring and K_0 an extension of k; on the other hand, saying that $B_{\mathfrak{n}}$ is regular is equivalent to saying that it is a k-algebra formally smooth for the $\mathfrak{n}$-preadic topology (19.6.4). All the conditions of application of (22.7.5) are thus realized. □

Remark (22.7.7). —

(i) We shall see further on, using (22.7.6), that the conclusion of (22.7.6) can be extended to the case of any complete Noetherian local ring (**IV**, 6.12.7).

(ii) The conclusion of the theorem (22.7.3) is no longer necessarily exact when one no longer assumes that $[k : k^p]$ is finite. Take for example $k = \mathbf{F}_p(X_n)_{n\geqslant 0}$, $A = k[[T, U]]$, $\mathfrak{q}$ the principal ideal Af, where $f = U^p - \sum_{n=0}^{\infty} X_n T^{np}$; A is a factorial ring in which f is an extremal element, for it is extremal in the polynomial ring $k((T))[U]$, hence also in the formal power series ring $k((T))[[U]]$ (Bourbaki, *Alg. comm.*, chap. VII, § 3), and *a fortiori* in A. Take $\mathfrak{p} = \mathfrak{q}$, so that $B_{\mathfrak{p}}$ is the field of fractions denoted by E in (21.9.7), which is separable over k (*loc. cit.*), hence a k-algebra formally smooth. But one has, with the notations of (22.7.3), $k = K_0 = K$, and the k-derivations of A into itself are combinations of $\partial/\partial T$ and $\partial/\partial U$; as one has $\partial f/\partial T = \partial f/\partial U = 0$, the criteria b) and b') of (22.7.3) are not satisfied.

§23. Japanese rings

The results of this section will be completed in **IV**, (**IV**, 7.6) and (**IV**, 7.7). $\mathbf{0}_{\mathbf{IV}\text{-}\mathbf{1}}$ | 213

23.1. Japanese rings

Definition (23.1.1). — We say that an integral ring A is a *Japanese ring* if, for every finite extension K' of its field of fractions K, the integral closure A' of A in K' is an A-module of finite type (in other words, a finite A-algebra). We say that a ring A is *universally Japanese* if every integral A-algebra of finite type is a Japanese ring. $\mathbf{0}_{\mathbf{IV}\text{-}\mathbf{1}}$ | 214

It is clear that if A is a Japanese ring, then every ring of fractions $S^{-1}A$ is also a Japanese ring, since (with the preceding notation) $S^{-1}A'$ is the integral closure of $S^{-1}A$ in K', and is evidently an $S^{-1}A$-module of finite type.

A Noetherian integral ring, even a *discrete valuation ring*, is not necessarily a Japanese ring [Nag62].

Proposition (23.1.2). — *Let A be a Noetherian integral ring, K its field of fractions. If, for every finite radicial extension K' of K, the integral closure of A in K' is an A-module of finite type, then A is a Japanese ring.*

Proof. Since A is Noetherian, it suffices, to verify that A is a Japanese ring, to see that for every finite *quasi-Galois* extension L of K, the integral closure B of A in L is an A-module of finite type. Now L is a *Galois* extension of the largest *radicial* extension K' of K contained in L; and if A' is the integral closure of A in K', B is the integral closure of A' in L. But we know that in a *separable* extension, the integral closure of A' is an A'-module of finite type (Bourbaki, *Alg. comm.*, chap. V, §1, n° 6, cor. 1 of prop. 20), whence the proposition. □

It follows from (23.1.2) that when K is of *characteristic* 0, saying that A is a Japanese ring means that its *integral closure* A' is an A-module of finite type.

Theorem (23.1.3). — (Tate) *Let A be a Noetherian integral ring, $x \neq 0$ an element of A. Suppose the following conditions are satisfied:*

(i) *A is integrally closed.*
(ii) *$\mathfrak{p} = xA$ is prime and A is separated and complete for the $\mathfrak{p}$-preadic topology.*
(iii) *A/xA is a Japanese ring.*

Then A is a Japanese ring.

We will use the following lemma:

Lemma (23.1.3.1). — *Let A be a ring, x an element of A that is a non-zero-divisor in A and such that $xA = \mathfrak{p}$ is prime; then, for every integer $n > 0$, the inverse image of $x^n A_{\mathfrak{p}}$ in A is $x^n A$.*

Proof. Indeed, suppose that $b \in A$ is an element such that $b/1 = x^n a/s$ in $A_{\mathfrak{p}}$, where $a \in A$ and $s \notin \mathfrak{p}$; then there exists $s' \notin \mathfrak{p}$ such that $s'sb = x^n as'$, whence $s'sb \in \mathfrak{p}$, and since $s's \notin \mathfrak{p}$, this implies $b \in \mathfrak{p}$, that is to say $b = xb'$ with $b' \in A$; since x is a non-zero-divisor, we conclude that $s'sb' = x^{n-1}as$, and it suffices to argue by induction on n. □

Proof of Theorem (23.1.3). To prove the theorem, we can restrict to the case where the field of fractions K of A is of characteristic $p > 0$, since A is integrally closed. Let K' be a finite radicial extension of K, so that there exists a power $q = p^e$ such that $K'^q \subset K$; by replacing K' by a larger radicial extension, we may even suppose that there exists $y \in K'$ such that $y^q = x$. Let A' be the integral closure of A in K'; since A is integrally closed, A' is the set of $x' \in K'$ such that $x'^q \in A' \cap K = A$. Set $V = A_{\mathfrak{p}}$; the maximal ideal $\mathfrak{m} = xV$ of V being principal, we know that the local Noetherian ring V is a *discrete valuation ring* (17.1.4); since V is integrally closed, the same argument as above shows $\mathbf{0_{IV\text{-}1}}$ | 215 that the integral closure V' of V in K' is the set of $x' \in K'$ such that $x'^q \in V$; we know (Bourbaki, *Alg. comm.*, chap. VI, §8, n° 6, prop. 6, and chap. V, §2, n° 3, lemma 4) that V' is a *discrete valuation ring*, whose maximal ideal $\mathfrak{m}'$ is the set of $x' \in K'$ such that $x'^q \in \mathfrak{m}$, and moreover the residue field $V'/\mathfrak{m}'$ is a *finite* extension of $V/\mathfrak{m}$ (*loc. cit.*, chap. VI, §8, n° 1, lemma 2). Let us show that, for every integer $n > 0$, we have

(23.1.3.2) $$\mathfrak{m}'^n \cap A' = y^n A'.$$

Indeed, since $y^q = x$, we have $y \in \mathfrak{m}'$, hence $y^n A' \subset \mathfrak{m}'^n \cap A'$. Conversely, let $x' \in \mathfrak{m}'^n \cap A'$, and set $x' = z'y^n$ with $z' \in K'$. We have $x'^q \in A'$; on the other hand, x' is a sum of products $t'_1 \cdots t'_n$ with $t'_i \in \mathfrak{m}'$, hence $t'^q_i \in \mathfrak{m}$, and we conclude that $x'^q \in \mathfrak{m}^n \cap A$. Now the lemma (23.1.3.1) proves that $\mathfrak{m}^n \cap A = x^n A$, hence we have $z'^q x^n \in x^n A$, or equivalently $z'^q \in A$ since $x \neq 0$, which establishes (23.1.3.2).

Let us show secondly that on A' the xA'-preadic topology is *separated*; this topology is also the yA'-preadic topology of A', and it follows from (23.1.3.2) that this topology is induced by the $\mathfrak{m}'$-*preadic* topology of V', which is separated since V' is a discrete valuation ring.

Let us then prove that A'/xA' is an A-module of *finite type*. Since $x = y^q$ and $y^k A'/y^{k+1}A'$ is isomorphic to A'/yA', it suffices to show that A'/yA' is an A-module of finite type; but the formula (23.1.3.2) applied for $n = 1$ shows that A'/yA' is a subring of $V'/\mathfrak{m}'$, that is to say of the *residue field* of V', which is a *finite* extension of the residue field $V/\mathfrak{m}$. Now $V/\mathfrak{m}$ is the field of fractions of $A/\mathfrak{p}$, and since A' is integral over A, A'/yA' is integral over $A/\mathfrak{p}$, hence contained in the integral closure of $A/\mathfrak{p}$ in $V'/\mathfrak{m}'$; since by hypothesis $A/\mathfrak{p}$ is a Japanese Noetherian ring, A'/yA' is an $(A/\mathfrak{p})$-module of finite type, and *a fortiori* an A-module of finite type.

This being the case, the xA'-preadic topology of A' being separated, A' is a subring of its completion $\widehat{A}'$ for this topology; but since A'/xA' is an A-module of finite type and A is separated and complete for the xA-preadic topology, $\widehat{A}'$ is an A-module of finite type by virtue of ($\mathbf{0}_{\mathbf{I}}$, 7.2.9), hence so is A'. ☐

Corollary (23.1.4). — *Let A be a Japanese Noetherian and integrally closed ring. Then every formal power series ring $A[[T_1, \ldots, T_r]]$ is a Japanese ring.*

Proof. We know that for every integrally closed Noetherian ring B, the formal power series ring $B[[T]]$ is Noetherian and integrally closed (Bourbaki, *Alg. comm.*, chap. V, §1, nº 4, prop. 14); we can thus, by induction on n, restrict to proving that $A[[T]]$ is a Japanese ring. Now the element $x = T$ satisfies all the conditions of (23.1.3), whence the conclusion. ☐

Theorem (23.1.5). — (Nagata) *Every complete local Noetherian integral ring A is a Japanese ring.*

Proof. We know (19.8.8, ii) that there exists a subring B of A that is a complete local ring and is in addition *regular*, such that A is a finite B-algebra; it clearly suffices to prove that B is a Japanese ring, that is to say, we can restrict to the case where A is in addition regular. Let us argue by induction on $n = \dim(A)$, the theorem being evident for $n = 0$. Suppose then $n > 0$, and, denoting by $\mathfrak{m}$ the maximal ideal of A, let x be an element of $\mathfrak{m} - \mathfrak{m}^2$; we know (17.1.8) that A/xA is a regular ring, and in addition ((17.1.7) and (16.3.4)) that $\dim(A/xA) = n - 1$; moreover, the ideal xA is closed in A ($\mathbf{0}_{\mathbf{I}}$, 7.3.5), hence A/xA is complete. By the induction hypothesis, A/xA is thus a Japanese ring, and it then follows from (23.1.3) that the same is true of A. ☐ $\mathbf{0}_{\mathbf{IV\text{-}1}}$ | 216

Corollary (23.1.6). — *Let A be a complete local Noetherian integral ring, K its field of fractions, K' a finite extension of K; then the integral closure A' of A in K' is a complete local ring.*

Proof. We already know from (23.1.5) that A' is a finite A-algebra, hence a complete semi-local Noetherian ring, and consequently a *direct product* of local rings; but since A' is integral, it is necessarily a local ring. ☐

Proposition (23.1.7). — *Let A be a local Noetherian integral ring, K its field of fractions, K' a finite extension of K, A' the integral closure of A in K'. Suppose that the completion $\widehat{A}$ is reduced, and let R denote its total ring of fractions.*

(i) *If the ring $R \otimes_K K'$ is* reduced *(which will be the case in particular when K' is a* separable *extension of K, R being a direct product of fields, hence extensions of K* (Bourbaki, *Alg.*, chap. VIII, §7, nº 3, cor. 1 of th. 1)*), then A' is an A-module of finite type.*

(ii) If in particular R is a separable K-algebra, then A is a Japanese ring.

Proof. (i). Set $A_1 = \widehat{A}$, $A'_1 = A' \otimes_A A_1$, $K'_1 = K' \otimes_A A_1$. Since A_1 is a flat A-module ($\mathbf{0}_{\mathbf{I}}$, 7.3.5), A'_1 is identified with a subring of K'_1 and is evidently integral over A_1. On the other hand, if we set $K_1 = K \otimes_A A_1$, we can write $K'_1 = K' \otimes_K K_1$; since A is integral and A_1 is a flat A-module, every element $\neq 0$ of A is A_1-regular ($\mathbf{0}_{\mathbf{I}}$, 6.3.4); since $K = S^{-1}A$, where $S = A - \{0\}$, we have $K_1 = S^{-1}A_1$, and the preceding remark proves that K_1 is identified with a *subring* of the total ring of fractions R of A_1. Since every K-module is flat, K'_1 is identified with a *subring* of $K' \otimes_K R$, which by hypothesis is *reduced* and is a *finite* R-algebra. Denoting by $\mathfrak{q}_i$ ($1 \leqslant i \leqslant n$) the minimal prime ideals of A_1, by B_i the integral ring $A_1/\mathfrak{q}_i$, by L_i the field of fractions of B_i, we see that R is the direct product of the L_i, and $K' \otimes_K R$ the direct product of the $K' \otimes_K L_i$; these latter K-algebras, being reduced, are direct products of fields, *finite* extensions of the L_i. Since B_i is a complete local Noetherian integral ring, the theorem of Nagata (23.1.5) proves that the integral closure of B_i in $K' \otimes_K L_i$ is a B_i-module of finite type, and *a fortiori* an A_1-module of finite type; since every element of $K' \otimes_K L_i$ that is integral over A_1 is also integral over B_i (being annihilated by $\mathfrak{q}_i$), we conclude finally that the integral closure of A_1 in $K' \otimes_K R$ is an A_1-module of finite type. But since A'_1 is contained in this integral closure and A_1 is Noetherian, A'_1 is also an A_1-module of finite type. Finally, since A_1 is a faithfully flat A-module ($\mathbf{0}_{\mathbf{I}}$, 7.3.5), we conclude that A' is an A-module of finite type (Bourbaki, *Alg. comm.*, chap. I, §3, nº 6, prop. 11).

(ii). The hypothesis implies that the L_i are separable extensions of K, hence $K' \otimes_K L_i$ is reduced (Bourbaki, *Alg.*, chap. VIII, §7, n° 3, th. 1) and we can apply (i) to *every* finite extension K' of K, which proves our assertion. □ $\mathbf{0_{IV\text{-}1}}$ | 217

23.2. Integral closure of a local Noetherian integral ring

(23.2.1). In what follows, for every ring A, we will write A_{red} for short for the quotient of A by its nilradical (so that if $X = \operatorname{Spec}(A)$, we have $X_{\mathrm{red}} = \operatorname{Spec}(A_{\mathrm{red}})$). We will say that a *local* ring A is *unibranch* if A_{red} is integral and if the integral closure of A_{red} is a *local* ring, which generalizes the definition given in (**III**, 4.3.6). We will say that A is *geometrically unibranch* if it is unibranch and if the residue field of the local ring that is the integral closure of A_{red} is a *radicial* extension of that of A. It is clear that a local ring that is integrally closed is geometrically unibranch; it follows from (23.1.6) that a complete local Noetherian integral ring is unibranch.

Lemma (23.2.2). — *Let A be an integral ring, A' its integral closure; for the canonical morphism $f : \operatorname{Spec}(A') \to \operatorname{Spec}(A)$ to be radiciel, it is necessary and sufficient that for every $\mathfrak{p} \in \operatorname{Spec}(A)$, $A_{\mathfrak{p}}$ be geometrically unibranch; when this is so, f is a homeomorphism.*[24]

Proof. Indeed, for every $\mathfrak{p} \in \operatorname{Spec}(A)$, the integral closure of $A_{\mathfrak{p}}$ is $A'_{\mathfrak{p}}$ (Bourbaki, *Alg. comm.*, chap. V, §1, n° 5, prop. 16), and all the prime ideals of $A'_{\mathfrak{p}}$ above $\mathfrak{p}A_{\mathfrak{p}}$ are maximal (*loc. cit.*, §2, n° 1, prop. 1). Saying that f is *injective* thus means that for every $\mathfrak{p} \in \operatorname{Spec}(A)$, $A'_{\mathfrak{p}}$ is a *local* ring, that is to say that the $A_{\mathfrak{p}}$ are unibranch. Saying that every $A_{\mathfrak{p}}$ is geometrically unibranch then means that f is radiciel by virtue of (**I**, 3.5.8). When this is so, f is surjective and closed (**II**, 6.1.10), hence a homeomorphism. □

Lemma (23.2.3). — *Let A be an integral ring, K its field of fractions, B a Noetherian ring, $\phi : A \to B$ a ring homomorphism making B an A-module that is flat. Let K' be an extension of K; set $B_1 = B_{\mathrm{red}}$, and let R be the total ring of fractions of B_1. Then, for every sub-A-algebra A' of K', the canonical homomorphism*

$$(A' \otimes_A B)_{\mathrm{red}} \longrightarrow (K' \otimes_A R)_{\mathrm{red}} \tag{23.2.3.1}$$

is injective.[25]

Proof. We can in fact consider the canonical homomorphism $h : A' \otimes_A B \to K' \otimes_A R$ as the composition of the following homomorphisms

$$A' \otimes_A B \xrightarrow{u} K' \otimes_A B \xrightarrow{v} K' \otimes_A B_1 \xrightarrow{w} K' \otimes_A R.$$

Since B is a flat A-module, u is injective; similarly, K' being a flat K-module and K a flat A-module, K' is a flat A-module, and w is therefore injective since B_1 is reduced, hence the homomorphism $B_1 \to R$ is injective. Finally, for the same reason, if $\mathfrak{N}$ is the nilradical of B, the kernel of v is $K' \otimes_A \mathfrak{N}$, hence it is contained in the nilradical of $K' \otimes_A B$; we immediately conclude that if the image by $h = w \circ v \circ u$ of an element $x \in A' \otimes_A B$ is nilpotent, then x is nilpotent, which proves the lemma. □ $\mathbf{0_{IV\text{-}1}}$ | 218

Proposition (23.2.4). — *Let A be an integral ring, K its field of fractions, B a Noetherian ring, $\mathfrak{q}_i$ $(1 \leqslant i \leqslant n)$ its minimal prime ideals, $\phi : A \to B$ a ring homomorphism. Suppose that the $B/\mathfrak{q}_i$ are Japanese rings, and that B is a flat A-module. Let K' be a finite extension of K, and let (C_α) be the increasing filtering family of subrings of K' that are finite A-algebras and admit K' as their field of fractions; the union A' of the C_α is thus the integral closure of A in K'. Then:*

(i) *There exists an index α such that for $\lambda \geqslant \alpha$, the canonical homomorphism*

$$(C_\alpha \otimes_A B)_{\mathrm{red}} \longrightarrow (C_\lambda \otimes_A B)_{\mathrm{red}} \tag{23.2.4.1}$$

is bijective.

(ii) *If in addition B is a faithfully flat A-module, the morphism* $\operatorname{Spec}(A') \to \operatorname{Spec}(C_\alpha)$ *is* radiciel.

[24] In the remainder of this item, we use notions and results set out in chap. IV, §§2 and 5; since the results of this item are not used before chap. IV, §6, this does not lead to circular reasoning.

[25] The French source prints "(23.1.8.1)"; the formula occurs in Lemma 23.2.3 and is therefore numbered (23.2.3.1) here.

Proof. (i). Let $B_1 = B_{\mathrm{red}}$, and let R be the total ring of fractions of B_1; since A is integral and B is a flat A-module, every element $\neq 0$ of A is B-regular ($\mathbf{0_I}$, 6.3.4), hence the composite homomorphism $A \to B \to B_1$ extends to a homomorphism $K \to R$. We can therefore write $K' \otimes_A R = (K' \otimes_A K) \otimes_K R$, and since $K' \otimes_A K$ is identified with K', we have $K' \otimes_A R = K' \otimes_K R$. Since R is the direct product of the fields of fractions L_i of the $B/\mathfrak{q}_i$, $K' \otimes_A R$ is the direct product of the $K' \otimes_K L_i$, and hence $(K' \otimes_A R)_{\mathrm{red}}$ is the direct product of a finite number of finite extensions of the L_i. By hypothesis, the integral closure of $B/\mathfrak{q}_i$ in a finite extension of L_i is a finite $(B/\mathfrak{q}_i)$-module, hence a finite B-module; it follows that the integral closure B' of B in $(K' \otimes_A R)_{\mathrm{red}}$ is a finite B-module. By virtue of (23.2.3), the $(C_\lambda \otimes_A B)_{\mathrm{red}}$ are canonically identified with subrings of $(K' \otimes_A R)_{\mathrm{red}}$ which are *finite* B-algebras, hence contained in B'. Since B is Noetherian and B' a B-module of finite type, the filtering family of the $(C_\alpha \otimes_A B)_{\mathrm{red}}$ admits a *greatest element* $(C_\alpha \otimes_A B)_{\mathrm{red}}$, which proves (i).

(ii). Since B is a faithfully flat A-module, it suffices (**IV**, 2.6.1, v) to show that the morphism $\operatorname{Spec}(A' \otimes_A B) \to \operatorname{Spec}(C_\alpha \otimes_A B)$ is radiciel, or, what amounts to the same (**I**, 5.1.6), that the morphism $\operatorname{Spec}(A' \otimes_A B)_{\mathrm{red}} \to \operatorname{Spec}(C_\alpha \otimes_A B)_{\mathrm{red}}$ is radiciel; but we have $A' \otimes_A B = \varinjlim (C_\lambda \otimes_A B)$, hence (**IV**, 5.13.2) $(A' \otimes_A B)_{\mathrm{red}} = \varinjlim (C_\lambda \otimes_A B)_{\mathrm{red}}$, and the conclusion follows from (i). ☐

Corollary (23.2.5). — *Let A be a local Noetherian integral ring, K its field of fractions, K' a finite extension of K. Let (C_α) be the increasing filtering family of subrings of K' that are finite A-algebras (hence Noetherian semi-local rings* (Bourbaki, *Alg. comm.*, chap. IV, §2, n° 5, cor. 3 of prop. 9)*) and admit K' as their field of fractions. Then there exists α such that the homomorphism $(\widehat{C}_\alpha)_{\mathrm{red}} \to (\widehat{C}_\lambda)_{\mathrm{red}}$ is an isomorphism for $\lambda \geqslant \alpha$, and if A' is the integral closure of A in K', the morphism* $\operatorname{Spec}(A') \to \operatorname{Spec}(C_\alpha)$ *is radiciel* (cf. (23.2.2)).

$\mathbf{0_{IV\text{-}1}}$ | 219

Proof. We apply (23.2.4) taking $B = \widehat{A}$; since the $B/\mathfrak{q}_i$ are complete local Noetherian rings, they are Japanese rings (23.1.5) and B is a faithfully flat A-module ($\mathbf{0_I}$, 7.3.5); moreover we have $C_\lambda \otimes_A B = \widehat{C}_\lambda$ (Bourbaki, *Alg. comm.*, chap. III, §3, n° 4, th. 3 and chap. IV, §2, n° 5, cor. 3 of prop. 9). ☐

Corollary (23.2.6). — *Under the hypotheses of* (23.2.5), *the integral closure A' of A in K' is a semi-local ring; if $\mathfrak{m}$ is the maximal ideal of A, then, for every maximal ideal $\mathfrak{m}'$ of A', $A'/\mathfrak{m}'$ is a finite extension of $A/\mathfrak{m}$.*

Proof. The fact that the homomorphism $(\widehat{C}_\alpha)_{\mathrm{red}} \to (\widehat{C}_\lambda)_{\mathrm{red}}$ is bijective for $\lambda \geqslant \alpha$ implies that the number of maximal ideals of C_λ is *constant* for $\lambda \geqslant \alpha$, and that if $\mathfrak{m}_\alpha$ is a maximal ideal of C_α and $\mathfrak{m}_\lambda$ is the unique maximal ideal of C_λ above $\mathfrak{m}_\alpha$, the fields $C_\alpha/\mathfrak{m}_\alpha$ and $C_\lambda/\mathfrak{m}_\lambda$ are canonically isomorphic. The conclusion follows from the fact that $\mathfrak{m}' = \varinjlim \mathfrak{m}_\lambda$ and $A'/\mathfrak{m}' = \varinjlim C_\lambda/\mathfrak{m}_\lambda$ ($\mathbf{0_{III}}$, 10.3.1.3). ☐

Proposition (23.2.7). — (Y. Mori) *Let A be a local Noetherian integral ring, K its field of fractions, and A' the integral closure of A. Then A' is a Krull ring* (Bourbaki, *Alg. comm.*, chap. VII, §1) *that is semi-local; in other words, there exists a family (V_λ) of discrete valuation rings having K as their field of fractions, such that $A' = \bigcap V_\lambda$ and that every $x \in K$ belongs to all but a finite number of the V_λ. Moreover, there exists a subalgebra C of K which is a finite A-algebra, and such that the V_λ are the integral closures of the rings $C_{\mathfrak{p}_\lambda}$, where $(\mathfrak{p}_\lambda)$ is the family of prime ideals of height 1 of the local ring C.*

We will first prove the following lemma:

Lemma (23.2.7.1). — *Let A, B be two rings, $\phi : A \to B$ a homomorphism making B a faithfully flat A-module. Suppose that A is integral; then, if $C = B_{\mathrm{red}}$, the composite homomorphism $\psi : A \to B \to B_{\mathrm{red}} = C$ is injective and extends to an injective homomorphism of the field of fractions K of A into the total ring of fractions R of C; moreover, if C' is the integral closure of C in R, $C' \cap K$ is the integral closure of A.*

Proof. Since A is integral and ϕ is injective, the intersection of $\phi(A)$ and the nilradical $\mathfrak{R}$ of B is 0, and since $C = B/\mathfrak{R}$, ψ is injective. Every $a \neq 0$ in A being a non-zero-divisor does not become a zero-divisor in B by flatness ($\mathbf{0_I}$, 6.3.4); we deduce that a is also a non-zero-divisor in C, since if $ax \in \mathfrak{R}$ for an $x \notin \mathfrak{R}$ in B, we would have $a^n x^n = 0$ for some integer n, which contradicts the above since $x^n \neq 0$. We can thus extend ψ to an injective homomorphism of K into R. To prove the last assertion, note that the integral closure A' of A is contained in $C' \cap K$. Conversely, let $x \in C' \cap K$; x is then integral over C, and *a fortiori* over B, that is to say $B[x]$ is a finite B-algebra; moreover, K

is identified with a subring of $B \otimes_A K$, and the subring $B[x]$ of $B \otimes_A K$ is identified with $B \otimes_A A[x]$ by flatness; we conclude that $A[x]$ is an A-module of finite type (Bourbaki, *Alg. comm.*, chap. I$^{\text{er}}$, §3, n$^{\text{o}}$ 6, prop. 11), hence $x \in A'$. □

Proof of Proposition (23.2.7). This lemma being established, let us apply it to the canonical injection of A into its completion $\widehat{A}$, which is a faithfully flat A-module; $B = (\widehat{A})_{\text{red}} = \widehat{A}/\mathfrak{N}$ (where $\mathfrak{N}$ is the nilradical of $\widehat{A}$) is a complete local Noetherian reduced ring, whose total ring of fractions R is a direct product of a finite number of fields L_i; the canonical image B_i of B in L_i is a complete local Noetherian *integral* ring, whose field of fractions is L_i, and the integral closure B' of B in R is the *direct product* of the B'_i, where B'_i is the integral closure of B_i. But by virtue of (23.1.5), B'_i is a finite B_i-algebra, hence an integrally closed local Noetherian ring. We know (Bourbaki, *Alg. comm.*, chap. VII, §1, n$^{\text{o}}$ 3, cor. of th. 2) that B'_i is a Krull ring. Now, for every i, there is a homomorphism $\phi_i : K \to L_i$, which is injective, and so $\phi_i^{-1}(B'_i)$ is a Krull ring in K. But since $A' = B' \cap K$ by virtue of the lemma and $A' = \bigcap \phi_i^{-1}(B'_i)$, A' is an intersection of a finite number of Krull rings and is therefore a Krull ring.[26] To prove the last assertion of the proposition, note that there exists a finite A-algebra $C \subset K$ such that the morphism $\operatorname{Spec}(A') \to \operatorname{Spec}(C)$ is radiciel and a homeomorphism (23.2.4); for every prime ideal $\mathfrak{p}' \in \operatorname{Spec}(A')$, $\mathfrak{p}'$ is thus the only prime ideal of A' above $\mathfrak{p} = \mathfrak{p}' \cap C$ and $A'_{\mathfrak{p}'}$ the integral closure of $C_{\mathfrak{p}}$; on the other hand the fact that $\operatorname{Spec}(A') \to \operatorname{Spec}(C)$ is a homeomorphism implies that the map $\mathfrak{p}' \mapsto \mathfrak{p}' \cap C$ is a *bijection* of the set of prime ideals of height 1 of A' onto the set of prime ideals of height 1 of C; whence the conclusion, by virtue of Bourbaki, *Alg. comm.*, chap. VII, §1, n$^{\text{o}}$ 6, th. 4. □ $\mathbf{0_{IV\text{-}1}}$ | 220

Remarks (23.2.8). —

(i) We should take care to note, in the application of (23.2.6) and (23.2.7), that the ring A' is *not necessarily Noetherian*, as an example of Nagata shows with $\dim(A) = 3$ [Nag62].

(ii) The conclusions of (23.2.7) remain valid if A' is the integral closure of A in a finite extension K' of K; it suffices in fact to consider a finite A-algebra B whose field of fractions is K'; B is a semi-local Noetherian ring, hence an intersection of a finite number of local Noetherian rings $B_{\mathfrak{m}_i}$ ($\mathfrak{m}_i$ the maximal ideals of B), and its integral closure (which is equal to A') is the intersection of the $A'_{\mathfrak{m}_i}$ (Bourbaki, *Alg. comm.*, chap. II, §3, n$^{\text{o}}$ 3, cor. 4 of th. 1) which are the integral closures of the $B_{\mathfrak{m}_i}$, hence Krull rings by (23.2.7); consequently A' is a Krull ring.

(iii) One can show ([Nag62], 3.3.10) that for every Noetherian integral ring A (not necessarily local), the integral closure of A is a Krull ring.

Corollary (23.2.9). — *Let A be a Noetherian integral ring, A' its integral closure. Suppose that for every ring C such that $A \subset C \subset A'$ and such that C is a finite A-algebra, and for every prime ideal $\mathfrak{q}$ of height 1 in C, $\mathfrak{q} \cap A$ is a prime ideal of height 1 in A. Let P be the set of prime ideals of height 1 in A; we then have*

$$A' = \bigcap_{\mathfrak{p} \in P} A'_{\mathfrak{p}}.$$

Proof. Since A' is an A-module without torsion, we have $A' = \bigcap A'_{\mathfrak{m}}$, where $\mathfrak{m}$ ranges over the set of maximal ideals of A (Bourbaki, *Alg. comm.*, chap. II, §3, n$^{\text{o}}$ 3, cor. 4 of th. 1); it will thus suffice to prove that $A'_{\mathfrak{m}}$ is the intersection of the $A'_{\mathfrak{p}}$ for the prime ideals $\mathfrak{p} \subset \mathfrak{m}$ of height 1, and since $A'_{\mathfrak{m}}$ is the integral closure of $A_{\mathfrak{m}}$, we see that it suffices to prove the corollary for $A_{\mathfrak{m}}$. Now there is, by virtue of (23.2.7), a finite $A_{\mathfrak{m}}$-algebra B contained in $A'_{\mathfrak{m}}$ such that $A'_{\mathfrak{m}}$ is the intersection of the integral closures of the rings $B_{\mathfrak{q}}$, where $\mathfrak{q}$ ranges over the set of prime ideals of height 1 of B. But B is of the form $C_{\mathfrak{m}}$, where C is a finite A-algebra; hence, for every prime ideal $\mathfrak{q}$ of height 1 in B, $\mathfrak{q} \cap A$ is by hypothesis a prime ideal of height 1 in A; since the integral closure of $B_{\mathfrak{q}}$ contains that of $A_{\mathfrak{q} \cap A}$ and the latter contains $A'_{\mathfrak{m}}$, it follows that $A'_{\mathfrak{m}}$ is indeed the intersection of the $A'_{\mathfrak{p}}$ for $\mathfrak{p} \in P$ and $\mathfrak{p} \subset \mathfrak{m}$, which finishes the proof. □ $\mathbf{0_{IV\text{-}1}}$ | 221

Remarks (23.2.10). —

[26] The French source prints $B' = \bigcap_i \phi_i^{-1}(B'_i)$ here; the required intersection inside K is $A' = \bigcap_i \phi_i^{-1}(B'_i)$.

(i) We will see (**IV**, 5.6.3) and (**IV**, 5.6.10) that the hypothesis of (23.2.9) is satisfied when A is *universally catenary*, in particular (**IV**, 5.10.17) and (**IV**, 5.11.2) when A is a *quotient of a regular ring*; finally, it is evidently satisfied if $\operatorname{Spec}(A') \to \operatorname{Spec}(A)$ is a homeomorphism, in particular if this morphism is radiciel (23.2.2).

(ii) The conclusion of (23.2.9) is no longer necessarily exact when one omits the hypothesis on the finite sub-A-algebras of A'. Indeed, one can define a local Noetherian integral ring A, of dimension 2, whose integral closure A' is a finite A-algebra, but such that there is a prime ideal $\mathfrak{p}'$ of A' of height 1 above the maximal ideal $\mathfrak{m}$ (of height 2) of A, and such moreover that for every prime ideal $\mathfrak{p}$ of height 1 in A, $A_{\mathfrak{p}}$ is integrally closed (**IV**, 5.6.11); the intersection of these rings $A_{\mathfrak{p}}$ can then not be equal to A' since A' is a Krull ring (Bourbaki, *Alg. comm.*, chap. VII, §1, n° 5, prop. 9).

The language of schemes

Alexander Grothendieck and Jean Dieudonné

Complete English reader

SUMMARY

In §§1–8 we do little more than develop a language to be used in what follows. It should be noted, however, that, in accordance with the general spirit of this treatise, §§7–8 will be used less than the others, and in a less essential way; we speak of Chevalley schemes only for the purpose of relating to the language of Chevalley [CC] and Nagata [Nag58a]. Then, in §9, we give definitions and results concerning quasi-coherent sheaves, some of which are no longer simply a translation of known notions of commutative algebra into a "geometric" language, but are instead already of a global nature; they will be indispensable, in the following chapters, when it comes to the global study of morphisms. Finally, in §10, we introduce a generalization of the notion of a scheme, which will be used as an intermediary in Chapter III to conveniently formulate and prove the fundamental results of the cohomological study of proper morphisms; moreover, it should be noted that the notion of formal schemes seems indispensable in expressing certain facts about the "theory of modules" (classification problems of algebraic varieties). The results of §10 will not be used before §3 of Chapter III, and it is recommended to skip their reading until then. **I** | 79

§1. AFFINE SCHEMES

1.1. The prime spectrum of a ring

(1.1.1). *Notation.* Let A be a (commutative) ring, and M an A-module. In this chapter and the following, we will constantly use the following notation: **I** | 80

- $\operatorname{Spec}(A)$ = *set of prime ideals* of A, also called the *prime spectrum* of A; for $x \in X = \operatorname{Spec}(A)$, it will often be convenient to write $\mathfrak{j}_x$ instead of x. For $\operatorname{Spec}(A)$ to be *empty*, it is necessary and sufficient for the ring A to be 0.
- $A_x = A_{\mathfrak{j}_x}$ = *(local) ring of fractions* $S^{-1}A$, where $S = A - \mathfrak{j}_x$.
- $\mathfrak{m}_x = \mathfrak{j}_x A_{\mathfrak{j}_x}$ = *maximal ideal of* A_x.
- $k(x) = A_x/\mathfrak{m}_x$ = *residue field of* A_x, canonically isomorphic to the fraction field of the integral domain $A/\mathfrak{j}_x$, with which we identify it.
- $f(x)$ = *class of* f *mod.* $\mathfrak{j}_x$ in $A/\mathfrak{j}_x \subset k(x)$, for $f \in A$ and $x \in X$. We also say that $f(x)$ is the *value* of f at a point $x \in \operatorname{Spec}(A)$; the relations $f(x) = 0$ and $f \in \mathfrak{j}_x$ are *equivalent*.
- $M_x = M \otimes_A A_x$ = *module of fractions with denominators in* $A - \mathfrak{j}_x$.
- $\mathfrak{r}(E)$ = *radical of the ideal of* A *generated by a subset* E *of* A.
- $V(E)$ = *set of* $x \in X$ *such that* $E \subset \mathfrak{j}_x$ (or the set of $x \in X$ such that $f(x) = 0$ for all $f \in E$), for $E \subset A$. So we have

(1.1.1.1) $$\mathfrak{r}(E) = \bigcap_{x \in V(E)} \mathfrak{j}_x.$$

- $V(f) = V(\{f\})$ for $f \in A$.
- $D(f) = X - V(f)$ = *set of* $x \in X$ *where* $f(x) \neq 0$.

Proposition (1.1.2). — *We have the following properties:*

(i) $V(0) = X$, $V(1) = \varnothing$.
(ii) *The relation* $E \subset E'$ *implies* $V(E) \supset V(E')$.

(iii) *For each family* (E_λ) *of subsets of* A, $V(\bigcup_\lambda E_\lambda) = V(\sum_\lambda E_\lambda) = \bigcap_\lambda V(E_\lambda)$.
(iv) $V(EE') = V(E) \cup V(E')$.
(v) $V(E) = V(\mathfrak{r}(E))$.

Proof. The properties (i), (ii), (iii) are trivial, and (v) follows from (ii) and from equation (1.1.1.1). It is evident that $V(EE') \supset V(E) \cup V(E')$; conversely, if $x \notin V(E)$ and $x \notin V(E')$, then there exists $f \in E$ and $f' \in E'$ such that $f(x) \neq 0$ and $f'(x) \neq 0$ in $k(x)$, hence $f(x)f'(x) \neq 0$, i.e., $x \notin V(EE')$, which proves (iv). □

Proposition (1.1.2) shows, among other things, that sets of the form $V(E)$ (where E varies over the subsets of A) are the *closed sets* of a topology on X, which we will call the *spectral topology* [1]; unless expressly stated otherwise, we always assume that $X = \operatorname{Spec}(A)$ is equipped with the spectral topology.

(1.1.3). For each subset Y of X, we denote by $\mathfrak{j}(Y)$ the set of $f \in A$ such that $f(y) = 0$ for all $y \in Y$; **I** | 81
equivalently, $\mathfrak{j}(Y)$ is the intersection of the prime ideals $\mathfrak{j}_y$ for $y \in Y$. It is clear that the relation $Y \subset Y'$ implies that $\mathfrak{j}(Y) \supset \mathfrak{j}(Y')$ and that we have

(1.1.3.1)
$$\mathfrak{j}\left(\bigcup_\lambda Y_\lambda\right) = \bigcap_\lambda \mathfrak{j}(Y_\lambda)$$

for each family (Y_λ) of subsets of X. Finally we have

(1.1.3.2)
$$\mathfrak{j}(\{x\}) = \mathfrak{j}_x.$$

Proposition (1.1.4). —

(i) *For each subset* E *of* A, *we have* $\mathfrak{j}(V(E)) = \mathfrak{r}(E)$.
(ii) *For each subset* Y *of* X, $V(\mathfrak{j}(Y)) = \overline{Y}$, *the closure of* Y *in* X.

Proof. (i) is an immediate consequence of the definitions and (1.1.1.1); on the other hand, $V(\mathfrak{j}(Y))$ is closed and contains Y; conversely, if $Y \subset V(E)$, we have $f(y) = 0$ for $f \in E$ and all $y \in Y$, so $E \subset \mathfrak{j}(Y)$, $V(E) \supset V(\mathfrak{j}(Y))$, which proves (ii). □

Corollary (1.1.5). — *The closed subsets of* $X = \operatorname{Spec}(A)$ *and the ideals of* A *equal to their radicals (in other words, those that are intersections of prime ideals) correspond bijectively by the inclusion-reversing maps* $Y \mapsto \mathfrak{j}(Y)$, $\mathfrak{a} \mapsto V(\mathfrak{a})$; *the union* $Y_1 \cup Y_2$ *of two closed subsets corresponds to* $\mathfrak{j}(Y_1) \cap \mathfrak{j}(Y_2)$, *and the intersection of any family* (Y_λ) *of closed subsets corresponds to the radical of the sum of the* $\mathfrak{j}(Y_\lambda)$.

Corollary (1.1.6). — *If* A *is a Noetherian ring,* $X = \operatorname{Spec}(A)$ *is a Noetherian space.*

Note that the converse of this corollary is false, as shown by the example of a non-Noetherian integral domain having exactly one prime ideal distinct from (0) (for example a nondiscrete valuation ring of rank 1).

As an example of a ring A whose spectrum is not a Noetherian space, one can consider the ring $\mathscr{C}(Y)$ of continuous real functions on an infinite compact space Y; we know that, as a set, Y corresponds to the set of maximal ideals of A, and it is easy to see that the topology induced on Y by that of $X = \operatorname{Spec}(A)$ is the original topology of Y. Since Y is not a Noetherian space, the same is true for X.

Corollary (1.1.7). — *For each* $x \in X$, *the closure of* $\{x\}$ *is the set of* $y \in X$ *such that* $\mathfrak{j}_x \subset \mathfrak{j}_y$. *For* $\{x\}$ *to be closed, it is necessary and sufficient that* $\mathfrak{j}_x$ *is maximal.*

Corollary (1.1.8). — *The space* $X = \operatorname{Spec}(A)$ *is a Kolmogoroff space.*

Proof. If x and y are two distinct points of X, we have either $\mathfrak{j}_x \not\subset \mathfrak{j}_y$ or $\mathfrak{j}_y \not\subset \mathfrak{j}_x$, so one of the points x, y does not belong to the closure of the other. □

[1]The introduction of this topology in algebraic geometry is due to Zariski. So this topology is usually called the "Zariski topology" on X.

(1.1.9). According to Proposition (1.1.2, iv), for two elements f, g of A, we have

$$D(fg) = D(f) \cap D(g). \tag{1.1.9.1}$$

Note also that the equality $D(f) = D(g)$ means, according to Proposition (1.1.4, i) and Proposition (1.1.2, v), that $\mathfrak{r}(f) = \mathfrak{r}(g)$, or that the minimal prime ideals containing (f) and (g) are the same; in particular, it is also the case when $f = ug$, where u is invertible.

Proposition (1.1.10). — I | 82

(i) *When f ranges over A, the sets $D(f)$ form a basis for the topology of X.*
(ii) *For every $f \in A$, $D(f)$ is quasi-compact. In particular, $X = D(1)$ is quasi-compact.*

Proof.

(i) Let U be an open set in X; by definition, we have $U = X - V(E)$ where E is a subset of A, and $V(E) = \bigcap_{f\in E} V(f)$, hence $U = \bigcup_{f\in E} D(f)$.
(ii) By (i), it suffices to prove that, if $(f_\lambda)_{\lambda\in L}$ is a family of elements of A such that $D(f) \subset \bigcup_{\lambda\in L} D(f_\lambda)$, then there exists a finite subset J of L such that $D(f) \subset \bigcup_{\lambda\in J} D(f_\lambda)$. Let $\mathfrak{a}$ be the ideal of A generated by the f_λ; we have, by hypothesis, that $V(f) \supset V(\mathfrak{a})$, so $\mathfrak{r}(f) \subset \mathfrak{r}(\mathfrak{a})$; since $f \in \mathfrak{r}(f)$, there exists an integer $n \geqslant 0$ such that $f^n \in \mathfrak{a}$. But then f^n belongs to the ideal $\mathfrak{b}$ generated by the finite subfamily $(f_\lambda)_{\lambda\in J}$, and we have $V(f) = V(f^n) \supset V(\mathfrak{b}) = \bigcap_{\lambda\in J} V(f_\lambda)$, that is to say, $D(f) \subset \bigcup_{\lambda\in J} D(f_\lambda)$.

□

Proposition (1.1.11). — *For each ideal $\mathfrak{a}$ of A,* $\operatorname{Spec}(A/\mathfrak{a})$ *is canonically identified with the closed subspace $V(\mathfrak{a})$ of* $\operatorname{Spec}(A)$.

Proof. We know there is a canonical bijective correspondence (respecting the inclusion order structure) between ideals (resp. prime ideals) of $A/\mathfrak{a}$ and ideals (resp. prime ideals) of A containing $\mathfrak{a}$. □

Recall that the set $\mathfrak{N}$ of nilpotent elements of A (the *nilradical* of A) is an ideal equal to $\mathfrak{r}(0)$, the intersection of all the prime ideals of A (**0**, 1.1.1).

Corollary (1.1.12). — *The topological spaces* $\operatorname{Spec}(A)$ *and* $\operatorname{Spec}(A/\mathfrak{N})$ *are canonically homeomorphic.*

Proposition (1.1.13). — *For $X = \operatorname{Spec}(A)$ to be irreducible* (**0**, 2.1.1)*, it is necessary and sufficient that the ring $A/\mathfrak{N}$ is an integral domain (or, equivalently, that the ideal $\mathfrak{N}$ is prime).*

Proof. By virtue of Corollary (1.1.12), we can restrict to the case where $\mathfrak{N} = 0$. If X is reducible, then there exist two proper closed subsets Y_1 and Y_2 of X such that $X = Y_1 \cup Y_2$, so $\mathfrak{j}(X) = \mathfrak{j}(Y_1) \cap \mathfrak{j}(Y_2) = 0$, since the ideals $\mathfrak{j}(Y_1)$ and $\mathfrak{j}(Y_2)$ are distinct from (0) (1.1.5); so A is not an integral domain. Conversely, if there are elements $f \neq 0$, $g \neq 0$ of A such that $fg = 0$, we have $V(f) \neq X$, $V(g) \neq X$ (since the intersection of all the prime ideals of A is (0)), and $X = V(fg) = V(f) \cup V(g)$. □

Corollary (1.1.14). —

(i) *In the bijective correspondence between closed subsets of $X =$* $\operatorname{Spec}(A)$ *and ideals of A equal to their radicals, the irreducible closed subsets of X correspond to the prime ideals of A. In particular, the irreducible components of X correspond to the minimal prime ideals of A.*
(ii) *The map $x \mapsto \overline{\{x\}}$ establishes a bijective correspondence between X and the set of closed irreducible subsets of X (*in other words, *all closed irreducible subsets of X admit exactly one generic point).*

Proof. (i) follows immediately from (1.1.13) and (1.1.11); and for proving (ii), we can, by (1.1.11), restrict to the case where X is irreducible; then, according to Proposition (1.1.13), there exists a least prime ideal $\mathfrak{N}$ in A, which corresponds to the generic point of X; in addition, X admits at most one generic point since it is a Kolmogoroff space ((1.1.8) and (**0**, 2.1.3)). □ I | 83

Proposition (1.1.15). — *If $\mathfrak{J}$ is an ideal of A contained in the Jacobson radical $\mathfrak{R}(A)$, the only neighbourhood of $V(\mathfrak{J})$ in $X =$* $\operatorname{Spec}(A)$ *is the whole space X.*

Proof. Each maximal ideal of A belongs, by definition, to $V(\mathfrak{J})$. As each ideal $\mathfrak{a} \neq A$ of A is contained in a maximal ideal, we have $V(\mathfrak{a}) \cap V(\mathfrak{J}) \neq \varnothing$, whence the proposition. □

1.2. Functorial properties of prime spectra of rings

(1.2.1). Let A, A' be two rings, and

$$\phi : A' \longrightarrow A$$

a homomorphism of rings. For each prime ideal $x = \mathfrak{j}_x \in \operatorname{Spec}(A) = X$, the ring $A'/\phi^{-1}(\mathfrak{j}_x)$ is canonically isomorphic to a subring of $A/\mathfrak{j}_x$, and so it is an integral domain, or, in other words, $\phi^{-1}(\mathfrak{j}_x)$ is a prime ideal of A'; we denote it by ${}^a\phi(x)$, and we have thus defined a map

$${}^a\phi : X = \operatorname{Spec}(A) \longrightarrow X' = \operatorname{Spec}(A')$$

(also denoted $\operatorname{Spec}(\phi)$), that we call the map *associated* to the homomorphism ϕ. We denote by ϕ^x the injective homomorphism from $A'/\phi^{-1}(\mathfrak{j}_x)$ to $A/\mathfrak{j}_x$ induced by ϕ by passing to quotients, as well as its canonical extension to a monomorphism of fields

$$\phi^x : k({}^a\phi(x)) \longrightarrow k(x);$$

for each $f' \in A'$, we therefore have, by definition,

$$\phi^x(f'({}^a\phi(x))) = (\phi(f'))(x) \qquad (x \in X). \tag{1.2.1.1}$$

Proposition (1.2.2). —

(i) *For each subset E' of A', we have*

$${}^a\phi^{-1}(V(E')) = V(\phi(E')), \tag{1.2.2.1}$$

and in particular, for each $f' \in A'$,

$${}^a\phi^{-1}(D(f')) = D(\phi(f')). \tag{1.2.2.2}$$

(ii) *For each ideal $\mathfrak{a}$ of A, we have*

$$\overline{{}^a\phi(V(\mathfrak{a}))} = V(\phi^{-1}(\mathfrak{a})). \tag{1.2.2.3}$$

Proof. The relation ${}^a\phi(x) \in V(E')$ is, by definition, equivalent to $E' \subset \phi^{-1}(\mathfrak{j}_x)$, so $\phi(E') \subset \mathfrak{j}_x$, and finally $x \in V(\phi(E'))$, hence (i). To prove (ii), we can suppose that $\mathfrak{a}$ is equal to its radical, since $V(\mathfrak{r}(\mathfrak{a})) = V(\mathfrak{a})$ (1.1.2, (v)) and $\phi^{-1}(\mathfrak{r}(\mathfrak{a})) = \mathfrak{r}(\phi^{-1}(\mathfrak{a}))$; if we set $Y = V(\mathfrak{a})$, and $\mathfrak{a}' = \mathfrak{j}({}^a\phi(Y))$, then we have $\overline{{}^a\phi(Y)} = V(\mathfrak{a}')$ ((1.1.4, (ii))). The relation $f' \in \mathfrak{a}'$ is, by definition, equivalent to $f'(x') = 0$ for each $x' \in {}^a\phi(Y)$, so, by Equation (1.2.1.1), it is also equivalent to $\phi(f')(x) = 0$ for each $x \in Y$, or to $\phi(f') \in \mathfrak{j}(Y) = \mathfrak{a}$, since $\mathfrak{a}$ is equal to its radical; hence (ii). □

Corollary (1.2.3). — *The map ${}^a\phi$ is continuous.*

We remark that, if A'' is a third ring, and ϕ' a homomorphism $A'' \to A'$, then we have ${}^a(\phi \circ \phi') = {}^a\phi' \circ {}^a\phi$; this result, with Corollary (1.2.3), says that $\operatorname{Spec}(A)$ is a *contravariant functor* in A, from the category of rings to that of topological spaces.

Corollary (1.2.4). — *Suppose that ϕ is such that every $f \in A$ can be written as $f = h\phi(f')$, where h is* **I | 84**
invertible in A (which, in particular, is the case when ϕ is *surjective*). *Then ${}^a\phi$ is a homeomorphism from X to ${}^a\phi(X)$.*

Proof. We show that for each subset $E \subset A$, there exists a subset E' of A' such that $V(E) = V(\phi(E'))$; according to the (T_0) axiom (1.1.8) and the formula (1.2.2.1), this implies first of all that ${}^a\phi$ is injective, and then, again by (1.2.2.1), that ${}^a\phi$ is a homeomorphism. But it suffices, for each $f \in E$, to take $f' \in A'$ such that $h\phi(f') = f$ with h invertible in A; the set E' of these elements f' is exactly what we are searching for. □

(1.2.5). In particular, when ϕ is the canonical homomorphism from A to a ring quotient $A/\mathfrak{a}$, we recover (1.1.11), and ${}^a\phi$ is the *canonical injection* of $V(\mathfrak{a})$, identified with $\operatorname{Spec}(A/\mathfrak{a})$, into $X = \operatorname{Spec}(A)$.

Another particular case of (1.2.4):

Corollary (1.2.6). — *If S is a multiplicative subset of A, the spectrum* $\operatorname{Spec}(S^{-1}A)$ *is canonically identified (with its topology) with the subspace of $X = \operatorname{Spec}(A)$ consisting of the x such that $\mathfrak{j}_x \cap S = \varnothing$.*

Proof. We know by (**0**, 1.2.6) that the prime ideals of $S^{-1}A$ are the ideals $S^{-1}\mathfrak{j}_x$ such that $\mathfrak{j}_x \cap S = \varnothing$, and that we have $\mathfrak{j}_x = (i_A^S)^{-1}(S^{-1}\mathfrak{j}_x)$. It then suffices to apply Corollary (1.2.4) to the i_A^S. □

Corollary (1.2.7). — *For ${}^a\phi(X)$ to be dense in X', it is necessary and sufficient for each element of the kernel* $\operatorname{Ker}\phi$ *to be nilpotent.*

Proof. Applying Equation (1.2.2.3) to the ideal $\mathfrak{a} = (0)$, we have $\overline{{}^a\phi(X)} = V(\operatorname{Ker}\phi)$, and for $V(\operatorname{Ker}\phi) = X'$ to hold, it is necessary and sufficient for $\operatorname{Ker}\phi$ to be contained in all the prime ideals of A', or, equivalently, in the nilradical $\mathfrak{N}$ of A'. □

1.3. Sheaf associated to a module

(1.3.1). Let A be a commutative ring, M an A-module, f an element of A, and S_f the multiplicative set consisting of the f^n, where $n \geqslant 0$. Recall that we set $A_f = S_f^{-1}A$, $M_f = S_f^{-1}M$. If S'_f is the saturated multiplicative subset of A consisting of the $g \in A$ which divide an element of S_f, we know that A_f and M_f are canonically identified with ${S'_f}^{-1}A$ and ${S'_f}^{-1}M$ (**0**, 1.4.3).

Lemma (1.3.2). — *The following conditions are equivalent:*

(a) $g \in S'_f$;
(b) $S'_g \subset S'_f$;
(c) $f \in \mathfrak{r}(g)$;
(d) $\mathfrak{r}(f) \subset \mathfrak{r}(g)$;
(e) $V(g) \subset V(f)$;
(f) $D(f) \subset D(g)$.

Proof. This follows immediately from the definitions and (1.1.5). □

(1.3.3). If $D(f) = D(g)$, then Lemma (1.3.2, b) shows that $M_f = M_g$. More generally, if $D(f) \supset D(g)$, then $S'_f \subset S'_g$, and we know (**0**, 1.4.1) that there exists a canonical functorial homomorphism

$$\rho_{g,f} : M_f \longrightarrow M_g,$$

and if $D(f) \supset D(g) \supset D(h)$, we have (**0**, 1.4.4)

$$\rho_{h,g} \circ \rho_{g,f} = \rho_{h,f}. \tag{1.3.3.1}$$

When f ranges over the elements of $A - \mathfrak{j}_x$ (for a given x in $X = \operatorname{Spec}(A)$), the sets S'_f constitute an increasing filtered set of subsets of $A - \mathfrak{j}_x$, since for elements f and g of $A - \mathfrak{j}_x$, S'_f and S'_g are contained in S'_{fg}; since the union of the S'_f over $f \in A - \mathfrak{j}_x$ is $A - \mathfrak{j}_x$, we conclude (**0**, 1.4.5) that the A_x-module M_x is canonically identified with the *inductive limit* $\varinjlim M_f$, relative to the family of homomorphisms $(\rho_{g,f})$. We denote by **I | 85**

$$\rho_x^f : M_f \longrightarrow M_x$$

the canonical homomorphism for $f \in A - \mathfrak{j}_x$ (or, equivalently, $x \in D(f)$).

Definition (1.3.4). — We define the structure sheaf of the prime spectrum $X = \operatorname{Spec}(A)$ (resp. the sheaf associated to the A-module M), denoted by $\widetilde{A}$ or $\mathscr{O}_X$ (resp. $\widetilde{M}$) as the sheaf of rings (resp. the $\widetilde{A}$-module) associated to the presheaf $D(f) \mapsto A_f$ (resp. $D(f) \mapsto M_f$), defined on the basis $\mathfrak{B}$ of X consisting of the $D(f)$ for $f \in A$ ((1.1.10), (**0**, 3.2.1), and (**0**, 3.5.6)).

We saw (**0**, 3.2.4) that the stalk $\widetilde{A}_x$ (resp. $\widetilde{M}_x$) *can be identified with the ring* A_x (resp. *the* A_x*-module* M_x); we denote by

$$\theta_f : A_f \longrightarrow \Gamma(D(f), \widetilde{A})$$
$$(\text{resp. } \theta_f : M_f \longrightarrow \Gamma(D(f), \widetilde{M})),$$

the canonical map, so that, for all $x \in D(f)$ and all $\xi \in M_f$, we have

$$(\theta_f(\xi))_x = \rho_x^f(\xi). \tag{1.3.4.1}$$

Proposition (1.3.5). — $\widetilde{M}$ *is an exact functor, covariant in M, from the category of A-modules to the category of $\widetilde{A}$-modules.*

Proof. Indeed, let M, N be two A-modules, and u a homomorphism $M \to N$; for each $f \in A$, u corresponds canonically to a homomorphism u_f from the A_f-module M_f to the A_f-module N_f, and the diagram (for $D(g) \subset D(f)$)

$$\begin{tikzcd} M_f \arrow[r, "u_f"] \arrow[d, "\rho_{g,f}"'] & N_f \arrow[d, "\rho_{g,f}"] \\ M_g \arrow[r, "u_g"'] & N_g \end{tikzcd}$$

is commutative (**0**, 1.4.1); these homomorphisms then define a homomorphism of $\widetilde{A}$-modules $\widetilde{u} : \widetilde{M} \to \widetilde{N}$ (**0**, 3.2.3). In addition, for each $x \in X$, $\widetilde{u}_x$ is the inductive limit of the u_f for $x \in D(f)$ ($f \in A$), and as a result (**0**, 1.4.5), if we canonically identify $\widetilde{M}_x$ and $\widetilde{N}_x$ with M_x and N_x respectively, then $\widetilde{u}_x$ is identified with the homomorphism u_x canonically induced by u. If P is a third A-module, v a homomorphism $N \to P$, and $w = v \circ u$, it is immediate that $w_x = v_x \circ u_x$, so $\widetilde{w} = \widetilde{v} \circ \widetilde{u}$. We have therefore clearly defined a *covariant (in M) functor* $\widetilde{M}$, from the category of A-modules to that of $\widetilde{A}$-modules. *This functor is exact*, since, for each $x \in X$, M_x is an exact functor in M (**0**, 1.3.2); in addition, we have $\operatorname{Supp}(M) = \operatorname{Supp}(\widetilde{M})$, by definition ((**0**, 1.7.1) and (**0**, 3.1.6)). □

I | 86

Proposition (1.3.6). — *For each $f \in A$, the open subset $D(f) \subset X$ is canonically identified with the prime spectrum* $\operatorname{Spec}(A_f)$*, and the sheaf $\widetilde{M_f}$ associated to the A_f-module M_f is canonically identified with the restriction $\widetilde{M}|D(f)$.*

Proof. The first assertion is a particular case of (1.2.6). In addition, if $g \in A$ is such that $D(g) \subset D(f)$, then M_g is canonically identified with the module of fractions of M_f whose denominators are the powers of the canonical image of g in A_f (**0**, 1.4.6). The canonical identification of $\widetilde{M_f}$ with $\widetilde{M}|D(f)$ then follows from the definitions. □

Theorem (1.3.7). — *For each A-module M and each $f \in A$, the homomorphism*

$$\theta_f : M_f \longrightarrow \Gamma(D(f), \widetilde{M})$$

is bijective (in other words, the presheaf $D(f) \mapsto M_f$ is a *sheaf*). *In particular, M can be identified with $\Gamma(X, \widetilde{M})$ via θ_1.*

Proof. We note that, if $M = A$, then θ_f is a ring homomorphism; Theorem (1.3.7) then implies that, if we identify the rings A_f and $\Gamma(D(f), \widetilde{A})$ via θ_f, the homomorphism $\theta_f : M_f \to \Gamma(D(f), \widetilde{M})$ is an isomorphism of *modules*.

We show first that θ_f is *injective*. Indeed, if $\xi \in M_f$ is such that $\theta_f(\xi) = 0$, then, for each prime ideal $\mathfrak{p}$ of A_f, there exists $h \notin \mathfrak{p}$ such that $h\xi = 0$; as the annihilator of ξ is not contained in any prime ideal of A_f, it is the whole ring A_f, and hence $\xi = 0$.

It remains to show that θ_f is *surjective*; we can restrict to the case where $f = 1$ (the general case then following by "localizing", using (1.3.6)). Now let s be a section of $\widetilde{M}$ over X; according to (1.3.4) and (1.1.10, ii), there exists a *finite* cover $(D(f_i))_{i \in I}$ of X ($f_i \in A$) such that, for each $i \in I$, the restriction $s_i = s|D(f_i)$ is of the form $\theta_{f_i}(\xi_i)$, where $\xi_i \in M_{f_i}$. If i, j are indices of I, and if the restrictions of s_i and s_j to $D(f_i) \cap D(f_j) = D(f_i f_j)$ are equal, then it follows, by definition of $\widetilde{M}$, that

(1.3.7.1) $$\rho_{f_i f_j, f_i}(\xi_i) = \rho_{f_i f_j, f_j}(\xi_j).$$

By definition, we can write, for each $i \in I$, $\xi_i = z_i / f_i^{n_i}$, where $z_i \in M$, and, since I is finite, by multiplying each z_i by a power of f_i, we can assume that all the n_i are equal to one single n. Then, by definition, (1.3.7.1) implies that there exists an integer $m_{ij} \geqslant 0$ such that $(f_i f_j)^{m_{ij}}(f_j^n z_i - f_i^n z_j) = 0$, and we may moreover suppose that all the m_{ij} are equal to the same integer m; then, replacing the z_i by $f_i^m z_i$, we are reduced to the case where $m = 0$, in other words, the case where we have

(1.3.7.2) $$f_j^n z_i = f_i^n z_j$$

for any i, j. We have $D(f_i^n) = D(f_i)$, and since the $D(f_i)$ form a cover of X, the ideal generated by the f_i^n is A; in other words, there exist elements $g_i \in A$ such that $\sum_i g_i f_i^n = 1$. Then consider the element $z = \sum_i g_i z_i$ of M; in (1.3.7.2), we have $f_i^n z = \sum_j g_j f_i^n z_j = (\sum_j g_j f_j^n) z_i = z_i$, so, by definition, $\xi_i = z/1$ in M_{f_i}. We conclude that the s_i are the restrictions to $D(f_i)$ of $\theta_1(z)$, which proves that **I** | 87
$s = \theta_1(z)$ and finishes the proof. □

Corollary (1.3.8). — *Let M and N be A-modules; the canonical homomorphism $u \mapsto \widetilde{u}$ from* $\operatorname{Hom}_A(M, N)$ *to* $\operatorname{Hom}_{\widetilde{A}}(\widetilde{M}, \widetilde{N})$ *is bijective. In particular, the equations $M = 0$ and $\widetilde{M} = 0$ are equivalent.*

Proof. Consider the canonical homomorphism

$$v \longmapsto \Gamma(v) : \operatorname{Hom}_{\widetilde{A}}(\widetilde{M}, \widetilde{N}) \longrightarrow \operatorname{Hom}_{\Gamma(\widetilde{A})}(\Gamma(\widetilde{M}), \Gamma(\widetilde{N}));$$

the latter module is canonically identified with $\operatorname{Hom}_A(M, N)$, by Theorem (1.3.7). It remains to show that $u \mapsto \widetilde{u}$ and $v \mapsto \Gamma(v)$ are inverses of each other; it is evident that $\Gamma(\widetilde{u}) = u$ by definition of $\widetilde{u}$; on the other hand, if we let $u = \Gamma(v)$ for $v \in \operatorname{Hom}_{\widetilde{A}}(\widetilde{M}, \widetilde{N})$, then the map $w : \Gamma(D(f), \widetilde{M}) \to \Gamma(D(f), \widetilde{N})$ canonically induced from v is such that the diagram

$$\begin{tikzcd} M \arrow[r, "u"] \arrow[d, "\rho_{f,1}"'] & N \arrow[d, "\rho_{f,1}"] \\ M_f \arrow[r, "w"'] & N_f \end{tikzcd}$$

is commutative; so we necessarily have that $w = u_f$ for all $f \in A$ (**0**, 1.2.4), which shows that $\widetilde{\Gamma(v)} = v$. □

Corollary (1.3.9). —

(i) *Let u be a homomorphism from an A-module M to an A-module N; then the sheaves associated to* $\operatorname{Ker} u$, $\operatorname{Im} u$, *and* $\operatorname{Coker} u$, *are* $\operatorname{Ker} \widetilde{u}$, $\operatorname{Im} \widetilde{u}$, *and* $\operatorname{Coker} \widetilde{u}$ *(respectively). In particular, for $\widetilde{u}$ to be injective (resp. surjective, bijective), it is necessary and sufficient for u to be so too.*

(ii) *If M is an inductive limit (resp. direct sum) of a family of A-modules (M_λ), then $\widetilde{M}$ is the inductive limit (resp. direct sum) of the family $(\widetilde{M_\lambda})$, via a canonical isomorphism.*

Proof.

(i) It suffices to apply the fact that $\widetilde{M}$ is an exact functor in M (1.3.5) to the two exact sequences of A-modules

$$0 \longrightarrow \operatorname{Ker} u \longrightarrow M \longrightarrow \operatorname{Im} u \longrightarrow 0,$$

$$0 \longrightarrow \operatorname{Im} u \longrightarrow N \longrightarrow \operatorname{Coker} u \longrightarrow 0.$$

The second claim then follows from Theorem (1.3.7).

(ii) Let $(M_\lambda, g_{\mu\lambda})$ be an inductive system of A-modules, with inductive limit M, and let g_λ be the canonical homomorphism $M_\lambda \to M$. Since we have $\widetilde{g_{\nu\mu}} \circ \widetilde{g_{\mu\lambda}} = \widetilde{g_{\nu\lambda}}$ and $\widetilde{g_\lambda} = \widetilde{g_\mu} \circ \widetilde{g_{\mu\lambda}}$ for $\lambda \leqslant \mu \leqslant \nu$, it follows that $(\widetilde{M_\lambda}, \widetilde{g_{\mu\lambda}})$ is an inductive system of sheaves on X, and if we denote by h_λ the canonical homomorphism $\widetilde{M_\lambda} \to \varinjlim \widetilde{M_\lambda}$, then there is a unique homomorphism $v : \varinjlim \widetilde{M_\lambda} \to \widetilde{M}$ such that $v \circ h_\lambda = \widetilde{g_\lambda}$. To see that v is bijective, it suffices to check, for each $x \in X$, that v_x is a bijection from $(\varinjlim \widetilde{M_\lambda})_x$ to $\widetilde{M}_x$; but $\widetilde{M}_x = M_x$, and

$$(\varinjlim \widetilde{M_\lambda})_x = \varinjlim (\widetilde{M_\lambda})_x = \varinjlim (M_\lambda)_x = M_x \quad (\mathbf{0},\ 1.3.3).$$

Conversely, it follows from the definitions that $(\widetilde{g_\lambda})_x$ and $(h_\lambda)_x$ are both equal to the canonical map from $(M_\lambda)_x$ to M_x; since $(\widetilde{g_\lambda})_x = v_x \circ (h_\lambda)_x$, v_x is the identity. Finally, if M is the direct **I** | 88
sum of two A-modules N and P, it is immediate that $\widetilde{M} = \widetilde{N} \oplus \widetilde{P}$; each direct sum being the inductive limit of finite direct sums, the claims of (ii) are thus proved.

□

We note that Corollary (1.3.8) proves that the sheaves isomorphic to the associated sheaves of A-modules form an *abelian category* (T, I, 1.4).

We also note that Corollary (1.3.9) implies that, if M is an A-module *of finite type* (that is to say, there exists a surjective homomorphism $A^n \to M$) then there exists a surjective homomorphism $\widetilde{A^n} \to \widetilde{M}$, or, in other words, the $\widetilde{A}$-module $\widetilde{M}$ is *generated by a finite family of sections over* X (**0**, 5.1.1), and vice versa.

(1.3.10). If N is a submodule of an A-module M, the canonical injection $j : N \to M$ gives, by (1.3.9), an injective homomorphism $\widetilde{N} \to \widetilde{M}$, which allows us to canonically identify $\widetilde{N}$ with an $\widetilde{A}$*-submodule* of $\widetilde{M}$; we will always assume that we have made this identification. If N and P are submodules of M, then we have

$$(N+P)^\sim = \widetilde{N} + \widetilde{P}, \tag{1.3.10.1}$$

$$(N \cap P)^\sim = \widetilde{N} \cap \widetilde{P}, \tag{1.3.10.2}$$

since $N+P$ and $N \cap P$ are the image of the canonical homomorphism $N \oplus P \to M$ and the kernel of the canonical homomorphism $M \to (M/N) \oplus (M/P)$ (respectively), and it suffices to apply (1.3.9).

We conclude from (1.3.10.1) and (1.3.10.2) that, if $\widetilde{N} = \widetilde{P}$, then we have $N = P$.

Corollary (1.3.11). — *On the category of sheaves isomorphic to the associated sheaves of A-modules, the functor Γ is exact.*

Proof. Let $\widetilde{M} \xrightarrow{\widetilde{u}} \widetilde{N} \xrightarrow{\widetilde{v}} \widetilde{P}$ be an exact sequence corresponding to two homomorphisms $u : M \to N$ and $v : N \to P$ of A-modules. If $Q = \operatorname{Im} u$ and $R = \operatorname{Ker} v$, we have $\widetilde{Q} = \operatorname{Im} \widetilde{u} = \operatorname{Ker} \widetilde{v} = \widetilde{R}$ (Corollary (1.3.9)), hence $Q = R$. □

Corollary (1.3.12). — *Let M and N be A-modules.*

(i) *The sheaf associated to $M \otimes_A N$ is canonically identified with $\widetilde{M} \otimes_{\widetilde{A}} \widetilde{N}$.*
(ii) *If, in addition, M admits a finite presentation, then the sheaf associated to* $\operatorname{Hom}_A(M,N)$ *is canonically identified with $\mathscr{H}om_{\widetilde{A}}(\widetilde{M}, \widetilde{N})$.*

Proof.

(i) The sheaf $\mathscr{F} = \widetilde{M} \otimes_{\widetilde{A}} \widetilde{N}$ is associated to the presheaf

$$U \longmapsto \mathscr{F}(U) = \Gamma(U, \widetilde{M}) \otimes_{\Gamma(U, \widetilde{A})} \Gamma(U, \widetilde{N}),$$

with U varying over the basis (1.1.10, i) of X consisting of the $D(f)$, where $f \in A$. We know that $\mathscr{F}(D(f))$ is canonically identified with $M_f \otimes_{A_f} N_f$, by (1.3.7) and (1.3.6). Moreover, we know that the A_f-module $M_f \otimes_{A_f} N_f$ is canonically isomorphic to $(M \otimes_A N)_f$ (**0**, 1.3.4), which is itself canonically isomorphic to $\Gamma(D(f), (M \otimes_A N)^\sim)$ (Theorem (1.3.7) and Proposition (1.3.6)). In addition, we see immediately that the canonical isomorphisms

$$\mathscr{F}(D(f)) \simeq \Gamma(D(f), (M \otimes_A N)^\sim)$$

thus obtained satisfy the compatibility conditions with respect to the restriction operations **I** | 89
(**0**, 1.4.2), so they define a canonical functorial isomorphism

$$\widetilde{M} \otimes_{\widetilde{A}} \widetilde{N} \simeq (M \otimes_A N)^\sim.$$

(ii) The sheaf $\mathscr{G} = \mathscr{H}om_{\widetilde{A}}(\widetilde{M}, \widetilde{N})$ is associated to the presheaf

$$U \longmapsto \mathscr{G}(U) = \operatorname{Hom}_{\widetilde{A}|U}(\widetilde{M}|U, \widetilde{N}|U),$$

with U varying over the basis of X consisting of the $D(f)$. We know that $\mathscr{G}(D(f))$ is canonically identified with $\operatorname{Hom}_{A_f}(M_f, N_f)$ (Proposition (1.3.6) and Corollary (1.3.8)), which, according to the hypotheses on M, is canonically identified with $(\operatorname{Hom}_A(M,N))_f$ (**0**, 1.3.5). Finally, $(\operatorname{Hom}_A(M,N))_f$ is canonically identified with $\Gamma(D(f), (\operatorname{Hom}_A(M,N))^\sim)$ (Proposition (1.3.6) and Theorem (1.3.7)), and the canonical isomorphisms $\mathscr{G}(D(f)) \simeq \Gamma(D(f), (\operatorname{Hom}_A(M,N))^\sim)$ thus obtained are compatible with the restriction operations (**0**, 1.4.2); they thus define a canonical isomorphism $\mathscr{H}om_{\widetilde{A}}(\widetilde{M}, \widetilde{N}) \simeq (\operatorname{Hom}_A(M,N))^\sim$.

□

(1.3.13). Now let B be a (commutative) A-algebra; this can be understood by saying that B is an A-module such that we have some given element $e \in B$ and an A-homomorphism $\phi : B \otimes_A B \to B$, so that: 1° the diagrams

$$\begin{tikzcd} B \otimes_A B \otimes_A B \arrow[r, "\phi\otimes 1"] \arrow[d, "1\otimes\phi"'] & B \otimes_A B \arrow[d, "\phi"] \\ B \otimes_A B \arrow[r, "\phi"'] & B \end{tikzcd} \qquad \begin{tikzcd} B \otimes_A B \arrow[rr, "\sigma"] \arrow[dr, "\phi"'] & & B \otimes_A B \arrow[dl, "\phi"] \\ & B & \end{tikzcd}$$

(σ being the canonical symmetry map) are commutative; 2° $\phi(e \otimes x) = \phi(x \otimes e) = x$. By Corollary (1.3.12), the homomorphism $\widetilde{\phi} : \widetilde{B} \otimes_{\widetilde{A}} \widetilde{B} \to \widetilde{B}$ of $\widetilde{A}$-modules satisfies the analogous conditions, and so it defines an $\widetilde{A}$-*algebra* structure on $\widetilde{B}$. In a similar way, the data of a B-module N is the same as the data of an A-module N and an A-homomorphism $\psi : B \otimes_A N \to N$ such that the diagram

$$\begin{tikzcd} B \otimes_A B \otimes_A N \arrow[r, "\phi\otimes 1"] \arrow[d, "1\otimes\psi"'] & B \otimes_A N \arrow[d, "\psi"] \\ B \otimes_A N \arrow[r, "\psi"'] & N \end{tikzcd}$$

is commutative and $\psi(e \otimes n) = n$; the homomorphism $\widetilde{\psi} : \widetilde{B} \otimes_{\widetilde{A}} \widetilde{N} \to \widetilde{N}$ satisfies the analogous condition, and so defines a $\widetilde{B}$-*module* structure on $\widetilde{N}$.

In a similar way, we see that if $u : B \to B'$ (resp. $v : N \to N'$) is a homomorphism of A-algebras (resp. of B-modules), then $\widetilde{u}$ (resp. $\widetilde{v}$) is a homomorphism of $\widetilde{A}$-algebras (resp. of $\widetilde{B}$-modules), and $\operatorname{Ker}\widetilde{u}$ is a $\widetilde{B}$-ideal (resp. $\operatorname{Ker}\widetilde{v}$, $\operatorname{Coker}\widetilde{v}$, and $\operatorname{Im}\widetilde{v}$ are $\widetilde{B}$-modules). If N is a B-module, then $\widetilde{N}$ is a $\widetilde{B}$-module of finite type if and only if N is a B-module of finite type (**0**, 5.2.3).

If M, N are B-modules, then the $\widetilde{B}$-module $\widetilde{M} \otimes_{\widetilde{B}} \widetilde{N}$ is canonically identified with $(M \otimes_B N)^{\sim}$; **I** | 90 similarly $\mathscr{H}om_{\widetilde{B}}(\widetilde{M}, \widetilde{N})$ is canonically identified with $(\operatorname{Hom}_B(M, N))^{\sim}$ whenever M admits a finite presentation; the proofs are similar to those for Corollary (1.3.12).

If $\mathfrak{J}$ is an ideal of B, and N is a B-module, then we have $(\mathfrak{J}N)^{\sim} = \widetilde{\mathfrak{J}} \cdot \widetilde{N}$.

Finally, if B is an A-algebra *graded* by the A-submodules B_n ($n \in \mathbf{Z}$), then the $\widetilde{A}$-algebra $\widetilde{B}$, the direct sum of the $\widetilde{A}$-modules $\widetilde{B_n}$ (1.3.9), is graded by these $\widetilde{A}$-submodules, the axiom of graded algebras saying that the image of the homomorphism $B_m \otimes_A B_n \to B$ is contained in B_{m+n}. Similarly, if M is a B-module graded by the submodules M_n, then $\widetilde{M}$ is a $\widetilde{B}$-module graded by the $\widetilde{M_n}$.

(1.3.14). If B is an A-algebra, and M a submodule of B, then the $\widetilde{A}$-subalgebra of $\widetilde{B}$ generated by $\widetilde{M}$ (**0**, 4.1.3) is the $\widetilde{A}$-subalgebra $\widetilde{C}$, where we denote by C the subalgebra of B generated by M. Indeed, C is the sum of the submodules of B which are the images of the homomorphisms $\bigotimes_A^n M \to B$ ($n \geqslant 0$), so it suffices to apply (1.3.9) and (1.3.12).

1.4. Quasi-coherent sheaves over a prime spectrum

Theorem (1.4.1). — *Let X be the prime spectrum of a ring A, V a quasi-compact open subset of X, and $\mathscr{F}$ an $(\mathscr{O}_X|V)$-module. The following four conditions are equivalent.*

(a) *There exists an A-module M such that $\mathscr{F}$ is isomorphic to $\widetilde{M}|V$.*
(b) *There exists a finite open cover (V_i) of V by sets of the form $D(f_i)$ ($f_i \in A$) contained in V, such that, for each i, $\mathscr{F}|V_i$ is isomorphic to a sheaf of the form $\widetilde{M_i}$, where M_i is an A_{f_i}-module.*
(c) *The sheaf $\mathscr{F}$ is quasi-coherent* (**0**, 5.1.3).
(d) *The two following properties are satisfied:*
   (d1) *For each $f \in A$ such that $D(f) \subset V$, and for each section $s \in \Gamma(D(f), \mathscr{F})$, there exists an integer $n \geqslant 0$ such that $f^n s$ extends to a section of $\mathscr{F}$ over V.*
   (d2) *For each $f \in A$ such that $D(f) \subset V$ and for each section $t \in \Gamma(V, \mathscr{F})$ such that the restriction of t to $D(f)$ is 0, there exists an integer $n \geqslant 0$ such that $f^n t = 0$.*

(In the statement of the conditions (d1) and (d2), we have tacitly identified A and $\Gamma(\widetilde{A})$ using Theorem (1.3.7)).

Proof. The fact that (a) implies (b) is an immediate consequence of Proposition (1.3.6) and the fact that the $D(f_i)$ form a basis for the topology of X (1.1.10). As each A-module is isomorphic to the cokernel of a homomorphism of the form $A^{(I)} \to A^{(J)}$, (1.3.9) implies that each sheaf associated to an A-module is quasi-coherent; so (b) implies (c). Conversely, if $\mathscr{F}$ is quasi-coherent, each $x \in V$ has a neighbourhood of the form $D(f) \subset V$ such that $\mathscr{F}|D(f)$ is isomorphic to the cokernel of a homomorphism $\widetilde{A_f}^{(I)} \to \widetilde{A_f}^{(J)}$, so also to the sheaf $\widetilde{N}$ associated to the module N, the cokernel of the corresponding homomorphism $A_f^{(I)} \to A_f^{(J)}$ (Corollaries (1.3.8) and (1.3.9)); since V is quasi-compact, it is clear that (c) implies (b).

To prove that (b) implies (d1) and (d2), we first assume that $V = D(g)$ for some $g \in A$, and that I | 91 $\mathscr{F}$ is isomorphic to the sheaf $\widetilde{N}$ associated to an A_g-module N; by replacing X with V and A with A_g (1.3.6), we can reduce to the case where $g = 1$. Then $\Gamma(D(f), \widetilde{N})$ and N_f are canonically identified with one another (Proposition (1.3.6) and Theorem (1.3.7)), so a section $s \in \Gamma(D(f), \widetilde{N})$ is identified with an element of the form z/f^n, where $z \in N$; the section $f^n s$ is identified with the element $z/1$ of N_f and, as a result, is the restriction to $D(f)$ of the section of $\widetilde{N}$ over X that is identified with the element $z \in N$; hence (d1) in this case. Similarly, $t \in \Gamma(X, \widetilde{N})$ is identified with an element $z' \in N$, the restriction of t to $D(f)$ is identified with the image $z'/1$ of z' in N_f, and to say that this image is zero means that there exists some $n \geqslant 0$ such that $f^n z' = 0$ in N, or, equivalently, $f^n t = 0$.

To finish proving that (b) implies (d1) and (d2), it suffices to establish the following lemma.

Lemma (1.4.1.1). — *Suppose that V is the finite union of sets of the form $D(g_i)$, and that all of the sheaves $\mathscr{F}|D(g_i)$ and $\mathscr{F}|(D(g_i) \cap D(g_j)) = \mathscr{F}|D(g_i g_j)$ satisfy* (d1) *and* (d2)*; then $\mathscr{F}$ has the following two properties:*

- (d′1) *For each $f \in A$ and for each section $s \in \Gamma(D(f) \cap V, \mathscr{F})$, there exists an integer $n \geqslant 0$ such that $f^n s$ extends to a section of $\mathscr{F}$ over V.*
- (d′2) *For each $f \in A$ and for each section $t \in \Gamma(V, \mathscr{F})$ such that the restriction of t to $D(f) \cap V$ is 0, there exists an integer $n \geqslant 0$ such that $f^n t = 0$.*

We first prove (d′2): since $D(f) \cap D(g_i) = D(f g_i)$, there exists, for each i, an integer n_i such that the restriction of $(f g_i)^{n_i} t$ to $D(g_i)$ is zero: since the image of g_i in A_{g_i} is invertible, the restriction of $f^{n_i} t$ to $D(g_i)$ is also zero; taking n to be the largest of the n_i, we have proved (d′2).

To show (d′1), we apply (d1) to the sheaf $\mathscr{F}|D(g_i)$: there exists an integer $n_i \geqslant 0$ and a section s'_i of $\mathscr{F}$ over $D(g_i)$ extending the restriction of $(f g_i)^{n_i} s$ to $D(f g_i)$; since the image of g_i in A_{g_i} is invertible, there is a section s_i of $\mathscr{F}$ over $D(g_i)$ such that $s'_i = g_i^{n_i} s_i$, and s_i extends the restriction of $f^{n_i} s$ to $D(f g_i)$; in addition we can suppose that all the n_i are equal to a single integer n. By construction, the restriction of $s_i - s_j$ to $D(f) \cap D(g_i) \cap D(g_j) = D(f g_i g_j)$ is zero; by (d2) applied to the sheaf $\mathscr{F}|D(g_i g_j)$, there exists an integer $m_{ij} \geqslant 0$ such that the restriction to $D(g_i g_j)$ of $(f g_i g_j)^{m_{ij}}(s_i - s_j)$ is zero; since the image of $g_i g_j$ in $A_{g_i g_j}$ is invertible, the restriction of $f^{m_{ij}}(s_i - s_j)$ to $D(g_i g_j)$ is zero. We can then assume that all the m_{ij} are equal to a single integer m, and so there exists a section $s' \in \Gamma(V, \mathscr{F})$ extending the $f^m s_i$; as a result, this section extends $f^{n+m} s$, hence we have proved (d′1).

It remains to show that (d1) and (d2) imply (a). We first show that (d1) and (d2) imply that these conditions are satisfied for each sheaf $\mathscr{F}|D(g)$, where $g \in A$ is such that $D(g) \subset V$. This is clear for (d1); on the other hand, if $t \in \Gamma(D(g), \mathscr{F})$ is such that its restriction to $D(f) \subset D(g)$ is zero, there exists, by (d1), an integer $m \geqslant 0$ such that $g^m t$ extends to a section s of $\mathscr{F}$ over V; applying (d2), we I | 92 see that there exists an integer $n \geqslant 0$ such that $f^n g^m t = 0$, and as the image of g in A_g is invertible, $f^n t = 0$.

That being so, since V is quasi-compact, Lemma (1.4.1.1) proves that the conditions (d′1) and (d′2) are satisfied. Consider then the A-module $M = \Gamma(V, \mathscr{F})$, and define a homomorphism of $\widetilde{A}$-modules $u : \widetilde{M} \to j_*(\mathscr{F})$, where j is the canonical injection $V \to X$. Since the $D(f)$ form a basis for the topology of X, it suffices, for each $f \in A$, to define a homomorphism $u_f : M_f \to \Gamma(D(f), j_*(\mathscr{F})) = \Gamma(D(f) \cap V, \mathscr{F})$, with the usual compatibility conditions (**0**, 3.2.5). Since the canonical image of f in A_f is invertible, the restriction homomorphism $M = \Gamma(V, \mathscr{F}) \to \Gamma(D(f) \cap V, \mathscr{F})$ factors as

$M \to M_f \xrightarrow{u_f} \Gamma(D(f) \cap V, \mathscr{F})$ (**0**, 1.2.4), and the verification of these compatibility conditions for $D(g) \subset D(f)$ is immediate. This being so, we show that the condition (d′1) (resp. (d′2)) implies that each u_f is surjective (resp. injective), which proves that u is *bijective*, and as a result that $\mathscr{F}$ is the restriction to V of an $\widetilde{A}$-module isomorphic to $\widetilde{M}$. If $s \in \Gamma(D(f) \cap V, \mathscr{F})$, there exists, by (d′1), an integer $n \geqslant 0$ such that $f^n s$ extends to a section $z \in M$; we then have $u_f(z/f^n) = s$, so u_f is surjective. Similarly, if $z \in M$ is such that $u_f(z/1) = 0$, this means that the restriction to $D(f) \cap V$ of the section z is zero; according to (d′2), there exists an integer $n \geqslant 0$ such that $f^n z = 0$, hence $z/1 = 0$ in M_f, and so u_f is injective. □

Corollary (1.4.2). — *Each quasi-coherent sheaf over a quasi-compact open subset of X is induced by a quasi-coherent sheaf on X.*

Corollary (1.4.3). — *Every quasi-coherent $\mathscr{O}_X$-algebra over $X = \operatorname{Spec}(A)$ is isomorphic to an $\mathscr{O}_X$-algebra of the form $\widetilde{B}$, where B is an algebra over A; every quasi-coherent $\widetilde{B}$-module is isomorphic to a $\widetilde{B}$-module of the form $\widetilde{N}$, where N is a B-module.*

Proof. Indeed, a quasi-coherent $\mathscr{O}_X$-algebra is a quasi-coherent $\mathscr{O}_X$-module, and therefore of the form $\widetilde{B}$, where B is an A-module; the fact that B is an A-algebra follows from the characterization of the structure of an $\mathscr{O}_X$-algebra using the homomorphism $\widetilde{B} \otimes_{\widetilde{A}} \widetilde{B} \to \widetilde{B}$ of $\widetilde{A}$-modules, as well as from Corollary (1.3.12). If $\mathscr{G}$ is a quasi-coherent $\widetilde{B}$-module, it suffices to show that it is also a quasi-coherent $\widetilde{A}$-module and then conclude in the same way; since the question is local, we can, by restricting to an open subset of X of the form $D(f)$, assume that $\mathscr{G}$ is the cokernel of a homomorphism $\widetilde{B}^{(I)} \to \widetilde{B}^{(J)}$ of $\widetilde{B}$-modules (and *a fortiori* of $\widetilde{A}$-modules); the proposition then follows from Corollaries (1.3.8) and (1.3.9). □

1.5. Coherent sheaves over a prime spectrum

Theorem (1.5.1). — *Let A be a* Noetherian *ring, $X = \operatorname{Spec}(A)$ its prime spectrum, V an open subset of X, and $\mathscr{F}$ an $(\mathscr{O}_X|V)$-module. The following conditions are equivalent.*

(a) *$\mathscr{F}$ is coherent.*
(b) *$\mathscr{F}$ is of finite type and quasi-coherent.*
(c) *There exists an A-module M of finite type such that $\mathscr{F}$ is isomorphic to the sheaf $\widetilde{M}|V$.*

Proof. (a) trivially implies (b). To see that (b) implies (c), first note that, since V is quasi-compact (**0**, 2.2.3), $\mathscr{F}$ is isomorphic to a sheaf $\widetilde{N}|V$, where N is an A-module (1.4.1). We have $N = \varinjlim M_\lambda$, where M_λ ranges over the set of A-submodules of N of finite type, hence (1.3.9) $\mathscr{F} = \widetilde{N}|V = \varinjlim \widetilde{M_\lambda}|V$; but since $\mathscr{F}$ is of finite type, and V is quasi-compact, there exists an index λ such that $\mathscr{F} = \widetilde{M_\lambda}|V$ (**0**, 5.2.3). **I | 93**

Finally, we show that (c) implies (a). It is clear that $\mathscr{F}$ is then of finite type ((1.3.6) and (1.3.9)); in addition, since the question is local, we can restrict to the case where $V = D(f)$, $f \in A$. Since A_f is Noetherian, we see that it suffices to prove that the kernel of a homomorphism $\widetilde{A}^n \to \widetilde{M}$, where M is an A-module, is of finite type. But such a homomorphism is of the form $\widetilde{u}$, where u is a homomorphism $A^n \to M$ (1.3.8), and if $P = \operatorname{Ker} u$ then we have $\widetilde{P} = \operatorname{Ker} \widetilde{u}$ (1.3.9). Since A is Noetherian, P is of finite type, which finishes the proof. □

Corollary (1.5.2). — *Under the hypotheses of (1.5.1), the sheaf $\mathscr{O}_X$ is a coherent sheaf of rings.*

Corollary (1.5.3). — *Under the hypotheses of (1.5.1), every coherent sheaf over an open subset of X is induced by a coherent sheaf on X.*

Corollary (1.5.4). — *Under the hypotheses of (1.5.1), every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$ is the inductive limit of the coherent $\mathscr{O}_X$-submodules of $\mathscr{F}$.*

Proof. Indeed, $\mathscr{F} = \widetilde{M}$, where M is an A-module, and M is the inductive limit of its submodules of finite type; we conclude the proof by appealing to (1.3.9) and (1.5.1). □

1.6. Functorial properties of quasi-coherent sheaves over a prime spectrum

(1.6.1). Let A, A' be rings,

$$\phi : A' \longrightarrow A$$

a homomorphism, and

$$^a\phi : X = \operatorname{Spec}(A) \longrightarrow X' = \operatorname{Spec}(A')$$

the continuous map associated to ϕ (1.2.1). We will define a *canonical homomorphism*

$$\widetilde{\phi} : \mathscr{O}_{X'} \longrightarrow {}^a\phi_*(\mathscr{O}_X)$$

of sheaves of rings. For each $f' \in A'$, we put $f = \phi(f')$; we have ${}^a\phi^{-1}(D(f')) = D(f)$ (1.2.2.2). The rings $\Gamma(D(f'), \widetilde{A'})$ and $\Gamma(D(f), \widetilde{A})$ are respectively identified with $A'_{f'}$ and A_f ((1.3.6) and (1.3.7)). The homomorphism ϕ canonically defines a homomorphism $\phi_{f'} : A'_{f'} \to A_f$ (**0**, 1.5.1), in other words, we have a homomorphism of rings

$$\Gamma(D(f'), \widetilde{A'}) \longrightarrow \Gamma({}^a\phi^{-1}(D(f')), \widetilde{A}) = \Gamma(D(f'), {}^a\phi_*(\widetilde{A})).$$

In addition, these homomorphisms satisfy the usual compatibility conditions: for $D(f') \supset D(g')$, **I** | 94
the diagram

$$\begin{tikzcd}
\Gamma(D(f'), \widetilde{A'}) \arrow[r] \arrow[d] & \Gamma(D(f'), {}^a\phi_*(\widetilde{A})) \arrow[d] \\
\Gamma(D(g'), \widetilde{A'}) \arrow[r] & \Gamma(D(g'), {}^a\phi_*(\widetilde{A}))
\end{tikzcd}$$

is commutative (**0**, 1.5.1); we have thus defined a homomorphism of $\mathscr{O}_{X'}$-algebras, as the $D(f')$ form a basis for the topology of X' (**0**, 3.2.3). The pair $\Phi = ({}^a\phi, \widetilde{\phi})$ is thus a *morphism* of ringed spaces

$$\Phi : (X, \mathscr{O}_X) \longrightarrow (X', \mathscr{O}_{X'}),$$

(**0**, 4.1.1).

We also note that, if we put $x' = {}^a\phi(x)$, then the homomorphism $\widetilde{\phi}_x^\sharp$ (**0**, 3.7.1) is exactly the homomorphism

$$\phi_x : A'_{x'} \longrightarrow A_x$$

canonically induced by $\phi : A' \to A$ (**0**, 1.5.1). Indeed, each $z' \in A'_{x'}$ can be written as g'/f', where f', g' are in A' and $f' \notin \mathfrak{j}_{x'}$; $D(f')$ is then a neighbourhood of x' in X', and the homomorphism $\Gamma(D(f'), \widetilde{A'}) \to \Gamma({}^a\phi^{-1}(D(f')), \widetilde{A})$ induced by $\widetilde{\phi}$ is exactly $\phi_{f'}$; by considering the section $s' \in \Gamma(D(f'), \widetilde{A'})$ corresponding to $g'/f' \in A'_{f'}$, we obtain $\widetilde{\phi}_x^\sharp(z') = \phi(g')/\phi(f')$ in A_x.

Example (1.6.2). — Let S be a multiplicative subset of A, and ϕ the canonical homomorphism $A \to S^{-1}A$; we have already seen (1.2.6) that ${}^a\phi$ is a *homeomorphism* from $Y = \operatorname{Spec}(S^{-1}A)$ to the subspace of $X = \operatorname{Spec}(A)$ consisting of the x such that $\mathfrak{j}_x \cap S = \varnothing$. In addition, for each x in this subspace, which is thus of the form ${}^a\phi(y)$ with $y \in Y$, the homomorphism $\widetilde{\phi}_y^\sharp : \mathscr{O}_x \to \mathscr{O}_y$ is *bijective* (**0**, 1.2.6); in other words, $\mathscr{O}_Y$ is identified with the sheaf on Y induced by $\mathscr{O}_X$.

Proposition (1.6.3). — *For every A-module M, there exists a canonical functorial isomorphism from the $\mathscr{O}_{X'}$-module $(M_{[\phi]})^\sim$ to the direct image $\Phi_*(\widetilde{M})$.*

Proof. For brevity, put $M' = M_{[\phi]}$, and for each $f' \in A'$, also put $f = \phi(f')$. The modules of sections $\Gamma(D(f'), \widetilde{M'})$ and $\Gamma(D(f), \widetilde{M})$ are identified, respectively, with the modules $M'_{f'}$ and M_f (over $A'_{f'}$ and A_f, respectively); in addition, the $A'_{f'}$-module $(M_f)_{[\phi_{f'}]}$ is canonically isomorphic to $M'_{f'}$ (**0**, 1.5.2). We thus have a functorial isomorphism of $\Gamma(D(f'), \widetilde{A'})$-modules: $\Gamma(D(f'), \widetilde{M'}) \simeq \Gamma({}^a\phi^{-1}(D(f')), \widetilde{M})_{[\phi_{f'}]}$ and these isomorphisms satisfy the usual compatibility conditions with the restrictions (**0**, 1.5.6), thus defining the desired functorial isomorphism. More precisely, if $u : M_1 \to M_2$ is a homomorphism of A-modules, it may be regarded as a homomorphism $(M_1)_{[\phi]} \to (M_2)_{[\phi]}$ of A'-modules; if we denote this homomorphism by $u_{[\phi]}$, then $\Phi_*(\widetilde{u})$ is identified with $(u_{[\phi]})^\sim$. □

This proof also shows that, for each A-*algebra* B, the canonical functorial isomorphism $(B_{[\phi]})^{\sim} \simeq \Phi_*(\widetilde{B})$ is an isomorphism of $\mathscr{O}_{X'}$-*algebras*; if M is a B-module, the canonical functorial isomorphism $(M_{[\phi]})^{\sim} \simeq \Phi_*(\widetilde{M})$ is an isomorphism of $\Phi_*(\widetilde{B})$-modules. **I | 95**

Corollary (1.6.4). — *The direct image functor Φ_* is exact on the category of quasi-coherent $\mathscr{O}_X$-modules.*

Proof. Indeed, it is clear that $M_{[\phi]}$ is an exact functor in M and $\widetilde{M'}$ is an exact functor in M' (1.3.5). □

Proposition (1.6.5). — *Let N' be an A'-module, and N the A-module $N' \otimes_{A'} A_{[\phi]}$; then there exists a canonical functorial isomorphism from the $\mathscr{O}_X$-module $\Phi^*(\widetilde{N'})$ to $\widetilde{N}$.*

Proof. We first remark that $j : z' \mapsto z' \otimes 1$ is an A'-homomorphism from N' to $N_{[\phi]}$: indeed, by definition, for $f' \in A'$, we have $(f'z') \otimes 1 = z' \otimes \phi(f') = \phi(f')(z' \otimes 1)$. It follows from (1.3.8) that there is a homomorphism $\widetilde{j} : \widetilde{N'} \to (N_{[\phi]})^{\sim}$ of $\mathscr{O}_{X'}$-modules, and by (1.6.3) we may regard $\widetilde{j}$ as mapping $\widetilde{N'}$ into $\Phi_*(\widetilde{N})$. Corresponding canonically to this homomorphism $\widetilde{j}$ is a homomorphism $h = \widetilde{j}^{\sharp}$ from $\Phi^*(\widetilde{N'})$ to $\widetilde{N}$ (**0**, 4.4.3); we will see that, for each stalk, h_x is *bijective*. Put $x' = {}^a\phi(x)$ and let $f' \in A'$ be such that $x' \in D(f')$; let $f = \phi(f')$. The ring $\Gamma(D(f), \widetilde{A})$ is identified with A_f, the modules $\Gamma(D(f), \widetilde{N})$ and $\Gamma(D(f'), \widetilde{N'})$ with N_f and $N'_{f'}$, respectively; let $s' \in \Gamma(D(f'), \widetilde{N'})$, identified with n'/f'^p ($n' \in N'$), and let s be its image under $\widetilde{j}$ in $\Gamma(D(f), \widetilde{N})$; s is identified with $(n' \otimes 1)/f^p$. On the other hand, let $t \in \Gamma(D(f), \widetilde{A})$, identified with g/f^q ($g \in A$); then, by definition, we have $h_x(s'_{x'} \otimes t_x) = t_x \cdot s_x$ (**0**, 4.4.3). But we can canonically identify N_f with $N'_{f'} \otimes_{A'_{f'}} (A_f)_{[\phi_{f'}]}$ (**0**, 1.5.4); s then corresponds to the element $(n'/f'^p) \otimes 1$, and the section $y \mapsto t_y \cdot s_y$ with $(n'/f'^p) \otimes (g/f^q)$. The compatibility diagrams of (**0**, 1.5.6) show that h_x is exactly the canonical isomorphism

(1.6.5.1) $$N'_{x'} \otimes_{A'_{x'}} (A_x)_{[\phi_x]} \simeq N_x = (N' \otimes_{A'} A_{[\phi]})_x.$$

In addition, let $v : N'_1 \to N'_2$ be a homomorphism of A'-modules; since $\widetilde{v}_{x'} = v_{x'}$ for each $x' \in X'$, it follows immediately from the above that $\Phi^*(\widetilde{v})$ is canonically identified with $(v \otimes 1)^{\sim}$, which finishes the proof of (1.6.5). □

If B' is an A'-algebra, the canonical isomorphism from $\Phi^*(\widetilde{B'})$ to $(B' \otimes_{A'} A_{[\phi]})^{\sim}$ is an isomorphism of $\mathscr{O}_X$-algebras; if, in addition, N' is a B'-module, then the canonical isomorphism from $\Phi^*(\widetilde{N'})$ to $(N' \otimes_{A'} A_{[\phi]})^{\sim}$ is an isomorphism of $\Phi^*(\widetilde{B'})$-modules.

Corollary (1.6.6). — *The sections of $\Phi^*(\widetilde{N'})$, the canonical images of the sections s', where s' varies over the A'-module $\Gamma(\widetilde{N'})$, generate the A-module $\Gamma(\Phi^*(\widetilde{N'}))$.*

Proof. Indeed, these images are identified with the elements $z' \otimes 1$ of N, when we identify N' and N with $\Gamma(\widetilde{N'})$ and $\Gamma(\widetilde{N})$, respectively (1.3.7), and z' varies over N'. □

(1.6.7). In the proof of (1.6.5), we proved in passing that the canonical map (**0**, 4.4.3.2) $\rho : \widetilde{N'} \to \Phi_*(\Phi^*(\widetilde{N'}))$ is exactly the homomorphism $\widetilde{j}$, where $j : N' \to N' \otimes_{A'} A_{[\phi]}$ is the homomorphism **I | 96** $z' \mapsto z' \otimes 1$. Similarly, the canonical map (**0**, 4.4.3.3) $\sigma : \Phi^*(\Phi_*(\widetilde{M})) \to \widetilde{M}$ is exactly $\widetilde{p}$, where $p : M_{[\phi]} \otimes_{A'} A_{[\phi]} \to M$ is the canonical homomorphism, which sends each tensor product $z \otimes a$ ($z \in M$, $a \in A$) to $a \cdot z$; this follows immediately from the definitions ((**0**, 3.7.1), (**0**, 4.4.3), and (1.3.7)).

We conclude (**0**, 4.4.3 and 3.5.4.4) that if $v : N' \to M_{[\phi]}$ is an A'-homomorphism, then $\widetilde{v}^{\sharp} = (v \otimes 1)^{\sim}$.

(1.6.8). Let N'_1 and N'_2 be A'-modules, and assume N'_1 admits a *finite presentation*; it then follows from (1.6.7) and (1.3.12, ii) that the canonical homomorphism (**0**, 4.4.6)

$$\Phi^*(\mathscr{H}om_{\widetilde{A'}}(\widetilde{N'_1}, \widetilde{N'_2})) \longrightarrow \mathscr{H}om_{\widetilde{A}}(\Phi^*(\widetilde{N'_1}), \Phi^*(\widetilde{N'_2}))$$

is exactly $\widetilde{\gamma}$, where γ denotes the canonical homomorphism of A-modules $\operatorname{Hom}_{A'}(N'_1, N'_2) \otimes_{A'} A \to \operatorname{Hom}_A(N'_1 \otimes_{A'} A, N'_2 \otimes_{A'} A)$.

(1.6.9). Let $\mathfrak{J}'$ be an ideal of A', and M an A-module; since, by definition, $\widetilde{\mathfrak{J}}'\widetilde{M}$ is the image of the canonical homomorphism $\Phi^*(\widetilde{\mathfrak{J}}') \otimes_{\widetilde{A}} \widetilde{M} \to \widetilde{M}$, it follows from Proposition (1.6.5) and Corollary (1.3.12, i) that $\widetilde{\mathfrak{J}}'\widetilde{M}$ canonically identifies with $(\mathfrak{J}'M)^{\sim}$; in particular, $\Phi^*(\widetilde{\mathfrak{J}}')\widetilde{A}$ is identified with $(\mathfrak{J}'A)^{\sim}$, and, taking the right exactness of the functor Φ^* into account, the $\widetilde{A}$-algebra $\Phi^*((A'/\mathfrak{J}')^{\sim})$ is identified with $(A/\mathfrak{J}'A)^{\sim}$.

(1.6.10). Let A'' be a third ring, ϕ' a homomorphism $A'' \to A'$, and write $\phi'' = \phi \circ \phi'$. It follows immediately from the definitions that ${}^a\phi'' = ({}^a\phi') \circ ({}^a\phi)$, and $\widetilde{\phi''} = \widetilde{\phi} \circ \widetilde{\phi'}$ (**0**, 1.5.7). We conclude that $\Phi'' = \Phi' \circ \Phi$; in other words, $(\operatorname{Spec}(A), \widetilde{A})$ is a *functor* from the category of rings to that of ringed spaces.

1.7. Characterization of morphisms of affine schemes

Definition (1.7.1). — We say that a ringed space $(X, \mathscr{O}_X)$ is an *affine scheme* if it is isomorphic to a ringed space of the form $(\operatorname{Spec}(A), \widetilde{A})$, where A is a ring; we then say that $\Gamma(X, \mathscr{O}_X)$, which, after choosing such an isomorphism, is canonically identified with the ring A (1.3.7), is the ring of the affine scheme $(X, \mathscr{O}_X)$, and we denote it by $A(X)$ when no confusion results.

By abuse of language, when we speak of the *affine scheme* $\operatorname{Spec}(A)$, we will always mean the ringed space $(\operatorname{Spec}(A), \widetilde{A})$.

(1.7.2). Let A and B be rings, and $(X, \mathscr{O}_X)$ and $(Y, \mathscr{O}_Y)$ the affine schemes corresponding to the prime spectra $X = \operatorname{Spec}(A)$, $Y = \operatorname{Spec}(B)$. We have seen (1.6.1) that each ring homomorphism $\phi : B \to A$ corresponds to a morphism $\Phi = ({}^a\phi, \widetilde{\phi}) = \operatorname{Spec}(\phi) : (X, \mathscr{O}_X) \to (Y, \mathscr{O}_Y)$. We note that ϕ is entirely determined by Φ, since we have, by definition, $\phi = \Gamma(\widetilde{\phi}) : \Gamma(\widetilde{B}) \to \Gamma({}^a\phi_*(\widetilde{A})) = \Gamma(\widetilde{A})$.

Theorem (1.7.3). — [2] *Let $(X, \mathscr{O}_X)$ and $(Y, \mathscr{O}_Y)$ be affine schemes. For a morphism of ringed spaces $(\psi, \theta) : (X, \mathscr{O}_X) \to (Y, \mathscr{O}_Y)$ to be of the form $({}^a\phi, \widetilde{\phi})$, where ϕ is a homomorphism of rings $A(Y) \to A(X)$, it is necessary and sufficient that, for each $x \in X$, $\theta_x^\sharp$ is a local homomorphism: $\mathscr{O}_{\psi(x)} \to \mathscr{O}_x$.*

Proof. Let $A = A(X)$, $B = A(Y)$. The condition is necessary, since we saw (1.6.1) that $\widetilde{\phi}_x^\sharp$ is the homomorphism from $B_{{}^a\phi(x)}$ to A_x canonically induced by ϕ, and, by definition, ${}^a\phi(x) = \phi^{-1}(\mathfrak{j}_x)$, so this homomorphism is local. I | 97

We now prove that the condition is sufficient. By definition, θ is a homomorphism $\mathscr{O}_Y \to \psi_*(\mathscr{O}_X)$, and we canonically obtain a ring homomorphism

$$\phi = \Gamma(\theta) : B = \Gamma(Y, \mathscr{O}_Y) \longrightarrow \Gamma(Y, \psi_*(\mathscr{O}_X)) = \Gamma(X, \mathscr{O}_X) = A.$$

The hypothesis on $\theta_x^\sharp$ means that this homomorphism induces, by passing to quotients, a monomorphism θ^x from the residue field $k(\psi(x))$ to the residue field $k(x)$, such that, for each section $f \in \Gamma(Y, \mathscr{O}_Y) = B$, we have $\theta^x(f(\psi(x))) = \phi(f)(x)$. The relation $f(\psi(x)) = 0$ is therefore equivalent to $\phi(f)(x) = 0$, which means that $\mathfrak{j}_{\psi(x)} = \mathfrak{j}_{{}^a\phi(x)}$; equivalently, $\psi(x) = {}^a\phi(x)$ for each $x \in X$, or $\psi = {}^a\phi$. We also know that the diagram

$$\begin{tikzcd}
B = \Gamma(Y, \mathscr{O}_Y) \arrow[r, "\phi"] \arrow[d] & \Gamma(X, \mathscr{O}_X) = A \arrow[d] \\
B_{\psi(x)} \arrow[r, "\theta_x^\sharp"'] & A_x
\end{tikzcd}$$

is commutative (**0**, 3.7.2), which means that $\theta_x^\sharp$ is equal to the homomorphism $\phi_x : B_{\psi(x)} \to A_x$ canonically induced by ϕ (**0**, 1.5.1). Since the homomorphisms $\theta_x^\sharp$ completely determine $\theta^\sharp$, and hence θ (**0**, 3.7.1), we conclude that $\theta = \widetilde{\phi}$, by the definition of $\widetilde{\phi}$ (1.6.1). □

We say that a morphism (ψ, θ) of ringed spaces satisfying the condition of (1.7.3) is a *morphism of affine schemes*.

---

[2] *[Trans.] See (1.8) and the footnote there.*

Corollary (1.7.4). — *If $(X, \mathscr{O}_X)$ and $(Y, \mathscr{O}_Y)$ are affine schemes, there exists a canonical isomorphism from the set of morphisms of affine schemes* $\mathrm{Hom}((X, \mathscr{O}_X),(Y, \mathscr{O}_Y))$ *to the set of ring homomorphisms from B to A, where $A = \Gamma(\mathscr{O}_X)$ and $B = \Gamma(\mathscr{O}_Y)$.*

Furthermore, we can say that the functors $(\mathrm{Spec}(A), \widetilde{A})$ in A and $\Gamma(X, \mathscr{O}_X)$ in $(X, \mathscr{O}_X)$ define an *equivalence* between the category of commutative rings and the opposite category of affine schemes (T, I, 1.2).

Corollary (1.7.5). — *If $\phi : B \to A$ is surjective, then the corresponding morphism $({}^a\phi, \widetilde{\phi})$ is a monomorphism of ringed spaces* (cf. (4.1.7)).

Proof. Indeed, we know that ${}^a\phi$ is injective (1.2.5), and, since ϕ is surjective, for each $x \in X$, $\phi_x^\sharp : B_{{}^a\phi(x)} \to A_x$, which is induced by ϕ by passing to rings of fractions, is also surjective (**0**, 1.5.1); hence the conclusion (**0**, 4.1.1). ☐

1.8. Morphisms from locally ringed spaces to affine schemes Due to a remark by J. Tate, the statements of Theorem (1.7.3) and Proposition (2.2.4) can be generalized as follows:[3] **II** | 217

Proposition (1.8.1). — *Let $(S, \mathscr{O}_S)$ be an affine scheme, and $(X, \mathscr{O}_X)$ a locally ringed space. Then there is a canonical bijection from the set of ring homomorphisms $\Gamma(S, \mathscr{O}_S) \to \Gamma(X, \mathscr{O}_X)$ to the set of morphisms* **II** | 218 *of ringed spaces $(\psi, \theta) : (X, \mathscr{O}_X) \to (S, \mathscr{O}_S)$ such that, for each $x \in X$, $\theta_x^\sharp$ is a local homomorphism $\mathscr{O}_{\psi(x)} \to \mathscr{O}_x$.*

Proof. We note first that if $(X, \mathscr{O}_X)$ and $(S, \mathscr{O}_S)$ are any two ringed spaces, then a morphism (ψ, θ) from $(X, \mathscr{O}_X)$ to $(S, \mathscr{O}_S)$ canonically defines a ring homomorphism $\Gamma(\theta) : \Gamma(S, \mathscr{O}_S) \to \Gamma(X, \mathscr{O}_X)$, hence a first map

(1.8.1.1) $$\rho : \mathrm{Hom}((X, \mathscr{O}_X),(S, \mathscr{O}_S)) \longrightarrow \mathrm{Hom}(\Gamma(S, \mathscr{O}_S), \Gamma(X, \mathscr{O}_X)).$$

Conversely, under the stated hypotheses, we set $A = \Gamma(S, \mathscr{O}_S)$, and consider a ring homomorphism $\phi : A \to \Gamma(X, \mathscr{O}_X)$. For each $x \in X$, it is clear that the set of the $f \in A$ such that $\phi(f)(x) = 0$ is a *prime ideal* of A, since $\mathscr{O}_x/\mathfrak{m}_x = k(x)$ is a field; it is therefore an element of $S = \mathrm{Spec}(A)$, which we denote by ${}^a\phi(x)$. In addition, for each $f \in A$, we have, by definition (**0**, 5.5.2), that ${}^a\phi^{-1}(D(f)) = X_f$, which proves that ${}^a\phi$ is a *continuous map* $X \to S$. We then define a homomorphism

$$\widetilde{\phi} : \mathscr{O}_S \longrightarrow {}^a\phi_*(\mathscr{O}_X)$$

of $\mathscr{O}_S$-modules; for each $f \in A$, we have $\Gamma(D(f), \mathscr{O}_S) = A_f$ (1.3.6); for each $s \in A$, we associate to $s/f \in A_f$ the element $(\phi(s)|X_f)(\phi(f)|X_f)^{-1}$ of $\Gamma(X_f, \mathscr{O}_X) = \Gamma(D(f), {}^a\phi_*(\mathscr{O}_X))$, and we immediately see (by passing from $D(f)$ to $D(fg)$) that this is a well-defined homomorphism of $\mathscr{O}_S$-modules, hence a morphism $({}^a\phi, \widetilde{\phi})$ of ringed spaces. In addition, with the same notation, and setting $y = {}^a\phi(x)$ for brevity, we immediately see (**0**, 3.7.1) that we have $\widetilde{\phi}_x^\sharp(s_y/f_y) = (\phi(s)_x)(\phi(f)_x)^{-1}$; since the relation $s_y \in \mathfrak{m}_y$ is, by definition, equivalent to $\phi(s)_x \in \mathfrak{m}_x$, we see that $\widetilde{\phi}_x^\sharp$ is a *local* homomorphism $\mathscr{O}_y \to \mathscr{O}_x$, and we have thus defined a second map $\sigma : \mathrm{Hom}(\Gamma(S, \mathscr{O}_S), \Gamma(X, \mathscr{O}_X)) \to \mathfrak{L}$, where $\mathfrak{L}$ is the set of the morphisms $(\psi, \theta) : (X, \mathscr{O}_X) \to (S, \mathscr{O}_S)$ such that $\theta_x^\sharp$ is local for each $x \in X$. It remains to prove that σ and ρ (restricted to $\mathfrak{L}$) are inverses of each other; the definition of $\widetilde{\phi}$ immediately shows that $\Gamma(\widetilde{\phi}) = \phi$, and, as a result, that $\rho \circ \sigma$ is the identity. To see that $\sigma \circ \rho$ is the identity, start with a morphism $(\psi, \theta) \in \mathfrak{L}$ and let $\phi = \Gamma(\theta)$; the hypotheses on $\theta_x^\sharp$ mean that this morphism induces, by passing to quotients, a monomorphism $\theta^x : k(\psi(x)) \to k(x)$ such that for each section $f \in A = \Gamma(S, \mathscr{O}_S)$, we have $\theta^x(f(\psi(x))) = \phi(f)(x)$; the equation $f(\psi(x)) = 0$ is therefore equivalent to $\phi(f)(x) = 0$, which proves that ${}^a\phi = \psi$. On the other hand, the definitions imply that the diagram

$$\begin{tikzcd} A \arrow[r, "\phi"] \arrow[d] & \Gamma(X, \mathscr{O}_X) \arrow[d] \\ A_{\psi(x)} \arrow[r, "\theta_x^\sharp"] & \mathscr{O}_x \end{tikzcd}$$

[3] *[Trans.] The following section (I.1.8) was added in the errata of EGA II, hence the temporary change in page numbers, which refer to EGA II.*

is commutative, and it is the same for the analogous diagram where $\theta_x^\sharp$ is replaced by $\widetilde{\varphi}_x^\sharp$, hence $\widetilde{\varphi}_x^\sharp = \theta_x^\sharp$ (**0**, 1.2.4), and, as a result, $\widetilde{\varphi} = \theta$. □

(1.8.2). When $(X, \mathscr{O}_X)$ and $(Y, \mathscr{O}_Y)$ are *locally* ringed spaces, we will consider the morphisms $(\psi, \theta) : (X, \mathscr{O}_X) \to (Y, \mathscr{O}_Y)$ such that, for each $x \in X$, $\theta_x^\sharp$ is a *local* homomorphism $\mathscr{O}_{\psi(x)} \to \mathscr{O}_x$. Henceforth when we speak of a *morphism of locally ringed spaces*, it will always be a morphism like the above; **II** | 219
with this definition of morphisms, it is clear that the locally ringed spaces form a *category*; for any two objects X and Y of this category, $\operatorname{Hom}(X, Y)$ thus denotes the set of morphisms of locally ringed spaces from X to Y (the set denoted $\mathfrak{L}$ in (1.8.1)); when we consider the set of *morphisms of ringed spaces* from X to Y, we will denote it by $\operatorname{Hom}_{\mathrm{rs}}(X, Y)$ to avoid any confusion. The map (1.8.1.1) is then written as

$$\rho : \operatorname{Hom}_{\mathrm{rs}}(X, Y) \longrightarrow \operatorname{Hom}(\Gamma(Y, \mathscr{O}_Y), \Gamma(X, \mathscr{O}_X)) \tag{1.8.2.1}$$

and its restriction

$$\rho' : \operatorname{Hom}(X, Y) \longrightarrow \operatorname{Hom}(\Gamma(Y, \mathscr{O}_Y), \Gamma(X, \mathscr{O}_X)) \tag{1.8.2.2}$$

is a *functorial* map in X and Y on the category of locally ringed spaces.

Corollary (1.8.3). — *Let $(Y, \mathscr{O}_Y)$ be a locally ringed space. For Y to be an affine scheme, it is necessary and sufficient that, for each locally ringed space $(X, \mathscr{O}_X)$, the map (1.8.2.2) be bijective.*

Proof. Proposition (1.8.1) shows that the condition is necessary. Conversely, if we suppose that the condition is satisfied, and if we put $A = \Gamma(Y, \mathscr{O}_Y)$, then it follows from the hypotheses and from (1.8.1) that the functors $X \mapsto \operatorname{Hom}(X, Y)$ and $X \mapsto \operatorname{Hom}(X, \operatorname{Spec}(A))$, from the category of locally ringed spaces to that of sets, are *isomorphic*. We know that this implies the existence of a canonical isomorphism $Y \to \operatorname{Spec}(A)$ (cf. **0**, 8).[4] □

(1.8.4). Let $S = \operatorname{Spec}(A)$ be an affine scheme; denote by (S', A') the ringed space whose underlying space is *a point* and the structure sheaf A' is the (necessarily simple) sheaf on S' defined by the ring A. Let $\pi : S \to S'$ be the unique map from S to S'; on the other hand, we note that, for each open subset U of S, we have a canonical map $\Gamma(S', A') = \Gamma(S, \mathscr{O}_S) \to \Gamma(U, \mathscr{O}_S)$ which thus defines a *π-morphism $\iota : A' \to \mathscr{O}_S$* of sheaves of rings. We have thus canonically defined a *morphism of ringed spaces $i = (\pi, \iota) : (S, \mathscr{O}_S) \to (S', A')$*. For each A-module M, we denote by M' the simple sheaf on S' defined by M, which is evidently an A'-module. It is clear that $i_*(\widetilde{M}) = M'$ (1.3.7).

Lemma (1.8.5). — *With the notation of (1.8.4), for each A-module M, the canonical functorial $\mathscr{O}_S$-homomorphism* (**0**, 4.4.3.3)

$$i^*(i_*(\widetilde{M})) \longrightarrow \widetilde{M} \tag{1.8.5.1}$$

is an isomorphism.

Proof. Indeed, both sides of (1.8.5.1) are right exact (the functor $M \mapsto i_*(\widetilde{M})$ evidently being exact) and commute with direct sums; by considering M as the cokernel of a homomorphism $A^{(I)} \to A^{(J)}$, we can reduce to proving the lemma for the case where $M = A$, and it is evident in this case. □

Corollary (1.8.6). — *Let $(X, \mathscr{O}_X)$ be a ringed space, and $u : X \to S$ a morphism of ringed spaces. For each* **II** | 220
A-module M, we have (with the notation of (1.8.4)) a canonical functorial isomorphism of $\mathscr{O}_X$-modules

$$u^*(\widetilde{M}) \simeq u^*(i^*(M')). \tag{1.8.6.1}$$

Corollary (1.8.7). — *Under the hypotheses of (1.8.6), we have, for each A-module M and each $\mathscr{O}_X$-module $\mathscr{F}$, a canonical isomorphism, functorial in M and $\mathscr{F}$,*

$$\operatorname{Hom}_{\mathscr{O}_S}(\widetilde{M}, u_*(\mathscr{F})) \simeq \operatorname{Hom}_A(M, \Gamma(X, \mathscr{F})). \tag{1.8.7.1}$$

[4] *[Trans.] The French text prints $X \to \operatorname{Spec}(A)$ here; the represented functor and the conclusion require $Y \to \operatorname{Spec}(A)$.*

Proof. We have, according to (**0**, 4.4.3) and Lemma (1.8.5), a canonical isomorphism of bifunctors

$$\mathrm{Hom}_{\mathscr{O}_S}(\widetilde{M}, u_*(\mathscr{F})) \simeq \mathrm{Hom}_{A'}(M', i_*(u_*(\mathscr{F})))$$

and it is clear that the right hand side is exactly $\mathrm{Hom}_A(M, \Gamma(X, \mathscr{F}))$. We note that the canonical homomorphism (1.8.7.1) sends each $\mathscr{O}_S$-homomorphism $h : \widetilde{M} \to u_*(\mathscr{F})$ (in other words, each u-morphism $\widetilde{M} \to \mathscr{F}$) to the A-homomorphism $\Gamma(h) : M \to \Gamma(S, u_*(\mathscr{F})) = \Gamma(X, \mathscr{F})$. □

(1.8.8). With the notation of (1.8.4), it is clear (**0**, 4.1.1) that each morphism of ringed spaces $(\psi, \theta) : X \to S'$ is equivalent to the data of a ring homomorphism $A \to \Gamma(X, \mathscr{O}_X)$. We can thus interpret Proposition (1.8.1) as defining a canonical bijection $\mathrm{Hom}(X, S) \simeq \mathrm{Hom}(X, S')$ (where we understand that the right-hand side is the collection of morphisms of ringed spaces, since in general A is not a local ring). More generally, if X and Y are locally ringed spaces, and if (Y', A') is the ringed space whose underlying space is a point and whose sheaf of rings A' is the simple sheaf defined by the ring $\Gamma(Y, \mathscr{O}_Y)$, we can interpret (1.8.2.1) as a map

$$\rho : \mathrm{Hom}_{\mathrm{rs}}(X, Y) \longrightarrow \mathrm{Hom}(X, Y'). \tag{1.8.8.1}$$

The result of Corollary (1.8.3) is interpreted by saying that affine schemes are characterized among locally ringed spaces as those for which the restriction of ρ to $\mathrm{Hom}(X, Y)$:

$$\rho' : \mathrm{Hom}(X, Y) \longrightarrow \mathrm{Hom}(X, Y') \tag{1.8.8.2}$$

is *bijective* for *every* locally ringed space X. In a later chapter, we generalize this definition, which allows us to associate to *any* ringed space Z (and not only to a ringed space whose underlying space is a point) a locally ringed space which we will call $\mathrm{Spec}(Z)$; this will be the starting point for a "relative" theory of preschemes over any ringed space, extending the results of Chapter I.

(1.8.9). We can consider the pairs $(X, \mathscr{F})$ consisting of a locally ringed space X and an $\mathscr{O}_X$-module $\mathscr{F}$ as forming a category, a *morphism* in this category being a pair (u, h) consisting of a morphism of locally ringed spaces $u : X \to Y$ and a u-morphism $h : \mathscr{G} \to \mathscr{F}$ of modules; these morphisms (for **II** | 221
$(X, \mathscr{F})$ and $(Y, \mathscr{G})$ fixed) form a set which we denote by $\mathrm{Hom}((X, \mathscr{F}), (Y, \mathscr{G}))$; the map $(u, h) \mapsto (\rho'(u), \Gamma(h))$ is a canonical map

$$\mathrm{Hom}((X, \mathscr{F}), (Y, \mathscr{G})) \longrightarrow \mathrm{Hom}((\Gamma(Y, \mathscr{O}_Y), \Gamma(Y, \mathscr{G})), (\Gamma(X, \mathscr{O}_X), \Gamma(X, \mathscr{F}))) \tag{1.8.9.1}$$

functorial in $(X, \mathscr{F})$ and $(Y, \mathscr{G})$, the right-hand side being the set of di-homomorphisms corresponding to the rings and modules considered (**0**, 1.0.2).

Corollary (1.8.10). — *Let Y be a locally ringed space, and $\mathscr{G}$ an $\mathscr{O}_Y$-module. For Y to be an affine scheme and $\mathscr{G}$ to be a quasi-coherent $\mathscr{O}_Y$-module, it is necessary and sufficient that, for each pair $(X, \mathscr{F})$ consisting of a locally ringed space X and an $\mathscr{O}_X$-module $\mathscr{F}$, the canonical map* (1.8.9.1) *be bijective.*

We leave the proof, which is modelled on that of (1.8.3), using (1.8.1) and (1.8.7), to the reader.

Remark (1.8.11). — The statements (1.7.3), (1.7.4), and (2.2.4) are particular cases of (1.8.1), as well as the definition in (1.6.1); similarly, (2.2.5) follows from (1.8.7). Corollary (1.8.7) also implies (1.6.3) (and, as a result, (1.6.4)) as a particular case, since if X is an affine scheme and $\Gamma(X, \mathscr{F}) = N$, then the functors $M \mapsto \mathrm{Hom}_{\mathscr{O}_S}(\widetilde{M}, u_*(\widetilde{N}))$ and $M \mapsto \mathrm{Hom}_{\mathscr{O}_S}(\widetilde{M}, (N_{[\phi]})^{\sim})$ (where $\phi : A \to \Gamma(X, \mathscr{O}_X)$ corresponds to u) are isomorphic, by Corollaries (1.8.7) and (1.3.8). Finally, (1.6.5) (and, as a result, (1.6.6)) follow from (1.8.6), and the fact that, for each $f \in A$, the A_f-modules $N' \otimes_{A'} A_f$ and $(N' \otimes_{A'} A)_f$ (with the notation of (1.6.5)) are canonically isomorphic.

§2. Preschemes and morphisms of preschemes

2.1. Definition of preschemes

(2.1.1). Given a ringed space $(X, \mathscr{O}_X)$, we say that an open subset V of X is an *affine open* subset if the ringed space $(V, \mathscr{O}_X|V)$ is an affine scheme (1.7.1).

Definition (2.1.2). — We define a prescheme to be a ringed space $(X, \mathscr{O}_X)$ such that every point of X admits an affine open neighbourhood.

Proposition (2.1.3). — *If $(X, \mathscr{O}_X)$ is a prescheme, then its affine open subsets form a basis for the topology of X.* I | 98

Proof. If V is an arbitrary open neighbourhood of $x \in X$, then there exists by hypothesis an open neighbourhood W of x such that $(W, \mathscr{O}_X|W)$ is an affine scheme; denote its ring by A. In the space W, $V \cap W$ is an open neighbourhood of x; so there exists $f \in A$ such that $D(f)$ is an open neighbourhood of x contained in $V \cap W$ (1.1.10, i). The ringed space $(D(f), \mathscr{O}_X|D(f))$ is thus an affine scheme whose ring is isomorphic to A_f (1.3.6), whence the proposition. □

Proposition (2.1.4). — *The underlying space of a prescheme is a Kolmogoroff space.*

Proof. If x and y are two distinct points of a prescheme X, then it is clear that there exists an open neighbourhood of one of these points that does not contain the other if x and y are not in the same affine open subset; and if they are in the same affine open subset, this is a result of (1.1.8). □

Proposition (2.1.5). — *If $(X, \mathscr{O}_X)$ is a prescheme, then every closed irreducible subset of X admits exactly one generic point, and the map $x \mapsto \overline{\{x\}}$ is thus a bijection of X onto its set of closed irreducible subsets.*

Proof. If Y is a closed irreducible subset of X and $y \in Y$, and if U is an affine open neighbourhood of y in X, then $U \cap Y$ is dense in Y, and also irreducible ((**0**, 2.1.1) and (**0**, 2.1.4)); thus, by Corollary (1.1.14), $U \cap Y$ is the closure in U of a point x, and so $Y \subset \overline{U}$ is the closure of x in X. The uniqueness of the generic point of Y is a result of Proposition (2.1.4) and of (**0**, 2.1.3).[5] □

(2.1.6). If Y is a closed irreducible subset of X, and y its generic point, then the local ring $\mathscr{O}_y$ (also written $\mathscr{O}_{X/Y}$) is called the *local ring of X along Y*, or the *local ring of Y in X*.

If X itself is irreducible and x its generic point then we say that $\mathscr{O}_x$ is the *ring of rational functions on X* (cf. §7).

Proposition (2.1.7). — *If $(X, \mathscr{O}_X)$ is a prescheme, then the ringed space $(U, \mathscr{O}_X|U)$ is a prescheme for every open subset U.*

Proof. This follows directly from Definition (2.1.2) and Proposition (2.1.3). □

We say that $(U, \mathscr{O}_X|U)$ is the prescheme *induced* on U by $(X, \mathscr{O}_X)$, or the *restriction* of $(X, \mathscr{O}_X)$ to U.

(2.1.8). We say that a prescheme $(X, \mathscr{O}_X)$ is *irreducible* (resp. *connected*) if the underlying space X is irreducible (resp. connected). We say that a prescheme is *integral* if it is *irreducible and reduced* (cf. (5.1.4)). We say that a prescheme $(X, \mathscr{O}_X)$ is *locally integral* if every $x \in X$ admits an open neighbourhood U such that the prescheme induced on U by $(X, \mathscr{O}_X)$ is integral.

2.2. Morphisms of preschemes

Definition (2.2.1). — Given two preschemes, $(X, \mathscr{O}_X)$ and $(Y, \mathscr{O}_Y)$, we define a morphism (of preschemes) from $(X, \mathscr{O}_X)$ to $(Y, \mathscr{O}_Y)$ to be a morphism of ringed spaces (ψ, θ) such that, for all $x \in X$, $\theta_x^\sharp$ is a local homomorphism $\mathscr{O}_{\psi(x)} \to \mathscr{O}_x$.

By passing to quotients, the map $\mathscr{O}_{\psi(x)} \to \mathscr{O}_x$ therefore gives a monomorphism $\theta^x : k(\psi(x)) \to k(x)$, which lets us consider $k(x)$ as an *extension* of the field $k(\psi(x))$. I | 99

(2.2.2). The composition (ψ'', θ'') of two morphisms (ψ, θ), (ψ', θ') of preschemes is also a morphism of preschemes, as follows from the formula $\theta''^\sharp = \theta^\sharp \circ \psi^*(\theta'^\sharp)$ (**0**, 3.5.5). From this we conclude that preschemes form a *category*; using the usual notation, we will write $\operatorname{Hom}(X, Y)$ to mean the set of morphisms from a prescheme X to a prescheme Y.

Example (2.2.3). — If U is an open subset of X, then the canonical injection (**0**, 4.1.2) of the induced prescheme $(U, \mathscr{O}_X|U)$ into $(X, \mathscr{O}_X)$ is a morphism of preschemes; it is further a *monomorphism* of ringed spaces (and *a fortiori* a monomorphism of preschemes), as follows immediately from (**0**, 4.1.1).

[5] *[Trans.] The French text prints "the generic point of X" here; the proposition and the preceding sentence concern the generic point of Y.*

Proposition (2.2.4). — [6] *Let $(X, \mathscr{O}_X)$ be a prescheme, and $(S, \mathscr{O}_S)$ an affine scheme associated to a ring A. Then there exists a canonical bijective correspondence between morphisms of preschemes from $(X, \mathscr{O}_X)$ to $(S, \mathscr{O}_S)$ and ring homomorphisms from A to $\Gamma(X, \mathscr{O}_X)$.*

Proof. First note that, if $(X, \mathscr{O}_X)$ and $(Y, \mathscr{O}_Y)$ are two arbitrary ringed spaces, a morphism (ψ, θ) from $(X, \mathscr{O}_X)$ to $(Y, \mathscr{O}_Y)$ canonically defines a ring homomorphism $\Gamma(\theta) : \Gamma(Y, \mathscr{O}_Y) \to \Gamma(Y, \psi_*(\mathscr{O}_X)) = \Gamma(X, \mathscr{O}_X)$. In the case that we consider, everything boils down to showing that any homomorphism $\phi : A \to \Gamma(X, \mathscr{O}_X)$ is of the form $\Gamma(\theta)$ for exactly one θ. Now, by hypothesis, there is a covering (V_α) of X by affine open subsets; by composing ϕ with the restriction homomorphism $\Gamma(X, \mathscr{O}_X) \to \Gamma(V_\alpha, \mathscr{O}_X|V_\alpha)$, we obtain a homomorphism $\phi_\alpha : A \to \Gamma(V_\alpha, \mathscr{O}_X|V_\alpha)$ that corresponds to a unique morphism $(\psi_\alpha, \theta_\alpha)$ from the prescheme $(V_\alpha, \mathscr{O}_X|V_\alpha)$ to $(S, \mathscr{O}_S)$, by Theorem (1.7.3). Furthermore, for each pair of indices (α, β), each point of $V_\alpha \cap V_\beta$ admits an affine open neighbourhood W contained in $V_\alpha \cap V_\beta$ (2.1.3); it is clear that, by composing ϕ_α and ϕ_β with the restriction homomorphisms to W, we obtain the same homomorphism $\Gamma(S, \mathscr{O}_S) \to \Gamma(W, \mathscr{O}_X|W)$; hence, by the relations $(\theta_\alpha^\sharp)_x = (\phi_\alpha)_x$ for all $x \in V_\alpha$ and all α (1.6.1), the restrictions to W of the morphisms $(\psi_\alpha, \theta_\alpha)$ and $(\psi_\beta, \theta_\beta)$ coincide. From this we conclude that there is a unique morphism of ringed spaces $(\psi, \theta) : (X, \mathscr{O}_X) \to (S, \mathscr{O}_S)$ whose restriction to each V_α is $(\psi_\alpha, \theta_\alpha)$; it is clear that this is a morphism of preschemes and that $\Gamma(\theta) = \phi$.

Let $u : A \to \Gamma(X, \mathscr{O}_X)$ be a ring homomorphism, and $v = (\psi, \theta)$ the corresponding morphism $(X, \mathscr{O}_X) \to (S, \mathscr{O}_S)$. For each $f \in A$, we have that

$$\psi^{-1}(D(f)) = X_{u(f)} \tag{2.2.4.1}$$

with the notation of (**0**, 5.5.2) relative to the locally free sheaf $\mathscr{O}_X$. In fact, it suffices to verify this formula when X itself is affine, and then this is nothing but (1.2.2.2). □

Proposition (2.2.5). — *Under the hypotheses of Proposition (2.2.4), let $\phi : A \to \Gamma(X, \mathscr{O}_X)$ be a ring homomorphism, $f : (X, \mathscr{O}_X) \to (S, \mathscr{O}_S)$ the corresponding morphism of preschemes, $\mathscr{G}$ (resp. $\mathscr{F}$) a quasi-coherent $\mathscr{O}_X$-module (resp. quasi-coherent $\mathscr{O}_S$-module), and $M = \Gamma(S, \mathscr{F})$. Then there exists a canonical bijective correspondence between f-morphisms $\mathscr{F} \to \mathscr{G}$ (**0**, 4.4.1) and A-homomorphisms $M \to$* **I** | 100
$(\Gamma(X, \mathscr{G}))_{[\phi]}$.

Proof. Reasoning as in Proposition (2.2.4), we reduce to the case where X is affine, and the proposition then follows from Proposition (1.6.3) and from Corollary (1.3.8). □

(2.2.6). We say that a morphism of preschemes $(\psi, \theta) : (X, \mathscr{O}_X) \to (Y, \mathscr{O}_Y)$ is *open* (resp. *closed*) if, for all open subsets U of X (resp. all closed subsets F of X), $\psi(U)$ is open (resp. $\psi(F)$ is closed) in Y. We say that (ψ, θ) is *dominant* if $\psi(X)$ is dense in Y, and *surjective* if ψ is surjective. We note that these conditions rely only on the continuous map ψ.

Proposition (2.2.7). — *Let*

$$f = (\psi, \theta) : (X, \mathscr{O}_X) \longrightarrow (Y, \mathscr{O}_Y)$$

and

$$g = (\psi', \theta') : (Y, \mathscr{O}_Y) \longrightarrow (Z, \mathscr{O}_Z)$$

be morphisms of preschemes.

(i) *If f and g are both open (resp. closed, dominant, surjective), then so is $g \circ f$.*
(ii) *If f is surjective and $g \circ f$ is closed, then g is closed.*
(iii) *If $g \circ f$ is surjective, then g is surjective.*

Proof. Assertions (i) and (iii) are evident. Write $g \circ f = (\psi'', \theta'')$. If F is closed in Y then $\psi^{-1}(F)$ is closed in X, so $\psi''(\psi^{-1}(F))$ is closed in Z; but since ψ is surjective, $\psi(\psi^{-1}(F)) = F$, so $\psi''(\psi^{-1}(F)) = \psi'(F)$, which proves (ii). □

Proposition (2.2.8). — *Let $f = (\psi, \theta)$ be a morphism $(X, \mathscr{O}_X) \to (Y, \mathscr{O}_Y)$, and (U_α) an open cover of Y. For f to be open (resp. closed, surjective, dominant), it is necessary and sufficient for its restriction to each induced prescheme $(\psi^{-1}(U_\alpha), \mathscr{O}_X|\psi^{-1}(U_\alpha))$, considered as a morphism of preschemes from this induced prescheme to the induced prescheme $(U_\alpha, \mathscr{O}_Y|U_\alpha)$ to be open (resp. closed, surjective, dominant).*

[6] *[Trans.] See (1.8) and the footnote there.*

Proof. The proposition follows immediately from the definitions, taking into account the fact that a subset F of Y is closed (resp. open, dense) in Y if and only if each $F \cap U_\alpha$ is closed (resp. open, dense) in U_α. □

(2.2.9). Let $(X, \mathscr{O}_X)$ and $(Y, \mathscr{O}_Y)$ be two preschemes; suppose that X and Y have the same finite number n of irreducible components X_i and Y_i, respectively $(1 \leqslant i \leqslant n)$; let ξ_i (resp. η_i) be the generic point of X_i (resp. Y_i) (2.1.5). We say that a morphism

$$f = (\psi, \theta) : (X, \mathscr{O}_X) \longrightarrow (Y, \mathscr{O}_Y)$$

is *birational* if, for all i, $\psi^{-1}(\eta_i) = \{\xi_i\}$ and $\theta^\sharp_{\xi_i} : \mathscr{O}_{\eta_i} \to \mathscr{O}_{\xi_i}$ is an *isomorphism*. It is clear that a birational morphism is dominant (**0**, 2.1.8), and thus it is surjective if it is also closed.

Notation (2.2.10). — In all that follows, when there is no risk of confusion, we *suppress* the structure sheaf (resp. the morphism of structure sheaves) from the notation of a prescheme (resp. morphism of preschemes). If U is an open subset of the underlying space X of a prescheme, then whenever we speak of U as a prescheme we always mean the induced prescheme on U.

2.3. Gluing preschemes

(2.3.1). It follows from Definition (2.1.2) that every ringed space obtained by *gluing* preschemes I | 101
(**0**, 4.1.6) is again a prescheme. In particular, since every prescheme admits, by definition, a cover by affine open sets, we see that every prescheme can actually be obtained by *gluing affine schemes*.

Example (2.3.2). — Let K be a field, let $B = K[s]$ and $C = K[t]$ be two polynomial rings in one indeterminate over K, and let $X_1 = \operatorname{Spec}(B)$ and $X_2 = \operatorname{Spec}(C)$, which are two isomorphic affine schemes. In X_1 (resp. X_2), let U_{12} (resp. U_{21}) be the affine open $D(s)$ (resp. $D(t)$) where the ring B_s (resp. C_t) is formed of rational fractions of the form $f(s)/s^m$ (resp. $g(t)/t^n$) with $f \in B$ (resp. $g \in C$). Let u_{12} be the isomorphism of preschemes $U_{21} \to U_{12}$ corresponding (2.2.4) to the isomorphism from B_s to C_t that, to $f(s)/s^m$, associates the rational fraction $f(1/t)/(1/t^m)$. We can glue X_1 and X_2 along U_{12} and U_{21} by using u_{12}, because there is clearly no gluing condition. We shall encounter again later the prescheme X thus obtained as a particular case of a general method of construction (**II**, 2.4.3). Here we show only that X *is not an affine scheme*; this will follow from the fact that the ring $\Gamma(X, \mathscr{O}_X)$ is *isomorphic* to K, and so its spectrum reduces to a point. Indeed, a section of $\mathscr{O}_X$ over X has a restriction over X_1 (resp. X_2), identified with an affine open of X, that is a polynomial $f(s)$ (resp. $g(t)$), and it follows from the definitions that we should have $g(t) = f(1/t)$, which is only possible if $f = g \in K$.

2.4. Local schemes

(2.4.1). We say that an affine scheme is a *local scheme* if its ring A is local; there then exists, in $X = \operatorname{Spec}(A)$, a single *closed point* $a \in X$, and for all other $b \in X$ we have that $a \in \overline{\{b\}}$ (1.1.7).

For every prescheme Y and every point $y \in Y$, the local scheme $\operatorname{Spec}(\mathscr{O}_y)$ is called the *local scheme of Y at the point y*. Let V be an affine open subset of Y containing y, and B the ring of the affine scheme V; then $\mathscr{O}_y$ is canonically identified with B_y (1.3.4), and the canonical homomorphism $B \to B_y$ thus corresponds (1.6.1) to a morphism of preschemes $\operatorname{Spec}(\mathscr{O}_y) \to V$. If we compose this morphism with the canonical injection $V \to Y$, then we obtain a morphism $\operatorname{Spec}(\mathscr{O}_y) \to Y$ which is *independent* of the affine open subset V (containing y) that we chose: indeed, if V' is some other affine open subset containing y, then there exists a third affine open subset W that contains y and is such that $W \subset V \cap V'$ (2.1.3); we can thus assume that $V \subset V'$, and then, if B' is the ring of V', it remains only to observe that the diagram

$$\begin{tikzcd} B' \arrow[rr] \arrow[dr] & & B \arrow[dl] \\ & \mathscr{O}_y & \end{tikzcd}$$

is commutative (**0**, 1.5.1). The morphism

$$\operatorname{Spec}(\mathscr{O}_y) \longrightarrow Y$$

thus defined is said to be *canonical*.

Proposition (2.4.2). — *Let $(Y, \mathscr{O}_Y)$ be a prescheme; for every $y \in Y$, let (ψ, θ) be the canonical morphism $(\operatorname{Spec}(\mathscr{O}_y), \widetilde{\mathscr{O}}_y) \to (Y, \mathscr{O}_Y)$. Then ψ is a homeomorphism from* $\operatorname{Spec}(\mathscr{O}_y)$ *onto the subspace S_y of Y consisting of those z such that $y \in \overline{\{z\}}$* (in other words, the *generalizations* of *y* (**0**, 2.1.2))*; furthermore, if $z = \psi(\mathfrak{p})$, then $\theta_z^\sharp : \mathscr{O}_z \to (\mathscr{O}_y)_\mathfrak{p}$ is an isomorphism; (ψ, θ) is thus a monomorphism of ringed spaces.* I | 102

Proof. Since the unique closed point a of $\operatorname{Spec}(\mathscr{O}_y)$ is contained in the closure of any point of this space, and since $\psi(a) = y$, the image of $\operatorname{Spec}(\mathscr{O}_y)$ under the continuous map ψ is contained in S_y. Since S_y is contained in every affine open containing y, we can reduce to the case in which Y is an affine scheme; but in that case the proposition follows from (1.6.2). □

We therefore see (2.1.5) that there is a bijective correspondence between $\operatorname{Spec}(\mathscr{O}_y)$ *and the set of closed irreducible subsets of Y containing y.*

Corollary (2.4.3). — *For $y \in Y$ to be the generic point of an irreducible component of Y, it is necessary and sufficient for the only prime ideal of the local ring $\mathscr{O}_y$ to be its maximal ideal* (in other words, for $\mathscr{O}_y$ to be of *dimension zero).*

Proposition (2.4.4). — *Let $(X, \mathscr{O}_X)$ be a local scheme with ring A, a its unique closed point, and $(Y, \mathscr{O}_Y)$ a prescheme. Every morphism $u = (\psi, \theta) : (X, \mathscr{O}_X) \to (Y, \mathscr{O}_Y)$ then factors uniquely as $X \to \operatorname{Spec}(\mathscr{O}_{\psi(a)}) \to Y$, where the second arrow denotes the canonical morphism, and the first corresponds to a local homomorphism $\mathscr{O}_{\psi(a)} \to A$. This establishes a canonical bijective correspondence between the set of morphisms $(X, \mathscr{O}_X) \to (Y, \mathscr{O}_Y)$ and the set of local homomorphisms $\mathscr{O}_y \to A$ as y ranges over Y.*

Indeed, for every $x \in X$, we have that $a \in \overline{\{x\}}$, so $\psi(a) \in \overline{\{\psi(x)\}}$, which shows that $\psi(X)$ is contained in every affine open subset that contains $\psi(a)$. So it suffices to consider the case where $(Y, \mathscr{O}_Y)$ is an affine scheme of ring B, and then we have that $u = ({}^a\phi, \widetilde{\phi})$, where $\phi \in \operatorname{Hom}(B, A)$ (1.7.3). Further, we have that $\phi^{-1}(\mathfrak{j}_a) = \mathfrak{j}_{\psi(a)}$, and hence that the image under ϕ of any element of $B - \mathfrak{j}_{\psi(a)}$ is invertible in the local ring A; the factorization asserted in the statement therefore follows from the universal property of the ring of fractions (**0**, 1.2.4). Conversely, to each local homomorphism $\mathscr{O}_y \to A$ there is a unique corresponding morphism $(\psi, \theta) : X \to \operatorname{Spec}(\mathscr{O}_y)$ such that $\psi(a) = y$ (1.7.3), and, by composing with the canonical morphism $\operatorname{Spec}(\mathscr{O}_y) \to Y$, we obtain a morphism $X \to Y$, which completes the proof of the proposition.

(2.4.5). The affine schemes whose ring is a field K have an underlying space that is just a point. If A is a local ring with maximal ideal $\mathfrak{m}$, then each local homomorphism $A \to K$ has kernel equal to $\mathfrak{m}$, and so factors as $A \to A/\mathfrak{m} \to K$, where the second arrow is a monomorphism. The morphisms $\operatorname{Spec}(K) \to \operatorname{Spec}(A)$ whose unique point maps to the closed point $\mathfrak{m}$ thus correspond bijectively to monomorphisms of fields $A/\mathfrak{m} \to K$.

Let $(Y, \mathscr{O}_Y)$ be a prescheme; for each $y \in Y$ and each ideal $\mathfrak{a}_y$ of $\mathscr{O}_y$, the canonical homomorphism $\mathscr{O}_y \to \mathscr{O}_y/\mathfrak{a}_y$ defines a morphism $\operatorname{Spec}(\mathscr{O}_y/\mathfrak{a}_y) \to \operatorname{Spec}(\mathscr{O}_y)$; if we compose this with the canonical morphism $\operatorname{Spec}(\mathscr{O}_y) \to Y$, then we obtain a morphism $\operatorname{Spec}(\mathscr{O}_y/\mathfrak{a}_y) \to Y$, again said to be *canonical*. For $\mathfrak{a}_y = \mathfrak{m}_y$, that is, $\mathscr{O}_y/\mathfrak{a}_y = k(y)$, Proposition (2.4.4) therefore gives:

Corollary (2.4.6). — *Let $(X, \mathscr{O}_X)$ be a local scheme whose ring K is a field, ξ the unique point of X, and $(Y, \mathscr{O}_Y)$ a prescheme. Then each morphism $u : (X, \mathscr{O}_X) \to (Y, \mathscr{O}_Y)$ factors uniquely as $X \to \operatorname{Spec}(k(\psi(\xi))) \to Y$, where the second arrow denotes the canonical morphism, and the first corresponds to a monomorphism $k(\psi(\xi)) \to K$. This establishes a canonical bijective correspondence between the set of morphisms $(X, \mathscr{O}_X) \to (Y, \mathscr{O}_Y)$ and the set of monomorphisms $k(y) \to K$ as y ranges over Y.* I | 103

Corollary (2.4.7). — *For every $y \in Y$, every canonical morphism* $\operatorname{Spec}(\mathscr{O}_y/\mathfrak{a}_y) \to Y$ *is a monomorphism of ringed spaces.*

Proof. We have already seen this when $\mathfrak{a}_y = 0$ (2.4.2), and it suffices to apply Corollary (1.7.5). □

Remark (2.4.8). — Let X be a local scheme, and a its unique closed point. Since every affine open subset containing a is necessarily equal to the whole of X, every *invertible* $\mathscr{O}_X$-module (**0**, 5.4.1) is necessarily *isomorphic to* $\mathscr{O}_X$ (or, as one also says, is *trivial*). This property does not hold in general for an arbitrary affine scheme $\operatorname{Spec}(A)$; we will see in Chapter V that if A is a normal ring then this is true when A is a unique factorisation domain.

2.5. Preschemes over a prescheme

Definition (2.5.1). — Given a prescheme S, we say that the data consisting of a prescheme X and a morphism of preschemes $\phi : X \to S$ define a prescheme X *over the prescheme* S, or an S-*prescheme*; we say that S is the *base prescheme* of the S-prescheme X. The morphism ϕ is called the *structure morphism* of the S-prescheme X. When S is an affine scheme of ring A, we also say that X endowed with ϕ is a prescheme *over the ring* A (or an A-*prescheme*).

It follows from (2.2.4) that the data of a prescheme over a ring A is equivalent to the data of a prescheme $(X, \mathscr{O}_X)$ whose structure sheaf $\mathscr{O}_X$ is a sheaf of A-*algebras*. *An arbitrary prescheme can always be considered as a* $\mathbf{Z}$-*prescheme in a unique way*.

If $\phi : X \to S$ is the structure morphism of an S-prescheme X, we say that a point $x \in X$ is *over a point* $s \in S$ if $\phi(x) = s$. We say that X *dominates* S if ϕ is a dominant morphism (2.2.6).

(2.5.2). Let X and Y be S-preschemes; we say that a morphism of preschemes $u : X \to Y$ is a *morphism of preschemes over* S (or an S-*morphism*) if the diagram

$$\begin{tikzcd} X \arrow[rr, "u"] \arrow[dr] & & Y \arrow[dl] \\ & S & \end{tikzcd}$$

(where the diagonal arrows are the structure morphisms) is commutative: this entails that, for every $s \in S$ and every $x \in X$ over s, $u(x)$ must also be over s.

It follows immediately from this definition that the composition of any two S-morphisms is an S-morphism; S-preschemes thus form a *category*.

We denote by $\mathrm{Hom}_S(X, Y)$ the set of S-morphisms from an S-prescheme X to an S-prescheme Y; the identity morphism of an S-prescheme X is denoted by 1_X.

When S is an affine scheme of ring A, we will also say A-*morphism* instead of S-morphism.

(2.5.3). If X is an S-prescheme, and $v : X' \to X$ a morphism of preschemes, then the composition $X' \to X \to S$ endows X' with the structure of an S-prescheme; in particular, every prescheme induced by an open set U of X can be considered as an S-prescheme by the canonical injection. **I** | 104

If $u : X \to Y$ is an S-morphism of S-preschemes, then the restriction of u to any prescheme induced by an open subset U of X is therefore an S-morphism $U \to Y$. Conversely, let (U_α) be an open cover of X, and for each α let $u_\alpha : U_\alpha \to Y$ be an S-morphism; if, for every pair of indices (α, β), the restrictions of u_α and u_β to $U_\alpha \cap U_\beta$ agree, then there exists a unique S-morphism $X \to Y$ whose restriction to each U_α is u_α.

If $u : X \to Y$ is an S-morphism such that $u(X) \subset V$, where V is an open subset of Y, then u, considered as a morphism from X to V, is also an S-morphism.

(2.5.4). Let $S' \to S$ be a morphism of preschemes; for every S'-prescheme X, the composition $X \to S' \to S$ endows X with the structure of an S-prescheme. Conversely, suppose that S' is the induced prescheme on an open subset of S; let X be an S-prescheme and suppose that the structure morphism $f : X \to S$ is such that $f(X) \subset S'$; then we can consider X as an S'-prescheme. In this latter case, if Y is another S-prescheme whose structure morphism sends the underlying space to S', then every S-morphism from X to Y is also an S'-morphism.

(2.5.5). If X is an S-prescheme,[7] with structure morphism $\phi : X \to S$, we define an S-*section of* X to be an S-morphism from S to X, that is to say a morphism of preschemes $\psi : S \to X$ such that $\phi \circ \psi$ is the identity on S. We denote by $\Gamma(X/S)$ the set of S-sections of X.

§3. Products of preschemes

3.1. Sums of preschemes Let (X_α) be any family of preschemes; let X be a topological space which is the *sum* of the underlying spaces X_α; X is then the union of pairwise disjoint open subspaces X'_α, and for each α there is a homeomorphism ϕ_α from X_α to X'_α. If we equip each of the X'_α with

[7] The French source prints "S-morphism" here; the structure morphism $X \to S$ and the definition of a section require an S-prescheme.

the sheaf $(\phi_\alpha)_*(\mathscr{O}_{X_\alpha})$, it is clear that X becomes a prescheme, which we call the *sum* of the family of preschemes (X_α) and which we denote $\bigsqcup_\alpha X_\alpha$. If Y is a prescheme, then the map $f \mapsto (f \circ \phi_\alpha)$ is a *bijection* from the set $\mathrm{Hom}(X,Y)$ to the product set $\prod_\alpha \mathrm{Hom}(X_\alpha, Y)$. In particular, if the X_α are S-preschemes, with structure morphisms ψ_α, then X is an S-prescheme by the unique morphism $\psi : X \to S$ such that $\psi \circ \phi_\alpha = \psi_\alpha$ for each α. The sum of two preschemes X and Y is denoted by $X \sqcup Y$. It is immediate that, if $X = \mathrm{Spec}(A)$ and $Y = \mathrm{Spec}(B)$, then $X \sqcup Y$ is canonically identified with $\mathrm{Spec}(A \times B)$.

3.2. Products of preschemes

Definition (3.2.1). — Given S-preschemes X and Y, we say that a triple (Z, p_1, p_2), consisting of an S-prescheme Z, and S-morphisms $p_1 : Z \to X$ and $p_2 : Z \to Y$, is a product of the S-preschemes I | 105
X and Y, if, for each S-prescheme T, the map $f \mapsto (p_1 \circ f, p_2 \circ f)$ is a bijection from the set of S-morphisms from T to Z, to the set of pairs consisting of an S-morphism $T \to X$ and an S-morphism $T \to Y$ (in other words, a bijection

$$\mathrm{Hom}_S(T,Z) \simeq \mathrm{Hom}_S(T,X) \times \mathrm{Hom}_S(T,Y)).$$

This is the general notion of a *product* of two objects in a category, applied to the category of S-preschemes (T, I, 1.1); in particular, a product of two S-preschemes is *unique* up to a unique S-isomorphism. Because of this uniqueness, most of the time we will denote a product of two S-preschemes X and Y by $X \times_S Y$ (or simply $X \times Y$, when there is no chance of confusion), with the morphisms p_1 and p_2 (the *canonical projections* of $X \times_S Y$ to X and to Y, respectively) being suppressed in the notation. If $g : T \to X$ and $h : T \to Y$ are S-morphisms, we denote by $(g,h)_S$, or simply (g,h), the S-morphism $f : T \to X \times_S Y$ such that $p_1 \circ f = g$, $p_2 \circ f = h$. If X' and Y' are two S-preschemes, p'_1 and p'_2 the canonical projections of $X' \times_S Y'$ (assumed to exist), and $u : X' \to X$ and $v : Y' \to Y$ are S-morphisms, we write $u \times_S v$ (or simply $u \times v$) for the S-morphism $(u \circ p'_1, v \circ p'_2)_S$ from $X' \times_S Y'$ to $X \times_S Y$.

When S is an affine scheme given by some ring A, we often replace S by A in the above notation.

Proposition (3.2.2). — *Let X, Y, and S be affine schemes, given by rings B, C, and A (respectively). Let $Z = \mathrm{Spec}(B \otimes_A C)$, and let p_1 and p_2 be the S-morphisms corresponding (2.2.4) to the canonical A-homomorphisms $u : b \mapsto b \otimes 1$ and $v : c \mapsto 1 \otimes c$ (respectively) from B and C to $B \otimes_A C$; then (Z, p_1, p_2) is a product of X and Y.*

Proof. According to (2.2.4), it suffices to check that, if, to each A-homomorphism $f : B \otimes_A C \to L$ (where L is an A-algebra), we associate the pair $(f \circ u, f \circ v)$, then this defines a bijection $\mathrm{Hom}_A(B \otimes_A C, L) \simeq \mathrm{Hom}_A(B,L) \times \mathrm{Hom}_A(C,L)$,[8] which follows immediately from the definitions and the fact that $b \otimes c = (b \otimes 1)(1 \otimes c)$. □

Corollary (3.2.3). — *Let T be an affine scheme given by some ring D, and $\alpha = ({}^a\rho, \widetilde{\rho})$ (resp. $\beta = ({}^a\sigma, \widetilde{\sigma})$) an S-morphism $T \to X$ (resp. $T \to Y$), where ρ (resp. σ) is an A-homomorphism from B (resp. C) to D; then $(\alpha, \beta)_S = ({}^a\tau, \widetilde{\tau})$, where τ is the homomorphism $B \otimes_A C \to D$ such that $\tau(b \otimes c) = \rho(b)\sigma(c)$.*

Proposition (3.2.4). — *Let $f : S' \to S$ be a* monomorphism *of preschemes* (T, I, 1.1), *and let X and Y be S'-preschemes, also considered as S-preschemes via f. Every product of the S-preschemes X and Y is then a product of the S'-preschemes X and Y, and vice versa.*

Proof. Let $\phi : X \to S'$ and $\psi : Y \to S'$ be the structure morphisms. If T is an S-prescheme, and $u : T \to X$ and $v : T \to Y$ are S-morphisms, then we have, by definition, that $f \circ \phi \circ u = f \circ \psi \circ v = \theta$, the structure morphism of T; the hypothesis on f implies that $\phi \circ u = \psi \circ v = \theta'$, and so we can consider T as an S'-prescheme with structure morphism θ', and u and v as S'-morphisms. The conclusion of the proposition follows immediately, taking (3.2.1) into account. □

Corollary (3.2.5). — *Let X and Y be S-preschemes, with structure morphisms $\phi : X \to S$ and $\psi : Y \to S$, and let S' be an open subset of S such that $\phi(X) \subset S'$ and $\psi(Y) \subset S'$. Every product of the S-preschemes X and Y is then also a product of the S'-preschemes X and Y, and conversely.*

It suffices to apply (3.2.4) to the canonical injection $S' \to S$. I | 106

[8] The notation Hom_A denotes here the set of homomorphisms of *A-algebras*.

Theorem (3.2.6). — *Given S-preschemes X and Y, there exists a product $X \times_S Y$.*

The proof proceeds in several steps.

Lemma (3.2.6.1). — *Let (Z, p, q) be a product of X and Y, and U and V open subsets of X and Y, respectively. If we let $W = p^{-1}(U) \cap q^{-1}(V)$, then the triple consisting of W and the restrictions of p and q to W* (considered as the morphisms $W \to U$ and $W \to V$, respectively) *is a product of U and V.*

Indeed, if T is an S-prescheme, then we can identify the S-morphisms $T \to W$ with the S-morphisms $T \to Z$ mapping T to W. Then, if $g : T \to U$ and $h : T \to V$ are any two S-morphisms, we can consider them as S-morphisms from T to X and to Y, respectively, and, by hypothesis, there is then a unique S-morphism $f : T \to Z$ such that $g = p \circ f$ and $h = q \circ f$. Since $p(f(T)) \subset U$ and $q(f(T)) \subset V$, we have

$$f(T) \subset p^{-1}(U) \cap q^{-1}(V) = W,$$

hence our claim.

Lemma (3.2.6.2). — *Let Z be an S-prescheme, $p : Z \to X$ and $q : Z \to Y$ both S-morphisms, (U_α) an open cover of X, and (V_λ) an open cover of Y. Suppose that, for each pair (α, λ), the S-prescheme $W_{\alpha\lambda} = p^{-1}(U_\alpha) \cap q^{-1}(V_\lambda)$ and the restrictions of p and q to $W_{\alpha\lambda}$ form a product of U_α and V_λ. Then (Z, p, q) is a product of X and Y.*

We first show that, if f_1 and f_2 are S-morphisms $T \to Z$, then the equations $p \circ f_1 = p \circ f_2$ and $q \circ f_1 = q \circ f_2$ imply that $f_1 = f_2$. Indeed, Z is the union of the $W_{\alpha\lambda}$, so the $f_1^{-1}(W_{\alpha\lambda})$ form an open cover of T, and similarly for $f_2^{-1}(W_{\alpha\lambda})$. In addition, we have

$$f_1^{-1}(W_{\alpha\lambda}) = f_1^{-1}(p^{-1}(U_\alpha)) \cap f_1^{-1}(q^{-1}(V_\lambda)) = f_2^{-1}(p^{-1}(U_\alpha)) \cap f_2^{-1}(q^{-1}(V_\lambda)) = f_2^{-1}(W_{\alpha\lambda})$$

by hypothesis, and it thus reduces to noting that the restrictions of f_1 and f_2 to $f_1^{-1}(W_{\alpha\lambda}) = f_2^{-1}(W_{\alpha\lambda})$ are identical for each pair of indices. But since these restrictions can be considered as S-morphisms from $f_1^{-1}(W_{\alpha\lambda})$ to $W_{\alpha\lambda}$, our claim follows from the hypotheses and Definition (3.2.1).

Suppose now that we are given S-morphisms $g : T \to X$ and $h : T \to Y$. Let $T_{\alpha\lambda} = g^{-1}(U_\alpha) \cap h^{-1}(V_\lambda)$; then the $T_{\alpha\lambda}$ form an open cover of T. By hypothesis, there exists an S-morphism $f_{\alpha\lambda}$ such that $p \circ f_{\alpha\lambda}$ and $q \circ f_{\alpha\lambda}$ are, respectively, the restrictions of g and h to $T_{\alpha\lambda}$. We will now show that the restrictions of $f_{\alpha\lambda}$ and $f_{\beta\mu}$ to $T_{\alpha\lambda} \cap T_{\beta\mu}$ coincide, which will finish the proof of Lemma (3.2.6.2). The images of $T_{\alpha\lambda} \cap T_{\beta\mu}$ under $f_{\alpha\lambda}$ and $f_{\beta\mu}$ are contained in $W_{\alpha\lambda} \cap W_{\beta\mu}$ by definition. Since

$$W_{\alpha\lambda} \cap W_{\beta\mu} = p^{-1}(U_\alpha \cap U_\beta) \cap q^{-1}(V_\lambda \cap V_\mu),$$

it follows from Lemma (3.2.6.1) that $W_{\alpha\lambda} \cap W_{\beta\mu}$ and the restrictions to this prescheme of p and q form a *product* of $U_\alpha \cap U_\beta$ and $V_\lambda \cap V_\mu$. Since $p \circ f_{\alpha\lambda}$ and $p \circ f_{\beta\mu}$ coincide on $T_{\alpha\lambda} \cap T_{\beta\mu}$ and similarly for $q \circ f_{\alpha\lambda}$ and $q \circ f_{\beta\mu}$, we see that $f_{\alpha\lambda}$ and $f_{\beta\mu}$ coincide on $T_{\alpha\lambda} \cap T_{\beta\mu}$. □

Lemma (3.2.6.3). — *Let (U_α) be an open cover of X, (V_λ) an open cover of Y, and suppose that, for each pair (α, λ), there exists a product of U_α and V_λ; then there exists a product of X and Y.* I | 107

Applying Lemma (3.2.6.1) to the open sets $U_\alpha \cap U_\beta$ and $V_\lambda \cap V_\mu$, we see that there exists a product of S-preschemes induced, respectively, by X and Y on these open sets; in addition, the uniqueness of the product shows that, if we set $i = (\alpha, \lambda)$ and $j = (\beta, \mu)$, then there is a canonical isomorphism h_{ij} (resp. h_{ji}) from this product to an S-prescheme W_{ij} (resp. W_{ji}) induced by $U_\alpha \times_S V_\lambda$ (resp. $U_\beta \times_S V_\mu$) on an open set; then $f_{ij} = h_{ij} \circ h_{ji}^{-1}$ is an isomorphism from W_{ji} to W_{ij}. In addition, for a third pair $k = (\gamma, \nu)$, we have $f_{ik} = f_{ij} \circ f_{jk}$ on $W_{ki} \cap W_{kj}$, by applying Lemma (3.2.6.1) to the open sets $U_\alpha \cap U_\beta \cap U_\gamma$ and $V_\lambda \cap V_\mu \cap V_\nu$ in U_β and V_μ, respectively. It follows that we have a prescheme Z, an open cover (Z_i) of the underlying space of Z, and, for each i, an isomorphism g_i from the induced prescheme Z_i to the prescheme $U_\alpha \times_S V_\lambda$, so that, for each pair (i, j), we have $f_{ij} = g_i \circ g_j^{-1}$ (2.3.1); in addition, we have $g_i(Z_i \cap Z_j) = W_{ij}$. Let p_i and q_i be the projections, and θ_i the structure morphism, of the S-prescheme $U_\alpha \times_S V_\lambda$. We immediately see that $p_i \circ g_i = p_j \circ g_j$ on $Z_i \cap Z_j$, and similarly for the two other morphisms. We can thus define the morphisms of preschemes $p : Z \to X$ (resp. $q : Z \to Y$, $\theta : Z \to S$) by the condition that p (resp. q, θ) coincide with $p_i \circ g_i$ (resp. $q_i \circ g_i$, $\theta_i \circ g_i$) on each of the Z_i; Z, equipped with θ, is then an S-prescheme.

We now show that $Z'_i = p^{-1}(U_\alpha) \cap q^{-1}(V_\lambda)$ is equal to Z_i. For each index $j = (\beta, \mu)$, we have $Z_j \cap Z'_i = g_j^{-1}(p_j^{-1}(U_\alpha) \cap q_j^{-1}(V_\lambda))$. We have

$$p_j^{-1}(U_\alpha) \cap q_j^{-1}(V_\lambda) = p_j^{-1}(U_\alpha \cap U_\beta) \cap q_j^{-1}(V_\lambda \cap V_\mu);$$

By Lemma (3.2.6.1), the restrictions of p_j and q_j to $p_j^{-1}(U_\alpha) \cap q_j^{-1}(V_\lambda)$ define, on this S-prescheme, the structure of a product of $U_\alpha \cap U_\beta$ and $V_\lambda \cap V_\mu$; but the uniqueness of the product then implies that $p_j^{-1}(U_\alpha) \cap q_j^{-1}(V_\lambda) = W_{ji}$. As a result, we have $Z_j \cap Z'_i = Z_j \cap Z_i$ for each j, hence $Z'_i = Z_i$. We then deduce from Lemma (3.2.6.2) that (Z, p, q) is a product of X and Y.

Lemma (3.2.6.4). — *Let $\phi : X \to S$ and $\psi : Y \to S$ be the structure morphisms of X and Y, (S_i) an open cover of S, and let $X_i = \phi^{-1}(S_i)$, $Y_i = \psi^{-1}(S_i)$. If each of the products $X_i \times_S Y_i$ exists, then $X \times_S Y$ exists.*

By Lemma (3.2.6.3), it suffices to prove that the products $X_i \times_S Y_j$ exist for all i and j. Set $X_{ij} = X_i \cap X_j = \phi^{-1}(S_i \cap S_j)$, $Y_{ij} = Y_i \cap Y_j = \psi^{-1}(S_i \cap S_j)$; by Lemma (3.2.6.1), the product $Z_{ij} = X_{ij} \times_S Y_{ij}$ exists. We now note that, if T is an S-prescheme, and if $g : T \to X_i$ and $h : T \to Y_j$ are S-morphisms, then we necessarily have that $\phi(g(T)) = \psi(h(T)) \subset S_i \cap S_j$ by the definition of an S-morphism, and thus that $g(T) \subset X_{ij}$ and $h(T) \subset Y_{ij}$; it is then immediate that Z_{ij} is the product of X_i and Y_j.

(3.2.6.5). We can now complete the proof of Theorem (3.2.6). If S is an *affine scheme*, then there are covers (U_α) and (V_λ) of X and Y (respectively) consisting of affine open subsets; since $U_\alpha \times_S V_\lambda$ exists by (3.2.2), Lemma (3.2.6.3) shows that $X \times_S Y$ exists. If S is any prescheme, then there is a cover (S_i) of S consisting of affine open subsets. If $\phi : X \to S$ and $\psi : Y \to S$ are the structure morphisms, and if we set $X_i = \phi^{-1}(S_i)$ and $Y_i = \psi^{-1}(S_i)$, then the products $X_i \times_{S_i} Y_i$ exist, by the above; but then the products $X_i \times_S Y_i$ also exist (3.2.5), and Lemma (3.2.6.4) therefore shows that **I** | 108
$X \times_S Y$ exists. □

Corollary (3.2.7). — *Let $Z = X \times_S Y$ be the product of two S-preschemes, p and q the projections from Z to X and to Y (respectively), and ϕ (resp. ψ) the structure morphism of X (resp. Y). Let S' be an open subset of S, and U (resp. V) an open subset of X (resp. Y) contained in $\phi^{-1}(S')$ (resp. $\psi^{-1}(S')$). Then the product $U \times_{S'} V$ is canonically identified with the prescheme induced on Z by $p^{-1}(U) \cap q^{-1}(V)$ (considered as an S'-prescheme). In addition, if $f : T \to X$ and $g : T \to Y$ are S-morphisms such that $f(T) \subset U$ and $g(T) \subset V$, then the S'-morphism $(f, g)_{S'}$ can be identified with $(f, g)_S$ regarded as a morphism into $p^{-1}(U) \cap q^{-1}(V)$.*

Proof. This follows from Corollary (3.2.5) and Lemma (3.2.6.1). □

(3.2.8). Let (X_α) and (Y_λ) be families of S-preschemes, and X (resp. Y) the sum of the family (X_α) (resp. (Y_λ)) (3.1). Then $X \times_S Y$ can be identified with the *sum* of the family $(X_\alpha \times_S Y_\lambda)$; this follows immediately from Lemma (3.2.6.3).

(3.2.9). [9] It follows from (1.8.1) that we can state (3.2.2) in the following manner: $Z = \operatorname{Spec}(B \otimes_A C)$ **II** | 221
is not only a product of $X = \operatorname{Spec}(B)$ and $Y = \operatorname{Spec}(C)$ in the category of *S-preschemes*, but also in the category of *locally ringed spaces over S* (with a definition of S-morphisms modelled on that of (2.5.2)). The proof of (3.2.6) also proves that, for any two S-preschemes X and Y, the prescheme $X \times_S Y$ is not only the product of X and Y in the category of S-preschemes, but also in the category of locally ringed spaces over the prescheme S.

[9] *[Trans.] (3.2.9) is from the errata of EGA II, on page 221, whence the change in page numbering.*

3.3. Formal properties of the product; change of the base prescheme

(3.3.1). The reader will notice that all the properties stated in this section, except (3.3.13), (3.3.15), and the assertion on sums in the final sentence of (3.3.10), are true without modification in *any category*, whenever the products involved in the statements *exist* (since it is clear that the notions of an S-object and of an S-morphism can be defined exactly as in (2.5) for any object S of the category).

(3.3.2). First of all, $X \times_S Y$ is a *covariant bifunctor* in X and Y on the category of S-preschemes: it suffices in fact to note that the diagram

$$\begin{tikzcd} X \times Y \arrow[r, "f\times 1"] \arrow[d] & X' \times Y \arrow[r, "f'\times 1"] \arrow[d] & X'' \times Y \arrow[d] \\ X \arrow[r, "f"'] & X' \arrow[r, "f'"'] & X'' \end{tikzcd}$$

is commutative.

Proposition (3.3.3). — *For each S-prescheme X, the first (resp. second) projection from $X \times_S S$ (resp. $S \times_S X$) is a functorial isomorphism from $X \times_S S$ (resp. $S \times_S X$) to X, whose inverse isomorphism is $(1_X, \phi)_S$ (resp. $(\phi, 1_X)_S$), where we denote by ϕ the structure morphism $X \to S$; we can therefore write, up to a canonical isomorphism,*

$$X \times_S S = S \times_S X = X.$$

Proof. It suffices to prove that the triple $(X, 1_X, \phi)$ is a product of X and S. If T is an S-prescheme, then the only S-morphism from T to S is necessarily the structure morphism $\psi : T \to S$. If f is an S-morphism from T to X, we necessarily have $\psi = \phi \circ f$, hence our claim. □

Corollary (3.3.4). — *Let X and Y be S-preschemes, with structure morphisms $\phi : X \to S$ and $\psi : Y \to S$. If we canonically identify X with $X \times_S S$, and Y with $S \times_S Y$, then the projections $X \times_S Y \to X$ and $X \times_S Y \to Y$ are identified with $1_X \times \psi$ and $\phi \times 1_Y$ (respectively).*

The proof is immediate and is left to the reader.

(3.3.5). We can define, in a manner similar to (3.2), the product of a finite number n of S-preschemes, **I** | 109
and the existence of these products follows from (3.2.6) by induction on n, and by noting that $(X_1 \times_S X_2 \times_S \cdots \times_S X_{n-1}) \times_S X_n$ satisfies the definition of a product. The uniqueness of the product implies, as in any category, its *commutativity* and *associativity* properties. If, for example, p_1, p_2, and p_3 denote the projections from $X_1 \times_S X_2 \times_S X_3$, and if we identify this prescheme with $(X_1 \times_S X_2) \times_S X_3$, then the projection to $X_1 \times_S X_2$ is identified with $(p_1, p_2)_S$.

(3.3.6). Let S and S' be preschemes, and $\phi : S' \to S$ a morphism, which lets us consider S' as an S-prescheme. For each S-prescheme X, consider the product $X \times_S S'$, and let p and π' be the projections to X and to S' (respectively). Equipped with π', this product is an S'-prescheme; when we consider it as such, we denote it by $X_{(S')}$ or $X_{(\phi)}$, and we say that this is the prescheme obtained by *base change* (or *a change of base*) from S to S' by means of the morphism ϕ, or the *inverse image* of X by ϕ. We note that, if π is the structure morphism of X, and θ the structure morphism of $X \times_S S'$, considered as an S-prescheme, then the diagram

$$\begin{tikzcd} X \arrow[d, "\pi"'] & X_{(S')} \arrow[l, "p"'] \arrow[d, "\pi'"] \arrow[dl, "\theta"'] \\ S & S' \arrow[l, "\phi"] \end{tikzcd}$$

is commutative.

(3.3.7). With the notation of (3.3.6), for each S-morphism $f : X \to Y$, we denote by $f_{(S')}$ the S'-morphism $f \times_S 1 : X_{(S')} \to Y_{(S')}$, and we say that $f_{(S')}$ is the *base change* (or *inverse image*) of f by ϕ. Therefore $X_{(S')}$ is a *covariant functor* in X, from the category of S-preschemes to that of S'-preschemes.

(3.3.8). The prescheme $X_{(S')}$ can be considered as a solution to a *universal mapping problem*: each S'-prescheme T is also an S-prescheme via ϕ; each S-morphism $g : T \to X$ is then uniquely written as $g = p \circ f$, where f is an S'-morphism $T \to X_{(S')}$, as follows from the definition of the product applied to the S-morphisms g[10] and $\psi : T \to S'$ (the structure morphism of T).

Proposition (3.3.9). — ("Transitivity of base change"). *Let S'' be a prescheme, and $\phi' : S'' \to S'$ a morphism. For each S-prescheme X, there exists a canonical functorial isomorphism from the S''-prescheme $(X_{(\phi)})_{(\phi')}$ to the S''-prescheme $X_{(\phi\circ\phi')}$.*

Proof. Let T be a S''-prescheme, ψ its structure morphism, and g an S-morphism from T to X (T being considered as an S-prescheme with structure morphism $\phi \circ \phi' \circ \psi$). Since T is also an S'-prescheme with structure morphism $\phi' \circ \psi$, we can write $g = p \circ g'$, where g' is an S'-morphism $T \to X_{(\phi)}$, and then $g' = p' \circ g''$, where g'' is an S''-morphism $T \to (X_{(\phi)})_{(\phi')}$:

$$\begin{tikzcd}
X \arrow[d, "\pi"'] & X_{(\phi)} \arrow[l, "p"'] \arrow[d, "\pi'"'] & (X_{(\phi)})_{(\phi')} \arrow[l, "p'"'] \arrow[d, "\pi''"'] \\
S & S' \arrow[l, "\phi"] & S'' \arrow[l, "\phi'"]
\end{tikzcd}$$

So the result follows by the uniqueness of the solution to a universal mapping problem. □ **I** | 110

This result can be written as the equality (up to a canonical isomorphism) $(X_{(S')})_{(S'')} = X_{(S'')}$ (if there is no chance of confusion), or also as

(3.3.9.1) $$(X \times_S S') \times_{S'} S'' = X \times_S S'';$$

the functorial nature of the isomorphism defined in (3.3.9) can similarly be expressed by the transitivity formula for base change morphisms

(3.3.9.2) $$(f_{(S')})_{(S'')} = f_{(S'')}$$

for each S-morphism $f : X \to Y$.

Corollary (3.3.10). — *If X and Y are S-preschemes, then there exists a canonical functorial isomorphism from the S'-prescheme $X_{(S')} \times_{S'} Y_{(S')}$ to the S'-prescheme $(X \times_S Y)_{(S')}$.*

Proof. We have, up to canonical isomorphism,

$$(X \times_S S') \times_{S'} (Y \times_S S') = X \times_S (Y \times_S S') = (X \times_S Y) \times_S S'$$

according to (3.3.9.1) and the associativity of products of S-preschemes. □

The functorial nature of the isomorphism defined in Corollary (3.3.10) can be expressed by the formula

(3.3.10.1) $$(u_{(S')}, v_{(S')})_{S'} = ((u, v)_S)_{(S')}$$

for each pair of S-morphisms $u : T \to X$, $v : T \to Y$.

In other words, the base change functor $X_{(S')}$ *commutes with products*; it also commutes with sums (3.2.8).

Corollary (3.3.11). — *Let Y be an S-prescheme, and $f : X \to Y$ a morphism which makes X a Y-prescheme (and, as a result, also an S-prescheme). The prescheme $X_{(S')}$ is then identified with the product $X \times_Y Y_{(S')}$, the projection $X \times_Y Y_{(S')} \to Y_{(S')}$ being identified with $f_{(S')}$.*

Proof. Let $\psi : Y \to S$ be the structure morphism of Y; we have the commutative diagram

$$\begin{tikzcd}
S' \arrow[d] & Y_{(S')} \arrow[l, "\psi_{(S')}"'] \arrow[d] & X_{(S')} \arrow[l, "f_{(S')}"'] \arrow[d] \\
S & Y \arrow[l, "\psi"] & X \arrow[l, "f"]
\end{tikzcd}$$

---

[10] *[Trans.] The French text prints f here; the defining pair is (g, ψ).*

We have that $Y_{(S')}$ is identified with $S'_{(\psi)}$, and $X_{(S')}$ with $S'_{(\psi\circ f)}$; taking (3.3.9) and (3.3.4) into account, we thus deduce the corollary. □

(3.3.12). Let $f : X \to X'$ and $g : Y \to Y'$ be S-morphisms which are *monomorphisms* of preschemes (T, I, 1.1); then $f \times_S g$ is a *monomorphism*. Indeed, if p and q are the projections of $X \times_S Y$, p' and q' the projections of $X' \times_S Y'$, and u and v are S-morphisms $T \to X \times_S Y$, then the equation $(f \times_S g) \circ u = (f \times_S g) \circ v$ implies that $p' \circ (f \times_S g) \circ u = p' \circ (f \times_S g) \circ v$, or, in other words, that $f \circ p \circ u = f \circ p \circ v$, and since f is a monomorphism, $p \circ u = p \circ v$; using the fact that g is a monomorphism, we similarly obtain $q \circ u = q \circ v$, hence $u = v$.

It follows that, for each base change $S' \to S$, **I** | 111

$$f_{(S')} : X_{(S')} \longrightarrow X'_{(S')}$$

is a monomorphism.[11]

(3.3.13). Let S and S' be affine schemes of rings A and A' (respectively); a morphism $S' \to S$ then corresponds to a ring homomorphism $A \to A'$. If X is an S-prescheme, we denote by $X_{(A')}$ or $X \otimes_A A'$ the S'-prescheme $X_{(S')}$; when X is also affine of ring B, $X_{(A')}$ is affine of ring $B_{(A')} = B \otimes_A A'$ obtained by extension of scalars from the A-algebra B to A'.

(3.3.14). With the notation of (3.3.6), for each *S-morphism* $f : S' \to X$, we have that $f' = (f, 1_{S'})_S$ is an S'-morphism $S' \to X' = X_{(S')}$ such that $p \circ f' = f$, $\pi' \circ f' = 1_{S'}$, or, in other words, an *S'-section of* X'; conversely, if f' is such an S'-section, then $f = p \circ f'$ is an S-morphism $S' \to X$. We thus define a canonical *bijective correspondence*

$$\mathrm{Hom}_S(S', X) \simeq \mathrm{Hom}_{S'}(S', X').$$

We say that f' is the *graph morphism* of f, and we denote it by Γ_f.

(3.3.15). Given a prescheme X, which we can always consider as a $\mathbf{Z}$-prescheme, it follows, in particular, from (3.3.14) that the *X-sections* of $X \otimes_{\mathbf{Z}} \mathbf{Z}[T]$ (where T is an indeterminate) correspond bijectively with *morphisms* $X \to \mathbf{Z}[T]$[12]. We will show that these X-sections also correspond bijectively with *sections of the structure sheaf* $\mathscr{O}_X$ *over* X. Indeed, let (U_α) be a cover of X by affine open subsets; let $u : X \to X \otimes_{\mathbf{Z}} \mathbf{Z}[T]$ be an X-morphism, and let u_α be its restriction to U_α; if A_α is the ring of the affine scheme U_α, then $U_\alpha \otimes_{\mathbf{Z}} \mathbf{Z}[T]$ is an affine scheme of ring $A_\alpha[T]$ (3.2.2), and u_α canonically corresponds to an A_α-homomorphism $A_\alpha[T] \to A_\alpha$ (1.7.3). Now, since such a homomorphism is completely determined by the data of the image of T in A_α, let $s_\alpha \in A_\alpha = \Gamma(U_\alpha, \mathscr{O}_X)$, and if we suppose that the restrictions of u_α and u_β to an affine open subset $V \subset U_\alpha \cap U_\beta$ coincide, then we see immediately that s_α and s_β coincide on V; thus the family (s_α) consists of the restrictions to U_α of a section s of $\mathscr{O}_X$ over X; conversely, it is clear that such a section defines a family (u_α) of morphisms which are the restrictions to U_α of an X-morphism $X \to X \otimes_{\mathbf{Z}} \mathbf{Z}[T]$. This result is generalized in (**II**, 1.7.12).

---

[11] *[Trans.] The French formula prints $Y_{(S')}$; since 3.3.12 assumes $f : X \to X'$, the base-changed codomain is $X'_{(S')}$.*

[12] *[Trans.] The French text prints $\mathbf{Z}[T] \to X$; Proposition (3.3.14) and the ensuing local ring homomorphisms $A_\alpha[T] \to A_\alpha$ require the scheme morphism $X \to \mathbf{Z}[T]$.*

3.4. Points of a prescheme with values in a prescheme; geometric points

(3.4.1). Let X be a prescheme; for each prescheme T, we then denote by $X(T)$ the set $\mathrm{Hom}(T, X)$ of morphisms $T \to X$, and the elements of this set are called *the points of X with values in T*. If we associate to each morphism $f : T \to T'$ the map $u' \mapsto u' \circ f$ from $X(T')$ to $X(T)$, we see, for fixed X, that $X(T)$ is a *contravariant functor in T*, from the category of preschemes to that of sets. In addition, each morphism of preschemes $g : X \to Y$ defines a functorial homomorphism $X(T) \to Y(T)$, which sends $v \in X(T)$ to $g \circ v$.

(3.4.2). Given sets P, Q, and R, and maps $\phi : P \to R$ and $\psi : Q \to R$, we define the *fibre product of P and Q over R* (with respect to ϕ and ψ) as the subset of the product set $P \times Q$ consisting of the pairs (p, q) such that $\phi(p) = \psi(q)$; we denote it by $P \times_R Q$. Definition (3.2.1) of the product of S-preschemes can be interpreted, with the notation of (3.4.1), via the formula I | 112

(3.4.2.1) $$(X \times_S Y)(T) = X(T) \times_{S(T)} Y(T),$$

where the maps $X(T) \to S(T)$ and $Y(T) \to S(T)$ correspond to the structure morphisms $X \to S$ and $Y \to S$.

(3.4.3). If we are given a prescheme S and we consider only the S-preschemes and S-morphisms, then we will denote by $X(T)_S$ the set $\mathrm{Hom}_S(T, X)$ of S-morphisms $T \to X$, and suppress the subscript S when there is no chance of confusion; we say that the elements of $X(T)_S$ are the *points* (or *S-points*, when there is a possibility of confusion) *of the S-prescheme X with values in the S-prescheme T*. In particular, an *S-section* of X is none other than a *point of X with values in S*. The formula (3.4.2.1) can then be written as

(3.4.3.1) $$(X \times_S Y)(T)_S = X(T)_S \times Y(T)_S;$$

more generally, if Z is an S-prescheme, and X, Y, and T are Z-preschemes (thus *ipso facto* S-preschemes), then we have

(3.4.3.2) $$(X \times_Z Y)(T)_S = X(T)_S \times_{Z(T)_S} Y(T)_S.$$

We note that, to show that a triple (W, r, s) consisting of an S-prescheme W and S-morphisms $r : W \to X$ and $s : W \to Y$ is a product of X and Y (over Z), it suffices, by definition, to check that, for *each S-prescheme T*, the diagram

$$\begin{tikzcd} W(T)_S \arrow[r, "r'"] \arrow[d, "s'"'] & X(T)_S \arrow[d, "\phi'"] \\ Y(T)_S \arrow[r, "\psi'"'] & Z(T)_S \end{tikzcd}$$

makes $W(T)_S$ the fibre product of $X(T)_S$ and $Y(T)_S$ over $Z(T)_S$, where r' and s' correspond to r and s, and ϕ' and ψ' to the structure morphisms $\phi : X \to Z$ and $\psi : Y \to Z$.

(3.4.4). When T (resp. S) in the above is an affine scheme of ring B (resp. A), we replace T (resp. S) by B (resp. A) in the above notation, and we then call the elements of $X(B)$ the *points of X with values in the ring B*, and the elements of $X(B)_A$ the *points of the A-prescheme X with values in the A-algebra B*. We note that $X(B)$ and $X(B)_A$ are *covariant* functors in B. We similarly write $X(T)_A$ for the set of points of the A-prescheme X with values in the A-prescheme T.

(3.4.5). Consider, in particular, the case where T is of the form $\mathrm{Spec}(A)$, where A is a *local* ring; the elements of $X(A)$ then correspond bijectively to *local* homomorphisms $\mathscr{O}_x \to A$ for $x \in X$ (2.4.4); we say that the point x of the underlying space of X is the *location*[13] of the point of X with values in A to which it corresponds.

More specifically, we define the *geometric points* of a prescheme X to be the *points of X with values in a field K*: the data of such a point is equivalent to the data of its location x in the underlying space of X, and of an *extension* K of $k(x)$; K will be called the *field of values* of the corresponding geometric I | 113

[13] *[Trans.] We also say that* the geometric point lies over this x.

point, and we say that this geometric point is *located at* x. We thus define a map $X(K) \to X$, sending a geometric point with values in K to its location.

If $S' = \operatorname{Spec}(K)$ is an S-prescheme (in other words, if K is considered as an extension of the residue field $k(s)$, where $s \in S$), and if X is an S-prescheme, then an element of $X(K)_S$, or, as we say, a *geometric point of X lying over s with values in K*, consists of the data of a $k(s)$-monomorphism from the residue field $k(x)$ to K, where x is a point of X *lying over* s (therefore $k(x)$ is an extension of $k(s)$).

In particular, if $S = \operatorname{Spec}(K) = \{\xi\}$, *then the geometric points of X with values in K can be identified with the points $x \in X$ such that $k(x) = K$*; we say that these latter points are the *K-rational points of the K-prescheme X*; if K' is an extension of K, then the geometric points of X with values in K' bijectively correspond to the K'-rational points of $X' = X_{(K')}$ (3.3.14).

Lemma (3.4.6). — *Let X_i ($1 \leqslant i \leqslant n$) be S-preschemes, s a point of S, and x_i ($1 \leqslant i \leqslant n$) points of X_i lying over s. Then there exists an extension K of $k(s)$ and a geometric point of the product $Y = X_1 \times_S X_2 \times_S \cdots \times_S X_n$, with values in K, whose projections to the X_i are localized at the x_i.*

Proof. There exist $k(s)$-monomorphisms $k(x_i) \to K$, all in the same extension K of $k(s)$ (Bourbaki, *Alg.*, chap. V, §4, prop. 2). The compositions $k(s) \to k(x_i) \to K$ are all identical, and so the morphisms $\operatorname{Spec}(K) \to X_i$ corresponding to the $k(x_i) \to K$ are all S-morphisms, and we thus conclude that they define a unique morphism $\operatorname{Spec}(K) \to Y$. If y is the corresponding point of Y, it is clear that its projection to each of the X_i is x_i. □

Proposition (3.4.7). — *Let X_i ($1 \leqslant i \leqslant n$) be S-preschemes, and, for each index i, let x_i be a point of X_i. For there to exist a point y of $Y = X_1 \times_S X_2 \times \ldots \times_S X_n$ whose image is x_i under the ith projection for each $1 \leqslant i \leqslant n$, it is necessary and sufficient that the x_i all lie above the same point s of S.*

Proof. The condition is evidently necessary; Lemma (3.4.6) proves that it is sufficient. □

In other words, if we denote by (X) the underlying set of X, we see that we have a canonical *surjective* function $(X \times_S Y) \to (X) \times_{(S)} (Y)$; we must point out that this function *is not injective* in general; in other words, *there can exist multiple distinct points z in $X \times_S Y$ that have the same projections $x \in X$ and $y \in Y$*; we have already seen this when S, X, and Y are prime spectra of fields k, K, and K' (respectively), since the tensor product $K \otimes_k K'$ has, in general, multiple distinct prime ideals (cf. (3.4.9)).

Corollary (3.4.8). — *Let $f : X \to Y$ be an S-morphism, and $f_{(S')} : X_{(S')} \to Y_{(S')}$ the S'-morphism obtained from f by the base extension $S' \to S$. Let p (resp. q) be the projection $X_{(S')} \to X$ (resp. $Y_{(S')} \to Y$); for every subset M of X, we have*

$$q^{-1}(f(M)) = f_{(S')}(p^{-1}(M)).$$

I | 114

Proof. Indeed, by (3.3.11), $X_{(S')}$ can be identified with the product $X \times_Y Y_{(S')}$ thanks to the commutative diagram

$$\begin{tikzcd} X \arrow[d, "f"'] & X_{(S')} \arrow[l, "p"'] \arrow[d, "f_{(S')}"] \\ Y & Y_{(S')} \arrow[l, "q"] \end{tikzcd}$$

By (3.4.7), the equation $q(y') = f(x)$ for $x \in M$ and $y' \in Y_{(S')}$ is equivalent to the existence of some $x' \in X_{(S')}$ such that $p(x') = x$ and $f_{(S')}(x') = y'$, whence the corollary. □

Lemma (3.4.6) can be made clearer in the following manner:

Proposition (3.4.9). — *Let X and Y be S-preschemes, x a point of X, and y a point of Y, with both x and y lying above the same point $s \in S$. The set of points of $X \times_S Y$ with projections x and y is in canonical bijective correspondence with the set of types of composite extensions of $k(x)$ and $k(y)$ considered as extensions of $k(s)$* (Bourbaki, *Alg.*, chap. VIII, §8, prop. 2).

Proof. Let p (resp. q) be the projection from $X \times_S Y$ to X (resp. Y), and E the subspace $p^{-1}(x) \cap q^{-1}(y)$ of the underlying space of $X \times_S Y$. First, note that the morphisms $\operatorname{Spec}(k(x)) \to S$ and $\operatorname{Spec}(k(y)) \to S$ factor as $\operatorname{Spec}(k(x)) \to \operatorname{Spec}(k(s)) \to S$ and $\operatorname{Spec}(k(y)) \to \operatorname{Spec}(k(s)) \to S$; since $\operatorname{Spec}(k(s)) \to S$ is a monomorphism (2.4.7), it follows from (3.2.4) that we have

$$P = \operatorname{Spec}(k(x)) \times_S \operatorname{Spec}(k(y)) = \operatorname{Spec}(k(x)) \times_{\operatorname{Spec}(k(s))} \operatorname{Spec}(k(y)) = \operatorname{Spec}(k(x) \otimes_{k(s)} k(y)).$$

We will define two maps, $\alpha : P_0 \to E$ and $\beta : E \to P_0$, inverse to one another (where P_0 denotes the underlying set of the prescheme P). If $i : \operatorname{Spec}(k(x)) \to X$ and $j : \operatorname{Spec}(k(y)) \to Y$ are the canonical morphisms (2.4.5), we take α to be the map of underlying spaces corresponding to the morphism $i \times_S j$. On the other hand, every $z \in E$ defines, by hypothesis, two $k(s)$-monomorphisms, $k(x) \to k(z)$ and $k(y) \to k(z)$, and thus a $k(s)$-homomorphism[14] $k(x) \otimes_{k(s)} k(y) \to k(z)$, and thus a morphism $\operatorname{Spec}(k(z)) \to P$; $\beta(z)$ will be the image of z in P_0 under this morphism. The verification of the fact that $\alpha \circ \beta$ and $\beta \circ \alpha$ are the identity maps follows from (2.4.5) and the definition of the product (3.2.1). Finally, we know that P_0 is in bijective correspondence with the set of types of composite extensions of $k(x)$ and $k(y)$ (Bourbaki, *Alg.*, chap. VIII, §8, prop. 1). □

3.5. Surjections and injections

(3.5.1). In a general sense, consider a property **P** of morphisms of preschemes, and the following two propositions:

(i) If $f : X \to X'$ and $g : Y \to Y'$ are S-morphisms that have property **P**, then $f \times_S g$ also has property **P**.

(ii) If $f : X \to Y$ is an S-morphism that has property **P**, then every S'-morphism $f_{(S')} : X_{(S')} \to Y_{(S')}$ obtained from f by a base extension $S' \to S$ also has property **P**.

Since $f_{(S')} = f \times_S 1_{S'}$, we see that, if, for every prescheme X, the *identity* 1_X has property **P**, then (i) implies (ii); on the other hand, since $f \times_S g$ is the composite morphism

$$X \times_S Y \xrightarrow{f \times 1_Y} X' \times_S Y \xrightarrow{1_{X'} \times g} X' \times_S Y',$$

we see that, if the *composite* of two morphisms having property **P** also has property **P**, then so does the product $f \times_S g$, and so (ii) implies (i).

A first application of this remark is

Proposition (3.5.2). —

(i) *If $f : X \to X'$ and $g : Y \to Y'$ are surjective S-morphisms, then $f \times_S g$ is surjective.*

(ii) *If $f : X \to Y$ is a surjective S-morphism, then $f_{(S')}$ is surjective for every base extension $S' \to S$.*

Proof. The composition of any two surjections being a surjection, it suffices to prove (ii); but this proposition follows immediately from (3.4.8) applied to $M = X$. □

Proposition (3.5.3). — *For a morphism $f : X \to Y$ to be surjective, it is necessary and sufficient that, for every field K and every morphism $\operatorname{Spec}(K) \to Y$, there exist an extension K' of K and a morphism $\operatorname{Spec}(K') \to X$ that make the following diagram commute:*

$$\begin{tikzcd} X \arrow[d, "f"'] & \operatorname{Spec}(K') \arrow[l] \arrow[d] \\ Y & \operatorname{Spec}(K). \arrow[l] \end{tikzcd}$$

Proof. The condition is sufficient because, for all $y \in Y$, it suffices to apply it to a morphism $\operatorname{Spec}(K) \to Y$ corresponding to a monomorphism $k(y) \to K$, with K being an extension of $k(y)$ (2.4.6). Conversely, suppose that f is surjective, and let $y \in Y$ be the image of the unique point of $\operatorname{Spec}(K)$; there exists some $x \in X$ such that $f(x) = y$; we will consider the corresponding monomorphism $k(y) \to k(x)$ (2.2.1); it then suffices to take K' to be an extension of $k(y)$ such that

[14] *[Trans.] The French text prints "monomorphism" here. The induced map from the tensor product need not be injective; only a homomorphism is needed to define the ensuing morphism of spectra.*

there exist $k(y)$-monomorphisms from $k(x)$ and K to K' (Bourbaki, *Alg.*, chap. V, §4, prop. 2); the morphism $\operatorname{Spec}(K') \to X$ corresponding to $k(x) \to K'$ is exactly that for which we are searching. □

With the language introduced in (3.4.5), we can further say that *every geometric point of Y with values in K comes from a geometric point of X with values in an extension of K.*

Definition (3.5.4). — We say that a morphism $f : X \to Y$ of preschemes is *universally injective*, or a *radicial morphism*, if, for every field K, the corresponding map $X(K) \to Y(K)$ is injective.

It follows immediately from the definitions that every *monomorphism of preschemes* (T, 1.1) is radicial.

(3.5.5). For a morphism $f : X \to Y$ to be radicial, it suffices that the condition of Definition (3.5.4) hold for every *algebraically closed* field. In fact, if K is an arbitrary field, and K' an algebraically closed extension of K, then the diagram

$$\begin{tikzcd} X(K) \arrow[r, "\alpha"] \arrow[d, "\phi"'] & Y(K) \arrow[d, "\phi'"] \\ X(K') \arrow[r, "\alpha'"'] & Y(K') \end{tikzcd}$$

commutes, where ϕ and ϕ' come from the morphism $\operatorname{Spec}(K') \to \operatorname{Spec}(K)$, and α and α' correspond to f. However, ϕ is injective, and so too is α', by hypothesis; hence α is necessarily injective.

Proposition (3.5.6). — *Let $f : X \to Y$ and $g : Y \to Z$ be two morphisms of preschemes.*

(i) *If f and g are radicial, then so is $g \circ f$.*
(ii) *Conversely, if $g \circ f$ is radicial, then so is f.*

Proof. Taking into account Definition (3.5.4), the proposition reduces to the corresponding claims for the maps $X(K) \to Y(K) \to Z(K)$, and these claims are evident. □

Proposition (3.5.7). —

(i) *If the S-morphisms $f : X \to X'$ and $g : Y \to Y'$ are radicial, then so is $f \times_S g$.*
(ii) *If the S-morphism $f : X \to Y$ is radicial, then so is $f_{(S')} : X_{(S')} \to Y_{(S')}$ for every extension $S' \to S$ of the base prescheme.*

Proof. Given (3.5.1), it suffices to prove (i). We have seen in (3.4.2.1) that

$$(X \times_S Y)(K) = X(K) \times_{S(K)} Y(K),$$
$$(X' \times_S Y')(K) = X'(K) \times_{S(K)} Y'(K),$$

with the map $(X \times_S Y)(K) \to (X' \times_S Y')(K)$ corresponding to $f \times_S g$ thus being identified with $(u, v) \to (f \circ u, g \circ v)$, and the proposition follows immediately. □

Proposition (3.5.8). — *For a morphism $f = (\psi, \theta) : X \to Y$ to be radicial, it is necessary and sufficient for ψ to be injective and for the monomorphism $\theta^x : k(\psi(x)) \to k(x)$ to make $k(x)$ a radicial extension of $k(\psi(x))$ for every $x \in X$.*

Proof. We suppose that f is radicial and first show that the equation $\psi(x_1) = \psi(x_2) = y$ necessarily implies that $x_1 = x_2$. Indeed, there exists a field K extending $k(y)$, together with $k(y)$-monomorphisms $k(x_1) \to K$ and $k(x_2) \to K$ (Bourbaki, *Alg.*, chap. V, §4, prop. 2); the corresponding morphisms $u_1 : \operatorname{Spec}(K) \to X$ and $u_2 : \operatorname{Spec}(K) \to X$ are then such that $f \circ u_1 = f \circ u_2$, and so $u_1 = u_2$ by hypothesis, and this implies, in particular, that $x_1 = x_2$. We now consider $k(x)$ as an extension of $k(\psi(x))$ by means of θ^x: if $k(x)$ is not a radicial extension of $k(\psi(x))$, then there exist two distinct $k(\psi(x))$-monomorphisms from $k(x)$ to an algebraically closed extension K of $k(\psi(x))$, and the two corresponding morphisms $\operatorname{Spec}(K) \to X$ would contradict the hypothesis. Conversely, taking (2.4.6) into account, it is immediate that the conditions stated are sufficient for f to be radicial. □

Corollary (3.5.9). — *If A is a ring, and S is a multiplicative set of A, then the canonical morphism $\operatorname{Spec}(S^{-1}A) \to \operatorname{Spec}(A)$ is radicial.*

Proof. Indeed, this morphism is a monomorphism (1.6.2). ☐

Corollary (3.5.10). — *Let $f : X \to Y$ be a radicial morphism, $g : Y' \to Y$ a morphism, and $X' = X_{(Y')} = X \times_Y Y'$. Then the radicial morphism $f_{(Y')}$ (3.5.7, ii) is a bijection from the underlying space of X' to $g^{-1}(f(X))$; further, for every field K, the set $X'(K)$ can be identified with the inverse image of the subset $X(K) \subseteq Y(K)$ under the map $Y'(K) \to Y(K)$ corresponding to g.*

Proof. The first claim follows immediately from (3.5.8) and (3.4.8); the second, from the commutativity of the following diagram: **I** | 117

$$\begin{tikzcd} X'(K) \arrow[r] \arrow[d] & Y'(K) \arrow[d] \\ X(K) \arrow[r] & Y(K) \end{tikzcd}$$

☐

Remark (3.5.11). — We say that a morphism $f = (\psi, \theta)$ of preschemes is *injective* if the map ψ is injective. For a morphism $f = (\psi, \theta) : X \to Y$ to be radicial, it is necessary and sufficient that, for every morphism $Y' \to Y$, the morphism $f_{(Y')} : X_{(Y')} \to Y'$ be injective (which justifies the terminology of a *universally injective* morphism). In fact, the condition is necessary by (3.5.7, ii) and (3.5.8). Conversely, the condition first implies that ψ is injective; if, for some $x \in X$, the monomorphism $\theta^x : k(\psi(x)) \to k(x)$ were not radicial, then there would be an extension K of $k(\psi(x))$, and two distinct morphisms $\operatorname{Spec}(K) \to X$ corresponding to the same morphism $\operatorname{Spec}(K) \to Y$ (3.5.8). But then, setting $Y' = \operatorname{Spec}(K)$, there would be two distinct Y'-sections of $X_{(Y')}$ (3.3.14), which contradicts the hypothesis that $f_{(Y')}$ is injective.

3.6. Fibres

Proposition (3.6.1). — *Let $f : X \to Y$ be a morphism, y a point of Y, and $\mathfrak{a}_y$ an ideal of definition of $\mathscr{O}_y$ for the $\mathfrak{m}_y$-preadic topology. Then the projection $p : X \times_Y \operatorname{Spec}(\mathscr{O}_y/\mathfrak{a}_y) \to X$ is a homeomorphism from the underlying space of the prescheme $X \times_Y \operatorname{Spec}(\mathscr{O}_y/\mathfrak{a}_y)$ to the fibre $f^{-1}(y)$ equipped with the topology induced from that of the underlying space of X.*

Proof. Since $\operatorname{Spec}(\mathscr{O}_y/\mathfrak{a}_y) \to Y$ is radicial ((3.5.4) and (2.4.7)), since $\operatorname{Spec}(\mathscr{O}_y/\mathfrak{a}_y)$ is a single point, and since the ideal $\mathfrak{m}_y/\mathfrak{a}_y$ is nilpotent by hypothesis (1.1.12), we already know ((3.5.10) and (3.3.4)) that p identifies, as *sets*, the underlying space of $X \times_Y \operatorname{Spec}(\mathscr{O}_y/\mathfrak{a}_y)$ with $f^{-1}(y)$; everything reduces to proving that p is a homeomorphism. By (3.2.7), the question is local on X and Y, and so we can suppose that $X = \operatorname{Spec}(B)$ and $Y = \operatorname{Spec}(A)$, with B being an A-algebra. The morphism p then corresponds to the homomorphism $1 \otimes \phi : B \to B \otimes_A A'$, where $A' = A_y/\mathfrak{a}_y$ and ϕ is the canonical map from A to A'. Then every element of $B \otimes_A A'$ can be written as

$$\sum_i b_i \otimes \phi(a_i)/\phi(s) = \left(\sum_i (a_i b_i \otimes 1)\right) (1 \otimes \phi(s))^{-1},$$

where $s \notin \mathfrak{j}_y$, and Proposition (1.2.4) applies. ☐

(3.6.2). Throughout the rest of this treatise, whenever we consider a fibre $f^{-1}(y)$ of a morphism as having the structure of a $k(y)$-prescheme, *it will always be the prescheme obtained by transporting the structure of $X \times_Y \operatorname{Spec}(k(y))$ by the projection to X.* We will also write this latter product as $X \times_Y k(y)$, or $X \otimes_{\mathscr{O}_Y} k(y)$; more generally, if B is an $\mathscr{O}_y$-algebra, we will denote by $X \times_Y B$ or $X \otimes_{\mathscr{O}_Y} B$ the product $X \times_Y \operatorname{Spec}(B)$.

With the preceding convention, it follows from (3.5.10) that the points of X with values in an extension K of $k(y)$ are identified with the *points of $f^{-1}(y)$ with values in K.*

(3.6.3). Let $f : X \to Y$ and $g : Y \to Z$ be two morphisms, and $h = g \circ f$ their composition; for all $z \in Z$, the fibre $h^{-1}(z)$ is a prescheme isomorphic to

$$X \times_Z \operatorname{Spec}(k(z)) = (X \times_Y Y) \times_Z \operatorname{Spec}(k(z)) = X \times_Y g^{-1}(z).$$

Inparticular, if U is an open subset of X, then the prescheme induced on $U \cap f^{-1}(y)$ by the prescheme $f^{-1}(y)$ is isomorphic to $f_U^{-1}(y)$ (f_U being the restriction of f to U). **I** | 118

Proposition (3.6.4). — (Transitivity of fibres) *Let $f : X \to Y$ and $g : Y' \to Y$ be morphisms; let $X' = X \times_Y Y' = X_{(Y')}$ and $f' = f_{(Y')} : X' \to Y'$. For every $y' \in Y'$, if we let $y = g(y')$, then the prescheme $f'^{-1}(y')$ is isomorphic to $f^{-1}(y) \otimes_{k(y)} k(y')$.*

Proof. Indeed, it suffices to remark that the two preschemes $(X \otimes_Y k(y)) \otimes_{k(y)} k(y')$ and $(X \times_Y Y') \otimes_{Y'} k(y')$ are both canonically isomorphic to $X \times_Y \operatorname{Spec}(k(y'))$ by (3.3.9.1). □

In particular, if V is an open neighbourhood of y in Y, and we denote by f_V the restriction of f to the induced prescheme on $f^{-1}(V)$, then the preschemes $f^{-1}(y)$ and $f_V^{-1}(y)$ are canonically identified.

Proposition (3.6.5). — *Let $f : X \to Y$ be a morphism, y a point of Y, Z the local prescheme* $\operatorname{Spec}(\mathscr{O}_y)$, *and $p = (\psi, \theta)$ the projection $X \times_Y Z \to X$; then p is a homeomorphism from the underlying space of $X \times_Y Z$ to the subspace $f^{-1}(Z)$ of X (*when the underlying space of Z is identified with a subspace of Y, cf. (2.4.2)*), and, for all $t \in X \times_Y Z$, letting $z = \psi(t)$, we have that $\theta_t^\sharp$ is an isomorphism from $\mathscr{O}_z$ to $\mathscr{O}_t$.*

Proof. Since Z (identified as a subspace of Y) is contained in every affine open containing y (2.4.2), we can, as in (3.6.1), reduce to the case where $X = \operatorname{Spec}(A)$ and $Y = \operatorname{Spec}(B)$ are affine schemes, with A being a B-algebra. Then $X \times_Y Z$ is the prime spectrum of $A \otimes_B B_y$, and this ring is canonically identified with $S^{-1}A$, where S is the image of $B - \mathfrak{j}_y$ in A (**0**, 1.5.2); since p then corresponds to the canonical homomorphism $A \to S^{-1}A$, the proposition follows from (1.6.2). □

3.7. Application: reduction of a prescheme mod. $\mathfrak{J}$ *This section, which makes use of notions and results from later in Chapter I and from Chapter II, will not be used in what follows in this treatise, and is only intended for readers familiar with classical algebraic geometry.*

(3.7.1). Let A be a ring, X an A-prescheme, and $\mathfrak{J}$ an ideal of A; then $X_0 = X \otimes_A (A/\mathfrak{J})$ is an $(A/\mathfrak{J})$-prescheme, which we sometimes say is induced from X by *reduction* mod. $\mathfrak{J}$.

(3.7.2). This terminology is used especially when A is a *local ring* and $\mathfrak{J}$ its maximal ideal, so that X_0 is a prescheme over the residue field $k = A/\mathfrak{J}$ of A.

When A is also integral, with field of fractions K, we can consider the K-prescheme $X' = X \otimes_A K$. By an abuse of language which we will not use, it has been customary until now to say that X_0 is *induced from* X' by reduction mod. $\mathfrak{J}$. In the cases where this language was used, A was a local ring of dimension 1 (most often a discrete valuation ring), and it was understood (more or less explicitly) that the given K-prescheme X' was a closed subprescheme of a K-prescheme P' (in fact, a projective space of type $\mathbf{P}_K^r$, cf. (**II**, 4.1.1)), itself of the form $P' = P \otimes_A K$, where P is a given A-prescheme (in fact, the A-scheme $\mathbf{P}_A^r$, with the notation of (**II**, 4.1.1)). In our language, the definition of X_0 in terms of X' is formulated as follows:

We consider the affine scheme $Y = \operatorname{Spec}(A)$, formed of two points, the unique closed point $y = \mathfrak{J}$ **I** | 119
and the generic point (0), the singleton set U of the generic point being thus an open $U = \operatorname{Spec}(K)$ in Y. If X is an A-prescheme (or, in other words, a Y-prescheme), then $X \otimes_A K = X'$ is exactly the prescheme induced by X on $\psi^{-1}(U)$, denoting by ψ the structure morphism $X \to Y$. In particular, if ϕ is the structure morphism $P \to Y$, then a closed subprescheme X' of $P' = \phi^{-1}(U)$ is a (locally closed) subprescheme of P. If P is Noetherian (for example, if A is Noetherian and P is of finite type over A), then there exists a smallest closed subprescheme $X = \overline{X'}$ of P containing X' (9.5.10), and X' is the prescheme induced by X on the open $\phi^{-1}(U) \cap X$, and so is isomorphic to $X \otimes_A K$ (9.5.10). *The immersion of X' into $P' = P \otimes_A K$ thus lets us canonically consider X' as being of the form $X' = X \otimes_A K$, where X is an A-prescheme.* We can then consider the reduced mod. $\mathfrak{J}$ prescheme $X_0 = X \otimes_A k$, which is exactly the fibre $\psi^{-1}(y)$ of the closed point y. Up until now, lacking the adequate terminology, we had avoided explicitly introducing the A-prescheme X. One should note, however, that all the claims normally made about the "reduced mod. $\mathfrak{J}$" prescheme X_0 should be seen as consequences of more complete claims about X itself, and cannot be satisfactorily formulated or understood except by interpreting them as such. It seems also that any hypotheses made on X_0 always reduce to hypotheses on X itself (independent of the prior data of an immersion of X' in $\mathbf{P}_K^r$), which lets us give more intrinsic statements.

(3.7.3). Lastly, we draw attention to a very particular fact, which has undoubtedly contributed to slowing the conceptual clarification of the situation envisaged here: if A is a discrete valuation ring, and if X is *proper* over A (which is indeed the case if X is a closed subprescheme of some $\mathbf{P}^r_A$, cf. (**II**, 5.5.4)), then the points of X with values in A and the points of X' with values in K are in bijective correspondence (**II**, 7.3.8). This is why we have often thought we were proving facts about X', when in reality we were proving facts about X; those facts remain valid (in this form) when the base local ring is no longer assumed to have dimension 1.

§4. Subpreschemes and immersion morphisms

4.1. Subpreschemes

(4.1.1). As the notion of a quasi-coherent sheaf (**0**, 5.1.3) is local, a quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$ on a prescheme X can be defined by the following condition: for each affine open V of X, $\mathscr{F}|V$ is isomorphic to the sheaf associated to a $\Gamma(V, \mathscr{O}_X)$-module (1.4.1). It is clear that, on a prescheme X, the structure sheaf $\mathscr{O}_X$ is quasi-coherent, and that the kernels, cokernels, and images of homomorphisms of quasi-coherent $\mathscr{O}_X$-modules, as well as inductive limits and direct sums of quasi-coherent $\mathscr{O}_X$-modules, are also quasi-coherent (Theorem (1.3.7) and Corollary (1.3.9)).

Proposition (4.1.2). — *Let X be a prescheme, and $\mathscr{I}$ a quasi-coherent sheaf of ideals of $\mathscr{O}_X$. Then the support Y of the sheaf $\mathscr{O}_X/\mathscr{I}$ is closed, and if we denote by $\mathscr{O}_Y$ the restriction of $\mathscr{O}_X/\mathscr{I}$ to Y, then $(Y, \mathscr{O}_Y)$ is a prescheme.*

Proof. It evidently suffices (2.1.3) to consider the case where X is an affine scheme, and to show that, **I** | 120
in this case, Y is closed in X, and is an *affine scheme*. Indeed, if $X = \operatorname{Spec}(A)$, then we have $\mathscr{O}_X = \widetilde{A}$ and $\mathscr{I} = \widetilde{\mathfrak{I}}$, where $\mathfrak{I}$ is an ideal of A (1.4.1); Y is then equal to the closed subset $V(\mathfrak{I})$ of X and can be identified with the prime spectrum of the ring $B = A/\mathfrak{I}$ (1.1.11); in addition, if ϕ is the canonical homomorphism $A \to B = A/\mathfrak{I}$, then the direct image ${}^a\phi_*(\widetilde{B})$ is canonically identified with the sheaf $\widetilde{A}/\widetilde{\mathfrak{I}} = \mathscr{O}_X/\mathscr{I}$ (Proposition (1.6.3) and Corollary (1.3.9)), which finishes the proof. □

We say that $(Y, \mathscr{O}_Y)$ is the *subprescheme* of $(X, \mathscr{O}_X)$ *defined by the sheaf of ideals* $\mathscr{I}$; this is a particular case of the more general notion of a *subprescheme*:

Definition (4.1.3). — We say that a ringed space $(Y, \mathscr{O}_Y)$ is a subprescheme of a prescheme $(X, \mathscr{O}_X)$ if:

1st. Y is a locally closed subspace of X;
2nd. if U denotes the largest open subset of X containing Y such that Y is closed in U (*equivalently*, the complement in X of the boundary of Y with respect to $\overline{Y}$), then $(Y, \mathscr{O}_Y)$ is a subprescheme of $(U, \mathscr{O}_X|U)$ defined by a quasi-coherent sheaf of ideals of $\mathscr{O}_X|U$.

We say that the subprescheme $(Y, \mathscr{O}_Y)$ of $(X, \mathscr{O}_X)$ is closed if Y is closed in X (in which case $U = X$).

It follows immediately from this definition and Proposition (4.1.2) that the closed subpreschemes of X are in canonical *bijective correspondence* with the quasi-coherent sheaves of ideals $\mathscr{J}$ of $\mathscr{O}_X$, since if two such sheaves $\mathscr{J}$ and $\mathscr{J}'$ have the same (closed) support Y, and if the restrictions of $\mathscr{O}_X/\mathscr{J}$ and $\mathscr{O}_X/\mathscr{J}'$ to Y are identical, then we have $\mathscr{J}' = \mathscr{J}$.

(4.1.4). Let $(Y, \mathscr{O}_Y)$ be a subprescheme of X, U the largest open subset of X such that Y is closed (and thus contained) in U, and V an open subset of X contained in U; then $V \cap Y$ is closed in V. In addition, if Y is defined by the quasi-coherent sheaf of ideals $\mathscr{J}$ of $\mathscr{O}_X|U$, then $\mathscr{J}|V$ is a quasi-coherent sheaf of ideals of $\mathscr{O}_X|V$, and it is immediate that the prescheme induced by Y on $Y \cap V$ is the closed subprescheme of V defined by the sheaf of ideals $\mathscr{J}|V$. Conversely:

Proposition (4.1.5). — *Let $(Y, \mathscr{O}_Y)$ be a ringed space such that Y is a subspace of X, and suppose there is a cover (V_α) of Y by open subsets of X such that, for each α, $Y \cap V_\alpha$ is closed in V_α, and the ringed space $(Y \cap V_\alpha, \mathscr{O}_Y|(Y \cap V_\alpha))$ is a closed subprescheme of the prescheme induced on V_α by X. Then $(Y, \mathscr{O}_Y)$ is a subprescheme of X.*

Proof. The hypotheses imply that Y is locally closed in X and that the largest open U in which Y is closed (and thus contained) contains all the V_α; we can thus reduce to the case where $U = X$ and Y is closed in X. We then define a quasi-coherent sheaf of ideals $\mathscr{J}$ of $\mathscr{O}_X$ by taking $\mathscr{J}|V_\alpha$ to be the sheaf of ideals of $\mathscr{O}_X|V_\alpha$ which defines the closed subprescheme $(Y \cap V_\alpha, \mathscr{O}_Y|(Y \cap V_\alpha))$, and, for each open subset W of X not intersecting Y, $\mathscr{J}|W = \mathscr{O}_X|W$. We see immediately, by Definition (4.1.3) and (4.1.4), that there exists a unique sheaf of ideals $\mathscr{J}$ satisfying these conditions, and that it defines the closed subprescheme $(Y, \mathscr{O}_Y)$. □

In particular, the *induced* (by X) prescheme on an *open subset* of X is a *subprescheme* of X.

Proposition (4.1.6). — *A subprescheme (resp. a closed subprescheme) of a subprescheme (resp. closed subprescheme) of X is canonically identified with a subprescheme (resp. closed subprescheme) of X.* I | 121

Proof. Since a locally closed subset of a locally closed subspace of X is a locally closed subspace of X, it is clear (4.1.5) that the question is local and that we can thus suppose that X is affine; the proposition then follows from the canonical identification of $A/\mathfrak{J}'$ with $(A/\mathfrak{J})/(\mathfrak{J}'/\mathfrak{J})$, where A is some ring, and $\mathfrak{J}$ and $\mathfrak{J}'$ are ideals of A such that $\mathfrak{J} \subset \mathfrak{J}'$. □

In what follows, we will always make use of the above identification.

(4.1.7). Let Y be a subprescheme of a prescheme X, and denote by ψ the canonical injection $Y \to X$ of the *underlying subspaces*; we know that the inverse image $\psi^*(\mathscr{O}_X)$ is the restriction $\mathscr{O}_X|Y$ (**0**, 3.7.1). If, for each $y \in Y$, we denote by ω_y the canonical homomorphism $(\mathscr{O}_X)_y \to (\mathscr{O}_Y)_y$, then these homomorphisms are the restrictions to stalks of a *surjective* homomorphism ω of sheaves of rings $\mathscr{O}_X|Y \to \mathscr{O}_Y$: indeed, it suffices to check locally on Y, that is to say, we can suppose that X is affine and that the subprescheme Y is closed; if in this case $\mathscr{I}$ is the sheaf of ideals of $\mathscr{O}_X$ which defines Y, then the ω_y are none other than the restrictions to stalks of the homomorphism $\mathscr{O}_X|Y \to (\mathscr{O}_X/\mathscr{I})|Y$. We have thus defined a *monomorphism of ringed spaces* (**0**, 4.1.1) $j = (\psi, \omega^\flat)$ which is evidently a morphism $Y \to X$ of preschemes (2.2.1), and we call this the *canonical injection morphism*.

If $f : X \to Z$ is a morphism, we then say that the composite morphism $Y \xrightarrow{j} X \xrightarrow{f} Z$ is the *restriction* of f to the subprescheme Y.

(4.1.8). Conforming to the general definitions (T, I, 1.1), we will say that a morphism of preschemes $f : Z \to X$ is *majoré*[15] by the injection morphism $j : Y \to X$ of a subprescheme Y of X if f factors as $Z \xrightarrow{g} Y \xrightarrow{j} X$, where g is a morphism of preschemes; further, g is necessarily *unique* since j is a monomorphism.

Proposition (4.1.9). — *For a morphism $f : Z \to X$ to factor through an injection morphism $j : Y \to X$, it is necessary and sufficient that $f(Z) \subset Y$ and, for all $z \in Z$, letting $y = f(z)$, that the homomorphism $(\mathscr{O}_X)_y \to \mathscr{O}_z$ corresponding to f factor as $(\mathscr{O}_X)_y \to (\mathscr{O}_Y)_y \to \mathscr{O}_z$* (or equivalently, *for the kernel of $(\mathscr{O}_X)_y \to \mathscr{O}_z$ to contain the kernel of $(\mathscr{O}_X)_y \to (\mathscr{O}_Y)_y$).*

Proof. The conditions are evidently necessary. To see that they are sufficient, we can reduce to the case where Y is a *closed* subprescheme of X, by replacing X by an open U such that Y is closed in U (4.1.3) if necessary; Y is then defined by a quasi-coherent sheaf of ideals $\mathscr{I}$ of $\mathscr{O}_X$. Let $f = (\psi, \theta)$, and let $\mathscr{J}$ be the sheaf of ideals of $\psi^*(\mathscr{O}_X)$ which is the kernel of $\theta^\sharp : \psi^*(\mathscr{O}_X) \to \mathscr{O}_Z$; considering the properties of the functor ψ^* (**0**, 3.7.2), the hypotheses imply that, for each $z \in Z$, we have $(\psi^*(\mathscr{I}))_z \subset \mathscr{J}_z$, and, as a result, that $\psi^*(\mathscr{I}) \subset \mathscr{J}$. Thus $\theta^\sharp$ factors as

$$\psi^*(\mathscr{O}_X) \longrightarrow \psi^*(\mathscr{O}_X)/\psi^*(\mathscr{I}) = \psi^*(\mathscr{O}_X/\mathscr{I}) \xrightarrow{\omega} \mathscr{O}_Z,$$

the first arrow being the canonical homomorphism. Let ψ' be the continuous map $Z \to Y$ coinciding with ψ; it is clear that we have $\psi'^*(\mathscr{O}_Y) = \psi^*(\mathscr{O}_X/\mathscr{I})$; on the other hand, ω is evidently a local homomorphism, so $g = (\psi', \omega^\flat)$ is a morphism of preschemes $Z \to Y$ (2.2.1), which, according to I | 122
the above, is such that $f = j \circ g$, hence the proposition. □

Corollary (4.1.10). — *For an injection morphism $Z \to X$ to factor through the injection morphism $Y \to X$, it is necessary and sufficient for Z to be a subprescheme of Y.*

We then write $Z \leqslant Y$, and this condition is evidently an *ordering* on the set of subpreschemes of X.

[15] *[Trans.] There doesn't seem to be an English equivalent of this, except for 'bounded above', which doesn't make much sense in this context. We would normally just say that 'f factors through j', but to avoid having to entirely restructure the often-lengthy sentences in the original, we sometimes (but as little as we can) use 'majoré'.*

4.2. Immersion morphisms

Definition (4.2.1). — We say that a morphism $f : Y \to X$ is an immersion (resp. a closed immersion, an open immersion) if it factors as $Y \xrightarrow{g} Z \xrightarrow{j} X$, where g is an isomorphism, Z is a subprescheme of X (resp. a closed subprescheme, a subprescheme induced by an open set), and j is the injection morphism.

The subprescheme Z and the isomorphism g are then determined in a *unique* way, since if Z' is a second subprescheme of X, j' the injection $Z' \to X$, and g' an isomorphism $Y \to Z'$ such that $j \circ g = j' \circ g'$, then we have $j' = j \circ g \circ g'^{-1}$, hence $Z' \leqslant Z$ (4.1.10), and we can similarly show that $Z \leqslant Z'$, hence $Z' = Z$, and, since j is a monomorphism of preschemes, $g' = g$.

We say that $f = j \circ g$ is the *canonical factorization* of the immersion f, and the subprescheme Z and the isomorphism g are those *associated to* f.

It is clear that an immersion is a *monomorphism* of preschemes (4.1.7) and *a fortiori* a *radicial* morphism (3.5.4).

Proposition (4.2.2). —

(a) *For a morphism $f = (\psi, \theta) : Y \to X$ to be an open immersion, it is necessary and sufficient for ψ to be a homeomorphism from Y to some open subset of X, and, for all $y \in Y$, that the homomorphism $\theta_y^\sharp : \mathscr{O}_{\psi(y)} \to \mathscr{O}_y$ be bijective.*

(b) *For a morphism $f = (\psi, \theta) : Y \to X$ to be an immersion (resp. a closed immersion), it is necessary and sufficient for ψ to be a homeomorphism from Y to some locally closed (resp. closed) subset of X, and, for all $y \in Y$, that the homomorphism $\theta_y^\sharp : \mathscr{O}_{\psi(y)} \to \mathscr{O}_y$ be surjective.*

Proof.

(a) The conditions are evidently necessary. Conversely, if they are satisfied, then it is clear that $\theta^\sharp$ is an isomorphism from $\psi^*(\mathscr{O}_X)$ to $\mathscr{O}_Y$[16], and $\psi^*(\mathscr{O}_X)$ is the sheaf induced by "transport of structure" via ψ^{-1} from $\mathscr{O}_X|\psi(Y)$; hence the conclusion.

(b) The conditions are evidently necessary—we prove that they are sufficient. Consider first the particular case where we suppose that X is an affine scheme, and that $Z = \psi(Y)$ is *closed* in X. We then know (**0**, 3.4.6) that $\psi_*(\mathscr{O}_Y)$ has support equal to Z, and that, denoting its restriction to Z by $\mathscr{O}'_Z$, the ringed space $(Z, \mathscr{O}'_Z)$ is induced from $(Y, \mathscr{O}_Y)$ by transport of structure via the homeomorphism ψ considered as a map from Y to Z. Let us now show that $f_*(\mathscr{O}_Y) = \psi_*(\mathscr{O}_Y)$ is a *quasi-coherent* $\mathscr{O}_X$-module. Indeed, for all $x \notin Z$, $\psi_*(\mathscr{O}_Y)$ restricted to a suitable neighbourhood of x is zero. If instead $x \in Z$, then we have $x = \psi(y)$ for a unique $y \in Y$; let V be an affine open neighbourhood of y in Y; $\psi(V)$ is then open in Z, and so equal to the intersection of Z with an open subset U of X, and the restriction to U of $\psi_*(\mathscr{O}_Y)$ is identical to the restriction to U of the direct image $(\psi_V)_*(\mathscr{O}_Y|V)$, where ψ_V is the restriction **I** | 123
of ψ to V. The restriction of the morphism (ψ, θ) to $(V, \mathscr{O}_Y|V)$ is a morphism from this prescheme to $(X, \mathscr{O}_X)$, and, as a result, is of the form $({}^a\phi, \widetilde{\phi})$, where ϕ is the homomorphism from the ring $A = \Gamma(X, \mathscr{O}_X)$ to the ring $\Gamma(V, \mathscr{O}_Y)$ (1.7.3); we conclude that $(\psi_V)_*(\mathscr{O}_Y|V)$ is a quasi-coherent $\mathscr{O}_X$-module (1.6.3), which proves our assertion, due to the local nature of quasi-coherent sheaves. In addition, the hypothesis that ψ is a homeomorphism implies (**0**, 3.4.5) that, for all $y \in Y$, ψ_y is an isomorphism $(\psi_*(\mathscr{O}_Y))_{\psi(y)} \to \mathscr{O}_y$; since the diagram

$$\begin{tikzcd}
\mathscr{O}_{\psi(y)} \arrow[r, "\theta_{\psi(y)}"] \arrow[d, "\psi_y \circ \rho_{\psi(y)}"'] & (\psi_*(\mathscr{O}_Y))_{\psi(y)} \arrow[d, "\psi_y"] \\
(\psi^*(\mathscr{O}_X))_y \arrow[r, "\theta_y^\sharp"] & \mathscr{O}_y
\end{tikzcd}$$

is commutative, and the vertical arrows are the isomorphisms (**0**, 3.7.2), the hypothesis that $\theta_y^\sharp$ is surjective implies that $\theta_{\psi(y)}$ is surjective as well. Since the support of $\psi_*(\mathscr{O}_Y)$ is $Z = \psi(Y)$,

[16] *[Trans.] The French source reverses the source and target here. By the definition of a morphism of preschemes and by the displayed stalk maps in Proposition 4.2.2(a), $\theta^\sharp$ has source $\psi^*(\mathscr{O}_X)$ and target $\mathscr{O}_Y$.*

θ is a *surjective* homomorphism from $\mathscr{O}_X = \widetilde{A}$ to the quasi-coherent $\mathscr{O}_X$-module $f_*(\mathscr{O}_Y)$. As a result, there exists a unique isomorphism ω from a sheaf quotient $\widetilde{A}/\widetilde{\mathfrak{J}}$ (with $\mathfrak{J}$ being an ideal of A) to $f_*(\mathscr{O}_Y)$ which, when composed with the canonical homomorphism $\widetilde{A} \to \widetilde{A}/\widetilde{\mathfrak{J}}$, gives θ (1.3.8); if $\mathscr{O}_Z$ denotes the restriction of $\widetilde{A}/\widetilde{\mathfrak{J}}$ to Z, then $(Z, \mathscr{O}_Z)$ is a subprescheme of $(X, \mathscr{O}_X)$, and f factors through the canonical injection of this subprescheme into X and the isomorphism (ψ_0, ω_0), where ψ_0 is ψ considered as a map from Y to Z, and ω_0 the restriction of ω to $\mathscr{O}_Z$.

We now pass to the general case. Let U be an affine open subset of X such that $U \cap \psi(Y)$ is closed in U and nonempty. By restricting f to the prescheme induced by Y on the open subset $\psi^{-1}(U)$, and by considering it as a morphism from this prescheme to the prescheme induced by X on U, we reduce to the first case; the restriction of f to $\psi^{-1}(U)$ is thus a closed immersion $\psi^{-1}(U) \to U$, canonically factoring as $j_U \circ g_U$, where g_U is an isomorphism from the prescheme $\psi^{-1}(U)$ to a subprescheme Z_U of U, and j_U is the canonical injection $Z_U \to U$. Let V be a second affine open subset of X such that $V \subset U$; since the restriction Z'_V of Z_U to V is a subprescheme of the prescheme V, the restriction of f to $\psi^{-1}(V)$ factors as $j'_V \circ g'_V$, where j'_V is the canonical injection $Z'_V \to V$ and g'_V is an isomorphism from $\psi^{-1}(V)$ to Z'_V. By the uniqueness of the canonical factorization of an immersion (4.2.1), we necessarily have that $Z'_V = Z_V$ and $g'_V = g_V$. We conclude (4.1.5) that there is a subprescheme Z of X whose underlying space is $\psi(Y)$, and whose restriction to each $U \cap \psi(Y)$ is Z_U; the g_U are then the restrictions to $\psi^{-1}(U)$ of an isomorphism $g : Y \to Z$ such that $f = j \circ g$, where j is the canonical injection $Z \to X$.

□

Corollary (4.2.3). — *Let X be an affine scheme. For a morphism $f = (\psi, \theta) : Y \to X$ to be a closed immersion, it is necessary and sufficient for Y to be an affine scheme, and the homomorphism $\Gamma(\theta) : \Gamma(\mathscr{O}_X) \to \Gamma(\mathscr{O}_Y)$ to be surjective.*

Corollary (4.2.4). —

(a) *Let f be a morphism $Y \to X$, and (V_λ) a cover of $f(Y)$ by open subsets of X. For f to be an immersion (resp. an open immersion), it is necessary and sufficient for its restriction to each of the induced preschemes $f^{-1}(V_\lambda)$ to be an immersion (resp. an open immersion) into V_λ.* I | 124

(b) *Let f be a morphism $Y \to X$, and (V_λ) an open cover of X. For f to be a closed immersion, it is necessary and sufficient for its restriction to each of the induced preschemes $f^{-1}(V_\lambda)$ to be a closed immersion into V_λ.*

Proof. Let $f = (\psi, \theta)$; in the case (a), $\theta^\sharp_y$ is surjective (resp. bijective) for all $y \in Y$, and in the case (b), $\theta^\sharp_y$ is surjective for all $y \in Y$; it thus suffices to check, in case (a), that ψ is a homeomorphism from Y to a locally closed (resp. open) subset of X, and, in case (b), that ψ is a homeomorphism from Y to a closed subset of X. Now ψ is evidently injective, and sends each neighbourhood of y in Y to a neighbourhood of $\psi(y)$ in $\psi(Y)$ for all $y \in Y$, by virtue of the hypothesis; in case (a), $\psi(Y) \cap V_\lambda$ is locally closed (resp. open) in V_λ, so $\psi(Y)$ is locally closed (resp. open) in the union of the V_λ, and *a fortiori* in X; in case (b), $\psi(Y) \cap V_\lambda$ is closed in V_λ, so $\psi(Y)$ is closed in X since $X = \bigcup_\lambda V_\lambda$. □

Proposition (4.2.5). — *The composition of any two immersions (resp. of two open immersions, of two closed immersions) is an immersion (resp. an open immersion, a closed immersion).*

Proof. This follows easily from (4.1.6). □

4.3. Products of immersions

Proposition (4.3.1). — *Let $\alpha : X' \to X$, $\beta : Y' \to Y$ be two S-morphisms; if α and β are immersions (resp. open immersions, closed immersions), then $\alpha \times_S \beta$ is an immersion (resp. an open immersion, a closed immersion). In addition, if α (resp. β) identifies X' (resp. Y') with a subprescheme X'' (resp. Y'') of X (resp. Y), then $\alpha \times_S \beta$ identifies the underlying space of $X' \times_S Y'$ with the subspace $p^{-1}(X'') \cap q^{-1}(Y'')$ of the underlying space of $X \times_S Y$, where p and q denote the projections from $X \times_S Y$ to X and Y respectively.*

Proof. According to Definition (4.2.1), we can restrict to the case where X' and Y' are subpreschemes, and α and β are the injection morphisms. The proposition has already been proved for the subpreschemes induced by open sets (3.2.7); since every subprescheme is a closed subprescheme of a prescheme induced by an open set (4.1.3), we can reduce to the case where X' and Y' are *closed* subpreschemes.

Let us first show that we can assume S is *affine*. Let (S_λ) be a cover of S by affine open sets; if ϕ and ψ are the structure morphisms of X and Y, then let $X_\lambda = \phi^{-1}(S_\lambda)$ and $Y_\lambda = \psi^{-1}(S_\lambda)$. The restriction X'_λ (resp. Y'_λ) of X' (resp. Y') to $X_\lambda \cap X'$ (resp. $Y_\lambda \cap Y'$) is a closed subprescheme of X_λ (resp. Y_λ), the preschemes X_λ, Y_λ, X'_λ, and Y'_λ can be considered as S_λ-preschemes, and the products $X_\lambda \times_S Y_\lambda$ and $X_\lambda \times_{S_\lambda} Y_\lambda$ (resp. $X'_\lambda \times_S Y'_\lambda$ and $X'_\lambda \times_{S_\lambda} Y'_\lambda$) are identical (3.2.5). If the proposition is true when S is affine, then the restriction of $\alpha \times_S \beta$ to each of the $X'_\lambda \times_S Y'_\lambda$ is thus an immersion (3.2.7). Since the product $X'_\lambda \times_S Y'_\mu$ (resp. $X_\lambda \times_S Y_\mu$) can be identified with $(X'_\lambda \cap X'_\mu) \times_S (Y'_\lambda \cap Y'_\mu)$ (resp. $(X_\lambda \cap X_\mu) \times_S (Y_\lambda \cap Y_\mu)$) (3.2.6.4), the restriction of $\alpha \times_S \beta$ to each of the $X'_\lambda \times_S Y'_\mu$ is also an immersion; the same is true for $\alpha \times_S \beta$ by (4.2.4). I | 125

Next, we show that we can assume X and Y are *affine*. Indeed, let (U_i) (resp. (V_j)) be a cover of X (resp. Y) by affine open sets, and let X'_i (resp. Y'_j) be the restriction of X' (resp. Y') to $X' \cap U_i$ (resp. $Y' \cap V_j$), which is a closed subprescheme of U_i (resp. V_j); $U_i \times_S V_j$ can be identified with the restriction of $X \times_S Y$ to $p^{-1}(U_i) \cap q^{-1}(V_j)$ (3.2.7); similarly, if p' and q' are the projections from $X' \times_S Y'$, then $X'_i \times_S Y'_j$ can be identified with the restriction of $X' \times_S Y'$ to $p'^{-1}(X'_i) \cap q'^{-1}(Y'_j)$. Set $\gamma = \alpha \times_S \beta$; we have, by definition, $p \circ \gamma = \alpha \circ p'$ and $q \circ \gamma = \beta \circ q'$; since $X'_i = \alpha^{-1}(U_i)$ and $Y'_j = \beta^{-1}(V_j)$, we also have $p'^{-1}(X'_i) = \gamma^{-1}(p^{-1}(U_i))$ and $q'^{-1}(Y'_j) = \gamma^{-1}(q^{-1}(V_j))$, hence

$$p'^{-1}(X'_i) \cap q'^{-1}(Y'_j) = \gamma^{-1}(p^{-1}(U_i) \cap q^{-1}(V_j)) = \gamma^{-1}(U_i \times_S V_j),$$

and we then conclude as in the previous part of the proof.

So suppose X, Y, and S are affine, and let B, C, and A be their respective rings. Then B and C are A-algebras, and X' and Y' are affine schemes whose rings are quotient algebras B' and C' of B and C respectively. In addition, we have $\alpha = ({}^a\rho, \widetilde{\rho})$ and $\beta = ({}^a\sigma, \widetilde{\sigma})$, where ρ and σ are (respectively) the canonical homomorphisms $B \to B'$ and $C \to C'$ (1.7.3). With that in mind, we know that $X \times_S Y$ (resp. $X' \times_S Y'$) is an affine scheme with ring $B \otimes_A C$ (resp. $B' \otimes_A C'$), and $\alpha \times_S \beta = ({}^a\tau, \widetilde{\tau})$, where τ is the homomorphism $\rho \otimes \sigma$ from $B \otimes_A C$ to $B' \otimes_A C'$ (Proposition (3.2.2) and Corollary (3.2.3)); since this homomorphism is surjective, $\alpha \times_S \beta$ is an immersion. In addition, if $\mathfrak{b}$ (resp. $\mathfrak{c}$) is the kernel of ρ (resp. σ), then the kernel of τ is $\operatorname{Im}(\mathfrak{b} \otimes_A C \to B \otimes_A C) + \operatorname{Im}(B \otimes_A \mathfrak{c} \to B \otimes_A C)$, equivalently the sum of the ideals generated by $u(\mathfrak{b})$ and $v(\mathfrak{c})$, where u (resp. v) is the homomorphism $b \mapsto b \otimes 1$ (resp. $c \mapsto 1 \otimes c$). Since $p = ({}^a u, \widetilde{u})$ and $q = ({}^a v, \widetilde{v})$, this kernel corresponds, in the prime spectrum of $B \otimes_A C$, to the closed set $p^{-1}(X') \cap q^{-1}(Y')$, by (1.2.2.1) and Proposition (1.1.2, iii), which finishes the proof. □

Corollary (4.3.2). — *If $f : X \to Y$ is an immersion (resp. an open immersion, a closed immersion) and an S-morphism, then $f_{(S')}$ is an immersion (resp. an open immersion, a closed immersion) for every extension $S' \to S$ of the base prescheme.*

4.4. Inverse images of a subprescheme

Proposition (4.4.1). — *Let $f : X \to Y$ be a morphism, Y' a subprescheme (resp. a closed subprescheme, a prescheme induced by an open set) of Y, and $j : Y' \to Y$ the injection morphism. Then the projection $p : X \times_Y Y' \to X$ is an immersion (resp. a closed immersion, an open immersion); the underlying space of the subprescheme of X associated to p is $f^{-1}(Y')$; in addition, if j' is the injection morphism of this subprescheme into X, then, for every morphism $h : Z \to X$, the composite $f \circ h : Z \to Y$ factors through j if and only if h factors through j'.*

Proof. Since $p = 1_X \times_Y j$ (3.3.4), the first claim follows from Proposition (4.3.1); the second is a particular case of Corollary (3.5.10) (after swapping the roles of X and Y'). Finally, if we have $f \circ h = j \circ h'$, where h' is a morphism $Z \to Y'$, then it follows from the definition of the product that we have $h = p \circ u$, where u is a morphism $Z \to X \times_Y Y'$, whence the last claim. □

We say that the subprescheme of X thus defined is the *inverse image* of the subprescheme Y' of Y under the morphism f, terminology which is consistent with that introduced more generally in (3.3.6). When we speak of $f^{-1}(Y')$ as a subprescheme of X, this will always be the subprescheme we mean. **I** | 126

When the preschemes $f^{-1}(Y')$ and X are identical, j' is the identity and each morphism $h : Z \to X$ thus factors through j'; taking $h = 1_X$, we see that *the morphism $f : X \to Y$ factors as $X \xrightarrow{g} Y' \xrightarrow{j} Y$.*

When y is a *closed* point of Y and $Y' = \operatorname{Spec}(k(y))$ is the smallest closed subprescheme of Y having $\{y\}$ as its underlying space (4.1.9), the closed subprescheme $f^{-1}(Y')$ is canonically isomorphic to the *fibre* $f^{-1}(y)$ defined in (3.6.2), and we will use this identification in all that follows.

Corollary (4.4.2). — *Let $f : X \to Y$ and $g : Y \to Z$ be morphisms, and $h = g \circ f$ their composition. For each subprescheme Z' of Z, the subpreschemes $f^{-1}(g^{-1}(Z'))$ and $h^{-1}(Z')$ of X are identical.*

Proof. This follows from the existence of the canonical isomorphism $X \times_Y (Y \times_Z Z') \simeq X \times_Z Z'$ (3.3.9.1). □

Corollary (4.4.3). — *Let X' and X'' be subpreschemes of X, and let $j' : X' \to X$ and $j'' : X'' \to X$ be their injection morphisms; then $j'^{-1}(X'')$ and $j''^{-1}(X')$ are both equal to the greatest lower bound $\inf(X', X'')$ of X' and X'' for the ordering $\leqslant$ on subpreschemes, and this is canonically isomorphic to $X' \times_X X''$.*

Proof. This follows immediately from Proposition (4.4.1) and Corollary (4.1.10). □

Corollary (4.4.4). — *Let $f : X \to Y$ be a morphism, and Y' and Y'' subpreschemes of Y; then we have $f^{-1}(\inf(Y', Y'')) = \inf(f^{-1}(Y'), f^{-1}(Y''))$.*

Proof. This follows from the existence of the canonical isomorphism between $(X \times_Y Y') \times_X (X \times_Y Y'')$ and $X \times_Y (Y' \times_Y Y'')$ (3.3.9.1). □

Proposition (4.4.5). — *Let $f : X \to Y$ be a morphism, and Y' a closed subprescheme of Y defined by a quasi-coherent sheaf of ideals $\mathscr{K}$ of $\mathscr{O}_Y$ (4.1.3); the closed subprescheme $f^{-1}(Y')$ of X is then defined by the quasi-coherent sheaf of ideals $f^*(\mathscr{K})\mathscr{O}_X$ of $\mathscr{O}_X$.*

Proof. The statement is evidently local on X and Y; it thus suffices to note that if A is a B-algebra and $\mathfrak{K}$ an ideal of B, then we have $A \otimes_B (B/\mathfrak{K}) = A/\mathfrak{K}A$, and then to apply (1.6.9). □ **Err**$_{\mathrm{II}}$

Corollary (4.4.6). — *Let X' be a closed subprescheme of X defined by a quasi-coherent sheaf of ideals $\mathscr{J}$ of $\mathscr{O}_X$, and i the injection $X' \to X$; for the restriction $f \circ i$ of f to X' to factor through the injection $j : Y' \to Y$* (in other words, for it to factor as $j \circ g$, with g a morphism $X' \to Y'$), *it is necessary and sufficient that $f^*(\mathscr{K})\mathscr{O}_X \subset \mathscr{J}$.*

Proof. It suffices to apply Proposition (4.4.1) to i, taking Proposition (4.4.5) into account. □

4.5. Local immersions and local isomorphisms

Definition (4.5.1). — Let $f : X \to Y$ be a morphism of preschemes. We say that f is a local immersion at a point $x \in X$ if there exists an open neighbourhood U of x in X and an open neighbourhood V of $f(x)$ in Y such that the restriction of f to the induced prescheme U is a closed immersion of U into the induced prescheme V. We say that f is a local immersion if f is a local immersion at each point of X.

Definition (4.5.2). — We say that a morphism $f : X \to Y$ is a local isomorphism at a point $x \in X$ if there exists an open neighbourhood U of x in X such that the restriction of f to the induced prescheme U is an open immersion of U into Y. We say that f is a local isomorphism if f is a local isomorphism at each point of X. **I** | 127

(4.5.3). An immersion (resp. a closed immersion) $f : X \to Y$ can be characterized as a local immersion such that f is a homeomorphism from the underlying space of X to a subset (resp. a closed subset) of Y. An open immersion f can be characterized as an *injective* local isomorphism.

Proposition (4.5.4). — *Let X be an irreducible prescheme, and $f : X \to Y$ a dominant injective morphism. If f is a local immersion, then f is an immersion, and $f(X)$ is open in Y.*

Proof. Let $x \in X$, and choose an open neighbourhood U of x and an open neighbourhood V of $f(x)$ in Y such that the restriction of f to U is a closed immersion into V; since U is dense in X, $f(U)$ is dense in Y by hypothesis, so $f(U) = V$, and f is a homeomorphism from U to V; the hypothesis that f is injective implies that $f^{-1}(V) = U$, hence the proposition. □

Proposition (4.5.5). —

(i) *The composition of any two local immersions (resp. of two local isomorphisms) is a local immersion (resp. a local isomorphism).*

(ii) *Let $f : X \to X'$ and $g : Y \to Y'$ be two S-morphisms. If f and g are local immersions (resp. local isomorphisms), then so too is $f \times_S g$.*

(iii) *If an S-morphism f is a local immersion (resp. a local isomorphism), then so too is $f_{(S')}$ for every extension $S' \to S$ of the base prescheme.*

Proof. According to (3.5.1), it suffices to prove (i) and (ii).

(i) follows immediately from the transitivity of closed (resp. open) immersions (4.2.5)[17] and from the fact that if f is a homeomorphism from X to a closed subset of Y, then for every open $U \subset X$, $f(U)$ is open in $f(X)$, so there exists an open subset V of Y such that $f(U) = V \cap f(X)$, and, as a result, $f(U)$ is closed in V.

To prove (ii), let $z \in X \times_S Y$, set $z' = (f \times_S g)(z)$[18], let p and q be the projections from $X \times_S Y$, and let p' and q' be the projections from $X' \times_S Y'$. There exist, by hypothesis, open neighbourhoods U, U', V, and V' of $x = p(z)$, $x' = p'(z')$, $y = q(z)$, and $y' = q'(z')$ (respectively), such that the restrictions of f and g to U and V (respectively) are closed (resp. open) immersions into U' and V' (respectively). Since the underlying spaces of $U \times_S V$ and $U' \times_S V'$ can be identified with the open neighbourhoods $p^{-1}(U) \cap q^{-1}(V)$ and $p'^{-1}(U') \cap q'^{-1}(V')$ of z and z' (respectively) (3.2.7), the proposition follows from Proposition (4.3.1). □

§5. Reduced preschemes; the separation condition

5.1. Reduced preschemes

Proposition (5.1.1). — *Let $(X, \mathscr{O}_X)$ be a prescheme, and $\mathscr{B}$ a quasi-coherent $\mathscr{O}_X$-algebra. Then there exists a unique quasi-coherent $\mathscr{O}_X$-module $\mathscr{N}$ whose stalk $\mathscr{N}_x$ at any $x \in X$ is the nilradical of the ring $\mathscr{B}_x$. When X is affine, and, consequently, $\mathscr{B} = \widetilde{B}$, where B is an algebra over $A(X)$, then we have $\mathscr{N} = \widetilde{\mathfrak{N}}$, where $\mathfrak{N}$ is the nilradical of B.*

---

[17] *[Trans.] The French source cites (4.2.4) here; transitivity is Proposition 4.2.5.*

[18] *[Trans.] The French source uses z and z' below without introducing them; this insertion supplies the required point and its image.*

Proof. The statement is local, so it suffices to show the latter claim. We know that $\widetilde{\mathfrak{N}}$ is a quasi-coherent $\mathscr{O}_X$-module (1.4.1), and that its stalk at a point $x \in X$ is the ideal $\mathfrak{N}_x$ of the ring of fractions B_x; it remains to prove that the nilradical of B_x is contained in $\mathfrak{N}_x$, the converse inclusion being evident. Let z/s be an element of the nilradical of B_x, with $z \in B$, and $s \notin \mathfrak{j}_x$; by hypothesis, there exists an integer k such that $(z/s)^k = 0$, which implies that there exists some $t \notin \mathfrak{j}_x$ such that $tz^k = 0$. We conclude that $(tz)^k = 0$, and, as a result, that $z/s = (tz)/(ts) \in \mathfrak{N}_x$. ☐ I | 128

We say that the quasi-coherent $\mathscr{O}_X$-module $\mathscr{N}$ thus defined is the *nilradical* of the $\mathscr{O}_X$-algebra $\mathscr{B}$; in particular, we denote by $\mathscr{N}_X$ the nilradical of $\mathscr{O}_X$.

Corollary (5.1.2). — *Let X be a prescheme; the closed subprescheme of X defined by the sheaf of ideals $\mathscr{N}_X$ is the only reduced subprescheme* (**0**, 4.1.4) *of X that has X as its underlying space; it is also the smallest subprescheme of X that has X as its underlying space.*

Proof. Let Y denote the closed subprescheme of X defined by $\mathscr{N}_X$. Since its structure sheaf is $\mathscr{O}_X/\mathscr{N}_X$, it is immediate that Y is reduced and has X as its underlying space, because $\mathscr{N}_x \neq \mathscr{O}_x$ for every $x \in X$. To show the other claims, note that a subprescheme Z of X that has X as its underlying space is defined by a sheaf of ideals $\mathscr{I}$ (4.1.3) such that $\mathscr{I}_x \neq \mathscr{O}_x$ for any $x \in X$. We can restrict to the case where X is affine, say $X = \operatorname{Spec}(A)$ and $\mathscr{I} = \widetilde{\mathfrak{I}}$, where $\mathfrak{I}$ is an ideal of A; then, for every $x \in X$, we have $\mathfrak{I} \subset \mathfrak{j}_x$, and so $\mathfrak{I}$ is contained in every prime ideal of A, and so also in their intersection $\mathfrak{N}$, the nilradical of A. This proves that Y is the smallest subprescheme of X that has X as its underlying space (4.1.9); furthermore, if Z is distinct from Y, we necessarily have $\mathscr{I}_x \neq \mathscr{N}_x$ for at least one $x \in X$, and so (5.1.1) Z is not reduced. ☐

Definition (5.1.3). — We define the reduced prescheme associated to a prescheme X, denoted by X_{red}, to be the unique reduced subprescheme of X that has X as its underlying space.

Saying that a prescheme X is reduced thus means that $X = X_{\text{red}}$.

Proposition (5.1.4). — *For the prime spectrum of a ring A to be a reduced (resp. integral) prescheme* (2.1.8), *it is necessary and sufficient for A to be a reduced (resp. integral) ring.*

Proof. Indeed, it follows immediately from (5.1.1) that the condition $\mathscr{N} = (0)$ is necessary and sufficient for $X = \operatorname{Spec}(A)$ to be reduced; the claim corresponding to integral rings is then a consequence of (1.1.13). ☐

Since every nonzero ring of fractions of an integral ring is integral, it follows from (5.1.4) that, for every *locally integral* prescheme X, $\mathscr{O}_x$ is an *integral* ring for every $x \in X$. The converse is true whenever the underlying space of X is *locally Noetherian*: indeed, X is then reduced, and if U is an affine open subset of X, which is a Noetherian space, then U has only a finite number of irreducible components, and so its ring A has only a finite number of minimal prime ideals (1.1.14). If two of the irreducible components of U had a common point x, then $\mathscr{O}_x$ would have at least two distinct minimal prime ideals, and would thus not be integral; the components of U are thus open subsets that are pairwise disjoint, and each of them is thus integral.

(5.1.5). Let $f = (\psi, \theta) : X \to Y$ be a morphism of preschemes; the homomorphism $\theta_x^\sharp : \mathscr{O}_{\psi(x)} \to \mathscr{O}_x$ I | 129
sends each nilpotent element of $\mathscr{O}_{\psi(x)}$ to a nilpotent element of $\mathscr{O}_x$; by passing to the quotients, $\theta^\sharp$ induces a homomorphism

$$\omega : \psi^*(\mathscr{O}_Y/\mathscr{N}_Y) \longrightarrow \mathscr{O}_X/\mathscr{N}_X.$$

It is clear that, for every $x \in X$, $\omega_x : \mathscr{O}_{\psi(x)}/\mathscr{N}_{\psi(x)} \to \mathscr{O}_x/\mathscr{N}_x$ is a local homomorphism, and so $(\psi, \omega^\flat)$ is a morphism of preschemes $X_{\text{red}} \to Y_{\text{red}}$, which we denote by f_{red}, and call the *reduced* morphism associated to f. It is immediate that, for morphisms $f : X \to Y$ and $g : Y \to Z$, we have $(g \circ f)_{\text{red}} = g_{\text{red}} \circ f_{\text{red}}$, and so we have defined X_{red} as a *functor*, *covariant* in X.

The preceding definition shows that the diagram

$$\begin{tikzcd}
X_{\text{red}} \arrow[r, "f_{\text{red}}"] \arrow[d] & Y_{\text{red}} \arrow[d] \\
X \arrow[r, "f"'] & Y
\end{tikzcd}$$

is commutative, where the vertical arrows are the injection morphisms; in other words, $X_{\text{red}} \to X$ is a *functorial* morphism. We note in particular that, if X is reduced, then every morphism $f : X \to Y$ factors as $X \xrightarrow{f_{\text{red}}} Y_{\text{red}} \to Y$; in other words, f factors through the injection morphism $Y_{\text{red}} \to Y$.

Proposition (5.1.6). — *Let $f : X \to Y$ be a morphism; if f is surjective (resp. radicial, an immersion, a closed immersion, an open immersion, a local immersion, a local isomorphism), then so too is f_{red}. Conversely, if f_{red} is surjective (resp. radicial), then so too is f.*

Proof. The proposition is trivial if f is surjective; if f is radicial, then the proposition follows from the fact that, for every $x \in X$, the field $k(x)$ is the same for the preschemes X and X_{red} (3.5.8). Finally, if $f = (\psi, \theta)$ is an immersion, a closed immersion, or a local immersion (resp. an open immersion, or a local isomorphism), then the proposition follows from the fact that, if $\theta_x^\sharp$ is surjective (resp. bijective), then so too is the homomorphism obtained by passing to the quotients by the nilradicals $\mathcal{O}_{\psi(x)}$ and $\mathcal{O}_x$ ((5.1.2) and (4.2.2)) (cf. (5.5.12)). □

Proposition (5.1.7). — *If X and Y are S-preschemes, then the preschemes $X_{\text{red}} \times_{S_{\text{red}}} Y_{\text{red}}$ and $X_{\text{red}} \times_S Y_{\text{red}}$ are identical, and canonically identified with a subprescheme of $X \times_S Y$ that has the same underlying space as that product.*

Proof. The canonical identification of $X_{\text{red}} \times_S Y_{\text{red}}$ with a subprescheme of $X \times_S Y$ that has the same underlying space follows from (4.3.1). Furthermore, if ϕ and ψ are the structure morphisms $X_{\text{red}} \to S$ and $Y_{\text{red}} \to S$ (respectively), then they factor through S_{red} (5.1.5), and since $S_{\text{red}} \to S$ is a monomorphism, the first claim of the proposition follows from (3.2.4). □

Corollary (5.1.8). — *The preschemes $(X \times_S Y)_{\text{red}}$ and $(X_{\text{red}} \times_{S_{\text{red}}} Y_{\text{red}})_{\text{red}}$ are canonically identified with one another.*

Proof. This follows from (5.1.2) and (5.1.7). □

We note that, even if X and Y are reduced preschemes, $X \times_S Y$ might not be reduced, because the tensor product of two reduced algebras can have nilpotent elements.

Proposition (5.1.9). — *Let X be a prescheme, and $\mathscr{I}$ a quasi-coherent sheaf of ideals of $\mathcal{O}_X$ such that $\mathscr{I}^n = 0$ for some integer $n > 0$. Let X_0 be the closed subprescheme $(X, \mathcal{O}_X/\mathscr{I})$ of X; for X to be an affine scheme, it is necessary and sufficient for X_0 to be an affine scheme.* I | 130

The condition is clearly necessary, so we will show that it is sufficient. If we set $X_k = (X, \mathcal{O}_X/\mathscr{I}^{k+1})$, it is enough to prove by induction on k that X_k is affine, and so we are led to consider the base case, where $\mathscr{I}^2 = 0$. We set

$$A = \Gamma(X, \mathcal{O}_X)$$
$$A_0 = \Gamma(X_0, \mathcal{O}_{X_0}) = \Gamma(X, \mathcal{O}_X/\mathscr{I}).$$

The canonical homomorphism $\mathcal{O}_X \to \mathcal{O}_X/\mathscr{I}$ induces a homomorphism of rings $\phi : A \to A_0$. We will see below that ϕ is *surjective*, which implies that

(5.1.9.1) $$0 \longrightarrow \Gamma(X, \mathscr{I}) \longrightarrow \Gamma(X, \mathcal{O}_X) \longrightarrow \Gamma(X, \mathcal{O}_X/\mathscr{I}) \longrightarrow 0$$

is an *exact* sequence. We now prove, assuming that this is true, the proposition. Note that $\mathfrak{K} = \Gamma(X, \mathscr{I})$ is an ideal whose square is zero in A, and thus a module over $A_0 = A/\mathfrak{K}$. By hypothesis, we have $X_0 = \operatorname{Spec}(A_0)$, and, since the underlying spaces of X_0 and X are identical, $\mathfrak{K} = \Gamma(X_0, \mathscr{I})$; Additionally, since $\mathscr{I}^2 = 0$, $\mathscr{I}$ is a quasi-coherent $(\mathcal{O}_X/\mathscr{I})$-module, so we have $\mathscr{I} \cong \widetilde{\mathfrak{K}}$ and $\mathfrak{K}_x = \mathscr{I}_x$ for all $x \in X_0$ (1.4.1). With this in mind, let $X' = \operatorname{Spec}(A)$, and consider the morphism $f = (\psi, \theta) : X \to X'$ of preschemes that corresponds to the identity map $A \to \Gamma(X, \mathcal{O}_X)$ (2.2.4). For every affine open subset V of X, the diagram

$$\begin{tikzcd} A \arrow[r] \arrow[d] & \Gamma(V, \mathcal{O}_X|V) \arrow[d] \\ A_0 = A/\mathfrak{K} \arrow[r] & \Gamma(V, \mathcal{O}_{X_0}|V) \end{tikzcd}$$

commutes, whence the diagram

$$\begin{tikzcd} X' & X \arrow[l, "f"'] \\ X'_0 \arrow[u, "j'"] & X_0 \arrow[l, "f_0"] \arrow[u, "j"'] \end{tikzcd}$$

also commutes (X'_0 being the closed subprescheme of X' defined by the quasi-coherent sheaf of ideals $\widetilde{\mathfrak{K}}$, and j and j' being the canonical injection morphisms). But since X_0 is affine, f_0 is an isomorphism, and since the underlying continuous maps of j and j' are identity maps, we see straight away that $\psi : X \to X'$ is a homeomorphism. Furthermore, the equation $\mathfrak{K}_x = \mathscr{I}_x$ shows that the restriction of $\theta^\sharp : \psi^*(\mathscr{O}_{X'}) \to \mathscr{O}_X$ is an *isomorphism* from $\psi^*(\widetilde{\mathfrak{K}})$ to $\mathscr{I}$; additionally, by passing to the quotients, $\theta^\sharp$ gives an *isomorphism* $\psi^*(\mathscr{O}_{X'}/\widetilde{\mathfrak{K}}) \to \mathscr{O}_X/\mathscr{I}$, because f_0 is an isomorphism; we thus immediately conclude, by the 5 lemma (M, I, 1.1), that $\theta^\sharp$ is itself an isomorphism, and thus that f is an *isomorphism*, and thus that X is affine. So everything reduces to proving the exactness of (5.1.9.1), which will follow from showing that $\mathrm{H}^1(X, \mathscr{I}) = 0$. But $\mathrm{H}^1(X, \mathscr{I}) = \mathrm{H}^1(X_0, \mathscr{I})$, and we have seen I | 131
that $\mathscr{I}$ is a quasi-coherent $\mathscr{O}_{X_0}$-module. Our proof will thus follow from

Lemma (5.1.9.2). — *If Y is an affine scheme, and $\mathscr{F}$ a quasi-coherent $\mathscr{O}_Y$-module, then $\mathrm{H}^1(Y, \mathscr{F}) = 0$.*

Proof. This lemma will be proven in Chapter III, §1, as a consequence of the more general theorem that $\mathrm{H}^i(Y, \mathscr{F}) = 0$ for all $i > 0$. To give an independent proof, note that $\mathrm{H}^1(Y, \mathscr{F})$ can be identified with the module $\mathrm{Ext}^1_{\mathscr{O}_Y}(Y; \mathscr{O}_Y, \mathscr{F})$ of extension classes of the $\mathscr{O}_Y$-module $\mathscr{O}_Y$ by the $\mathscr{O}_Y$-module $\mathscr{F}$ (T, 4.2.3); so everything reduces to proving that such an extension $\mathscr{G}$ is trivial. But, for every $y \in Y$, there is a neighbourhood V of y in Y such that $\mathscr{G}|V$ is isomorphic to $\mathscr{F}|V \oplus \mathscr{O}_Y|V$[19] (**0**, 5.4.9); from this we conclude that $\mathscr{G}$ is a *quasi-coherent* $\mathscr{O}_Y$-module. If A is the ring of Y, then we have $\mathscr{F} = \widetilde{M}$ and $\mathscr{G} = \widetilde{N}$, where M and N are A-modules, and, by hypothesis, N is an extension of the A-module A by the A-module M (1.3.11). Since this extension is necessarily trivial, the lemma is proven, and thus so too is (5.1.9). ☐

Corollary (5.1.10). — *Let X be a prescheme such that $\mathscr{N}_X$ is nilpotent. For X to be an affine scheme, it is necessary and sufficient for X_{red} to be an affine scheme.*

5.2. Existence of a subprescheme with a given underlying space

Proposition (5.2.1). — *For every locally closed subspace Y of the underlying space of a prescheme X, there exists exactly one reduced subprescheme of X that has Y as its underlying space.*

Proof. The uniqueness follows from (5.1.2), so it remains only to show the existence of the prescheme in question.

If X is affine with ring A, and Y is closed in X, then the proposition is immediate: $\mathfrak{j}(Y)$ is the largest ideal $\mathfrak{a} \subset A$ such that $V(\mathfrak{a}) = Y$, and it is equal to its radical (1.1.4, i), so $A/\mathfrak{j}(Y)$ is a reduced ring.

In the general case, for every affine open $U \subset X$ such that $U \cap Y$ is closed in U, consider the closed subprescheme Y_U of U defined by the sheaf of ideals associated to the ideal $\mathfrak{j}(U \cap Y)$ of $A(U)$. This subprescheme is reduced. We claim that, if V is an affine open subset of X contained in U, then Y_V is *induced* by Y_U on $V \cap Y$. Indeed, this induced prescheme is a closed reduced subprescheme of V having $V \cap Y$ as its underlying space; the uniqueness of Y_V therefore proves the claim. ☐

Proposition (5.2.2). — *Let X be reduced, let $f : X \to Y$ be a morphism, and let Z be a closed subprescheme of Y such that $f(X) \subset Z$. Then f factors as $X \xrightarrow{g} Z \xrightarrow{j} Y$, where j is the injection morphism.*

Proof. It follows from the hypotheses that the closed subprescheme $f^{-1}(Z)$ of X has all of X as its underlying space (4.4.1); since X is reduced, this closed subprescheme agrees with X (5.1.2), and the proposition then follows from (4.4.1). ☐

---

[19] *[Trans.] The French source prints $\mathscr{F}|Y$ here; the restriction required on the neighbourhood V is $\mathscr{F}|V$.*

Corollary (5.2.3). — *Let X be a reduced subprescheme of a prescheme Y; if Z is the closed reduced subprescheme of Y that has $\overline{X}$ as its underlying space, then X is a subprescheme induced on an open subset of Z.*

Proof. There is indeed an open subset U of Y such that $X = U \cap \overline{X}$; since, by (5.2.2), X is a reduced subprescheme of Z, the subprescheme X is induced by Z on the open subspace X by uniqueness (5.2.1). □ **I** | 132

Corollary (5.2.4). — *Let $f : X \to Y$ be a morphism, and X' (resp. Y') a closed subprescheme of X (resp. Y) defined by a quasi-coherent sheaf of ideals $\mathscr{J}$ (resp. $\mathscr{K}$) of $\mathscr{O}_X$ (resp. $\mathscr{O}_Y$). Suppose that X' is reduced, and that $f(X') \subset Y'$. Then $f^*(\mathscr{K})\mathscr{O}_X \subset \mathscr{J}$.*

Proof. Since, by (5.2.2), the restriction of f to X' factors as $X' \to Y' \to Y$, it suffices to apply (4.4.6). □

5.3. Diagonal; graph of a morphism

(5.3.1). Let X be an S-prescheme; we define the *diagonal morphism* from X into $X \times_S X$, denoted by $\Delta_{X|S}$, or Δ_X, or even Δ if no confusion may arise, to be the S-morphism $(1_X, 1_X)_S$, or, in other words, the unique S-morphism Δ_X such that

(5.3.1.1) $$p_1 \circ \Delta_X = p_2 \circ \Delta_X = 1_X,$$

where p_1 and p_2 are the projections of $X \times_S X$ (Definition (3.2.1)). If $f : T \to X$ and $g : T \to Y$ are S-morphisms, we immediately have that

(5.3.1.2) $$(f, g)_S = (f \times_S g) \circ \Delta_{T|S}.$$

The reader will note that the preceding definition and the results stated in (5.3.1) to (5.3.8) are true in any category, *provided that the products used within exist in the category.*

Proposition (5.3.2). — *Let X and Y be S-preschemes; if we make the canonical identification between $(X \times Y) \times (X \times Y)$ and $(X \times X) \times (Y \times Y)$, then the morphism $\Delta_{X\times Y}$ is identified with $\Delta_X \times \Delta_Y$.*

Proof. Indeed, if $p_1 : X \times X \to X$ and $q_1 : Y \times Y \to Y$ are the projections onto the first component, then the projection onto the first component $(X \times Y) \times (X \times Y) \to X \times Y$ is identified with $p_1 \times q_1$, and we have
$$(p_1 \times q_1) \circ (\Delta_X \times \Delta_Y) = (p_1 \circ \Delta_X) \times (q_1 \circ \Delta_Y) = 1_{X\times Y}$$
and we can argue similarly for the projections onto the second component. □

Corollary (5.3.4). — *For every base extension $S' \to S$, $\Delta_{X_{(S')}}$ is canonically identified with $(\Delta_X)_{(S')}$.*

Proof. It suffices to remark that $(X \times_S X)_{(S')}$ is canonically identified with $X_{(S')} \times_{S'} X_{(S')}$ (3.3.10). □

Proposition (5.3.5). — *Let X and Y be S-preschemes, and $\phi : S \to T$ a morphism of preschemes, which lets us consider every S-prescheme as a T-prescheme. Let $f : X \to S$ and $g : Y \to S$*[20] *be the structure morphisms, p and q the projections of $X \times_S Y$, and $\pi = f \circ p = g \circ q$ the structure morphism $X \times_S Y \to S$. Then the diagram*

(5.3.5.1)
$$\begin{tikzcd}
X \times_S Y \arrow[r, "(p,q)_T"] \arrow[d, "\pi"'] & X \times_T Y \arrow[d, "f \times_T g"] \\
S \arrow[r, "\Delta_{S|T}"'] & S \times_T S
\end{tikzcd}$$

commutes, and identifies $X \times_S Y$ with the product of the $(S \times_T S)$-preschemes S and $X \times_T Y$, and the projections with π and $(p, q)_T$. **I** | 133

Proof. By (3.4.3), we are led to proving the corresponding proposition *in the category of sets*, replacing X, Y, and S by $X(Z)_T$, $Y(Z)_T$, and $S(Z)_T$ (respectively), with Z being an arbitrary T-prescheme. But, in the category of sets, the proof is immediate and left to the reader. □

[20] *[Trans.] The French source prints only $Y \to S$ here, omitting the name g; the following identity $\pi = f \circ p = g \circ q$ identifies this second structure morphism as g.*

Corollary (5.3.6). — *The morphism $(p,q)_T$ can be identified (letting $P = S \times_T S$) with $1_{X \times_T Y} \times_P \Delta_S$.*

Proof. This follows from (5.3.5) and (3.3.4). □

Corollary (5.3.7). — *If $f : X \to Y$ is an S-morphism, then the diagram*

$$\begin{tikzcd} X \arrow[r, "(1_X, f)_S"] \arrow[d, "f"'] & X \times_S Y \arrow[d, "f \times_S 1_Y"] \\ Y \arrow[r, "\Delta_Y"'] & Y \times_S Y \end{tikzcd}$$

commutes, and identifies X with the product of the $(Y \times_S Y)$-preschemes Y and $X \times_S Y$.

Proof. It suffices to apply (5.3.5), replacing S by Y, and T by S, and noting that $X \times_Y Y = X$ (3.3.3). □

Proposition (5.3.8). — *For $f : X \to Y$ to be a monomorphism of preschemes, it is necessary and sufficient for $\Delta_{X|Y}$ to be an isomorphism from X to $X \times_Y X$.*

Proof. Indeed, f is a monomorphism if and only if, for every Y-prescheme Z, the corresponding map $f' : X(Z)_Y \to Y(Z)_Y$ is injective. Since $Y(Z)_Y$ consists of a single element, this is equivalent to saying that $X(Z)_Y$ has at most one element[21], or, equivalently, that the diagonal map from $X(Z)_Y$ to $X(Z)_Y \times X(Z)_Y$ is a bijection. The latter product is exactly the set $(X \times_Y X)(Z)_Y$ (3.4.3.1), so this is equivalent to $\Delta_{X|Y}$ being an isomorphism. □

Proposition (5.3.9). — *The diagonal morphism Δ_X is an immersion from X to $X \times_S X$.*

Proof. The proof printed in the French source is insufficient, because it does not show that $\Delta_X(X)$ is locally closed in $X \times_S X$.[22] For a correct proof, it suffices to use (4.2.4, a): for every $x \in X$ and every affine neighbourhood U of x in X, $U \times_S U$ is an affine neighbourhood of $\Delta_X(x)$. Taking account of (5.3.16) (whose proof uses only Definition (5.3.1.1)), we are reduced to proving (5.3.9) when $S = \operatorname{Spec}(B)$ and $X = \operatorname{Spec}(A)$ are affine schemes. It is then clear from (5.3.1.1) that Δ_X corresponds to the canonical homomorphism $A \otimes_B A \to A$ taking $x \otimes y$ to xy. Since this homomorphism is surjective, Δ_X is in this case a closed immersion (4.2.3), which completes the proof. □

We say that the subprescheme of $X \times_S X$ associated to the immersion Δ_X (4.2.1) is *the diagonal* of $X \times_S X$.

Corollary (5.3.10). — *Under the hypotheses of* (5.3.5), *$(p,q)_T$ is an immersion.*

Proof. This follows from (5.3.6) and (4.3.1). □

We say (under the hypotheses of (5.3.5)) that $(p,q)_T$ is the *canonical immersion* of $X \times_S Y$ into $X \times_T Y$.

Corollary (5.3.11). — *Let X and Y be S-preschemes, and $f : X \to Y$ an S-morphism; then the graph morphism $\Gamma_f = (1_X, f)_S$ of f* (3.3.14) *is an immersion of X into $X \times_S Y$.*

Proof. This is a particular case of Corollary (5.3.10), where we replace S by Y, and T by S (cf. (5.3.7)). □

The subprescheme of $X \times_S Y$ associated to the immersion Γ_f (4.2.1) is called *the graph* of the morphism f; the subpreschemes of $X \times_S Y$ that are graphs of morphisms $X \to Y$ are characterised by the property that the restriction to such a subprescheme G of the projection $p_1 : X \times_S Y \to X$ is an *isomorphism* g from G to X: G is the graph of the morphism $p_2 \circ g^{-1}$, where p_2 is the projection $X \times_S Y \to Y$. **I** | 134

When we take, in particular, $X = S$, then the S-morphisms $S \to Y$ (which are exactly the *S-sections* of Y (2.5.5)) are equal to their graph morphisms; the subpreschemes of Y that are the graphs of

[21] *[Trans.] The French says that $X(Z)_Y$ is likewise reduced to one element; injectivity into the singleton $Y(Z)_Y$ yields only at most one element, allowing the empty case.*

[22] *[Trans.] Published EGA III.2, Errata and Addenda (list 2), item $\mathrm{Err}_{\mathrm{III}}$, 10, explicitly identifies this gap and gives the affine-local proof translated here.*

S-sections (in other words, those that are isomorphic to S by the restriction of the structure morphism $Y \to S$) are then also called the *images* of these sections, or, by an abuse of language, the *S-sections* of Y.

Corollary (5.3.12). — *With the hypotheses and notation of (5.3.11), for every morphism $g : S' \to S$, let f' be the inverse image of f under g (3.3.7); then $\Gamma_{f'}$ is the inverse image of Γ_f under g.*

Proof. This is a particular case of (3.3.10.1). □

Corollary (5.3.13). — *Let $f : X \to Y$ and $g : Y \to Z$ be morphisms; if $g \circ f$ is an immersion (resp. a local immersion), then so too is f.*

Proof. Indeed, f factors as $X \xrightarrow{\Gamma_f} X \times_Z Y \xrightarrow{p_2} Y$. Furthermore, p_2 can be identified with $(g \circ f) \times_Z 1_Y$ (3.3.4); if $g \circ f$ is an immersion (resp. a local immersion), then so too is p_2 ((4.3.1) and (4.5.5)), and since Γ_f is an immersion (5.3.11), we are done, by (4.2.5)[23] (resp. (4.5.5)). □

Corollary (5.3.14). — *Let $j : X \to Y$ and $g : X \to Z$ be S-morphisms. If j is an immersion (resp. a local immersion), then so too is $(j, g)_S$.*

Proof. Indeed, if $p : Y \times_S Z \to Y$ is the projection onto the first component, then we have $j = p \circ (j, g)_S$, and it suffices to apply (5.3.13). □

Proposition (5.3.15). — *If $f : X \to Y$ is an S-morphism, then the diagram*

(5.3.15.1)
$$\begin{tikzcd} X \arrow[r, "\Delta_X"] \arrow[d, "f"'] & X \times_S X \arrow[d, "f \times_S f"] \\ Y \arrow[r, "\Delta_Y"'] & Y \times_S Y \end{tikzcd}$$

commutes (in other words, Δ_X is a functorial morphism in the category of preschemes).

Proof. The proof is immediate and left to the reader. □

Corollary (5.3.16). — *If X is a subprescheme of Y, then the diagonal $\Delta_X(X)$ can be identified with a subprescheme of $\Delta_Y(Y)$, and the underlying space can be identified with*

$$\Delta_Y(Y) \cap p_1^{-1}(X) = \Delta_Y(Y) \cap p_2^{-1}(X)$$

(p_1 and p_2 being the projections of $Y \times_S Y$).

Proof. Applying (5.3.15) to the injection morphism $f : X \to Y$, we see that $f \times_S f$ is an immersion that identifies the underlying space of $X \times_S X$ with the subspace $p_1^{-1}(X) \cap p_2^{-1}(X)$ of $Y \times_S Y$ (4.3.1); further, if $z \in \Delta_Y(Y) \cap p_1^{-1}(X)$, then we have $z = \Delta_Y(y)$ and $y = p_1(z) \in X$, so $y = f(y)$, and $z = \Delta_Y(f(y))$ belongs to $\Delta_X(X)$ by the commutativity of (5.3.15.1). □ **I | 135**

Corollary (5.3.17). — *Let $f_1 : Y \to X$ and $f_2 : Y \to X$ be S-morphisms, and y a point of Y such that $f_1(y) = f_2(y) = x$, and such that the homomorphisms $k(x) \to k(y)$ corresponding to f_1 and f_2 are identical. Then, if $f = (f_1, f_2)_S$, the point $f(y)$ belongs to the diagonal $\Delta_{X|S}(X)$.*

Proof. The two homomorphisms $k(x) \to k(y)$ corresponding to f_i ($i = 1, 2$) define two S-morphisms $g_i : \mathrm{Spec}(k(y)) \to \mathrm{Spec}(k(x))$ such that the diagrams

$$\begin{tikzcd} \mathrm{Spec}(k(y)) \arrow[r, "g_i"] \arrow[d] & \mathrm{Spec}(k(x)) \arrow[d] \\ Y \arrow[r, "f_i"'] & X \end{tikzcd}$$

[23] *[Trans.] The French source prints (4.2.4) here; published EGA III.2, Errata and Addenda (list 2), explicitly directs its replacement by (4.2.5).*

commute. The diagram

$$\begin{tikzcd}
\operatorname{Spec}(k(y)) \arrow[r, "(g_1,g_2)_S"] \arrow[d] & \operatorname{Spec}(k(x)) \times_S \operatorname{Spec}(k(x)) \arrow[d] \\
Y \arrow[r, "(f_1,f_2)_S"'] & X \times_S X
\end{tikzcd}$$

thus also commutes. But it follows from the equality $g_1 = g_2$ that the image under $(g_1, g_2)_S$ of the unique point of $\operatorname{Spec}(k(y))$ belongs to the diagonal of $\operatorname{Spec}(k(x)) \times_S \operatorname{Spec}(k(x))$; the conclusion then follows from (5.3.15). □

5.4. Separated morphisms and separated preschemes

Definition (5.4.1). — We say that a morphism of preschemes $f : X \to Y$ is *separated* if the diagonal morphism $X \to X \times_Y X$ is a *closed* immersion; we then also say that X is a *separated prescheme over* Y, or a Y*-scheme*. We say that a prescheme X is separated if it is separated over $\operatorname{Spec}(\mathbf{Z})$; we then also say that X is a *scheme*[24] *(cf.* (5.5.7)*)*.

By (5.3.9), for X to be separated over Y, it is necessary and sufficient for $\Delta_X(X)$ to be a *closed subspace* of the underlying space of $X \times_Y X$.

Proposition (5.4.2). — *Let $S \to T$ be a separated morphism. If X and Y are S-preschemes, then the canonical immersion $X \times_S Y \to X \times_T Y$* (5.3.10) *is closed.*

Proof. Indeed, if we refer to the diagram in (5.3.5.1), we see that $(p, q)_T$ can be considered as being obtained from $\Delta_{S|T}$ by the base extension $f \times_T g : X \times_T Y \to S \times_T S$; the proposition then follows from (4.3.2). □

Corollary (5.4.3). — *Let Y be an S-scheme, and $f : X \to Y$ an S-morphism. Then the graph morphism $\Gamma_f : X \to X \times_S Y$* (5.3.11) *is a closed immersion.*

Proof. This is a particular case of (5.4.2), where we replace S by Y, and T by S. □

Corollary (5.4.4). — *Let $f : X \to Y$ and $g : Y \to Z$ be morphisms, with g separated. If $g \circ f$ is a closed immersion, then so too is f.*

Proof. The proof using (5.4.3) is the same as that of (5.3.13) using (5.3.11). □

I | 136

Corollary (5.4.5). — *Let Z be an S-scheme, and $j : X \to Y$ and $g : X \to Z$ S-morphisms. If j is a closed immersion, then so too is $(j, g)_S : X \to Y \times_S Z$.*

Proof. The proof using (5.4.4) is the same as that of (5.3.14) using (5.3.13). □

Corollary (5.4.6). — *If X is an S-scheme, then every S-section of X* (2.5.5) *is a closed immersion.*

Proof. If $\phi : X \to S$ is the structure morphism, and $\psi : S \to X$ an S-section of X, it suffices to apply (5.4.5) to $\phi \circ \psi = 1_S$. □

Corollary (5.4.7). — *Let S be an integral prescheme with generic point s, and X an S-scheme. If two S-sections f and g are such that $f(s) = g(s)$, then $f = g$.*

Proof. Indeed, if $x = f(s) = g(s)$, then the homomorphisms $k(x) \to k(s)$ corresponding to f and g are necessarily identical. If $h = (f, g)_S$, we thus deduce from (5.3.17) that $h(s)$ belongs to the diagonal $Z = \Delta_X(X)$; but since $S = \overline{\{s\}}$, and since Z is closed by hypothesis, we have $h(S) \subset Z$. It then follows from (5.2.2) that h factors as $S \to Z \to X \times_S X$, and we thus conclude that $f = g$, by definition of the diagonal. □

---

[24] *[Trans.] We repeat here the warning given at the very start of this translation: the early versions of the EGA use* prescheme *to mean what is now usually called a scheme, and* scheme *for what is now usually called a separated scheme.* Grothendieck himself later said that the more modern terminology was preferable, but we have decided to keep this translation 'historically accurate' by using the older nomenclature.

Remark (5.4.8). — If we suppose, conversely, that the conclusion of (5.4.3) is true when $f = 1_Y$, then we can conclude that Y is separated over S; similarly, if we suppose that the conclusion of (5.4.4) applies to the two morphisms $Y \xrightarrow{\Delta_Y} Y \times_Z Y \xrightarrow{p_1} Y$, then we can conclude that Δ_Y is a closed immersion, and thus that Y is separated over Z; finally, if we assume that the conclusion of (5.4.6) is true for the Y-section Δ_Y of the Y-prescheme $Y \times_S Y \to Y$, then this implies that Y is separated over S.

5.5. Separation criteria

Proposition (5.5.1). —

(i) *Every monomorphism of preschemes (and, in particular, every immersion) is a separated morphism.*
(ii) *The composition of any two separated morphisms is separated.*
(iii) *If $f : X \to X'$ and $g : Y \to Y'$ are separated S-morphisms, then $f \times_S g$ is separated.*
(iv) *If $f : X \to Y$ is a separated S-morphism, then the S'-morphism $f_{(S')}$ is separated for every extension $S' \to S$ of the base prescheme.*
(v) *If the composition $g \circ f$ is separated, then f is separated.*
(vi) *For a morphism f to be separated, it is necessary and sufficient for f_{red} (5.1.5) to be separated.*

Proof. Note that (i) is an immediate consequence of (5.3.8). If $f : X \to Y$ and $g : Y \to Z$ are morphisms, then the diagram

(5.5.1.1)
$$\begin{tikzcd} X \arrow[rr, "\Delta_{X|Z}"] \arrow[dr, "\Delta_{X|Y}"'] & & X \times_Z X \\ & X \times_Y X \arrow[ur, "j"'] & \end{tikzcd}$$

commutes (where j denotes the canonical immersion (5.3.10)), as can be immediately verified. If f and g are separated, then $\Delta_{X|Y}$ is a closed immersion by definition, and j is a closed immersion by (5.4.2), whence $\Delta_{X|Z}$ is a closed immersion by (4.2.4), which proves (ii). Given (i) and (ii), (iii) and (iv) **I** | 137
are equivalent (3.5.1), so it suffices to prove (iv). But $X_{(S')} \times_{Y_{(S')}} X_{(S')}$ is canonically identified with $(X \times_Y X) \times_Y Y_{(S')}$ by (3.3.11) and (3.3.9.1), and we immediately see that the diagonal morphism $\Delta_{X_{(S')}}$ can then be identified with $\Delta_X \times_Y 1_{Y_{(S')}}$; the proposition then follows from (4.3.1).

To prove (v), consider, as in (5.3.13), the factorisation $X \xrightarrow{\Gamma_f} X \times_Z Y \xrightarrow{p_2} Y$ of f, noting that $p_2 = (g \circ f) \times_Z 1_Y$; the hypothesis (that $g \circ f$ is separated) implies that p_2 is separated, by (iii) and (i), and, since Γ_f is an immersion, Γ_f is separated, by (i), whence f is separated, by (ii). Finally, to prove (vi), recall that the preschemes $X_{\mathrm{red}} \times_{Y_{\mathrm{red}}} X_{\mathrm{red}}$ and $X_{\mathrm{red}} \times_Y X_{\mathrm{red}}$ are canonically identified with one another (5.1.7); if we denote by j the injection $X_{\mathrm{red}} \to X$, then the diagram

$$\begin{tikzcd} X_{\mathrm{red}} \arrow[r, "\Delta_{X_{\mathrm{red}}}"] \arrow[d, "j"'] & X_{\mathrm{red}} \times_Y X_{\mathrm{red}} \arrow[d, "j \times_Y j"] \\ X \arrow[r, "\Delta_X"'] & X \times_Y X \end{tikzcd}$$

commutes (5.3.15), and the proposition follows from the fact that the vertical arrows are homeomorphisms of the underlying spaces (4.3.1). □

Corollary (5.5.2). — *If $f : X \to Y$ is separated, then the restriction of f to any subprescheme of X is separated.*

Proof. This follows from (5.5.1, i and ii). □

Corollary (5.5.3). — *If X and Y are S-preschemes such that Y is separated over S, then $X \times_S Y$ is separated over X.*

Proof. This is a particular case of (5.5.1, iv). □

Proposition (5.5.4). — *Let X be a prescheme, and assume that its underlying space is a* finite *union of closed subsets X_k ($1 \leqslant k \leqslant n$); for each k, consider the reduced subprescheme of X that has X_k as its underlying space (5.2.1), and denote this again by X_k. Let $f : X \to Y$ be a morphism, and, for each k, let Y_k be a closed subset of Y such that $f(X_k) \subset Y_k$; we again denote by Y_k the reduced subprescheme of Y that has Y_k as its underlying space, so that the restriction $X_k \to Y$ of f to X_k factors as $X_k \xrightarrow{f_k} Y_k \to Y$ (5.2.2). For f to be separated, it is necessary and sufficient for all the f_k to be separated.*

Proof. The necessity follows from (5.5.1, i, ii, and v). Conversely, if the condition of the statement is satisfied, then each of the restrictions $X_k \to Y$ of f is separated (5.5.1, (i) and (ii)); if p_1 and p_2 are the projections of $X \times_Y X$, then the subspace $\Delta_{X_k}(X_k)$ can be identified with the subspace $\Delta_X(X) \cap p_1^{-1}(X_k)$ of the underlying space of $X \times_Y X$ (5.3.16); these subspaces are closed in $X \times_Y X$, and thus so too is their union $\Delta_X(X)$. □

Suppose, in particular, that the X_k are the *irreducible components* of X; then we can suppose that the Y_k are the irreducible components of Y (**0**, 2.1.5); Proposition (5.5.4) therefore reduces, in this case, the notion of separation to the case of *integral* preschemes (2.1.7).

I | 138

Proposition (5.5.5). — *Let (Y_λ) be an open cover of a prescheme Y; for a morphism $f : X \to Y$ to be separated, it is necessary and sufficient for each of its restrictions $f^{-1}(Y_\lambda) \to Y_\lambda$ to be separated.*

Proof. If we set $X_\lambda = f^{-1}(Y_\lambda)$, everything reduces, by taking (4.2.4, b) and the identification of the products $X_\lambda \times_Y X_\lambda$ and $X_\lambda \times_{Y_\lambda} X_\lambda$ (3.2.5) into account, to proving that the $X_\lambda \times_Y X_\lambda$ form a cover of $X \times_Y X$. But if we set $Y_{\lambda\mu} = Y_\lambda \cap Y_\mu$ and $X_{\lambda\mu} = X_\lambda \cap X_\mu = f^{-1}(Y_{\lambda\mu})$, then $X_\lambda \times_Y X_\mu$ can be identified with the product $X_{\lambda\mu} \times_{Y_{\lambda\mu}} X_{\lambda\mu}$ (3.2.6.4), and so also with $X_{\lambda\mu} \times_Y X_{\lambda\mu}$ (3.2.5), and finally with an open subset of $X_\lambda \times_Y X_\lambda$, which proves our claim (3.2.7). □

Proposition (5.5.5) allows us, by taking an affine open cover of Y, to reduce the study of separated morphisms to that of separated morphisms taking values in affine schemes.

Proposition (5.5.6). — *Let Y be an* affine *scheme, X a prescheme, and (U_α) a cover of X by affine open subsets. For a morphism $f : X \to Y$ to be separated, it is necessary and sufficient for $U_\alpha \cap U_\beta$ to be, for every pair of indices (α, β), an affine open subset,* and *for the ring $\Gamma(U_\alpha \cap U_\beta, \mathcal{O}_X)$ to be generated by the union of the canonical images of the rings $\Gamma(U_\alpha, \mathcal{O}_X)$ and $\Gamma(U_\beta, \mathcal{O}_X)$.*

Proof. The $U_\alpha \times_Y U_\beta$ form an open cover of $X \times_Y X$ (3.2.7); denoting the projections of $X \times_Y X$ by p and q, we have

$$\begin{aligned}\Delta_X^{-1}(U_\alpha \times_Y U_\beta) &= \Delta_X^{-1}(p^{-1}(U_\alpha) \cap q^{-1}(U_\beta)) \\ &= \Delta_X^{-1}(p^{-1}(U_\alpha)) \cap \Delta_X^{-1}(q^{-1}(U_\beta)) = U_\alpha \cap U_\beta;\end{aligned}$$

so everything reduces to proving that the restriction of Δ_X to $U_\alpha \cap U_\beta$ is a closed immersion into $U_\alpha \times_Y U_\beta$. But this restriction is exactly $(j_\alpha, j_\beta)_Y$, where j_α (resp. j_β) denotes the injection morphism from $U_\alpha \cap U_\beta$ to U_α (resp. U_β), as follows from the definitions. Since $U_\alpha \times_Y U_\beta$ is an affine scheme whose ring is canonically isomorphic to $\Gamma(U_\alpha, \mathcal{O}_X) \otimes_{\Gamma(Y, \mathcal{O}_Y)} \Gamma(U_\beta, \mathcal{O}_X)$ (3.2.2), we see that $U_\alpha \cap U_\beta$ must be an affine scheme, and that the map $h_\alpha \otimes h_\beta \mapsto h_\alpha h_\beta$ from the ring $A(U_\alpha \times_Y U_\beta)$ to $\Gamma(U_\alpha \cap U_\beta, \mathcal{O}_X)$ must be surjective (4.2.3), which finishes the proof. □

Corollary (5.5.7). — *An affine scheme is separated* (and is thus a *scheme*, which justifies the terminology of (5.4.1)).

Corollary (5.5.8). — *Let Y be an affine scheme; for $f : X \to Y$ to be a separated morphism, it is necessary and sufficient for X to be separated* (in other words, for X to be a *scheme*).

Proof. Indeed, we see that the criterion of (5.5.6) does not depend on f. □

Corollary (5.5.9). — *For a morphism $f : X \to Y$ to be separated, it is necessary for the induced prescheme $f^{-1}(U)$ to be separated for every open subset U on which Y induces a separated prescheme, and it is sufficient for this to hold for every affine open subset $U \subset Y$.*

Proof. The necessity of the condition follows from (5.5.5) and (5.5.1, ii); the sufficiency follows from (5.5.5) and (5.5.8), taking into account the existence of affine open covers of Y. ☐

In particular, if X and Y are affine schemes, then *every* morphism $X \to Y$ is separated.

Proposition (5.5.10). — *Let Y be a* scheme, *and $f : X \to Y$ a morphism. For every affine open subset U of X, and every affine open subset V of Y, $U \cap f^{-1}(V)$ is affine.*

Proof. Let p_1 and p_2 be the projections of $X \times_{\mathbf{Z}} Y$; the subspace $U \cap f^{-1}(V)$ is the image of $\Gamma_f(X) \cap p_1^{-1}(U) \cap p_2^{-1}(V)$ under p_1. But $p_1^{-1}(U) \cap p_2^{-1}(V)$ can be identified with the underlying space of the prescheme $U \times_{\mathbf{Z}} V$ (3.2.7), and is thus an affine scheme (3.2.2); since $\Gamma_f(X)$ is closed in I | 139
$X \times_{\mathbf{Z}} Y$ (5.4.3), $\Gamma_f(X) \cap p_1^{-1}(U) \cap p_2^{-1}(V)$ is closed in $U \times_{\mathbf{Z}} V$, and so the prescheme induced by the subprescheme of $X \times_{\mathbf{Z}} Y$ associated to Γ_f (4.2.1) on the open subset $\Gamma_f(X) \cap p_1^{-1}(U) \cap p_2^{-1}(V)$ of its underlying space is a closed subprescheme of an affine scheme, and thus an affine scheme (4.2.3). The proposition then follows from the fact that Γ_f is an immersion. ☐

Examples (5.5.11). — The prescheme from Example (2.3.2) ("the projective line over a field K") is *separated*, because, for the cover (X_1, X_2) of X by affine open subsets, $X_1 \cap X_2 = U_{12}$ is affine, and $\Gamma(U_{12}, \mathscr{O}_X)$, the ring of rational fractions of the form $f(s)/s^m$ with $f \in K[s]$, is generated by $K[s]$ and $1/s$, so the conditions of (5.5.6) are satisfied.

With the same choice of X_1, X_2, U_{12}, and U_{21} as in Example (2.3.2), now take u_{12} to be the isomorphism which sends $f(s)$ to $f(t)$; we now obtain, by gluing, a *non-separated integral* prescheme X, because the first condition of (5.5.6) is satisfied, but not the second. It is immediate here that $\Gamma(X, \mathscr{O}_X) \to \Gamma(X_1, \mathscr{O}_X) = K[s]$ is an isomorphism; the inverse isomorphism defines a morphism $f : X \to \operatorname{Spec}(K[s])$ that is surjective, and for every $y \in \operatorname{Spec}(K[s])$ such that $\mathfrak{j}_y \neq (s)$, $f^{-1}(y)$ consists of a single point, but for $\mathfrak{j}_y = (s)$, $f^{-1}(y)$ consists of *two* distinct points[25] (we say that X is the "affine line over K with the point 0 doubled").

We can also give an example where the first of the two conditions of (5.5.6) is not satisfied. First note that, in the prime spectrum Y of the ring $A = K[s,t]$ of polynomials in two indeterminates over a field K, the open subset U given by the union of $D(s)$ and $D(t)$ is *not an affine open subset*. Indeed, if z is a section of $\mathscr{O}_Y$ over U, there exist two integers $m, n \geqslant 0$ such that $s^m z$ and $t^n z$ are the restrictions of polynomials in s and t to U (1.4.1), which is clearly possible only if the section z extends to a section over the whole of Y, identified with a polynomial in s and t. If U were an affine open subset, then the injection morphism $U \to Y$ would be an isomorphism (1.7.3), which is a contradiction, since $U \neq Y$.

With the above in mind, take two affine schemes Y_1 and Y_2, prime spectra of the rings $A_1 = K[s_1, t_1]$ and $A_2 = K[s_2, t_2]$ (respectively); take $U_{12} = D(s_1) \cup D(t_1)$ and $U_{21} = D(s_2) \cup D(t_2)$, and take u_{12} to be the restriction of an isomorphism $Y_2 \to Y_1$ to U_{21} corresponding to the isomorphism of rings that sends $f(s_1, t_1)$ to $f(s_2, t_2)$; we then have an example where the first condition of (5.5.6) is not satisfied, while the second is satisfied (the integral prescheme thus obtained is called "the affine plane over K with the point 0 doubled").

Remark (5.5.12). — Given some property $\mathbf{P}$ of morphisms of preschemes, consider the following propositions.

(i) *Every closed immersion has property $\boldsymbol{P}$.*
(ii) *The composition of any two morphisms that both have property $\boldsymbol{P}$ also has property $\boldsymbol{P}$.*
(iii) *If $f : X \to X'$ and $g : Y \to Y'$ are S-morphisms that have property $\boldsymbol{P}$, then $f \times_S g$ has property $\boldsymbol{P}$.* I | 140
(iv) *If $f : X \to Y$ is an S-morphism that has property $\boldsymbol{P}$, then every S'-morphism $f_{(S')}$ obtained by an extension $S' \to S$ of the base prescheme also has property $\boldsymbol{P}$.*
(v) *If the composition $g \circ f$ of two morphisms $f : X \to Y$ and $g : Y \to Z$ has property $\boldsymbol{P}$, and g is separated, then f has property $\boldsymbol{P}$.*
(vi) *If a morphism $f : X \to Y$ has property $\boldsymbol{P}$, then so too does f_{red} (5.1.5).*

[25] *[Trans.] The French source prints* (0) *in both ideal conditions. For the doubled origin in* $\operatorname{Spec}(K[s])$, *the relevant prime ideal is* (s); (0) *is the generic point.*

If we suppose that (i) and (ii) are both true, then (iii) and (iv) are *equivalent*, and (v) and (vi) are *consequences* of (i), (ii), and (iii).

The first claim has already been shown (3.5.1). Consider the factorisation (5.3.13) $X \xrightarrow{\Gamma_f} X \times_Z Y \xrightarrow{p_2} Y$ of f; the equation $p_2 = (g \circ f) \times_Z 1_Y$ shows that, if $g \circ f$ has property **P**, then so too does p_2, by (iii); if g is separated, then Γ_f is a closed immersion (5.4.3), and so also has property **P**, by (i); finally, by (ii), f has property **P**.

Finally, consider the commutative diagram

$$\begin{tikzcd} X_{\mathrm{red}} \arrow[r, "f_{\mathrm{red}}"] \arrow[d] & Y_{\mathrm{red}} \arrow[d] \\ X \arrow[r, "f"'] & Y, \end{tikzcd}$$

where the vertical arrows are the closed immersions (5.1.5), and thus have property **P**, by (i). The hypothesis that f has property **P** implies, by (ii), that $X_{\mathrm{red}} \xrightarrow{f_{\mathrm{red}}} Y_{\mathrm{red}} \to Y$ has property **P**; finally, since a closed immersion is separated (5.5.1, i), f_{red} has property **P**, by (v).

Note that, if we consider the propositions

(i') *Every immersion has property* ***P****;*

(v') *If $g \circ f$ has property* ***P****, then so too does f;*

then the above arguments show that (v') is a consequence of (i'), (ii), and (iii).

(5.5.13). Note that (v) and (vi) are again consequences of (i), (iii), and

(ii') *If $j : X \to Y$ is a closed immersion, and $g : Y \to Z$ is a morphism that has property* ***P****, then $g \circ j$ has property* ***P****.*

Similarly, (v') is a consequence of (i'), (iii), and

(ii'') *If $j : X \to Y$ is an immersion, and $g : Y \to Z$ is a morphism that has property* ***P****, then $g \circ j$ has property* ***P****.*

This follows immediately from the arguments of (5.5.12).

§6. Finiteness conditions

6.1. Noetherian and locally Noetherian preschemes

Definition (6.1.1). — We say that a prescheme X is Noetherian (resp. locally Noetherian) if it is a finite union (resp. union) of affine open subsets V_α such that the ring of the scheme induced on each V_α is Noetherian.

It follows immediately from (1.5.2) that, if X is locally Noetherian, then the structure sheaf $\mathscr{O}_X$ is a *coherent sheaf of rings*, since the question is a local one. Every *quasi-coherent $\mathscr{O}_X$-submodule* (resp. I | 141
quasi-coherent quotient $\mathscr{O}_X$-module) of a *coherent* $\mathscr{O}_X$-module $\mathscr{F}$ is *coherent*, as the question is once again a local one, and it suffices to apply (1.5.1), (1.4.1), and (1.3.10), combined with the fact that a submodule (resp. quotient module) of a module of finite type over a Noetherian ring is of finite type. In particular, every *quasi-coherent sheaf of ideals* of $\mathscr{O}_X$ is *coherent*.

If a prescheme X is a finite union (resp. union) of open subsets W_λ in such a way that the preschemes induced on the W_λ are Noetherian (resp. locally Noetherian), it is clear that X is Noetherian (resp. locally Noetherian).

Proposition (6.1.2). — *For a prescheme X to be Noetherian, it is necessary and sufficient for it to be locally Noetherian and have a quasi-compact underlying space. The underlying space itself is then also Noetherian.*

Proof. The first claim follows immediately from the definitions and (1.1.10, ii). The second follows from (1.1.6) and the fact that every space that is a finite union of Noetherian subspaces is itself Noetherian (**0**, 2.2.3). ☐

Proposition (6.1.3). — *Let X be an affine scheme given by a ring A. The following conditions are equivalent:* (a) *X is Noetherian;* (b) *X is locally Noetherian;* (c) *A is Noetherian.*

Proof. The equivalence between (a) and (b) follows from (6.1.2) and the fact that the underlying space of every affine scheme is quasi-compact (1.1.10); it is furthermore clear that (c) implies (a). To see that (a) implies (c), we remark that there is a finite cover (V_i) of X by affine open subsets such that the ring A_i of the prescheme induced on V_i is Noetherian. So let $(\mathfrak{a}_n)$ be an increasing sequence of ideals of A; under the canonical bijective correspondence (1.3.7), there corresponds to it an increasing sequence $(\widetilde{\mathfrak{a}}_n)$ of sheaves of ideals in $\widetilde{A} \equiv \mathscr{O}_X$; to see that the sequence $(\mathfrak{a}_n)$ is stationary, it suffices to prove that the sequence $(\widetilde{\mathfrak{a}}_n)$ is. But the restriction $\widetilde{\mathfrak{a}}_n|V_i$ is a quasi-coherent sheaf of ideals of $\mathscr{O}_X|V_i$, being the inverse image of $\widetilde{\mathfrak{a}}_n$ under the canonical injection $V_i \to X$ (**0**, 5.1.4); $\widetilde{\mathfrak{a}}_n|V_i$ is thus of the form $\widetilde{\mathfrak{a}}_{ni}$, where $\mathfrak{a}_{ni}$ is an ideal of A_i (1.3.7). Since A_i is Noetherian, the sequence $(\mathfrak{a}_{ni})$ is stationary for all i, whence the proposition. □

We note that the above argument proves also that *if X is a Noetherian prescheme, then every increasing sequence of coherent sheaves of ideals of $\mathscr{O}_X$ is stationary.*

Proposition (6.1.4). — *Every subprescheme of a Noetherian (resp. locally Noetherian) prescheme is Noetherian (resp. locally Noetherian).*

Proof. It suffices to give a proof for a Noetherian prescheme X; further, by definition (6.1.1), we can also restrict to the case where X is an affine scheme. Since every subprescheme of X is a closed subprescheme of a prescheme induced on an open subset (4.1.3), we can restrict to the case of a subprescheme Y, either closed or induced on an open subset of X. The proof in the case where Y is closed is immediate, since if A is the ring of X, we know that Y is an affine scheme given by the ring $A/\mathfrak{J}$, where $\mathfrak{J}$ is an ideal of A (4.2.3); since A is Noetherian (6.1.3), so too is $A/\mathfrak{J}$.

Now suppose that Y is open in X; the underlying space of Y is Noetherian (6.1.2), hence quasi-compact, and thus a finite union of open subsets $D(f_i)$ $(f_i \in A)$; everything reduces to showing the proposition in the case where $Y = D(f)$ with $f \in A$. But then Y is an affine scheme whose ring is isomorphic to A_f (1.3.6); since A is Noetherian (6.1.3), so too is A_f. □ **I | 142**

(6.1.5). We note that the *product* of two Noetherian S-preschemes is not necessarily Noetherian, even if the preschemes are affine, since the tensor product of two Noetherian algebras is not necessarily a Noetherian ring (cf. (6.3.8)).

Proposition (6.1.6). — *If X is a Noetherian prescheme, the nilradical $\mathscr{N}_X$ of $\mathscr{O}_X$ is nilpotent.*

Proof. We can in fact cover X with a finite number of affine open subsets U_i, and it suffices to prove that there exist integers n_i such that $(\mathscr{N}_X|U_i)^{n_i} = 0$; if n is the largest of the n_i, then we will have $\mathscr{N}_X^n = 0$. We can thus restrict to the case where $X = \operatorname{Spec}(A)$ is affine, with A a Noetherian ring; by (5.1.1) and (1.3.13), it suffices to observe that the nilradical of A is nilpotent ([Sam53b, p. 127, cor. 4]). □

Corollary (6.1.7). — *Let X be a Noetherian prescheme; for X to be an affine scheme, it is necessary and sufficient that X_{red} be affine.*

Proof. This follows from (6.1.6) and (5.1.10). □

Lemma (6.1.8). — *Let X be a topological space, x a point of X, and U an open neighbourhood of x having only a finite number of irreducible components. Then there exists a neighbourhood V of x such that every open neighbourhood of x contained in V is connected.*

Proof. Let U_i $(1 \leqslant i \leqslant m)$ be the irreducible components of U not containing x; the complement (in U) of the union of the U_i is an open neighbourhood V of x inside U, and thus so too in X; it is also, incidentally, the intersection with U of the complement (in X) of the union of the irreducible components of X that do not contain x (**0**, 2.1.6). So let W be an open neighbourhood of x contained in V. The irreducible components of W are the intersections with W of the irreducible components of U that meet W (**0**, 2.1.6), so these components contain x; since they are connected, so too is W. □

Corollary (6.1.9). — *A locally Noetherian topological space is locally connected (which implies, amongst other things, that its connected components are open).*

Proposition (6.1.10). — *Let X be a locally Noetherian topological space. The following conditions are equivalent.*

(a) *The irreducible components of X are open.*
(b) *The irreducible components of X are exactly its connected components.*
(c) *The connected components of X are irreducible.*
(d) *Two distinct irreducible components of X have an empty intersection.*

Finally, if X is a prescheme, then these conditions are also equivalent to

(e) *For every $x \in X$,* $\operatorname{Spec}(\mathscr{O}_x)$ *is irreducible (or, in other words, the nilradical of $\mathscr{O}_x$ is prime).*

Proof. It is immediate that (a) implies (b), because an irreducible space is connected, and (a) implies that the irreducible components of X are the sets that are both open and closed. It is trivial that (b) implies (c); conversely, a closed set F containing a connected component C of X, with C distinct **I** | 143
from F, cannot be irreducible, because not being connected means that F is the union of two disjoint nonempty sets that are both open and closed in F, and thus closed in X; as a result, (c) implies (b). We immediately conclude from this that (c) implies (d), since two distinct connected components have no points in common.

We have not yet used the fact that X is locally Noetherian. Suppose now that this is indeed the case, and we will show that (d) implies (a): by (**0**, 2.1.6), we can restrict ourselves to the case where the space X is Noetherian, and so has only a finite number of irreducible components. Since they are closed and pairwise disjoint, they are open.

Finally, the equivalence between (d) and (e) holds true even without the assumption that the underlying space of the prescheme X is locally Noetherian. We can in fact restrict ourselves to the case where $X = \operatorname{Spec}(A)$ is affine, by (**0**, 2.1.6); to say that x is contained in only one single irreducible component of X is to say that $\mathfrak{j}_x$ contains only one single minimal ideal of A (1.1.14), which is equivalent to saying that $\mathfrak{j}_x\mathscr{O}_x$ contains only one single minimal ideal of $\mathscr{O}_x$, whence the conclusion. □

Corollary (6.1.11). — *Let X be a locally Noetherian space. For X to be irreducible, it is necessary and sufficient that X be connected and nonempty, and that any two distinct irreducible components of X have an empty intersection. If X is a prescheme, this latter condition is equivalent to asking that* $\operatorname{Spec}(\mathscr{O}_x)$ *be irreducible for all $x \in X$.*

Proof. The second claim has already been shown in (6.1.10); the only thing thus remaining to show is that the conditions in the first claim are sufficient. But by (6.1.10), these conditions imply that the irreducible components of X are exactly its connected components, and since X is connected and nonempty, it is irreducible. □

Corollary (6.1.12). — *Let X be a locally Noetherian prescheme. For X to be integral, it is necessary and sufficient that X be connected and nonempty, and that $\mathscr{O}_x$ be integral for all $x \in X$.*

Proposition (6.1.13). — *Let X be a locally Noetherian prescheme, and let $x \in X$ be a point such that the nilradical $\mathscr{N}_x$ of $\mathscr{O}_x$ is prime (resp. such that $\mathscr{O}_x$ is reduced, resp. integral); then there exists an open neighbourhood U of x that is irreducible (resp. reduced, resp. integral).*

Proof. It suffices to consider two cases: where $\mathscr{N}_x$ is prime, and where $\mathscr{N}_x = 0$; the third hypothesis is a combination of the first two. If $\mathscr{N}_x$ is prime, then x belongs to only one single irreducible component Y of X (6.1.10); the union of the irreducible components of X that do not contain x is closed (the set of these components being locally finite), and the complement U of this union is thus open and contained in Y, and thus irreducible (**0**, 2.1.6). If $\mathscr{N}_x = 0$, we also have $\mathscr{N}_y = 0$ for any y in a neighbourhood of x, because $\mathscr{N}$ is quasi-coherent (5.1.1), and thus coherent, since X is locally Noetherian, and the conclusion then follows from (**0**, 5.2.2). □

6.2. Artinian preschemes

Definition (6.2.1). — We say that a prescheme is *Artinian* if it is affine and its ring is Artinian.

I | 144

Proposition (6.2.2). — *Given a prescheme X, the following conditions are equivalent:*

(a) *X is an Artinian scheme;*
(b) *X is Noetherian and its underlying space is discrete;*
(c) *X is Noetherian and the points of its underlying space are closed* (the T_1 condition).

When any of the above hold, the underlying space of X is finite, and the ring A of X is the direct product of the local (Artinian) rings at the points of X.

Proof. We know that (a) implies the last claim ([SZ60, p. 205, th. 3]), so every prime ideal of A is thus maximal and is the inverse image of a maximal ideal of one of the local components of A, and so the space X is finite and discrete; (a) thus implies (b), and (b) clearly implies (c). To see that (c) implies (a), we first show that X is then finite; we can indeed restrict to the case where X is affine, and we know that a Noetherian ring whose prime ideals are all maximal is Artinian ([SZ60, p. 203]), whence our claim. The underlying space X is then discrete, the topological sum of a finite number of points x_i, and the local rings $\mathscr{O}_{x_i} = A_i$ are Artinian; it is clear that X is isomorphic to the affine scheme $\operatorname{Spec}(A)$, where A is the direct product of the A_i (1.7.3). □

6.3. Morphisms of finite type

Definition (6.3.1). — We say that a morphism $f : X \to Y$ is *of finite type* if Y is the union of a family (V_α) of affine open subsets having the following property:

(P) $f^{-1}(V_\alpha)$ is a finite union of affine open subsets $U_{\alpha i}$ such that each ring $A(U_{\alpha i})$ is an algebra of finite type over $A(V_\alpha)$.

We then say that X is a prescheme of finite type over Y, or a Y-prescheme of finite type.

Proposition (6.3.2). — *If $f : X \to Y$ is a morphism of finite type, then every affine open subset W of Y satisfies property* (P) *of* (6.3.1).

We first show

Lemma (6.3.2.1). — *If $T \subset Y$ is an affine open subset, satisfying property* (P)*, then, for every $g \in A(T)$, $D(g)$ also satisfies property* (P).

Proof. By hypothesis, $f^{-1}(T)$ is a finite union of affine open subsets Z_j such that $A(Z_j)$ is an algebra of finite type over $A(T)$; let $\phi_j : A(T) \to A(Z_j)$ be the homomorphism of rings corresponding to the restriction of f to Z_j (2.2.4), and set $g_j = \phi_j(g)$; we then have $f^{-1}(D(g)) \cap Z_j = D(g_j)$ (1.2.2.2). But $A(D(g_j)) = A(Z_j)_{g_j} = A(Z_j)[1/g_j]$ is of finite type over $A(Z_j)$, and *a fortiori* over $A(T)$ by the hypothesis, and so also over $A(D(g)) = A(T)[1/g]$, which proves the lemma. □

Proof. With the above lemma, since W is quasi-compact (1.1.10), there exists a finite covering of W by sets of the form $D(g_i) \subset W$, where each g_i belongs to a ring $A(V_{\alpha(i)})$. Each $D(g_i)$, being quasi-compact, is a finite union of sets $D(h_{ik})$, where $h_{ik} \in A(W)$; if $\phi_i : A(W) \to A(D(g_i))$ is the canonical map, then we have $D(h_{ik}) = D(\phi_i(h_{ik}))$ by (1.2.2.2). By (6.3.2.1), each of the $f^{-1}(D(h_{ik}))$ admits a finite covering by affine open subsets U_{ijk} such that the $A(U_{ijk})$ are algebras of finite type over $A(D(h_{ik})) = A(W)[1/h_{ik}]$, whence the proposition. □ Err$_{\mathrm{II}}$

We can thus say that the notion of a prescheme of finite type over Y is *local on Y*. I | 145

Proposition (6.3.3). — *Let X and Y be affine schemes; for X to be of finite type over Y, it is necessary and sufficient that $A(X)$ be an algebra of finite type over $A(Y)$.*

Proof. Since the condition clearly suffices, we show that it is necessary. Set $A = A(Y)$ and $B = A(X)$; by (6.3.2), there exists a finite affine open cover (V_i) of X such that each of the rings $A(V_i)$ is an A-algebra of finite type. Further, since the V_i are quasi-compact, we can cover each of them with a finite number of open subsets of the form $D(g_{ij}) \subset V_i$, where $g_{ij} \in B$; if ϕ_i is a homomorphism $B \to A(V_i)$ that corresponds to the canonical injection $V_i \to X$, then we have $B_{g_{ij}} = (A(V_i))_{\phi_i(g_{ij})} =$

$A(V_i)[1/\phi_i(g_{ij})]$, so $B_{g_{ij}}$ is an A-algebra of finite type. We can thus restrict to the case where $V_i = D(g_i)$ with $g_i \in B$. By hypothesis, there exists a finite subset F_i of B and an integer $n_i \geqslant 0$ such that B_{g_i} is the algebra generated over A by the elements $b_i/g_i^{n_i}$, where the b_i run over all of F_i. Since there are only finitely many of the g_i, we can assume that all the n_i are equal to the same integer n. Further, since the $D(g_i)$ form a cover of X, the ideal generated in B by the g_i is equal to B, or, in other words, there exist $h_i \in B$ such that $\sum_i h_i g_i = 1$. So let F be the finite subset of B given by the union of the F_i, the set of the g_i, and the set of the h_i; we will show that the subring $B' = A[F]$ of B is equal to B. By hypothesis, for every $b \in B$ and every i, the canonical image of b in B_{g_i} is of the form $b'_i/g_i^{m_i}$, where $b'_i \in B'$; by multiplying the b'_i by suitable powers of the g_i, we can again assume that all the m_i are equal to the same integer m. By the definition of the ring of fractions, there is thus an integer N (dependent on b) such that $N \geqslant m$ and $g_i^N b \in B'$ for all i; but, *in the ring* B', the g_i^N generate the ideal B', because the g_i do (and the h_i belong to B'); there are thus $c_i \in B'$ such that $\sum_i c_i g_i^N = 1$, whence $b = \sum_i c_i g_i^N b \in B'$, Q.E.D. □

Proposition (6.3.4). —

(i) *Every closed immersion is of finite type.*
(ii) *The composition of any two morphisms of finite type is of finite type.*
(iii) *If $f : X \to X'$ and $g : Y \to Y'$ are S-morphisms of finite type, then $f \times_S g$ is of finite type.*
(iv) *If $f : X \to Y$ is an S-morphism of finite type, then $f_{(S')}$ is of finite type for any extension $g : S' \to S$ of the base prescheme.*
(v) *If the composition $g \circ f$ of two morphisms is of finite type, with g separated, then f is of finite type.*
(vi) *If a morphism f is of finite type, then f_{red} is of finite type.*

Proof. By (5.5.12), it suffices to prove (i), (ii), and (iv).

To show (i), we can restrict to the case of a canonical injection $X \to Y$, with X being a closed subprescheme of Y; further, by (6.3.2), we can assume that Y is affine, in which case X is also affine (4.2.3) and its ring is isomorphic to a quotient ring $A/\mathfrak{J}$, where A is the ring of Y and $\mathfrak{J}$ is an ideal of A; since $A/\mathfrak{J}$ is of finite type over A, the conclusion follows.

Now we show (ii). Let $f : X \to Y$ and $g : Y \to Z$ be two morphisms of finite type, and let U be an affine open subset of Z; $g^{-1}(U)$ admits a finite covering by affine open subsets V_i such that each $A(V_i)$ is an algebra of finite type over $A(U)$ (6.3.2); similarly, each of the $f^{-1}(V_i)$ admits a finite **I** | 146
cover by affine open subsets W_{ij} such that each $A(W_{ij})$ is an algebra of finite type over $A(V_i)$, and so also an algebra of finite type over $A(U)$, whence the conclusion.

Finally, to show (iv), we can restrict to the case where $S = Y$; then $f_{(S')}$ is also equal to $f_{(Y_{(S')})}$, where we consider f as a Y-morphism, and the base extension is $Y_{(S')} \to Y$ (3.3.9). So let p and q be the projections $X_{(S')} \to X$ and $X_{(S')} \to S'$. Let V be an affine open subset of S; $f^{-1}(V)$ is a finite union of affine open subsets W_i such that $A(W_i)$ is an algebra of finite type over $A(V)$ (6.3.2). Let V' be an affine open subset of S' contained in $g^{-1}(V)$; since $f \circ p = g \circ q$, $q^{-1}(V')$ is contained in the union of the $p^{-1}(W_i)$; on the other hand, the intersection $p^{-1}(W_i) \cap q^{-1}(V')$ can be identified with the product $W_i \times_V V'$ (3.2.7), which is an affine scheme whose ring is isomorphic to $A(W_i) \otimes_{A(V)} A(V')$ (3.2.2); this ring is, by hypothesis, an algebra of finite type over $A(V')$, which proves the proposition. □

Corollary (6.3.5). — *Let $f : X \to Y$ be an immersion morphism. If the underlying space of Y (resp. X) is locally Noetherian (resp. Noetherian), then f is of finite type.*

Proof. We can always assume that Y is affine (6.3.2); if the underlying space of Y is locally Noetherian, then we can further assume that it is Noetherian, and then the underlying space of X, which is a subspace, is also Noetherian. In other words, we can assume that Y is affine and that the underlying space of X is Noetherian; there then exists a covering of X by a finite number of affine open subsets $D(g_i) \subset Y$, where $g_i \in A(Y)$, such that the $X \cap D(g_i)$ are closed in $D(g_i)$ (and thus affine schemes (4.2.3)), because X is locally closed in Y (4.1.3). Then $A(X \cap D(g_i))$ is an algebra of finite type over $A(D(g_i))$, by (6.3.4, i) and (6.3.3), and $A(D(g_i)) = A(Y)_{g_i} = A(Y)[1/g_i]$ is of finite type over $A(Y)$, which finishes the proof. □

Corollary (6.3.6). — *Let $f : X \to Y$ and $g : Y \to Z$ be morphisms. If $g \circ f$ is of finite type, with either X Noetherian or $X \times_Z Y$ locally Noetherian, then f is of finite type.*

Proof. This follows immediately from the proof of (5.5.12) and from (6.3.5) applied to the immersion morphism Γ_f. □

Proposition (6.3.7). — *Let $f : X \to Y$ be a morphism of finite type; if Y is Noetherian (resp. locally Noetherian), then X is Noetherian (resp. locally Noetherian).*

Proof. We can restrict to proving the proposition for when Y is Noetherian. Then Y is a finite union of affine open subsets V_i such that the $A(V_i)$ are Noetherian rings. By (6.3.2), each of the $f^{-1}(V_i)$ is a finite union of affine open subsets W_{ij} such that the $A(W_{ij})$ are algebras of finite type over $A(V_i)$, and thus Noetherian rings; this proves that X is Noetherian. □

Corollary (6.3.8). — *Let X be a prescheme of finite type over S. For every base extension $S' \to S$ with S' Noetherian (resp. locally Noetherian), $X_{(S')}$ is Noetherian (resp. locally Noetherian).*

Proof. This follows from (6.3.7), since $X_{(S')}$ is of finite type over S' by (6.3.4, iv). □

We can also say that, for a product $X \times_S Y$ of S-preschemes, if *one* of the factors X or Y is *of finite type* over S and *the other is Noetherian* (resp. *locally Noetherian*), then $X \times_S Y$ is *Noetherian* (resp. *locally Noetherian*). **I** | 147

Corollary (6.3.9). — *Let X be a prescheme of finite type over a locally Noetherian prescheme S. Then every S-morphism $f : X \to Y$ is of finite type.*

Proof. In fact, we can assume that S is Noetherian; if $\phi : X \to S$ and $\psi : Y \to S$ are the structure morphisms, then we have $\phi = \psi \circ f$, and X is Noetherian by (6.3.7); f is thus of finite type by (6.3.6). □

Proposition (6.3.10). — *Let $f : X \to Y$ be a morphism of finite type. For f to be surjective, it is necessary and sufficient that, for every* algebraically closed *field Ω, the map $X(\Omega) \to Y(\Omega)$ that corresponds to f (3.4.1) be surjective.*

Proof. The condition suffices, as we can see by considering, for all $y \in Y$, an algebraically closed extension Ω of $k(y)$, and the commutative diagram

$$\begin{tikzcd} X \arrow[dd, "f"'] & \\ & \mathrm{Spec}(\Omega) \arrow[ul] \arrow[dl] \\ Y & \end{tikzcd}$$

(cf. (3.5.3)). Conversely, suppose that f is surjective, and let $g : \{\xi\} = \mathrm{Spec}(\Omega) \to Y$ be a morphism, where Ω is an algebraically closed field. If we consider the diagram

$$\begin{tikzcd} X \arrow[d, "f"'] & X_{(\Omega)} \arrow[l] \arrow[d, "f_{(\Omega)}"] \\ Y & \mathrm{Spec}(\Omega) \arrow[l] \end{tikzcd}$$

then it suffices to show that there exists a *rational point over* Ω in $X_{(\Omega)}$ ((3.3.14), (3.4.3), and (3.4.4)). Since f is surjective, $X_{(\Omega)}$ is nonempty (3.5.10), and since f is of finite type, so too is $f_{(\Omega)}$ (6.3.4, iv); thus $X_{(\Omega)}$ contains a nonempty affine open subset Z such that $A(Z)$ is a nonzero algebra of finite type over Ω. By Hilbert's Nullstellensatz [Zar47], there exists an Ω-homomorphism $A(Z) \to \Omega$, and thus a section of $X_{(\Omega)}$ over $\mathrm{Spec}(\Omega)$, which proves the proposition. □

6.4. Algebraic preschemes

Definition (6.4.1). — Given a field K, we define an *algebraic K-prescheme* to be a prescheme X of finite type over K; K is called the base field of X. If in addition X is a scheme *(or if X is a K-*scheme*, which is equivalent (5.5.8))*, we say that X is an *algebraic K-scheme*.

Every algebraic K-prescheme is *Noetherian* (6.3.7).

Proposition (6.4.2). — *Let X be an algebraic K-prescheme. For a point $x \in X$ to be closed, it is necessary and sufficient that $k(x)$ be an algebraic extension of K of finite degree.*

Proof. We can assume that X is affine, with its ring A a K-algebra of finite type. Indeed, the affine open subsets U of X such that $A(U)$ is a K-algebra of finite type cover X (6.3.1). The closed points of X are thus the points such that $\mathfrak{j}_x$ is a maximal ideal of A, or in other words, such that $A/\mathfrak{j}_x$ is a field (necessarily equal to $k(x)$). Since $A/\mathfrak{j}_x$ is a K-algebra of finite type, we see that if x is closed, then $k(x)$ is a field that is an algebra of finite type over K, and so necessarily a K-algebra of *finite rank* [Zar47]. Conversely, if $k(x)$ is of finite rank over K, then so is $A/\mathfrak{j}_x \subset k(x)$, and since every integral ring that is also a K-algebra of finite rank is a field, we have that $A/\mathfrak{j}_x = k(x)$, and hence x is closed. ☐ I | 148

Corollary (6.4.3). — *Let K be an algebraically closed field, and X an algebraic K-prescheme; the closed points of X are then the rational points over K (3.4.4) and can be canonically identified with the points of X with values in K.*

Proposition (6.4.4). — *Let X be an algebraic prescheme over a field K. The following properties are equivalent.*

(a) *X is Artinian.*
(b) *The underlying space of X is discrete.*
(c) *The underlying space of X has only a finite number of closed points.*
(c′) *The underlying space of X is finite.*
(d) *The points of X are closed.*
(e) *X is isomorphic to* $\operatorname{Spec}(A)$, *where A is a K-algebra of finite rank.*

Proof. Since X is Noetherian, it follows from (6.2.2) that the conditions (a), (b), and (d) are equivalent, and imply (c) and (c′); it is also clear that (e) implies (a). It remains to see that (c) implies (d) and (e); we can restrict to the case where X is affine. Then $A(X)$ is a K-algebra of finite type (6.3.3), and thus a Jacobson ring ([CC, p. 3-11 and 3-12]), in which there are, by hypothesis, only a finite number of maximal ideals. Since a finite intersection of prime ideals can only be a prime ideal if it is equal to one of the prime ideals being intersected, every prime ideal of $A(X)$ is thus maximal, whence (d). Further, we then know (6.2.2) that $A(X)$ is an Artinian K-algebra of finite type, and so necessarily of *finite rank* [Zar47]. ☐

(6.4.5). When the conditions of (6.4.4) are satisfied, we say that X is a scheme *finite over K* (cf. (**II**, 6.1.1)), or a *finite K-scheme*, of *rank* $[A : K]$, which we also denote by $\mathrm{rg}_K(X)$; if X and Y are finite K-schemes, we have

$$\mathrm{rg}_K(X \sqcup Y) = \mathrm{rg}_K(X) + \mathrm{rg}_K(Y), \tag{6.4.5.1}$$

$$\mathrm{rg}_K(X \times_K Y) = \mathrm{rg}_K(X)\,\mathrm{rg}_K(Y), \tag{6.4.5.2}$$

as a result of (3.2.2).

Corollary (6.4.6). — *Let X be a finite K-scheme. For every extension K' of K, $X \otimes_K K'$ is a finite K'-scheme, and its rank over K' is equal to the rank of X over K.*

Proof. If $A = A(X)$, then we have $[A \otimes_K K' : K'] = [A : K]$. ☐

Corollary (6.4.7). — *Let X be a scheme finite over a field K; we let $n = \sum_{x \in X} [k(x) : K]_s$* (we recall that if K' is an extension of K, then $[K' : K]_s$ is the *separable rank* of K' over K, the rank of the largest algebraic separable extension of K contained in K')*; then for every algebraically closed extension Ω of K, the underlying space of $X \otimes_K \Omega$ has exactly n points, which can be identified with the points of X with values in Ω.* I | 149

Proof. We can clearly restrict to the case where the ring $A = A(X)$ is *local* (6.2.2); let $\mathfrak{m}$ be its maximal ideal, and $L = A/\mathfrak{m}$ its residue field, an algebraic extension of K. The points of X with values in Ω then correspond, bijectively, to the Ω-sections of $X \otimes_K \Omega$ ((3.4.1) and (3.3.14)), and also to the K-homomorphisms from L to Ω ((1.7.3)), whence the proposition (Bourbaki, *Alg.*, chap. V, §7, nº 5, prop. 8), taking (6.4.3) into account. □

(6.4.8). The number n defined in (6.4.7) is called the *separable rank* of A (or of X) over K, or also the *geometric number of points* of X; it is equal to the number of elements of $X(\Omega)_K$. It follows immediately from this definition that, for every extension K' of K, $X \otimes_K K'$ has the same geometric number of points as X. If we denote this number by $n(X)$, it is clear that, if X and Y are two schemes, finite over K, then

(6.4.8.1) $$n(X \sqcup Y) = n(X) + n(Y).$$

Under the same hypotheses, we also have

(6.4.8.2) $$n(X \times_K Y) = n(X)n(Y)$$

because of the interpretation of $n(X)$ as the number of elements of $X(\Omega)_K$ and Equation (3.4.3.1).

Proposition (6.4.9). — *Let K be a field, X and Y algebraic K-preschemes, $f : X \to Y$ a K-morphism, and Ω an algebraically closed extension of K of infinite transcendence degree over K. For f to be surjective, it is necessary and sufficient that the map $X(\Omega)_K \to Y(\Omega)_K$ that corresponds to f (3.4.1) be surjective.*

Proof. The necessity follows from (6.3.10), noting that f is necessarily of finite type (6.3.9). To see that the condition is sufficient, we argue as in (6.3.10), noting that, for every $y \in Y$, $k(y)$ is an extension of K of finite type, and so is K-isomorphic to a subfield of Ω. □

Remark (6.4.10). — We will see in chapter IV that the conclusion of (6.4.9) still holds without the hypothesis on the transcendence degree of Ω over K.

Proposition (6.4.11). — *If $f : X \to Y$ is a morphism of finite type, then, for every $y \in Y$, the fibre $f^{-1}(y)$ is an algebraic prescheme over the residue field $k(y)$, and for every $x \in f^{-1}(y)$, $k(x)$ is an extension of $k(y)$ of finite type.*

Proof. Since $f^{-1}(y) = X \otimes_Y k(y)$ (3.6.3), the proposition follows from (6.3.4, iv) and (6.3.3). □

Proposition (6.4.12). — *Let $f : X \to Y$ and $g : Y' \to Y$ be morphisms; set $X' = X \times_Y Y'$, and let $f' = f_{(Y')} : X' \to Y'$. Let $y' \in Y'$ and set $y = g(y')$; if the fibre $f^{-1}(y)$ is a finite algebraic scheme over $k(y)$, then the fibre $f'^{-1}(y')$ is a finite algebraic scheme over $k(y')$, and has the same rank and geometric number of points as $f^{-1}(y)$ does.*

Proof. Taking into account the transitivity of fibres (3.6.5), this follows immediately from (6.4.6) and (6.4.8). □

(6.4.13). Proposition (6.4.11) shows that morphisms of finite type correspond, intuitively, to "algebraic families of algebraic varieties", with the points of Y playing the role of "parameters", which gives these morphisms a "geometric" meaning. Morphisms which are not of finite type will occur later mainly in questions of "changing the base prescheme", for example by localisation or completion. I | 150

6.5. Local determination of a morphism

Proposition (6.5.1). — *Let X and Y be S-preschemes, with Y of finite type over S; let $x \in X$ and $y \in Y$ lie over the same point $s \in S$.*

(i) *If two S-morphisms $f = (\psi, \theta)$ and $f' = (\psi', \theta')$ from X to Y satisfy $\psi(x) = \psi'(x) = y$, and the (local) $\mathscr{O}_s$-homomorphisms $\theta_x^\sharp$ and $\theta_x'^\sharp$ from $\mathscr{O}_y$ to $\mathscr{O}_x$ are identical, then f and f' agree on an open neighbourhood of x.*

(ii) *Suppose further that S is locally Noetherian. For every local $\mathscr{O}_s$-homomorphism $\phi : \mathscr{O}_y \to \mathscr{O}_x$, there exists an open neighbourhood U of x in X, and an S-morphism $f = (\psi, \theta)$ from U to Y such that $\psi(x) = y$ and $\theta_x^\sharp = \phi$.*

Proof.

(i) Since the question is local on S, X, and Y, we can assume that S, X, and Y are affine, given by rings A, B, and C (respectively), and with f and f' of the form $({}^a\phi, \widetilde{\phi})$ and $({}^a\phi', \widetilde{\phi}')$ (respectively), where ϕ and ϕ' are A-homomorphisms from C to B such that $\phi^{-1}(\mathfrak{j}_x) = \phi'^{-1}(\mathfrak{j}_x) = \mathfrak{j}_y$, and the homomorphisms ϕ_x and ϕ'_x from C_y to B_x, induced by ϕ and ϕ', are identical; we can further suppose that C is an A-algebra *of finite type*. Let c_i ($1 \leqslant i \leqslant n$) be the generators of the A-algebra C, and set $b_i = \phi(c_i)$ and $b'_i = \phi'(c_i)$; by hypothesis, we have $b_i/1 = b'_i/1$ in the ring of fractions B_x ($1 \leqslant i \leqslant n$). This implies that there exist elements $s_i \in B - \mathfrak{j}_x$ such that $s_i(b_i - b'_i) = 0$ for $1 \leqslant i \leqslant n$, and we can clearly assume that all the s_i are equal to a single element $g \in B - \mathfrak{j}_x$. From this, we conclude that we have $b_i/1 = b'_i/1$ for $1 \leqslant i \leqslant n$ in the ring of fractions B_g; if i_g is the canonical homomorphism $B \to B_g$, we then have $i_g \circ \phi = i_g \circ \phi'$; so the restrictions of f and f' to $D(g)$ are identical.

(ii) We can restrict to the situation as in (i), and further assume that the ring A is Noetherian. Let c_i ($1 \leqslant i \leqslant n$) be the generators of the A-algebra C, and let $\alpha : A[X_1, \ldots, X_n] \to C$ be the homomorphism from the polynomial algebra $A[X_1, \ldots, X_n]$ onto C that sends X_i to c_i for $1 \leqslant i \leqslant n$. Also let i_y be the canonical homomorphism $C \to C_y$, and consider the composite homomorphism
$$\beta : A[X_1, \ldots, X_n] \xrightarrow{\alpha} C \xrightarrow{i_y} C_y \xrightarrow{\phi} B_x.$$
We denote by $\mathfrak{a}$ the kernel of β; since A is Noetherian, so too is $A[X_1, \ldots, X_n]$, and so $\mathfrak{a}$ admits a finite system of generators $Q_j(X_1, \ldots, X_n)$ ($1 \leqslant j \leqslant m$). Furthermore, each of the elements $\phi(i_y(c_i))$ can be written in the form b_i/s_i, where $b_i \in B$ and $s_i \notin \mathfrak{j}_x$; we can further assume that all of the s_i are equal to a single element $g \in B - \mathfrak{j}_x$. With this, by hypothesis, we have $Q_j(b_1/g, \ldots, b_n/g) = 0$ in B_x; set
$$Q_j(X_1/T, \ldots, X_n/T) = P_j(X_1, \ldots, X_n, T)/T^{k_j}$$
where P_j is homogeneous of degree k_j. Then let $d_j = P_j(b_1, \ldots, b_n, g) \in B$. By hypothesis, we have $t_j d_j = 0$ for some $t_j \in B - \mathfrak{j}_x$ ($1 \leqslant j \leqslant m$), and we can clearly assume that all the t_j are equal to a single element $h \in B - \mathfrak{j}_x$; from this we conclude that $P_j(hb_1, \ldots, hb_n, hg) = 0$ **I** | 151
for $1 \leqslant j \leqslant m$. With this, consider the homomorphism ρ from $A[X_1, \ldots, X_n]$ to the ring of fractions B_{hg} which sends X_i to hb_i/hg ($1 \leqslant i \leqslant n$); the image of $\mathfrak{a}$ under this homomorphism is 0, and *a fortiori* so is the image of the kernel $\alpha^{-1}(0)$ under ρ. So ρ factors as $A[X_1, \ldots, X_n] \xrightarrow{\alpha} C \xrightarrow{\gamma} B_{hg}$, with $\gamma(c_i) = hb_i/hg$, and it is clear that, if i_x is the canonical homomorphism $B_{hg} \to B_x$, then the diagram

(6.5.1.1)
$$\begin{tikzcd} C \arrow[r, "\gamma"] \arrow[d, "i_y"'] & B_{hg} \arrow[d, "i_x"] \\ C_y \arrow[r, "\phi"] & B_x \end{tikzcd}$$

is commutative; we thus have $\phi = \gamma_x$, and since ϕ is a local homomorphism, ${}^a\gamma(x) = y$; $f = ({}^a\gamma, \widetilde{\gamma})$ is thus an S-morphism from the neighbourhood $D(hg)$ of x to Y as claimed in the proposition.

□

Corollary (6.5.2). — *Under the hypotheses of (6.5.1, ii), if, further, X is of finite type over S, then we can assume that the morphism f is of finite type.*

Proof. This follows from Corollary (6.3.6). □

Corollary (6.5.3). — *Suppose that the hypotheses of Proposition (6.5.1, ii) are satisfied, and suppose further that Y is integral, and that ϕ is an injective homomorphism. Then we can assume that $f = ({}^a\gamma, \widetilde{\gamma})$, where γ is injective.*

Proof. Indeed, we can assume C to be integral (5.1.4), hence i_y injective; it then follows from the diagram (6.5.1.1) that γ is injective. □

Proposition (6.5.4). — *Let $f = (\psi, \theta) : X \to Y$ be a morphism of finite type, x a point of X, and $y = \psi(x)$.*

(i) *For f to be a local immersion at the point x (4.5.1), it is necessary and sufficient that $\theta_x^\sharp : \mathscr{O}_y \to \mathscr{O}_x$ be surjective.*
(ii) *Assume further that Y is locally Noetherian. For f to be a local isomorphism at the point x (4.5.2), it is necessary and sufficient that $\theta_x^\sharp$ be an isomorphism.*

Proof.

(ii) By (6.5.1), there exists an open neighbourhood V of y and a morphism $g : V \to X$ such that $g \circ f$ (resp. $f \circ g$) is defined and agrees with the identity on a neighbourhood of x (resp. y), whence we can easily see that f is a local isomorphism.
(i) Since the question is local on X and Y, we can assume that X and Y are affine, given by rings A and B (respectively); we have $f = ({}^a\phi, \widetilde{\phi})$, where ϕ is a homomorphism of rings $B \to A$ that makes A a B-algebra of finite type; we have $\phi^{-1}(\mathfrak{j}_x) = \mathfrak{j}_y$, and the homomorphism $\phi_x : B_y \to A_x$ induced by ϕ is *surjective*. Let (t_i) $(1 \leqslant i \leqslant n)$ be a system of generators of the B-algebra A; the hypothesis on ϕ_x implies that there exist $b_i \in B$ and some $c \in B - \mathfrak{j}_y$ such that, in the ring of fractions A_x, we have $t_i/1 = \phi(b_i)/\phi(c)$ for $1 \leqslant i \leqslant n$. Consequently (1.3.3), there exists some $a \in A - \mathfrak{j}_x$ such that, if we let $g = a\phi(c)$, we also have $t_i/1 = a\phi(b_i)/g$ *in the ring of fractions* A_g. With this, there exists, by hypothesis, a polynomial $Q(X_1, \ldots, X_n)$, with coefficients in the ring $\phi(B)$, such that $a = Q(t_1, \ldots, t_n)$; let $Q(X_1/T, \ldots, X_n/T) = P(X_1, \ldots, X_n, T)/T^m$, where P is homogeneous of degree m. In the ring A_g, we have **I** | 152

$$a/1 = a^m P(\phi(b_1), \ldots, \phi(b_n), \phi(c))/g^m = a^m \phi(d)/g^m$$

where $d \in B$. Since, in A_g, $g/1 = (a/1)(\phi(c)/1)$ is invertible by definition, so too are $a/1$ and $\phi(c)/1$, and we can thus write $a/1 = (\phi(d)/1)(\phi(c)/1)^{-m}$. From this we conclude that $\phi(d)/1$ is also invertible in A_g. So let $h = cd$; since $\phi(h)/1$ is invertible in A_g, the composite homomorphism $B \xrightarrow{\phi} A \to A_g$ factors as $B \to B_h \xrightarrow{\gamma} A_g$ (**0**, 1.2.4). We will show that γ is *surjective*; it suffices to show that the image of B_h in A_g contains the $t_i/1$ and $(g/1)^{-1}$. But we have $(g/1)^{-1} = (\phi(c)/1)^{m-1}(\phi(d)/1)^{-1} = \gamma(c^m/h)$, and $a/1 = \gamma(d^{m+1}/h^m)$, so $(a\phi(b_i))/1 = \gamma(b_i d^{m+1}/h^m)$, and since $t_i/1 = (a\phi(b_i)/1)(g/1)^{-1}$, our claim is proved. The choice of h implies that $\psi(D(g)) \subset D(h)$, and we also know that the restriction of f to $D(g)$ is equal to $({}^a\gamma, \widetilde{\gamma})$; since γ is surjective, this restriction is a closed immersion of $D(g)$ into $D(h)$ (4.2.3).

□

Corollary (6.5.5). — *Let $f = (\psi, \theta) : X \to Y$ be a morphism of finite type. Assume that X is irreducible, and denote by x its generic point, and let $y = \psi(x)$.*

(i) *For f to be a local immersion at some point of X, it is necessary and sufficient that $\theta_x^\sharp : \mathscr{O}_y \to \mathscr{O}_x$ be surjective.*
(ii) *Assume further that Y is irreducible and locally Noetherian. For f to be a local isomorphism at some point of X, it is necessary and sufficient that y be the generic point of Y* (or, equivalently

(**0**, 2.1.4), that f be a *dominant* morphism) *and that* $\theta_x^\sharp$ *be an isomorphism* (in other words, that f be *birational* (2.2.9)).

Proof. It is clear that (i) follows from (6.5.4, i), taking into account the fact that every nonempty open subset of X contains x; similarly, (ii) follows from (6.5.4, ii). □

6.6. Quasi-compact morphisms and morphisms locally of finite type

Definition (6.6.1). — We say that a morphism $f : X \to Y$ is *quasi-compact* if the inverse image of any quasi-compact open subset of Y under f is quasi-compact.

Let $\mathfrak{B}$ be a base for the topology of Y consisting of quasi-compact open subsets (for example, affine open subsets); for f to be quasi-compact, it is necessary and sufficient that the inverse image of every set of $\mathfrak{B}$ under f be quasi-compact (or, equivalently, a *finite* union of affine open subsets), because every quasi-compact open subset of Y is a finite union of sets of $\mathfrak{B}$. For example, if X is *quasi-compact* and Y *affine*, then *every* morphism $f : X \to Y$ is quasi-compact: indeed, X is a finite union of affine open subsets U_i, and for every affine open subset V of Y, $U_i \cap f^{-1}(V)$ is affine (5.5.10), and so quasi-compact.

If $f : X \to Y$ is a quasi-compact morphism, it is clear that, for every open subset V of Y, the restriction of f to $f^{-1}(V)$ is a quasi-compact morphism $f^{-1}(V) \to V$. Conversely, if (U_α) is an open cover of Y, and $f : X \to Y$ a morphism such that the restrictions $f^{-1}(U_\alpha) \to U_\alpha$ are quasi-compact, then f is quasi-compact.

Definition (6.6.2). — We say that a morphism $f : X \to Y$ is *locally of finite type* if, for every $x \in X$, there exists an open neighbourhood U of x and an open neighbourhood $V \supset f(U)$ of $f(x)$ such that the restriction of f to U is a morphism of finite type from U to V. We then also say that X is a prescheme locally of finite type over Y, or a Y-prescheme locally of finite type. **I** | 153

It follows immediately from (6.3.2) that, if f is locally of finite type, then, for every open subset W of Y, the restriction of f to $f^{-1}(W)$ is a morphism $f^{-1}(W) \to W$ that is locally of finite type.

If Y is locally Noetherian and X locally of finite type over Y, then X is locally Noetherian by (6.3.7).

Proposition (6.6.3). — *For a morphism $f : X \to Y$ to be of finite type, it is necessary and sufficient that it be quasi-compact and locally of finite type.*

Proof. The necessity of the conditions is immediate, given (6.3.1) and the remark following (6.6.1). Conversely, suppose that the conditions are satisfied, and let U be an affine open subset of Y, given by some ring A; for all $x \in f^{-1}(U)$, there is, by hypothesis, a neighbourhood $V(x) \subset f^{-1}(U)$ of x, and a neighbourhood $W(x) \subset U$ of $y = f(x)$ containing $f(V(x))$, and such that the restriction of f to $V(x)$ is a morphism $V(x) \to W(x)$ of finite type. Replacing $W(x)$ with a neighbourhood $W_1(x) \subset W(x)$ of $y = f(x)$[26] of the form $D(g)$ (with $g \in A$), and $V(x)$ with $V(x) \cap f^{-1}(W_1(x))$, we can assume that $W(x)$ is of the form $D(g)$, and thus of finite type over U (because its ring can be written as $A[1/g]$); so $V(x)$ is of finite type over U. Further, $f^{-1}(U)$ is quasi-compact by hypothesis, and hence is a union of finitely many open subsets $V(x_i)$, which finishes the proof. □

Proposition (6.6.4). —

(i) *An immersion $X \to Y$ is quasi-compact if it is closed, or if the underlying space of Y is locally Noetherian, or if the underlying space of X is Noetherian.*
(ii) *The composition of any two quasi-compact morphisms is quasi-compact.*
(iii) *If $f : X \to Y$ is a quasi-compact S-morphism, then so too is $f_{(S')} : X_{(S')} \to Y_{(S')}$ for any extension $g : S' \to S$ of the base prescheme.*
(iv) *If $f : X \to X'$ and $g : Y \to Y'$ are two quasi-compact S-morphisms, then $f \times_S g$ is quasi-compact.*
(v) *If the composite $g \circ f$ of two morphisms $f : X \to Y$ and $g : Y \to Z$ is quasi-compact, and if either g is separated or the underlying space of X is locally Noetherian, then f is quasi-compact.*
(vi) *For a morphism f to be quasi-compact, it is necessary and sufficient that f_{red} be quasi-compact.*

[26] *[Trans.] The French text prints "of x" here. Since $W_1(x) \subset W(x) \subset U \subset Y$, it must be a neighbourhood of $y = f(x)$.*

Proof. We note that (vi) is evident because the property of being quasi-compact, for a morphism, depends only on the corresponding continuous map of underlying spaces. We will similarly prove the part of (v) corresponding to the case where the underlying space of X is locally Noetherian. Set $h = g \circ f$, and let U be a quasi-compact open subset of Y; $g(U)$ is quasi-compact (but not necessarily open) in Z, and so contained in a finite union of quasi-compact open subsets V_j (2.1.3), and $f^{-1}(U)$ is thus contained in the union of the $h^{-1}(V_j)$, which are quasi-compact subspaces of X, and thus Noetherian subspaces. We thus conclude (**0**, 2.2.3) that $f^{-1}(U)$ is a Noetherian space, and *a fortiori* quasi-compact.

To prove the other claims, it suffices to prove (i), (ii), and (iii) (5.5.12). But (ii) is evident, and (i) follows from (6.3.5) whenever the space Y is locally Noetherian or the space X is Noetherian, and is evident for a closed immersion. To show (iii), we can restrict to the case where $S = Y$ **I** | 154
(3.3.11); let $f' = f_{(S')}$, and let U' be a quasi-compact open subset of S'. For every $s' \in U'$, let T be an affine open neighbourhood of $g(s')$ in S, and let W be an affine open neighbourhood of s' contained in $U' \cap g^{-1}(T)$; it will suffice to show that $f'^{-1}(W)$ is quasi-compact; in other words, we can restrict to showing that, when S and S' are *affine*, the underlying space of $X \times_S S'$ is quasi-compact. But since X is then, by hypothesis, a finite union of affine open subsets V_j, $X \times_S S'$ is a finite union of the underlying spaces of the affine schemes $V_j \times_S S'$ ((3.2.2) and (3.2.7)), which proves the proposition. □

We note also that, if $X = X' \sqcup X''$ is the sum of two preschemes, a morphism $f : X \to Y$ is quasi-compact if and only if its restrictions to both X' and X'' are quasi-compact.

Proposition (6.6.5). — *Let $f : X \to Y$ be a quasi-compact morphism. For f to be dominant, it is necessary and sufficient that, for every generic point y of an irreducible component of Y, $f^{-1}(y)$ contain a generic point of an irreducible component of X.*

Proof. It is immediate that the condition is sufficient (even without assuming that f is quasi-compact). To see that it is necessary, consider an affine open neighbourhood U of y; $f^{-1}(U)$ is quasi-compact, and so a *finite* union of affine open subsets V_i, and the hypothesis that f be dominant implies that y belongs to the closure *in* U of one of the $f(V_i)$. We can clearly assume X and Y to be reduced; since the closure in X of an irreducible component of V_i is an irreducible component of X (**0**, 2.1.6), we can replace X by V_i, and Y by the closed reduced subprescheme of U that has $\overline{f(V_i)} \cap U$ as its underlying space (5.2.1), and we are thus led to proving the proposition when $X = \operatorname{Spec}(A)$ and $Y = \operatorname{Spec}(B)$ are affine and reduced. Since f is dominant, B is a subring of A (1.2.7), and the proposition then follows from the fact that every minimal prime ideal of B is the intersection of B with a minimal prime ideal of A (**0**, 1.5.8). □

Proposition (6.6.6). —

(i) *Every local immersion is locally of finite type.*
(ii) *If two morphisms $f : X \to Y$ and $g : Y \to Z$ are locally of finite type, then so too is $g \circ f$.*
(iii) *If $f : X \to Y$ is an S-morphism locally of finite type, then $f_{(S')} : X_{(S')} \to Y_{(S')}$ is locally of finite type for any extension $S' \to S$ of the base prescheme.*
(iv) *If $f : X \to X'$ and $g : Y \to Y'$ are S-morphisms locally of finite type, then $f \times_S g$ is locally of finite type.*
(v) *If the composition $g \circ f$ of two morphisms is locally of finite type, then f is locally of finite type.*
(vi) *If a morphism f is locally of finite type, then so too is f_{red}.*

Proof. By (5.5.12), it suffices to prove (i), (ii), and (iii). If $j : X \to Y$ is a local immersion then, for every $x \in X$, there is an open neighbourhood V of $j(x)$ in Y and an open neighbourhood U of x in X such that the restriction of j to U is a closed immersion $U \to V$ (4.5.1), and so this restriction is of finite type. To prove (ii), consider a point $x \in X$; by hypothesis, there is an open neighbourhood W of $g(f(x))$ and an open neighbourhood V of $f(x)$ such that $g(V) \subset W$ and such that V is of finite type over W; furthermore, $f^{-1}(V)$ is locally of finite type over V (6.6.2), so there is an open neighbourhood U of x that is contained in $f^{-1}(V)$ and is of finite type over V; thus we have **I** | 155
$g(f(U)) \subset W$, and U is of finite type over W (6.3.4, ii). Finally, to prove (iii), we can restrict to the case where $Y = S$ (3.3.11); for every $x' \in X' = X_{(S')}$, let x be the image of x' in X, s the image of x in

S, T an open neighbourhood of s, T' the inverse image of T in S', and U an open neighbourhood of x that is of finite type over T and whose image is contained in T; then $U \times_S T' = U \times_T T'$ is an open neighbourhood of x' (3.2.7) that is of finite type over T' (6.3.4, iv). □

Corollary (6.6.7). — *Let X and Y be S-preschemes that are locally of finite type over S. If S is locally Noetherian, then $X \times_S Y$ is locally Noetherian.*

Proof. Indeed, since S is locally Noetherian and X is locally of finite type over S, X is locally Noetherian; moreover, $X \times_S Y$ is locally of finite type over X, and so it too is locally Noetherian. □

Remark (6.6.8). — Proposition (6.3.10) and its proof extend immediately to the case where we suppose only that the morphism f is locally of finite type. Similarly, propositions (6.4.2) and (6.4.9) remain valid when we suppose only that the preschemes X and Y in their statements are locally of finite type over the field K.

§7. Rational maps

7.1. Rational maps and rational functions

(7.1.1). Let X and Y be preschemes, U and V dense open subsets of X, and f (resp. g) a morphism from U (resp. V) to Y; we say that f and g are *equivalent* if they agree on a dense open subset of $U \cap V$. Since a finite intersection of dense open subsets of X is a dense open subset of X, it is clear that this relation is an *equivalence relation*.

Definition (7.1.2). — Given preschemes X and Y, we define a rational map from X to Y to be an equivalence class of morphisms from dense open subsets of X to Y, under the equivalence relation defined in (7.1.1). If X and Y are S-preschemes, we say that such a class is a rational S-map if there exists a representative of the class that is also an S-morphism. We define a rational S-section of X to be any rational S-map from S to X. We define a rational function on a prescheme X to be any rational X-section on the X-prescheme $X \otimes_{\mathbf{Z}} \mathbf{Z}[T]$ (where T is an indeterminate).

By an abuse of language, whenever we are discussing only S-preschemes, we will say "rational map" instead of "rational S-map" if no confusion may arise.

Let f be a rational map from X to Y, and U an open subset of X; if f_1 and f_2 are two morphisms belonging to the class of f, defined (respectively) on dense open subsets V and W of X, then the restrictions $f_1|(U \cap V)$ and $f_2|(U \cap W)$ agree on $U \cap V \cap W$, which is dense in U; the class f of morphisms thus defines a rational map from U to Y, called the *restriction of f to U*, and denoted by $f|U$.

If, to every S-morphism $f : X \to Y$, we take the corresponding rational S-map to which f **I** | 156
belongs, we obtain a canonical map from $\operatorname{Hom}_S(X,Y)$ to the set of rational S-maps from X to Y. We denote by $\Gamma_{\mathrm{rat}}(X/Y)$ the set of rational Y-sections on X, and we thus have a canonical map $\Gamma(X/Y) \to \Gamma_{\mathrm{rat}}(X/Y)$. It is also clear that, if X and Y are S-preschemes, then the set of rational S-maps from X to Y is canonically identified with $\Gamma_{\mathrm{rat}}((X \times_S Y)/X)$ (3.3.14).

(7.1.3). It also follows from (7.1.2) and (3.3.14) that the rational functions on X are canonically identified with *equivalence classes of sections of the structure sheaf $\mathscr{O}_X$* over dense open subsets of X, where two such sections are equivalent if they agree on some dense open subset of X contained inside the intersection of the subsets on which they are defined. In particular, it follows that the rational functions on X form a *ring* $R(X)$.

(7.1.4). When X is an *irreducible* prescheme, every nonempty open subset of X is dense in X; so we can say that the nonempty open subsets of X are the *open neighbourhoods of the generic point x* of X. To say that two morphisms from nonempty open subsets of X to Y are equivalent thus means, in this case, that they have the *same germ* at the point x. In other words, the rational maps (resp. rational S-maps) $X \to Y$ are identified with the *germs of morphisms* (resp. *S-morphisms*) from nonempty open subsets of X to Y at the generic point x of X. In particular:

Proposition (7.1.5). — *If X is an irreducible prescheme, then the ring $R(X)$ of rational functions on X is canonically identified with the local ring $\mathscr{O}_x$ of the generic point x of X. It is a local ring of dimension 0, and thus a local Artinian ring when X is Noetherian; it is a field when X is integral, and, when X is further an affine scheme, it is identified with the field of fractions of $A(X)$.*

Proof. Given the above, and the identification of rational functions with sections of $\mathscr{O}_X$ over a dense open subset of X, the first claim is nothing but the definition of the stalk of a sheaf at a point. For the other claims, we can reduce to the case where X is affine, given by some ring A; then $\mathfrak{j}_x$ is the nilradical of A, and $\mathscr{O}_x$ is thus of dimension 0; if A is integral, then $\mathfrak{j}_x = (0)$, and $\mathscr{O}_x$ is thus the field of fractions of A. Finally, if A is Noetherian, we know ([Sam53b, p. 127, cor. 4]) that $\mathfrak{j}_x$ is nilpotent, and $\mathscr{O}_x = A_{\mathfrak{j}_x}$ is Artinian. □

If X is *integral*, then the ring $\mathscr{O}_z$ is integral for all $z \in X$; every affine open subset U containing z also contains x, and $R(U)$, being equal to the field of fractions of $A(U)$, is identified with $R(X)$; we thus conclude that $R(X)$ can also be identified with the *field of fractions of* $\mathscr{O}_z$: the canonical identification of $\mathscr{O}_z$ with a subring of $R(X)$ consists of associating, to every germ of a section $s \in \mathscr{O}_z$, the unique rational function on X, class of a section of $\mathscr{O}_X$, (necessarily defined on a dense open subset of X) having s as its germ at the point z.

(7.1.6). Now suppose that X has a *finite* number of irreducible components X_i ($1 \leqslant i \leqslant n$) (which will be the case whenever the underlying space of X is *Noetherian*); let X'_i be the open subset of X obtained by removing from X_i the union of the $X_j \cap X_i$ for $j \neq i$; X'_i is irreducible, its generic point x_i is the generic point of X_i, and the X'_i are pairwise disjoint, with their union being dense in X (**0**, 2.1.6). For every dense open subset U of X, $U_i = U \cap X'_i$ is a nonempty dense open subset of X'_i, **I** | 157
with the U_i being pairwise disjoint, and so $U' = \bigcup_i U_i$ is dense in X. Giving a morphism from U' to Y consists of giving (arbitrarily) a morphism from each of the U_i to Y.

Thus:

Proposition (7.1.7). — *Let X and Y be two preschemes (resp. S-preschemes) such that X has a finite number of irreducible components X_i, with generic points x_i ($1 \leqslant i \leqslant n$). If R_i is the set of germs of morphisms (resp. S-morphisms) from open subsets of X to Y at the point x_i, then the set of rational maps (resp. rational S-maps) from X to Y can be identified with the product of the R_i ($1 \leqslant i \leqslant n$).*

Corollary (7.1.8). — *Let X be a Noetherian prescheme. The ring of rational functions on X is an Artinian ring, whose local components are the rings $\mathscr{O}_{x_i}$ of the generic points x_i of the irreducible components of X.*

Corollary (7.1.9). — *Let A be a Noetherian ring, and $X = \operatorname{Spec}(A)$. If Q is the complement of the union of the minimal prime ideals of A, then the ring of rational functions on X can be canonically identified with the ring of fractions $Q^{-1}A$.*

This will follow from the following lemma:

Lemma (7.1.9.1). — *For an element $f \in A$ to be such that $D(f)$ is dense in X, it is necessary and sufficient that $f \in Q$; every dense open subset of X contains an open subset of the form $D(f)$, where $f \in Q$.*

Indeed, suppose the lemma proved. Since the ring of sections $\Gamma(D(f), \mathscr{O}_X)$ is identified with A_f (1.3.6) and (1.3.7), the facts that the $D(f)$ with $f \in Q$ form a cofinal family in the ordered set (under reverse inclusion) of dense open subsets of X, and that rational functions are defined by (7.1.1), show that the ring of rational functions on X is identified with the direct limit of the A_f for $f \in Q$ (for the preorder relation "g is a multiple of f"), that is, with $Q^{-1}A$ (**0**, 1.4.5).

Proof. To show (7.1.9.1), we again denote by X_i ($1 \leqslant i \leqslant n$) the irreducible components of X; if $D(f)$ is dense in X then $D(f) \cap X_i \neq \varnothing$ for $1 \leqslant i \leqslant n$, and vice-versa; but this means that $f \notin \mathfrak{p}_i$ for $1 \leqslant i \leqslant n$, where we set $\mathfrak{p}_i = \mathfrak{j}(X_i)$, and since the $\mathfrak{p}_i$ are the minimal prime ideals of A (1.1.14), the conditions $f \notin \mathfrak{p}_i$ ($1 \leqslant i \leqslant n$) are equivalent to $f \in Q$, whence the first claim of the lemma. For the other claim, if U is a dense open subset of X, the complement of U is a set of the form $V(\mathfrak{a})$, where $\mathfrak{a}$ is an ideal which is not contained in any of the $\mathfrak{p}_i$; it is thus not contained in their union ([Nor53, p. 13]), and there thus exists some $f \in \mathfrak{a}$ belonging to Q; whence $D(f) \subset U$, which finishes the proof. □

(7.1.10). Suppose again that X is irreducible, with generic point x. Since every nonempty open subset U of X contains x, and thus also contains every $z \in X$ such that $x \in \overline{\{z\}}$, every morphism $U \to Y$ can be composed with the canonical morphism $\operatorname{Spec}(\mathscr{O}_x) \to X$ (2.4.1); and any two morphisms into Y from two nonempty open subsets of X which agree on a nonempty open subset of X give, by composition, the same morphism $\mathrm{Spec}(\mathscr{O}_x) \to Y$. In other words, to every rational map from X to Y there is a corresponding well-defined morphism $\mathrm{Spec}(\mathscr{O}_x) \to Y$.

I | 158

Proposition (7.1.11). — *Let X and Y be two S-preschemes; suppose that X is irreducible with generic point x, and that Y is of finite type over S. Any two rational S-maps from X to Y that correspond to the same S-morphism $\mathrm{Spec}(\mathscr{O}_x) \to Y$ are then identical. If we further suppose S to be locally Noetherian, then every S-morphism from $\mathrm{Spec}(\mathscr{O}_x)$ to Y corresponds to exactly one rational S-map from X to Y.*

Proof. Taking into account that every nonempty open subset of X is dense in X, this follows from (6.5.1). □

Corollary (7.1.12). — *Suppose that S is locally Noetherian, and that the other hypotheses of (7.1.11) are satisfied. The rational S-maps from X to Y can then be identified with points of the S-prescheme Y, with values in the S-prescheme $\mathrm{Spec}(\mathscr{O}_x)$.*

Proof. This is nothing but (7.1.11), with the terminology introduced in (3.4.1). □

Corollary (7.1.13). — *Suppose that the conditions of (7.1.12) are satisfied. Let s be the image of x in S. The data of a rational S-map from X to Y is equivalent to the data of a point y of Y over s along with a local $\mathscr{O}_s$-homomorphism $\mathscr{O}_y \to \mathscr{O}_x = R(X)$.*

Proof. This follows from (7.1.11) and (2.4.4). □

In particular:

Corollary (7.1.14). — *Under the conditions of (7.1.12), rational S-maps from X to Y depend only (for any given Y) on the S-prescheme $\mathrm{Spec}(\mathscr{O}_x)$, and, in particular, remain the same whenever X is replaced by $\mathrm{Spec}(\mathscr{O}_z)$, for any $z \in X$.*

Proof. Since $z \in \overline{\{x\}}$, x is the generic point of $Z = \mathrm{Spec}(\mathscr{O}_z)$, and $\mathscr{O}_{X,x} = \mathscr{O}_{Z,x}$. □

When X is integral, $R(X) = \mathscr{O}_x = k(x)$ is a field (7.1.5); the preceding corollaries then specialize to the following:

Corollary (7.1.15). — *Suppose that the conditions of (7.1.12) are satisfied, and further that X is integral. Let s be the image of x in S. Then rational S-maps from X to Y can be identified with the geometric points of $Y \otimes_S k(s)$ with values in the extension $R(X)$ of $k(s)$, or, in other words, every such map is equivalent to the data of a point $y \in Y$ above s along with a $k(s)$-monomorphism from $k(y)$ to $k(x) = R(X)$.*

Proof. The points of Y above s are identified with the points of $Y \otimes_S k(s)$ (3.6.3), and the local $\mathscr{O}_s$-homomorphisms $\mathscr{O}_y \to R(X)$ with the $k(s)$-monomorphisms $k(y) \to R(X)$. □

More precisely:

Corollary (7.1.16). — *Let k be a field, and X and Y two algebraic preschemes over k (6.4.1); suppose further that X is integral. Then the rational k-maps from X to Y can be identified with the geometric points of Y with values in the extension $R(X)$ of k (3.4.4).*

7.2. Domain of definition of a rational map

(7.2.1). Let X and Y be preschemes, and f a rational map from X to Y. We say that f is *defined at a point* $x \in X$ if there exists a dense open subset U of X that contains x, and a morphism $U \to Y$ belonging to the equivalence class of f. The set of points $x \in X$ where f is defined is called the *domain of definition* of f; it is clear that it is an open dense subset of X.

I | 159

Proposition (7.2.2). — *Let X and Y be S-preschemes such that X is reduced and Y is separated over S. Let f be a rational S-map from X to Y, with domain of definition U_0. Then there exists exactly one S-morphism $U_0 \to Y$ belonging to the class of f.*

Since, for every morphism $U \to Y$ belonging to the class of f, we necessarily have $U \subset U_0$, it is clear that the proposition will be a consequence of the following:

Lemma (7.2.2.1). — *Under the hypotheses of (7.2.2), let U_1 and U_2 be two dense open subsets of X, and $f_i : U_i \to Y$ $(i = 1, 2)$ two S-morphisms such that there exists an open subset $V \subset U_1 \cap U_2$, dense in X, and on which f_1 and f_2 agree. Then f_1 and f_2 agree on $U_1 \cap U_2$.*

Proof. We can clearly restrict to the case where $X = U_1 = U_2$. Since X (and thus V) is reduced, X is the smallest closed subprescheme of X containing V (5.2.2). Let $g = (f_1, f_2)_S : X \to Y \times_S Y$; since, by hypothesis, the diagonal $T = \Delta_Y(Y)$ is a closed subprescheme of $Y \times_S Y$, $Z = g^{-1}(T)$ is a closed subprescheme of X (4.4.1). If $h : V \to Y$ is the common restriction of f_1 and f_2 to V, then the restriction of g to V is $g' = (h, h)_S$, which factors as $g' = \Delta_Y \circ h$; since $\Delta_Y^{-1}(T) = Y$, we have that $g'^{-1}(T) = V$, and so Z is a closed subprescheme of X inducing V, thus containing V, which implies that $Z = X$. From the equation $g^{-1}(T) = X$, we deduce (4.4.1) that g factors as $\Delta_Y \circ f$, where f is a morphism $X \to Y$, which implies, by the definition of the diagonal morphism, that $f_1 = f_2 = f$. □

It is clear that the morphism $U_0 \to Y$ defined in (7.2.2) is the unique morphism of the class f that *cannot be extended* to a morphism from an open subset of X that strictly contains U_0. *Under the hypotheses of* (7.2.2), we can thus *identify* the rational maps from X to Y with the *non-extendible* (to strictly larger open subsets) morphisms from dense open subsets of X to Y. With this identification, Proposition (7.2.2) implies:

Corollary (7.2.3). — *With the hypotheses from (7.2.2) on X and Y, let U be a dense open subset of X. Then there exists a canonical bijective correspondence between S-morphisms from U to Y and rational S-maps from X to Y that are defined at all points of U.*

Proof. By (7.2.2), for every S-morphism f from U to Y, there exists exactly one rational S-map $\overline{f}$ from X to Y which extends f. □

Corollary (7.2.4). — *Let S be a scheme, X a reduced S-prescheme, Y an S-scheme, and $f : U \to Y$ an S-morphism from a dense open subset U of X to Y. If $\overline{f}$ is the rational $\mathbf{Z}$-map from X to Y that extends f, then $\overline{f}$ is an S-morphism (and thus the rational S-map from X to Y that extends f).*

Proof. Indeed, if $\phi : X \to S$ and $\psi : Y \to S$ are the structure morphisms, U_0 the domain of definition of $\overline{f}$, and j the injection $U_0 \to X$, then it suffices to show that $\psi \circ \overline{f} = \phi \circ j$, but this follows from (7.2.2.1), since f is an S-morphism. □

Corollary (7.2.5). — *Let X and Y be two S-preschemes; suppose that X is reduced, and that X and Y are separated over S. Let $p : Y \to X$ be an S-morphism (making Y an X-prescheme), U a dense open subset of X, and f a U-section of Y; then the rational map $\overline{f}$ from X to Y extending f is a rational X-section of Y.*

I | 160

Proof. We have to show that $p \circ \overline{f}$ is the identity on the domain of definition of $\overline{f}$; since X is separated over S, this again follows from (7.2.2.1). □

Corollary (7.2.6). — *Let X be a reduced prescheme, and U a dense open subset of X. Then there is a canonical bijective correspondence between sections of $\mathscr{O}_X$ over U and rational functions on X defined at every point of U.*

Proof. Taking (7.2.3), (7.1.2), and (7.1.3) into account, it suffices to note that the X-prescheme $X \otimes_{\mathbf{Z}} \mathbf{Z}[T]$ is separated over X (5.5.1, iv). ☐

Corollary (7.2.7). — *Let Y be a reduced prescheme, $f : X \to Y$ a separated morphism, U a dense open subset of Y, $g : U \to f^{-1}(U)$ a U-section of $f^{-1}(U)$, and Z the reduced subprescheme of X that has $\overline{g(U)}$ as its underlying space (5.2.1). For g to be the restriction of a Y-section of X* (in other words (7.2.5), for the rational map from Y to X extending g to be defined everywhere), *it is necessary and sufficient for the restriction of f to Z to be an isomorphism from Z to Y.*

Proof. The restriction of f to $f^{-1}(U)$ is a separated morphism (5.5.1, i), so g is a closed immersion (5.4.6), and so $g(U) = Z \cap f^{-1}(U)$, and the subprescheme induced by Z on the open subset $g(U)$ of Z is identical to the closed subprescheme of $f^{-1}(U)$ associated to g (5.2.1). It is then clear that the stated condition is sufficient, because, if satisfied, and if $f_Z : Z \to Y$ is the restriction of f to Z, and $\overline{g} : Y \to Z$ is the inverse isomorphism, then $\overline{g}$ extends g. Conversely, if g is the restriction to U of a Y-section h of X, then h is a closed immersion (5.4.6), and so $h(Y)$ is closed, and, since it is contained in Z, is equal to Z, and it follows from (5.2.1) that h is necessarily an isomorphism from Y to the closed subprescheme Z of X. ☐

(7.2.8). Let X and Y be two S-preschemes, with X reduced, and Y separated over S. Let f be a rational S-map from X to Y, and let x be a point of X; we can compose f with the canonical S-morphism $\operatorname{Spec}(\mathcal{O}_x) \to X$ (2.4.1) provided that the intersection of $\operatorname{Spec}(\mathcal{O}_x)$ with the domain of definition of f is dense in $\operatorname{Spec}(\mathcal{O}_x)$ (identified with the set of $z \in X$ such that $x \in \overline{\{z\}}$ (2.4.2)). This will happen in the following cases:

1st. X is *irreducible* (and thus *integral*), because then the generic point ξ of X is the generic point of $\operatorname{Spec}(\mathcal{O}_x)$; since the domain of definition U of f contains ξ, $U \cap \operatorname{Spec}(\mathcal{O}_x)$ contains ξ, and so is dense in $\operatorname{Spec}(\mathcal{O}_x)$.

2nd. X is *locally Noetherian*; our claim then follows from:

Lemma (7.2.8.1). — *Let X be a prescheme whose underlying space is locally Noetherian, and x a point of X. The irreducible components of* $\operatorname{Spec}(\mathcal{O}_x)$ *are the intersections of* $\operatorname{Spec}(\mathcal{O}_x)$ *with the irreducible components of X containing x. For an open subset $U \subset X$ to be such that $U \cap \operatorname{Spec}(\mathcal{O}_x)$ is dense in* $\operatorname{Spec}(\mathcal{O}_x)$, *it is necessary and sufficient for it to have a nonempty intersection with the irreducible components of X that contain x* (which will be the case whenever U is *dense* in X).

Proof. It suffices to show just the first claim, since the second then follows. Since $\operatorname{Spec}(\mathcal{O}_x)$ is contained in every affine open subset U that contains x, and since the irreducible components of U that contain x are the intersections of U with the irreducible components of X containing x (**0**, 2.1.6), we can suppose that X is affine, given by some ring A. Since the prime ideals of A_x correspond bijectively to the prime ideals of A that are contained in $\mathfrak{j}_x$ (2.1.6), the minimal prime ideals of A_x correspond to the minimal prime ideals of A that are contained in $\mathfrak{j}_x$, hence the lemma (1.1.14). ☐ **I** | 161

With this in mind, suppose that we are in one of the two cases mentioned in (7.2.8). If U is the domain of definition of the rational S-map f, then we denote by f' the rational map from $\operatorname{Spec}(\mathcal{O}_x)$ to Y which agrees (taking (2.4.2) into account) with f on $U \cap \operatorname{Spec}(\mathcal{O}_x)$; we say that this rational map is *induced by f*.

Proposition (7.2.9). — *Let S be a locally Noetherian prescheme, X a reduced S-prescheme, and Y an S-scheme of finite type. Suppose further that X is either irreducible or locally Noetherian. Then let f be a rational S-map from X to Y, and x a point of X. For f to be defined at the point x, it is necessary and sufficient for the rational map f' from* $\operatorname{Spec}(\mathcal{O}_x)$ *to Y, induced by f (7.2.8), to be a morphism.*

Proof. The condition clearly being necessary (since $\operatorname{Spec}(\mathcal{O}_x)$ is contained in every open subset containing x), we show that it is sufficient. By (6.5.1), there exists an open neighbourhood U of x in X, and an S-morphism g from U to Y that induces f' on $\operatorname{Spec}(\mathcal{O}_x)$. If X is irreducible, then U is dense in X, and, by (7.2.3), we can suppose that g is a rational S-map. Further, the generic point of X belongs to both $\operatorname{Spec}(\mathcal{O}_x)$ and the domain of definition of f, and so f and g agree at this point, and thus on a nonempty open subset of X (6.5.1). But since f and g are rational S-maps, they are identical (7.2.3), and so f is defined at x.

If we now suppose that X is locally Noetherian, then we can suppose that U is Noetherian; then there are only a finite number of irreducible components X_i of X that contain x (7.2.8.1), and we can suppose that they are the only ones that have a nonempty intersection with U, by replacing, if needed, U with a smaller open subset (since there are only a finite number of irreducible components of X that have a nonempty intersection with U, because U is Noetherian). We then have, as above, that f and g agree on a nonempty open subset of each of the X_i. Taking into account the fact that each of the X_i is contained in $\overline{U}$, we consider the morphism f_1, defined on a dense open subset of $U \cup (X - \overline{U})$, equal to g on U, and to f on the intersection of $X - \overline{U}$ with the domain of definition of f. Since $U \cup (X - \overline{U})$ is dense in X, f_1 and f agree on a dense open subset of X, and since f is a rational map, f is an extension of f_1 (7.2.3), and is thus defined at the point x. □

7.3. Sheaf of rational functions

(7.3.1). Let X be a prescheme. For every open subset $U \subset X$, we denote by $R(U)$ the ring of rational functions on U (7.1.3); this is a $\Gamma(U, \mathscr{O}_X)$-algebra. Further, if $V \subset U$ is a second open subset of X, then every section of $\mathscr{O}_X$ over a dense open subset of U gives, by restriction to V, a section over a dense open subset of V, and if two sections agree on a dense open subset of U, then their restrictions to V agree on a dense open subset of V. We can thus define a di-homomorphism of algebras $\rho_{V,U} : R(U) \to R(V)$, and it is clear that, if $U \supset V \supset W$ are open subsets of X, then we have $\rho_{W,U} = \rho_{W,V} \circ \rho_{V,U}$; the $R(U)$ thus define a *presheaf* of algebras on X.

I | 162

Definition (7.3.2). — We define the sheaf of rational functions on a prescheme X, denoted by $\mathscr{R}(X)$, to be the $\mathscr{O}_X$-algebra associated to the presheaf defined by the $R(U)$.

For every prescheme X and open subset $U \subset X$, it is clear that the induced sheaf $\mathscr{R}(X)|U$ is exactly $\mathscr{R}(U)$.

Proposition (7.3.3). — *Let X be a prescheme such that the family (X_λ) of its irreducible components is locally finite (which is the case whenever the underlying space of X is locally Noetherian). Then the $\mathscr{O}_X$-module $\mathscr{R}(X)$ is quasi-coherent, and for every open subset U of X that has a nonempty intersection with only finitely many of the components X_λ, $R(U)$ is equal to $\Gamma(U, \mathscr{R}(X))$, and can be canonically identified with the direct product of the local rings of the generic points of the X_λ such that $U \cap X_\lambda \neq \varnothing$.*

Proof. We can evidently restrict to the case where X has only a finite number of irreducible components X_i, with generic points x_i ($1 \leqslant i \leqslant n$). The fact that $R(U)$ can be canonically identified with the direct product of the $\mathscr{O}_{x_i} = R(X_i)$ such that $U \cap X_i \neq \varnothing$ then follows from (7.1.7). We will show that the presheaf $U \to R(U)$ satisfies the sheaf axioms, which will prove that $R(U) = \Gamma(U, \mathscr{R}(X))$. Indeed, it satisfies (F1) by what has already been discussed. To see that it satisfies (F2), consider a cover of an open subset U of X by open subsets $V_\alpha \subset U$; if the $s_\alpha \in R(V_\alpha)$ are such that the restrictions of s_α and s_β to $V_\alpha \cap V_\beta$ agree for every pair of indices, then we can conclude that, for every index i such that $U \cap X_i \neq \varnothing$, the components in $R(X_i)$ of all the s_α such that $V_\alpha \cap X_i \neq \varnothing$ are all the same; denoting this component by t_i, it is clear that the element of $R(U)$ that has the t_i as its components has s_α as its restriction to each V_α. Finally, to see that $\mathscr{R}(X)$ is quasi-coherent, we can restrict to the case where $X = \operatorname{Spec}(A)$ is affine; by taking U to be an affine open subset of the form $D(f)$, where $f \in A$, it follows from the above and from Definition (1.3.4) that we have $\mathscr{R}(X) = \widetilde{M}$, where M is the direct sum of the A-modules A_{x_i}. □

Corollary (7.3.4). — *Let X be a reduced prescheme that has only a finite number of irreducible components, and let X_i ($1 \leqslant i \leqslant n$) be the closed reduced preschemes of X that have the irreducible components of X as their underlying spaces (5.2.1). If h_i is the canonical injection $X_i \to X$, then $\mathscr{R}(X)$ is the direct product of the $\mathscr{O}_X$-algebras $(h_i)_*(\mathscr{R}(X_i))$.*

Corollary (7.3.5). — *If X is irreducible, then every quasi-coherent $\mathscr{R}(X)$-module $\mathscr{F}$ is a simple sheaf.*

Proof. It suffices to show that every $x \in X$ admits a neighbourhood U such that $\mathscr{F}|U$ is a simple sheaf (**0**, 3.6.2); in other words, we are led to considering the case where X is affine; we can further suppose that $\mathscr{F}$ is the cokernel of a homomorphism $(\mathscr{R}(X))^I \to (\mathscr{R}(X))^J$ (**0**, 5.1.3), and everything then follows from showing that $\mathscr{R}(X)$ is a simple sheaf; but this is evident, because $\Gamma(U, \mathscr{R}(X)) = R(X)$ for every nonempty open subset U, where U contains the generic point of X. □

Corollary (7.3.6). — *If X is irreducible, then, for every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$, $\mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{R}(X)$ is a simple sheaf; if, further, X is reduced (and thus integral), then $\mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{R}(X)$ is isomorphic to a sheaf of the form $(\mathscr{R}(X))^{(I)}$.*

Proof. The second claim follows from the fact that $R(X)$ is a field. □

Proposition (7.3.7). — *Suppose that the prescheme X is locally integral or locally Noetherian. Then $\mathscr{R}(X)$ is a quasi-coherent $\mathscr{O}_X$-algebra; if, further, X is reduced (which will be the case whenever X is locally integral), then the canonical homomorphism $\mathscr{O}_X \to \mathscr{R}(X)$ is injective.* I | 163

Proof. Since the question is local, the first claim follows from (7.3.3); the second follows from (7.2.3). □

(7.3.8). [27] Let X and Y be two *integral* preschemes, which implies that $\mathscr{R}(X)$ (resp. $\mathscr{R}(Y)$) is a quasi-coherent $\mathscr{O}_X$-module (resp. $\mathscr{O}_Y$-module) (7.3.3). Let $f : X \to Y$ be a *dominant* morphism; then there exists a canonical homomorphism of $\mathscr{O}_X$-modules

$$\tau : f^*(\mathscr{R}(Y)) \longrightarrow \mathscr{R}(X). \tag{7.3.8.1}$$

Proof. Suppose first that $X = \operatorname{Spec}(A)$ and $Y = \operatorname{Spec}(B)$ are affine, given by integral rings A and B, with f thus corresponding to an injective homomorphism $B \to A$ which extends to a monomorphism $L \to K$ from the field of fractions L of B to the field of fractions K of A. The homomorphism (7.3.8.1) then corresponds to the canonical homomorphism $L \otimes_B A \to K$ (1.6.5). In the general case, for each pair of nonempty affine open sets $U \subset X$ and $V \subset Y$ such that $f(U) \subset V$, we define, as above, a homomorphism $\tau_{U,V}$ and we immediately have that, if $U' \subset U$, $V' \subset V$, $f(U') \subset V'$, then $\tau_{U,V}$ extends $\tau_{U',V'}$, and hence our assertion. If x and y are the generic points of X and Y respectively, then we have $f(x) = y$,

$$(f^*(\mathscr{R}(Y)))_x = \mathscr{O}_y \otimes_{\mathscr{O}_y} \mathscr{O}_x = \mathscr{O}_x$$

(**0**, 4.3.1) and τ_x is thus an *isomorphism*. □

7.4. Torsion sheaves and torsion-free sheaves

(7.4.1). Let X be an *integral* prescheme. For every $\mathscr{O}_X$-module $\mathscr{F}$, the canonical homomorphism $\mathscr{O}_X \to \mathscr{R}(X)$ defines, by tensoring, a homomorphism (again said to be *canonical*) $\mathscr{F} \to \mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{R}(X)$, which, on each fibre, is exactly the homomorphism $z \to z \otimes 1$ from $\mathscr{F}_x$ to $\mathscr{F}_x \otimes_{\mathscr{O}_x} R(X)$. The *kernel* $\mathscr{T}$ of this homomorphism is an $\mathscr{O}_X$-submodule of $\mathscr{F}$, called the *torsion sheaf* of $\mathscr{F}$; it is quasi-coherent if $\mathscr{F}$ is quasi-coherent ((4.1.1) and (7.3.6)). We say that $\mathscr{F}$ is *torsion free* if $\mathscr{T} = 0$, and that $\mathscr{F}$ is a *torsion sheaf* if $\mathscr{T} = \mathscr{F}$. For every $\mathscr{O}_X$-module $\mathscr{F}$, $\mathscr{F}/\mathscr{T}$ is torsion free. We deduce from (7.3.5) that:

Proposition (7.4.2). — *If X is an integral prescheme, then every torsion-free quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$ is isomorphic to a subsheaf $\mathscr{G}$ of a simple sheaf of the form $(\mathscr{R}(X))^{(I)}$, generated (as a $\mathscr{R}(X)$-module) by $\mathscr{G}$.*

The cardinality of I is called the *rank* of $\mathscr{F}$; for every nonempty affine open subset U of X, the rank of $\mathscr{F}$ is equal to the rank of $\Gamma(U, \mathscr{F})$ as a $\Gamma(U, \mathscr{O}_X)$-module, as we see by considering the generic point of X, contained in U. In particular:

Corollary (7.4.3). — *On an integral prescheme X, every torsion-free quasi-coherent $\mathscr{O}_X$-module of rank* 1 *(in particular, every invertible $\mathscr{O}_X$-module) is isomorphic to an $\mathscr{O}_X$-submodule of $\mathscr{R}(X)$, and vice versa.*

Corollary (7.4.4). — *Let X be an integral prescheme, $\mathscr{L}$ and $\mathscr{L}'$ torsion-free $\mathscr{O}_X$-modules, and f (resp. f') a section of $\mathscr{L}$ (resp. $\mathscr{L}'$) over X. In order to have $f \otimes f' = 0$, it is necessary and sufficient for one of the sections f and f' to be zero.*

Proof. Let x be the generic point of X; we have, by hypothesis, that $(f \otimes f')_x = f_x \otimes f'_x = 0$. Since $\mathscr{L}_x$ and $\mathscr{L}'_x$ can be identified with $\mathscr{O}_x$-submodules of the field $\mathscr{O}_x$, the above equation leads to $f_x = 0$ or $f'_x = 0$, and thus $f = 0$ or $f' = 0$, since $\mathscr{L}$ and $\mathscr{L}'$ are torsion free (7.3.5). □

Proposition (7.4.5). — *Let X and Y be integral preschemes, and $f : X \to Y$ a dominant morphism. For every torsion-free quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$, $f_*(\mathscr{F})$ is a torsion-free $\mathscr{O}_Y$-module.*

I | 164

[27] *[Trans.] This paragraph was changed entirely in the Errata of EGA II.*

Proof. Since f_* is left exact (**0**, 4.2.1), it suffices, by (7.4.2), to prove the proposition in the case where $\mathscr{F} = (\mathscr{R}(X))^{(I)}$. But every nonempty open subset U of Y contains the generic point of Y, so $f^{-1}(U)$ contains the generic point of X (**0**, 2.1.5), so we have that $\Gamma(U, f_*(\mathscr{F})) = \Gamma(f^{-1}(U), \mathscr{F}) = (R(X))^{(I)}$; in other words, $f_*(\mathscr{F})$ is the simple sheaf with fibre $(R(X))^{(I)}$, considered as a $\mathscr{R}(Y)$-module, and it is clearly torsion free. □

Proposition (7.4.6). — *Let X be an integral prescheme, and x its generic point. For every quasi-coherent $\mathcal{O}_X$-module $\mathscr{F}$ of finite type, the following conditions are equivalent:* (a) *$\mathscr{F}$ is a torsion sheaf;* (b) *$\mathscr{F}_x = 0$;* (c) $\operatorname{Supp}(\mathscr{F}) \neq X$.

Proof. By (7.3.5) and (7.4.1), the equations $\mathscr{F}_x = 0$ and $\mathscr{F} \otimes_{\mathcal{O}_X} \mathscr{R}(X) = 0$ are equivalent, so (a) and (b) are equivalent; then $\operatorname{Supp}(\mathscr{F})$ is closed in X (**0**, 5.2.2), and since every nonempty open subset of X contains x, (b) and (c) are equivalent. □

(7.4.7). We generalise (by an abuse of language) the definitions of (7.4.1) to the case where X is a *reduced* prescheme having only a *finite* number of irreducible components; it then follows from (7.3.4) that the equivalence between *a)* and *c)* in (7.4.6) still holds true for such a prescheme.

§8. CHEVALLEY SCHEMES

8.1. Allied local rings For each local ring A, we denote by $\mathfrak{m}(A)$ the maximal ideal of A.

Lemma (8.1.1). — *Let A and B be two local rings such that $A \subset B$. Then the following conditions are equivalent.*

(i) $\mathfrak{m}(B) \cap A = \mathfrak{m}(A)$.
(ii) $\mathfrak{m}(A) \subset \mathfrak{m}(B)$.
(iii) 1 *is not an element of the ideal of B generated by $\mathfrak{m}(A)$.*

Proof. It is evident that (i) implies (ii), and (ii) implies (iii); lastly, if (iii) is true, then $\mathfrak{m}(B) \cap A$ contains $\mathfrak{m}(A)$, and does not contain 1, and is thus equal to $\mathfrak{m}(A)$.

When the equivalent conditions of (8.1.1) are satisfied, we say that B *dominates* A; this is equivalent to saying that the injection $A \to B$ is a *local* homomorphism. It is clear that, in the set of local subrings of a ring R, the relation given by domination is an order. □

(8.1.2). Now consider a *field* R. For all subrings A of R, we denote by $L(A)$ the set of local rings $A_\mathfrak{p}$, where $\mathfrak{p}$ ranges over the prime spectrum of A; such local rings are identified with the subrings of R containing A. Since $\mathfrak{p} = (\mathfrak{p}A_\mathfrak{p}) \cap A$, the map $\mathfrak{p} \mapsto A_\mathfrak{p}$ from $\operatorname{Spec}(A)$ to $L(A)$ is bijective.

Lemma (8.1.3). — *Let R be a field, and A a subring of R. For a local subring M of R to dominate a ring $A_\mathfrak{p} \in L(A)$, it is necessary and sufficient that $A \subset M$; the local ring $A_\mathfrak{p}$ dominated by M is then unique, and corresponds to $\mathfrak{p} = \mathfrak{m}(M) \cap A$.*

Proof. If M dominates $A_\mathfrak{p}$, then $\mathfrak{m}(M) \cap A_\mathfrak{p} = \mathfrak{p}A_\mathfrak{p}$, by (8.1.1), whence the uniqueness of $\mathfrak{p}$; on the other hand, if $A \subset M$, then $\mathfrak{m}(M) \cap A = \mathfrak{p}$ is prime in A, and since $A - \mathfrak{p} \subset M$, we have that $A_\mathfrak{p} \subset M$ and $\mathfrak{p}A_\mathfrak{p} \subset \mathfrak{m}(M)$, so M dominates $A_\mathfrak{p}$. □

I | 165

Lemma (8.1.4). — *Let R be a field, M and N local subrings of R, and P the subring of R generated by $M \cup N$. Then the following conditions are equivalent.*

(i) *There exists a prime ideal $\mathfrak{p}$ of P such that $\mathfrak{m}(M) = \mathfrak{p} \cap M$ and $\mathfrak{m}(N) = \mathfrak{p} \cap N$.*
(ii) *The ideal $\mathfrak{a}$ generated in P by $\mathfrak{m}(M) \cup \mathfrak{m}(N)$ is distinct from P.*
(iii) *There exists a local subring Q of R simultaneously dominating both M and N.*

Proof. It is clear that (i) implies (ii); conversely, if $\mathfrak{a} \neq P$, then $\mathfrak{a}$ is contained in a maximal ideal $\mathfrak{n}$ of P, and since $1 \notin \mathfrak{n}$, $\mathfrak{n} \cap M$ contains $\mathfrak{m}(M)$ and is distinct from M, so $\mathfrak{n} \cap M = \mathfrak{m}(M)$, and similarly $\mathfrak{n} \cap N = \mathfrak{m}(N)$. It is clear that, if Q dominates both M and N, then $P \subset Q$ and $\mathfrak{m}(M) = \mathfrak{m}(Q) \cap M = (\mathfrak{m}(Q) \cap P) \cap M$, and $\mathfrak{m}(N) = (\mathfrak{m}(Q) \cap P) \cap N$, so (iii) implies (i); the converse is evident when we take $Q = P_\mathfrak{p}$. □

When the conditions of (8.1.4) are satisfied, we say, with C. Chevalley, that the local rings M and N are *allied*.

Proposition (8.1.5). — *Let A and B be subrings of a field R, and C the subring of R generated by $A \cup B$. Then the following conditions are equivalent.*

(i) *For every local ring Q containing A and B, we have that $A_{\mathfrak{p}} = B_{\mathfrak{q}}$, where $\mathfrak{p} = \mathfrak{m}(Q) \cap A$ and $\mathfrak{q} = \mathfrak{m}(Q) \cap B$.*
(ii) *For all prime ideals $\mathfrak{r}$ of C, we have that $A_{\mathfrak{p}} = B_{\mathfrak{q}}$, where $\mathfrak{p} = \mathfrak{r} \cap A$ and $\mathfrak{q} = \mathfrak{r} \cap B$.*
(iii) *If $M \in L(A)$ and $N \in L(B)$ are allied, then they are identical.*
(iv) *$L(A) \cap L(B) = L(C)$.*

Proof. Lemmas (8.1.3) and (8.1.4) prove that (i) and (iii) are equivalent; it is clear that (i) implies (ii) by taking $Q = C_{\mathfrak{r}}$; conversely, (ii) implies (i), because if Q contains $A \cup B$ then it contains C, and if $\mathfrak{r} = \mathfrak{m}(Q) \cap C$, then $\mathfrak{p} = \mathfrak{r} \cap A$ and $\mathfrak{q} = \mathfrak{r} \cap B$, by (8.1.3). It is immediate that (iv) implies (i), because if Q contains $A \cup B$ then it dominates a local ring $C_{\mathfrak{r}} \in L(C)$ by (8.1.3); by hypothesis we have that $C_{\mathfrak{r}} \in L(A) \cap L(B)$, and (8.1.1) and (8.1.3) prove that $C_{\mathfrak{r}} = A_{\mathfrak{p}} = B_{\mathfrak{q}}$. We prove finally that (iii) implies (iv). Let $Q \in L(C)$; Q dominates some $M \in L(A)$ and some $N \in L(B)$ (8.1.3), so M and N, being allied, are identical by hypothesis. As we then have that $C \subset M$, we know that M dominates some $Q' \in L(C)$ (8.1.3), so Q dominates Q', whence necessarily (8.1.3) $Q = Q' = M$, so $Q \in L(A) \cap L(B)$. Conversely, if $Q \in L(A) \cap L(B)$, then $C \subset Q$, so (8.1.3) Q dominates some $Q'' \in L(C) \subset L(A) \cap L(B)$; Q and Q'', being allied, are identical, so $Q'' = Q \in L(C)$, which completes the proof. □

8.2. Local rings of an integral scheme

(8.2.1). Let X be an *integral* prescheme, and R its field of rational functions, identical to the local ring of the generic point a of X; for all $x \in X$, we know that $\mathscr{O}_x$ can be canonically identified with a subring of R (7.1.5), and for every rational function $f \in R$, the domain of definition $\delta(f)$ of f is the open set of $x \in X$ such that $f \in \mathscr{O}_x$. It thus follows, from (7.2.6), that, for every open $U \subset X$, we have

(8.2.1.1) $$\Gamma(U, \mathscr{O}_X) = \bigcap_{x \in U} \mathscr{O}_x.$$

I | 166

Proposition (8.2.2). — *Let X be an integral prescheme, and R its field of rational functions. For X to be a scheme, it is necessary and sufficient for the relation "$\mathscr{O}_x$ and $\mathscr{O}_y$ are allied" (8.1.4), for points x and y of X, to imply that $x = y$.*

Proof. We suppose that this condition is satisfied, and aim to show that X is separated. Let U and V be two distinct affine open subsets of X, given by rings A and B (respectively), identified with subrings of R; U (resp. V) is thus identified (8.1.2) with $L(A)$ (resp. $L(B)$), and the hypotheses tell us (8.1.5) that C is the subring of R generated by $A \cup B$, and $W = U \cap V$ is identified with $L(A) \cap L(B) = L(C)$. Furthermore, we know ([CC], p. 5-03, 4 *bis*) that every subring E of R is equal to the intersection of the local rings belonging to $L(E)$; C is thus identified with the intersection of the rings $\mathscr{O}_z$ for $z \in W$, or, equivalently (8.2.1.1), with $\Gamma(W, \mathscr{O}_X)$. So consider the subprescheme induced by X on W; to the identity morphism $\phi : C \to \Gamma(W, \mathscr{O}_X)$ there corresponds (2.2.4) a morphism $\Phi = (\psi, \theta) : W \to \operatorname{Spec}(C)$; we will see that Φ is an *isomorphism* of preschemes, whence W is an *affine* open subset. The identification of W with $L(C) = \operatorname{Spec}(C)$ shows that ψ is *bijective*. On the other hand, for all $x \in W$, $\theta_x^\sharp$ is the injection $C_{\mathfrak{r}} \to \mathscr{O}_x$, where $\mathfrak{r} = \mathfrak{m}_x \cap C$, and, by definition, $C_{\mathfrak{r}}$ is identified with $\mathscr{O}_x$, so $\theta_x^\sharp$ is bijective. It thus remains to show that ψ is a *homeomorphism*, or, in other words, that for every closed subset $F \subset W$, $\psi(F)$ is closed in $\operatorname{Spec}(C)$. But F is the intersection of W with a closed subset of U of the form $V(\mathfrak{a})$, where $\mathfrak{a}$ is an ideal of A; we will show that $\psi(F) = V(\mathfrak{a}C)$, which proves our claim. In fact, the prime ideals of C containing $\mathfrak{a}C$ are the prime ideals of C containing $\mathfrak{a}$, and so are the ideals of the form $\psi(x) = \mathfrak{m}_x \cap C$, where $\mathfrak{a} \subset \mathfrak{m}_x$ and $x \in W$; since, for $x \in W$, $\mathfrak{a} \subset \mathfrak{m}_x$ is equivalent to $x \in V(\mathfrak{a})$, and hence to $x \in F = W \cap V(\mathfrak{a})$, we do indeed have that $\psi(F) = V(\mathfrak{a}C)$[28].

[28] *[Trans.] The French text prints $x \in V(\mathfrak{a}) = W \cap F$. Since F was defined immediately above as the trace of $V(\mathfrak{a})$ on W, the required equality is $F = W \cap V(\mathfrak{a})$.*

It follows that X is separated, because $U \cap V$ is affine and its ring C is generated by the union $A \cup B$ of the rings of U and V (5.5.6).

Conversely, suppose that X is separated, and let x and y be points of X such that $\mathscr{O}_x$ and $\mathscr{O}_y$ are allied. Let U (resp. V) be an affine open subset containing x (resp. y), of ring A (resp. B); we then know that $U \cap V$ is affine and that its ring C is generated by $A \cup B$ (5.5.6). If $\mathfrak{p} = \mathfrak{m}_x \cap A$ and $\mathfrak{q} = \mathfrak{m}_y \cap B$, then $A_\mathfrak{p} = \mathscr{O}_x$ and $B_\mathfrak{q} = \mathscr{O}_y$, and since $A_\mathfrak{p}$ and $B_\mathfrak{q}$ are allied, there exists a prime ideal $\mathfrak{r}$ of C such that $\mathfrak{p} = \mathfrak{r} \cap A$ and $\mathfrak{q} = \mathfrak{r} \cap B$ (8.1.4). But then there exists a point $z \in U \cap V$ such that $\mathfrak{r} = \mathfrak{m}_z \cap C$, since $U \cap V$ is affine, and so evidently $x = z$ and $y = z$, whence $x = y$. □

Corollary (8.2.3). — *Let X be an integral scheme, and x and y points of X. In order for $x \in \overline{\{y\}}$, it is necessary and sufficient for $\mathscr{O}_x \subset \mathscr{O}_y$, or, equivalently, for every rational function defined at x to also be defined at y.*

Proof. The condition is evidently necessary because the domain of definition $\delta(f)$ of a rational function $f \in R$ is open; we now show that it is sufficient. If $\mathscr{O}_x \subset \mathscr{O}_y$, then there exists a prime ideal $\mathfrak{p}$ of $\mathscr{O}_x$ such that $\mathscr{O}_y$ dominates $(\mathscr{O}_x)_\mathfrak{p}$ (8.1.3); but by (2.4.2) there exists some $z \in X$ such that $x \in \overline{\{z\}}$ and $\mathscr{O}_z = (\mathscr{O}_x)_\mathfrak{p}$; since $\mathscr{O}_z$ and $\mathscr{O}_y$ are allied, we have that $z = y$ by (8.2.2), whence the corollary. □

Corollary (8.2.4). — *If X is an integral scheme then the map $x \to \mathscr{O}_x$ is injective; equivalently, if x and y are two distinct points of X, then there exists a rational function defined at one of these points but not the other.*

I | 167

Proof. This follows from (8.2.3) and the axiom (T_0) (2.1.4). □

Corollary (8.2.5). — *Let X be an integral scheme whose underlying space is Noetherian; letting f range over the field R of rational functions on X, the sets $\delta(f)$ generate the topology of X.*

In fact, every closed subset of X is thus a finite union of irreducible closed subsets, that is, of subsets of the form $\overline{\{y\}}$ (2.1.5). But, if $x \notin \overline{\{y\}}$, then there exists a rational function f defined at x but not at y (8.2.3), or, equivalently, we have that $x \in \delta(f)$ and that $\delta(f)$ is disjoint from $\overline{\{y\}}$. The complement of $\overline{\{y\}}$ is thus a union of sets of the form $\delta(f)$, and, by virtue of the first remark, every open subset of X is the union of finite intersections of open sets of the form $\delta(f)$.

(8.2.6). Corollary (8.2.5) shows that the topology of X is entirely characterised by the data of the local rings $(\mathscr{O}_x)_{x \in X}$ that have R as their field of fractions. It is equivalent to say that the closed subsets of X are defined in the following manner: given a finite subset $\{x_1, \ldots, x_n\}$ of X, consider the set of $y \in X$ such that $\mathscr{O}_y \subset \mathscr{O}_{x_i}$ for at least one index i, and these sets (over all choices of $\{x_1, \ldots, x_n\}$) are the closed subsets of X. Further, once the topology on X is known, the structure sheaf $\mathscr{O}_X$ is also determined by the family of the $\mathscr{O}_x$, since $\Gamma(U, \mathscr{O}_X) = \bigcap_{x \in U} \mathscr{O}_x$, by (8.2.1.1). The family $(\mathscr{O}_x)_{x \in X}$ thus completely determines the prescheme X when X is an integral scheme whose underlying space is Noetherian.

Proposition (8.2.7). — *Let X and Y be integral schemes, $f : X \to Y$ a dominant morphism (2.2.6), and K (resp. L) the field of rational functions on X (resp. Y). Then L can be identified with a subfield of K, and, for all $x \in X$, $\mathscr{O}_{f(x)}$ is the unique local ring of Y dominated by $\mathscr{O}_x$.*

Proof. If $f = (\psi, \theta)$ and a is the generic point of X, then $\psi(a)$ is the generic point of Y (**0**, 2.1.5); $\theta_a^\sharp$ is then a monomorphism of fields, from $L = \mathscr{O}_{\psi(a)}$ to $K = \mathscr{O}_a$. Since every nonempty affine open subset U of Y contains $\psi(a)$, it follows from (2.2.4) that the homomorphism $\Gamma(U, \mathscr{O}_Y) \to \Gamma(\psi^{-1}(U), \mathscr{O}_X)$ corresponding to f is the restriction of $\theta_a^\sharp$ to $\Gamma(U, \mathscr{O}_Y)$. So, for every $x \in X$, $\theta_x^\sharp$ is the restriction to $\mathscr{O}_{\psi(x)}$ of $\theta_a^\sharp$, and is thus a monomorphism. We also know that $\theta_x^\sharp$ is a local homomorphism, so, if we identify L with a subfield of K by $\theta_a^\sharp$, $\mathscr{O}_{\psi(x)}$ is dominated by $\mathscr{O}_x$ (8.1.1); it is also the only local ring of Y dominated by $\mathscr{O}_x$, since two local rings of Y that are allied are identical (8.2.2). □

Proposition (8.2.8). — *Let X be an* irreducible *prescheme, $f : X \to Y$ a local immersion (resp. local isomorphism), and suppose further that f is separated. Then f is an immersion (resp. an open immersion).*

Proof. Let $f = (\psi, \theta)$; it suffices, in both cases, to prove that ψ is a *homeomorphism* from X to $\psi(X)$ (4.5.3). Replacing f by f_{red} ((5.1.6) and (5.5.1, vi)), we can assume that X and Y are *reduced*. If Y' is the closed reduced subprescheme of Y that has $\overline{\psi(X)}$ as its underlying space, then f factors as $X \xrightarrow{f'} Y' \xrightarrow{j} Y$, where j is the canonical injection (5.2.2). It follows from (5.5.1, v) that f' is again a separated morphism; further, f' is again a local immersion (resp. a local isomorphism), because, **I** | 168
since the condition is local on X and Y, we can restrict to the case where f is a closed immersion (resp. open immersion), and our claim then follows immediately from (4.2.2).

We can thus suppose that f is a *dominant* morphism, which leads to the fact that Y is, itself, irreducible (**0**, 2.1.5), and so X and Y are both *integral*. Further, since the condition is local on Y, we can suppose that Y is an affine scheme; since f is separated, X is a scheme (5.5.1, ii), and we are finally at the hypotheses of Proposition (8.2.7). Then, for all $x \in X$, $\theta_x^\sharp$ is injective; but the hypothesis that f is a local immersion implies that $\theta_x^\sharp$ is surjective (4.2.2), so $\theta_x^\sharp$ is bijective, or, equivalently (with the identification of Proposition (8.2.7)) we have that $\mathscr{O}_{\psi(x)} = \mathscr{O}_x$. This implies, by Corollary (8.2.4), that ψ is an *injective* map, which already proves the proposition when f is a local isomorphism (4.5.3). When we suppose that f is only a local immersion, for all $x \in X$ there exists an open neighbourhood U of x in X and an open neighbourhood V of $\psi(x)$ in Y such that the restriction of ψ to U is a homeomorphism from U to a *closed* subset of V. But U is dense in X, so $\psi(U)$ is dense in Y and *a fortiori* in V, which proves that $\psi(U) = V$; since ψ is injective, $\psi^{-1}(V) = U$ and this proves that ψ is a homeomorphism from X to $\psi(X)$. □

8.3. Chevalley schemes

(8.3.1). Let X be a *Noetherian* integral scheme, and R its field of rational functions; we denote by X' the set of local subrings $\mathscr{O}_x \subset R$, where x ranges over all points of X. The set X' satisfies the following three conditions.

(Sch. 1) For all $M \in X'$, R is the field of fractions of M.

(Sch. 2) There exists a finite set of Noetherian subrings A_i of R such that $X' = \bigcup_i L(A_i)$, and, for all pairs of indices i, j, the subring A_{ij} of R generated by $A_i \cup A_j$ is an algebra of finite type over A_i.

(Sch. 3) Any two elements M and N of X' that are allied are identical.

We have seen in (8.2.1) that (Sch. 1) is satisfied, and (Sch. 3) follows from (8.2.2). To show (Sch. 2), it suffices to cover X by a finite number of affine open subsets U_i whose rings are Noetherian, and to take $A_i = \Gamma(U_i, \mathscr{O}_X)$; the hypothesis that X is a scheme implies that $U_i \cap U_j$ is affine, and also that $\Gamma(U_i \cap U_j, \mathscr{O}_X) = A_{ij}$ (5.5.6); further, since the space U_i is Noetherian, the immersion $U_i \cap U_j \to U_i$ is of finite type (6.3.5), so A_{ij} is an A_i-algebra of finite type (6.3.3).

(8.3.2). The structures whose axioms are (Sch. 1), (Sch. 2), and (Sch. 3) generalise "schemes", in the sense of C. Chevalley, who additionally supposes that R is an extension of finite type of a field K, and that the A_i are K-algebras of finite type (which renders a part of (Sch. 2) useless) [CC]. Conversely, if we have such a structure on a set X', then we can associate to it an integral scheme X by using the remarks from (8.2.6): the underlying space of X is equal to X' endowed with the topology defined in (8.2.6), and with the sheaf $\mathscr{O}_X$ such that $\Gamma(U, \mathscr{O}_X) = \bigcap_{x \in U} \mathscr{O}_x$ for all open $U \subset X$, with the evident **I** | 169
definition of restriction homomorphisms. We leave to the reader the task of verifying that we thus obtain an integral scheme, whose local rings are the elements of X'; we will not use this result in what follows.

§9. Supplement on quasi-coherent sheaves

9.1. Tensor product of quasi-coherent sheaves

Proposition (9.1.1). — *Let X be a prescheme (resp. a locally Noetherian prescheme). Let $\mathscr{F}$ and $\mathscr{G}$ be quasi-coherent (resp. coherent) $\mathscr{O}_X$-modules; then $\mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{G}$ is quasi-coherent (resp. coherent); it is further of finite type if both $\mathscr{F}$ and $\mathscr{G}$ are of finite type. If $\mathscr{F}$ admits a finite presentation and if $\mathscr{G}$ is quasi-coherent (resp. coherent), then $\mathscr{H}om_{\mathscr{O}_X}(\mathscr{F}, \mathscr{G})$ is quasi-coherent (resp. coherent).*

Proof. Being a local proposition, we can suppose that X is affine (resp. Noetherian affine); further, if $\mathscr{F}$ is coherent, then we can assume that it is the cokernel of a homomorphism $\mathscr{O}_X^m \to \mathscr{O}_X^n$. The claims pertaining to quasi-coherent sheaves then follow from Corollaries (1.3.12) and (1.3.9); the claims pertaining to coherent sheaves follow from Theorem (1.5.1) and from the fact that if M and N are modules of finite type over a Noetherian ring A then $M \otimes_A N$ and $\mathrm{Hom}_A(M, N)$ are both A-modules of finite type. □

Definition (9.1.2). — Let X and Y be S-preschemes, p and q the projections of $X \times_S Y$, and $\mathscr{F}$ (resp. $\mathscr{G}$) a quasi-coherent $\mathscr{O}_X$-module (resp. quasi-coherent $\mathscr{O}_Y$-module). We define the tensor product of $\mathscr{F}$ and $\mathscr{G}$ over $\mathscr{O}_S$ (*or* over S), denoted by $\mathscr{F} \otimes_{\mathscr{O}_S} \mathscr{G}$ (*or* $\mathscr{F} \otimes_S \mathscr{G}$) to be the tensor product $p^*(\mathscr{F}) \otimes_{\mathscr{O}_{X\times_S Y}} q^*(\mathscr{G})$ over the prescheme $X \times_S Y$.

If X_i $(1 \leqslant i \leqslant n)$ are S-preschemes, and $\mathscr{F}_i$ $(1 \leqslant i \leqslant n)$ are quasi-coherent $\mathscr{O}_{X_i}$-modules, then we similarly define the tensor product $\mathscr{F}_1 \otimes_S \mathscr{F}_2 \otimes_S \cdots \otimes_S \mathscr{F}_n$ over the prescheme $Z = X_1 \times_S X_2 \times_S \cdots \times_S X_n$; it is a *quasi-coherent* $\mathscr{O}_Z$-module by virtue of (9.1.1) and (**0**, 5.1.4); it is further *coherent* if all the $\mathscr{F}_i$ are coherent *and* Z is *locally Noetherian*, by virtue of (9.1.1), (**0**, 5.3.11), and (6.1.1).

Note that, if we take $X = Y = S$, then Definition (9.1.2) gives us back the tensor product of $\mathscr{O}_S$-modules. Furthermore, since $q^*(\mathscr{O}_Y) = \mathscr{O}_{X\times_S Y}$ (**0**, 4.3.4), the product $\mathscr{F} \otimes_S \mathscr{O}_Y$ is canonically identified with $p^*(\mathscr{F})$, and, in the same way, $\mathscr{O}_X \otimes_S \mathscr{G}$ is canonically identified with $q^*(\mathscr{G})$. In particular, if we take $Y = S$ and denote by f the structure morphism $X \to Y$, then we have that $\mathscr{O}_X \otimes_Y \mathscr{G} = f^*(\mathscr{G})$: the ordinary tensor product and the inverse image thus appear as particular cases of the general tensor product.

Definition (9.1.2) leads immediately to the fact that, for fixed X and Y, $\mathscr{F} \otimes_S \mathscr{G}$ is a *right-exact additive covariant bifunctor* in $\mathscr{F}$ and $\mathscr{G}$.

Proposition (9.1.3). — *Let S, X, and Y be affine schemes of rings A, B, and C (respectively), with B and C being A-algebras. Let M (resp. N) be a B-module (resp. C-module), and $\mathscr{F} = \widetilde{M}$ (resp. $\mathscr{G} = \widetilde{N}$) the associated quasi-coherent sheaf; then $\mathscr{F} \otimes_S \mathscr{G}$ is canonically isomorphic to the sheaf associated to the $(B \otimes_A C)$-module $M \otimes_A N$.*

Proof. According to Proposition (1.6.5), $\mathscr{F} \otimes_S \mathscr{G}$ is canonically isomorphic to the sheaf associated to the $(B \otimes_A C)$-module **I** | 170

$$\big(M \otimes_B (B \otimes_A C)\big) \otimes_{B\otimes_A C} \big((B \otimes_A C) \otimes_C N\big)$$

and, by the canonical isomorphisms between tensor products, this latter module is isomorphic to

$$M \otimes_B (B \otimes_A C) \otimes_C N = (M \otimes_B B) \otimes_A (C \otimes_C N) = M \otimes_A N.$$

□

Proposition (9.1.4). — *Let $f : T \to X$ and $g : T \to Y$ be S-morphisms, and $\mathscr{F}$ (resp. $\mathscr{G}$) a quasi-coherent $\mathscr{O}_X$-module (resp. quasi-coherent $\mathscr{O}_Y$-module). Then*

$$(f, g)_S^*(\mathscr{F} \otimes_S \mathscr{G}) = f^*(\mathscr{F}) \otimes_{\mathscr{O}_T} g^*(\mathscr{G}).$$

Proof. If p, q are the projections of $X \times_S Y$, then the formula follows from the equalities $(f, g)_S^* \circ p^* = f^*$ and $(f, g)_S^* \circ q^* = g^*$ (**0**, 3.5.5), and the fact that the inverse image of a tensor product of algebraic sheaves is the tensor product of their inverse images (**0**, 4.3.3). □

Corollary (9.1.5). — *Let $f : X \to X'$ and $g : Y \to Y'$ be S-morphisms, and $\mathscr{F}'$ (resp. $\mathscr{G}'$) a quasi-coherent $\mathscr{O}_{X'}$-module (resp. quasi-coherent $\mathscr{O}_{Y'}$-module). Then*

$$(f \times_S g)^*(\mathscr{F}' \otimes_S \mathscr{G}') = f^*(\mathscr{F}') \otimes_S g^*(\mathscr{G}').$$

Proof. This follows from (9.1.4) and the fact that $f \times_S g = (f \circ p, g \circ q)_S$, where p and q are the projections of $X \times_S Y$. □

Corollary (9.1.6). — *Let X, Y, and Z be S-preschemes, and $\mathscr{F}$ (resp. $\mathscr{G}$, $\mathscr{H}$) a quasi-coherent $\mathscr{O}_X$-module (resp. quasi-coherent $\mathscr{O}_Y$-module, quasi-coherent $\mathscr{O}_Z$-module); then the sheaf $\mathscr{F} \otimes_S \mathscr{G} \otimes_S \mathscr{H}$ is the inverse image of $(\mathscr{F} \otimes_S \mathscr{G}) \otimes_S \mathscr{H}$ by the canonical isomorphism from $X \times_S Y \times_S Z$ to $(X \times_S Y) \times_S Z$.*

Proof. This isomorphism is given by $(p_1, p_2)_S \times_S p_3$, where p_1, p_2, and p_3 are the projections of $X \times_S Y \times_S Z$.

Similarly, the inverse image of $\mathscr{G} \otimes_S \mathscr{F}$ under the canonical isomorphism from $X \times_S Y$ to $Y \times_S X$ is $\mathscr{F} \otimes_S \mathscr{G}$. □

Corollary (9.1.7). — *If X is an S-prescheme, then every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$ is the inverse image of $\mathscr{F} \otimes_S \mathscr{O}_S$ by the canonical isomorphism from X to $X \times_S S$ (3.3.3).*

Proof. This isomorphism is $(1_X, \phi)_S$, where ϕ is the structure morphism $X \to S$, and the corollary follows from (9.1.4) and the fact that $\phi^*(\mathscr{O}_S) = \mathscr{O}_X$. □

(9.1.8). Let X be an S-prescheme, $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-module, and $\phi : S' \to S$ a morphism; we denote by $\mathscr{F}_{(\phi)}$ or $\mathscr{F}_{(S')}$ the quasi-coherent sheaf $\mathscr{F} \otimes_S \mathscr{O}_{S'}$ over $X \times_S S' = X_{(\phi)} = X_{(S')}$; so $\mathscr{F}_{(S')} = p^*(\mathscr{F})$, where p is the projection $X_{(S')} \to X$.

Proposition (9.1.9). — *Let $\phi' : S'' \to S'$ be a morphism. For every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$ on the S-prescheme X, $(\mathscr{F}_{(\phi)})_{(\phi')}$ is the inverse image of $\mathscr{F}_{(\phi\circ\phi')}$ by the canonical isomorphism $(X_{(\phi)})_{(\phi')} \simeq X_{(\phi\circ\phi')}$ (3.3.9).*

Proof. This follows immediately from the definitions and from (3.3.9), and is written

(9.1.9.1) $$(\mathscr{F} \otimes_S \mathscr{O}_{S'}) \otimes_{S'} \mathscr{O}_{S''} = \mathscr{F} \otimes_S \mathscr{O}_{S''}.$$

□

Proposition (9.1.10). — *Let Y be an S-prescheme, and $f : X \to Y$ an S-morphism. For every quasi-coherent $\mathscr{O}_Y$-module $\mathscr{G}$ and every morphism $S' \to S$, we have that $(f_{(S')})^*(\mathscr{G}_{(S')}) = (f^*(\mathscr{G}))_{(S')}$.*

Proof. This follows immediately from the commutativity of the diagram I | 171

$$\begin{tikzcd} X_{(S')} \arrow[r, "f_{(S')}"] \arrow[d] & Y_{(S')} \arrow[d] \\ X \arrow[r, "f"'] & Y. \end{tikzcd}$$

□

Corollary (9.1.11). — *Let X and Y be S-preschemes, and $\mathscr{F}$ (resp. $\mathscr{G}$) a quasi-coherent $\mathscr{O}_X$-module (resp. quasi-coherent $\mathscr{O}_Y$-module). Then the inverse image of the sheaf $(\mathscr{F}_{(S')}) \otimes_{S'} (\mathscr{G}_{(S')})$ by the canonical isomorphism $(X \times_S Y)_{(S')} \simeq (X_{(S')}) \times_{S'} (Y_{(S')})$ (3.3.10) is equal to $(\mathscr{F} \otimes_S \mathscr{G})_{(S')}$.*

Proof. If p and q are the projections of $X \times_S Y$, then the isomorphism in question is nothing but $(p_{(S')}, q_{(S')})_{S'}$; the corollary then follows from Propositions (9.1.4) and (9.1.10). □

Proposition (9.1.12). — *With the notation from Definition (9.1.2), let z be a point of $X \times_S Y$, and let $x = p(z)$, and $y = q(z)$; the stalk $(\mathscr{F} \otimes_S \mathscr{G})_z$ is isomorphic to $(\mathscr{F}_x \otimes_{\mathscr{O}_x} \mathscr{O}_z) \otimes_{\mathscr{O}_z} (\mathscr{G}_y \otimes_{\mathscr{O}_y} \mathscr{O}_z) = \mathscr{F}_x \otimes_{\mathscr{O}_x} \mathscr{O}_z \otimes_{\mathscr{O}_y} \mathscr{G}_y$.*

Proof. Since we can reduce to the affine case, the proposition follows from Equation (1.6.5.1). □

Corollary (9.1.13). — *If $\mathscr{F}$ and $\mathscr{G}$ are of finite type, then*

$$\operatorname{Supp}(\mathscr{F} \otimes_S \mathscr{G}) = p^{-1}(\operatorname{Supp}(\mathscr{F})) \cap q^{-1}(\operatorname{Supp}(\mathscr{G})).$$

Proof. Since $p^*(\mathscr{F})$ and $q^*(\mathscr{G})$ are both of finite type over $\mathscr{O}_{X\times_S Y}$, we reduce, by Proposition (9.1.12) and by (**0**, 1.7.5), to the case where $\mathscr{G} = \mathscr{O}_Y$, that is, it remains to prove the following equation:[29]

(9.1.13.1) $$\operatorname{Supp}(p^*(\mathscr{F})) = p^{-1}(\operatorname{Supp}(\mathscr{F})).$$

The same reasoning as in (**0**, 1.7.5) leads us to prove that, for all $z \in X \times_S Y$, we have $\mathscr{O}_z/\mathfrak{m}_x\mathscr{O}_z \neq 0$ (with $x = p(z)$), which follows from the fact that the homomorphism $\mathscr{O}_x \to \mathscr{O}_z$ is *local*, by hypothesis. □

[29] *[Trans.] The French source prints* $\operatorname{Supp}(p^{-1}(\mathscr{F}))$ *in (9.1.13.1). The reduction just made identifies* $\mathscr{F} \otimes_S \mathscr{O}_Y$ *with* $p^*(\mathscr{F})$*, and the following test* $\mathscr{O}_z/\mathfrak{m}_x\mathscr{O}_z \neq 0$ *is the stalk calculation for that pullback; we therefore use* $p^*(\mathscr{F})$*.*

We leave it to the reader to extend the results in this section to the more general case of an arbitrary (but finite) number of factors, instead of just two.

9.2. Direct image of a quasi-coherent sheaf

Proposition (9.2.1). — *Let $f : X \to Y$ be a morphism of preschemes. We suppose that there exists a cover (Y_α) of Y by affine opens having the following property: every $f^{-1}(Y_\alpha)$ admits a* finite *cover $(X_{\alpha i})$ by affine opens that are contained in $f^{-1}(Y_\alpha)$ and that are such that every intersection $X_{\alpha i} \cap X_{\alpha j}$ is itself a* finite *union of affine opens. With these hypotheses, for every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$, $f_*(\mathscr{F})$ is a quasi-coherent $\mathscr{O}_Y$-module.*

Proof. Since this is a local condition on Y, we can assume that Y is equal to one of the Y_α, and thus omit the indices α.

(a) First, suppose that the $X_i \cap X_j$ are themselves *affine* opens. We set $\mathscr{F}_i = \mathscr{F}|X_i$ and $\mathscr{F}_{ij} = \mathscr{F}|(X_i \cap X_j)$, and let $\mathscr{F}'_i$ and $\mathscr{F}'_{ij}$ be the images of $\mathscr{F}_i$ and $\mathscr{F}_{ij}$ (respectively) by the restriction of f to X_i and to $X_i \cap X_j$ (respectively); we know that the $\mathscr{F}'_i$ and $\mathscr{F}'_{ij}$ are quasi-coherent (1.6.3). Set $\mathscr{G} = \bigoplus_i \mathscr{F}'_i$ and $\mathscr{H} = \bigoplus_{i,j} \mathscr{F}'_{ij}$; $\mathscr{G}$ and $\mathscr{H}$ are quasi-coherent $\mathscr{O}_Y$-modules; we will define a homomorphism $u : \mathscr{G} \to \mathscr{H}$ such that $f_*(\mathscr{F})$ is the *kernel* of u; it will follow from this that $f_*(\mathscr{F})$ is quasi-coherent (1.3.9). It suffices to define u as a homomorphism of presheaves; taking into account the definitions of $\mathscr{G}$ and $\mathscr{H}$, it thus suffices, for every open subset $W \subset Y$, to define a homomorphism **I | 172**

$$u_W : \bigoplus_i \Gamma(f^{-1}(W) \cap X_i, \mathscr{F}) \longrightarrow \bigoplus_{i,j} \Gamma(f^{-1}(W) \cap X_i \cap X_j, \mathscr{F})$$

that satisfies the usual compatibility conditions when we let W vary. If, for every section $s_i \in \Gamma(f^{-1}(W) \cap X_i, \mathscr{F})$, we denote by $s_{i|j}$ its restriction to $f^{-1}(W) \cap X_i \cap X_j$, then we set

$$u_W\big((s_i)\big) = (s_{i|j} - s_{j|i})$$

and the compatibility conditions are clearly satisfied. To prove that the kernel $\mathscr{R}$ of u is $f_*(\mathscr{F})$, we define a homomorphism from $f_*(\mathscr{F})$ to $\mathscr{R}$ by sending each section $s \in \Gamma(f^{-1}(W), \mathscr{F})$ to the family (s_i), where s_i is the restriction of s to $f^{-1}(W) \cap X_i$; axioms (F1) and (F2) of sheaves (G, II, 1.1) tell us that this homomorphism is *bijective*, which finishes the proof in this case.

(b) In the general case, the same reasoning applies once we have established that the $\mathscr{F}'_{ij}$ are quasi-coherent. But, by hypothesis, $X_i \cap X_j$ is a finite union of affine opens X_{ijk}; and since the X_{ijk} are affine opens *in a scheme*, the intersection of any two of them is again an affine open (5.5.6). We are thus led to the first case, and so we have proved Proposition (9.2.1).

□

Corollary (9.2.2). — *The conclusion of Proposition (9.2.1) holds true in each of the following cases:*

(a) *f is separated and quasi-compact;*
(b) *f is separated and of finite type;*
(c) *f is quasi-compact, and the underlying space of X is locally Noetherian.*

Proof. In case (a), the $X_{\alpha i} \cap X_{\alpha j}$ are affine (5.5.6). Case (b) is a particular example of case (a) (6.6.3). Finally, in case (c), we can reduce to the case where Y is affine and the underlying space of X is Noetherian; then X admits a finite cover of affine opens (X_i), and the $X_i \cap X_j$, being quasi-compact, are finite unions of affine opens (2.1.3). □

9.3. Extension of sections of quasi-coherent sheaves

Theorem (9.3.1). — *Let X be a prescheme whose underlying space is Noetherian, or a scheme whose underlying space is quasi-compact. Let $\mathscr{L}$ be an invertible $\mathscr{O}_X$-module (**0**, 5.4.1), f a section of $\mathscr{L}$ over X, X_f the open set of $x \in X$ such that $f(x) \neq 0$ (**0**, 5.5.1), and $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-module.*

(i) *If $s \in \Gamma(X, \mathscr{F})$ is such that $s|X_f = 0$, then there exists an integer $n > 0$ such that $s \otimes f^{\otimes n} = 0$.*
(ii) *For every section $s \in \Gamma(X_f, \mathscr{F})$, there exists an integer $n > 0$ such that $s \otimes f^{\otimes n}$ extends to a section of $\mathscr{F} \otimes \mathscr{L}^{\otimes n}$ over X.*

Proof.

(i) Since the underlying space of X is quasi-compact, and thus the union of finitely-many affine opens U_i with $\mathscr{L}|U_i$ isomorphic to $\mathscr{O}_X|U_i$, we can reduce to the case where X is affine and $\mathscr{L} = \mathscr{O}_X$. In this case, f can be identified with an element of $A(X)$, and we have that $X_f = D(f)$; s can be identified with an element of an $A(X)$-module M, and $s|X_f$ to the corresponding element of M_f, and the result is then trivial, recalling the definition of a module of fractions. **I** | 173
(ii) Again, X is a finite union of affine opens U_i ($1 \leqslant i \leqslant r$) such that $\mathscr{L}|U_i \cong \mathscr{O}_X|U_i$, and, for every i, $(s \otimes f^{\otimes n})|(U_i \cap X_f)$ can be identified (by the aforementioned isomorphism) with $(f|(U_i \cap X_f))^n (s|(U_i \cap X_f))$. We then know (1.4.1) that there exists an integer $n > 0$ such that, for all i, $(s \otimes f^{\otimes n})|(U_i \cap X_f)$ extends to a section s_i of $\mathscr{F} \otimes \mathscr{L}^{\otimes n}$ over U_i. Let $s_{i|j}$ be the restriction of s_i to $U_i \cap U_j$; by definition we have that $s_{i|j} - s_{j|i} = 0$ on $X_f \cap U_i \cap U_j$. But, if X is a Noetherian space, then $U_i \cap U_j$ is quasi-compact; if X is a scheme, then $U_i \cap U_j$ is an affine open (5.5.6), and so again quasi-compact. By virtue of (i), there thus exists an integer m (independent of i and j) such that $(s_{i|j} - s_{j|i}) \otimes f^{\otimes m} = 0$. It immediately follows that there exists a section s' of $\mathscr{F} \otimes \mathscr{L}^{\otimes (n+m)}$ over X that restricts to $s_i \otimes f^{\otimes m}$ over each U_i, and restricts to $s \otimes f^{\otimes (n+m)}$ over X_f.

□

The following corollaries give an interpretation of Theorem (9.3.1) in a more algebraic language:

Corollary (9.3.2). — *With the hypotheses of (9.3.1), consider the graded ring $A_* = \Gamma_*(\mathscr{L})$ and the graded A_*-module $M_* = \Gamma_*(\mathscr{L}, \mathscr{F})$ (**0**, 5.4.6). If $f \in A_n$, where $n \in \mathbf{Z}$, then there is a canonical isomorphism $\Gamma(X_f, \mathscr{F}) \simeq ((M_*)_f)_0$ (*the subgroup of the module of fractions $(M_*)_f$ consisting of elements of degree 0*).*

Corollary (9.3.3). — *Suppose that the hypotheses of (9.3.1) are satisfied, and suppose further that $\mathscr{L} = \mathscr{O}_X$. Then, setting $A = \Gamma(X, \mathscr{O}_X)$ and $M = \Gamma(X, \mathscr{F})$, the A_f-module $\Gamma(X_f, \mathscr{F})$ is canonically isomorphic to M_f.*

Proposition (9.3.4). — *Let X be a Noetherian prescheme, $\mathscr{F}$ a coherent $\mathscr{O}_X$-module, and $\mathscr{J}$ a coherent sheaf of ideals of $\mathscr{O}_X$, such that the support of $\mathscr{F}$ is contained in that of $\mathscr{O}_X/\mathscr{J}$. Then there exists an integer $n > 0$ such that $\mathscr{J}^n \mathscr{F} = 0$.*

Proof. Since X is a union of finitely-many affine opens whose rings are Noetherian, we can suppose that X is affine, given by some Noetherian ring A; then $\mathscr{F} = \widetilde{M}$, where $M = \Gamma(X, \mathscr{F})$ is an A-module of finite type, and $\mathscr{J} = \widetilde{\mathfrak{J}}$, where $\mathfrak{J} = \Gamma(X, \mathscr{J})$ is an ideal of A ((1.4.1) and (1.5.1)). Since A is Noetherian, $\mathfrak{J}$ admits a finite system of generators f_i ($1 \leqslant i \leqslant m$). By hypothesis, every section of $\mathscr{F}$ over X is zero on each of the $D(f_i)$; if s_j ($1 \leqslant j \leqslant q$) are sections of $\mathscr{F}$ that generate M, then there exists an integer h, independent of i and j, such that $f_i^h s_j = 0$ (1.4.1), whence $f_i^h s = 0$ for all $s \in M$. We thus conclude that, if $n = mh$, then $\mathfrak{J}^n M = 0$, and so the corresponding $\mathscr{O}_X$-module $\mathscr{J}^n \mathscr{F} = \widetilde{\mathfrak{J}^n M}$ (1.3.13) is zero. □

Corollary (9.3.5). — *With the hypotheses of (9.3.4), there exists a closed subprescheme Y of X, whose underlying space is the support of $\mathscr{O}_X/\mathscr{J}$, such that, if $j : Y \to X$ is the canonical injection, then $\mathscr{F} = j_*(j^*(\mathscr{F}))$.*

Proof. First, note that the supports of $\mathscr{O}_X/\mathscr{J}$ and $\mathscr{O}_X/\mathscr{J}^n$ are the same, since, if $\mathscr{J}_x = \mathscr{O}_x$, then $\mathscr{J}_x^n = \mathscr{O}_x$, and we also have that $\mathscr{J}_x^n \subset \mathscr{J}_x$ for all $x \in X$. We can, thanks to (9.3.4), thus suppose that $\mathscr{J}\mathscr{F} = 0$; we can then take Y to be the closed subprescheme of X defined by $\mathscr{J}$, and since $\mathscr{F}$ is then an $(\mathscr{O}_X/\mathscr{J})$-module, the conclusion follows immediately. ☐

I | 174

9.4. Extension of quasi-coherent sheaves

(9.4.1). Let X be a topological space, $\mathscr{F}$ a sheaf of sets (resp. of groups, of rings) on X, U an open subset of X, $\psi : U \to X$ the canonical injection, and $\mathscr{G}$ a subsheaf of $\mathscr{F}|U = \psi^*(\mathscr{F})$. Since ψ_* is left exact, $\psi_*(\mathscr{G})$ is a subsheaf of $\psi_*(\psi^*(\mathscr{F}))$; we denote by ρ the canonical homomorphism $\mathscr{F} \to \psi_*(\psi^*(\mathscr{F}))$ (**0**, 3.5.3), and we denote by $\overline{\mathscr{G}}$ the subsheaf $\rho^{-1}(\psi_*(\mathscr{G}))$ of $\mathscr{F}$. It follows immediately from the definitions that, for every open subset V of X, $\Gamma(V, \overline{\mathscr{G}})$ consists of sections $s \in \Gamma(V, \mathscr{F})$ whose restriction to $V \cap U$ is a section of $\mathscr{G}$ over $V \cap U$. We thus have that $\overline{\mathscr{G}}|U = \psi^*(\overline{\mathscr{G}}) = \mathscr{G}$, and that $\overline{\mathscr{G}}$ is the *largest* subsheaf of $\mathscr{F}$ that restricts to $\mathscr{G}$ over U; we say that $\overline{\mathscr{G}}$ is the *canonical extension* of the subsheaf $\mathscr{G}$ of $\mathscr{F}|U$ to a subsheaf of $\mathscr{F}$.

Proposition (9.4.2). — *Let X be a prescheme, and U an open subset of X such that the canonical injection $j : U \to X$ is a quasi-compact morphism* (which will be the case for *all* U if the underlying space of X is *locally Noetherian* (6.6.4, i)). *Then:*

(i) *for every quasi-coherent $(\mathscr{O}_X|U)$-module $\mathscr{G}$, $j_*(\mathscr{G})$ is a quasi-coherent $\mathscr{O}_X$-module, and $j_*(\mathscr{G})|U = j^*(j_*(\mathscr{G})) = \mathscr{G}$;*

(ii) *for every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$ and every quasi-coherent $(\mathscr{O}_X|U)$-submodule $\mathscr{G}$, the canonical extension $\overline{\mathscr{G}}$ of $\mathscr{G}$ (9.4.1) is a quasi-coherent $\mathscr{O}_X$-submodule of $\mathscr{F}$.*

Proof. If $j = (\psi, \theta)$ (ψ being the injection $U \to X$ of underlying spaces), then, by definition, we have that $j_*(\mathscr{G}) = \psi_*(\mathscr{G})$ for every $(\mathscr{O}_X|U)$-module $\mathscr{G}$, and, further, that $j^*(\mathscr{H}) = \psi^*(\mathscr{H}) = \mathscr{H}|U$ for every $\mathscr{O}_X$-module $\mathscr{H}$, by definition of the prescheme induced over an open subset. So (i) is thus a particular case of ((9.2.2, a)); for the same reason, $j_*(j^*(\mathscr{F}))$ is quasi-coherent, and since $\overline{\mathscr{G}}$ is the inverse image of $j_*(\mathscr{G})$ by the homomorphism $\rho : \mathscr{F} \to j_*(j^*(\mathscr{F}))$, (ii) follows from (4.1.1). ☐

Note that the hypothesis that the morphism $j : U \to X$ is quasi-compact holds whenever the open subset U is *quasi-compact* and X is a *scheme*: indeed, U is then a union of finitely-many affine opens U_i, and, for every affine open V of X, $V \cap U_i$ is an affine open (5.5.6), and thus quasi-compact.

Corollary (9.4.3). — *Let X be a prescheme, and U a quasi-compact open subset of X such that the injection morphism $j : U \to X$ is quasi-compact. Suppose as well that every quasi-coherent $\mathscr{O}_X$-module is the inductive limit of its quasi-coherent $\mathscr{O}_X$-submodules of finite type* (which will be the case if X is an *affine scheme*). *Then let $\mathscr{F}$ be a quasi-coherent $\mathscr{O}_X$-module, and $\mathscr{G}$ a quasi-coherent $(\mathscr{O}_X|U)$-submodule of $\mathscr{F}|U$* of finite type. *Then there exists a quasi-coherent $\mathscr{O}_X$-submodule $\mathscr{G}'$ of $\mathscr{F}$* of finite type *such that $\mathscr{G}'|U = \mathscr{G}$.*

Proof. We have $\mathscr{G} = \overline{\mathscr{G}}|U$, and $\overline{\mathscr{G}}$ is quasi-coherent, from (9.4.2), so the inductive limit of its quasi-coherent $\mathscr{O}_X$-submodules $\mathscr{H}_\lambda$ of finite type. It follows that $\mathscr{G}$ is the inductive limit of the $\mathscr{H}_\lambda|U$, and thus equal to one of the $\mathscr{H}_\lambda|U$, since it is of finite type (**0**, 5.2.3). ☐

Remark (9.4.4). — Suppose that for *every* affine open $U \subset X$, the injection morphism $U \to X$ is quasi-compact. Then, if the conclusion of (9.4.3) holds for every affine open U and for every quasi-coherent $(\mathscr{O}_X|U)$-submodule $\mathscr{G}$ of $\mathscr{F}|U$ of finite type, it follows that $\mathscr{F}$ is the inductive limit of **I** | 175
its quasi-coherent $\mathscr{O}_X$-submodules of finite type. Indeed, for every affine open $U \subset X$, we have that $\mathscr{F}|U = \widetilde{M}$, where M is an $A(U)$-module, and since the latter is the inductive limit of its submodules of finite type, $\mathscr{F}|U$ is the inductive limit of its $(\mathscr{O}_X|U)$-submodules of finite type (1.3.9). But, by hypothesis, each of these submodules is induced on U by a quasi-coherent $\mathscr{O}_X$-submodule $\mathscr{G}_{\lambda,U}$ of $\mathscr{F}$ of finite type. The finite sums of the $\mathscr{G}_{\lambda,U}$ are again quasi-coherent $\mathscr{O}_X$-modules of finite type, because this is a local property, and the case where X is affine was covered in (1.3.10); it is clear then that $\mathscr{F}$ is the inductive limit of these finite sums, whence our claim.

Corollary (9.4.5). — *Under the hypotheses of Corollary (9.4.3), for every quasi-coherent $(\mathscr{O}_X|U)$-module $\mathscr{G}$ of finite type, there exists a quasi-coherent $\mathscr{O}_X$-module $\mathscr{G}'$ of finite type such that $\mathscr{G}'|U = \mathscr{G}$.*

Proof. Since $\mathscr{F} = j_*(\mathscr{G})$ is quasi-coherent (9.4.2) and $\mathscr{F}|U = \mathscr{G}$, it suffices to apply Corollary (9.4.3) to $\mathscr{F}$. □

Lemma (9.4.6). — *Let X be a prescheme, L a well-ordered set, $(V_\lambda)_{\lambda\in L}$ a cover of X by affine opens, and U an open subset of X; for all $\lambda \in L$, we set $W_\lambda = \bigcup_{\mu<\lambda} V_\mu$. Suppose that: (1) for every $\lambda \in L$, $V_\lambda \cap W_\lambda$ is quasi-compact; and (2) the immersion morphism $U \to X$ is quasi-compact. Then, for every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$ and every quasi-coherent $(\mathscr{O}_X|U)$-submodule $\mathscr{G}$ of $\mathscr{F}|U$* of finite type, *there exists a quasi-coherent $\mathscr{O}_X$-submodule $\mathscr{G}'$ of $\mathscr{F}$* of finite type *such that $\mathscr{G}'|U = \mathscr{G}$.*

Proof. Let $U_\lambda = U \cup W_\lambda$; we will define a family $(\mathscr{G}'_\lambda)$ by transfinite induction, where $\mathscr{G}'_\lambda$ is a quasi-coherent $(\mathscr{O}_X|U_\lambda)$-submodule of $\mathscr{F}|U_\lambda$ of finite type, such that $\mathscr{G}'_\lambda|U_\mu = \mathscr{G}'_\mu$ for $\mu < \lambda$ and $\mathscr{G}'_\lambda|U = \mathscr{G}$. The unique $\mathscr{O}_X$-submodule $\mathscr{G}'$ of $\mathscr{F}$ such that $\mathscr{G}'|U_\lambda = \mathscr{G}'_\lambda$ for all $\lambda \in L$ (**0**, 3.3.1) will then give us what we want. So suppose that the $\mathscr{G}'_\mu$ are defined and have the preceding properties for $\mu < \lambda$; if λ does not have a predecessor then we take $\mathscr{G}'_\lambda$ to be the unique $(\mathscr{O}_X|U_\lambda)$-submodule of $\mathscr{F}|U_\lambda$ such that $\mathscr{G}'_\lambda|U_\mu = \mathscr{G}'_\mu$ for all $\mu < \lambda$, which is allowed since the U_μ with $\mu < \lambda$ then form a cover of U_λ. If, conversely, $\lambda = \mu + 1$, then $U_\lambda = U_\mu \cup V_\mu$, and it suffices to define a quasi-coherent $(\mathscr{O}_X|V_\mu)$-submodule $\mathscr{G}''_\mu$ of $\mathscr{F}|V_\mu$ of finite type such that

$$\mathscr{G}''_\mu|(U_\mu \cap V_\mu) = \mathscr{G}'_\mu|(U_\mu \cap V_\mu);$$

and then to take $\mathscr{G}'_\lambda$ to be the $(\mathscr{O}_X|U_\lambda)$-submodule of $\mathscr{F}|U_\lambda$ such that $\mathscr{G}'_\lambda|U_\mu = \mathscr{G}'_\mu$ and $\mathscr{G}'_\lambda|V_\mu = \mathscr{G}''_\mu$ (**0**, 3.3.1). But, since V_μ is affine, the existence of $\mathscr{G}''_\mu$ is guaranteed by (9.4.3) as soon as we show that $U_\mu \cap V_\mu$ is quasi-compact; but $U_\mu \cap V_\mu$ is the union of $U \cap V_\mu$ and $W_\mu \cap V_\mu$, which are both quasi-compact by virtue of the hypotheses. □

Theorem (9.4.7). — *Let X be a prescheme, and U an open subset of X. Suppose that one of the following conditions is verified:*

(a) *the underlying space of X is locally Noetherian;*
(b) *X is a quasi-compact scheme and U is a quasi-compact open.*

Then, for every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$ and every quasi-coherent $(\mathscr{O}_X|U)$-submodule $\mathscr{G}$ of $\mathscr{F}|U$ of finite type, *there exists a quasi-coherent $\mathscr{O}_X$-submodule $\mathscr{G}'$ of $\mathscr{F}$* of finite type *such that $\mathscr{G}'|U = \mathscr{G}$.*

I | 176

Proof. Let $(V_\lambda)_{\lambda\in L}$ be a cover of X by affine opens, with L assumed to be finite in case (b); since L is equipped with the structure of a well-ordered set, it suffices to check that the conditions of (9.4.6) are satisfied. It is clear in the case of (a), since the spaces V_λ are Noetherian. For case (b), the $V_\lambda \cap V_\mu$ are affine (5.5.6), and thus quasi-compact, and, since L is finite, $V_\lambda \cap W_\lambda$ is quasi-compact. Whence the theorem. □

Corollary (9.4.8). — *Under the hypotheses of (9.4.7), for every quasi-coherent $(\mathscr{O}_X|U)$-module $\mathscr{G}$ of finite type, there exists a quasi-coherent $\mathscr{O}_X$-module $\mathscr{G}'$ of finite type such that $\mathscr{G}'|U = \mathscr{G}$.*

Proof. It suffices to apply (9.4.7) to $\mathscr{F} = j_*(\mathscr{G})$, which is quasi-coherent (9.4.2) and such that $\mathscr{F}|U = \mathscr{G}$. □

Corollary (9.4.9). — *Let X be a prescheme whose underlying space is locally Noetherian, or a quasi-compact scheme. Then every quasi-coherent $\mathscr{O}_X$-module is the inductive limit of its quasi-coherent $\mathscr{O}_X$-submodules of finite type.*

Proof. This follows from Theorem (9.4.7) and Remark (9.4.4). □

Corollary (9.4.10). — *Under the hypotheses of (9.4.9), if a quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$ is such that every quasi-coherent $\mathscr{O}_X$-submodule of finite type of $\mathscr{F}$ is generated by its sections over X, then $\mathscr{F}$ is generated by its sections over X.*

Proof. Let U be an affine open neighbourhood of a point $x \in X$, and let s be a section of $\mathscr{F}$ over U; the $\mathscr{O}_X$-submodule $\mathscr{G}$ of $\mathscr{F}|U$ generated by s is quasi-coherent and of finite type, so there exists a quasi-coherent $\mathscr{O}_X$-submodule $\mathscr{G}'$ of $\mathscr{F}$ of finite type such that $\mathscr{G}'|U = \mathscr{G}$ (9.4.7). By hypothesis, there thus exists a finite number of sections t_i of $\mathscr{G}'$ over X and of sections a_i of $\mathscr{O}_X$ over a neighbourhood $V \subset U$ of x such that $s|V = \sum_i a_i(t_i|V)$, which proves the corollary. □

9.5. Closed image of a prescheme; closure of a subprescheme

Proposition (9.5.1). — *Let $f : X \to Y$ be a morphism of preschemes such that $f_*(\mathscr{O}_X)$ is a quasi-coherent $\mathscr{O}_Y$-module (which will be the case if f is quasi-compact* and, *in addition, either f is separated or X is locally Noetherian* (9.2.2)*). Then there exists a smallest subprescheme Y' of Y such that f factors through the canonical injection $j : Y' \to Y$* (or, equivalently (4.4.1), such that the subprescheme $f^{-1}(Y')$ of X is *identical* to X*).*

More precisely:

Corollary (9.5.2). — *Under the conditions of* (9.5.1)*, let $f = (\psi, \theta)$, and let $\mathscr{J}$ be the (quasi-coherent) kernel of the homomorphism $\theta : \mathscr{O}_Y \to f_*(\mathscr{O}_X)$. Then the closed subprescheme Y' of Y defined by $\mathscr{J}$ satisfies the conditions of* (9.5.1)*.*

Proof. Since the functor ψ^* is exact, the canonical factorization $\theta : \mathscr{O}_Y \to \mathscr{O}_Y/\mathscr{J} \xrightarrow{\theta'} \psi_*(\mathscr{O}_X)$ gives (**0**, 3.5.4.3) a factorization $\theta^\sharp : \psi^*(\mathscr{O}_Y) \to \psi^*(\mathscr{O}_Y)/\psi^*(\mathscr{J}) \xrightarrow{\theta'^\sharp} \mathscr{O}_X$; since $\theta_x^\sharp$ is a local homomorphism for every $x \in X$, the same is true of $\theta_x'^\sharp$; if we denote by ψ_0 the continuous map ψ considered as a map from X to Y', and by θ_0 the restriction $\theta'|Y' : (\mathscr{O}_Y/\mathscr{J})|Y' \to \psi_*(\mathscr{O}_X)|Y' = (\psi_0)_*(\mathscr{O}_X)$, **Err**$_{\mathrm{II}}$
then we see that $f_0 = (\psi_0, \theta_0)$ is a morphism of preschemes $X \to Y'$ (2.2.1) such that $f = j \circ f_0$. Now, if Y'' is a second closed subprescheme of Y, defined by a quasi-coherent sheaf of ideals **I** | 177
$\mathscr{J}'$ of $\mathscr{O}_Y$, such that f factors through the injection $j' : Y'' \to Y$, then we must first have that $\psi(X) \subset Y''$, and thus that $Y' \subset Y''$, since Y'' is closed. Furthermore, for all $y \in Y''$, θ must factor as $\mathscr{O}_y \to \mathscr{O}_y/\mathscr{J}'_y \to (\psi_*(\mathscr{O}_X))_y$, which, by definition, leads to $\mathscr{J}'_y \subset \mathscr{J}_y$, and thus Y' is a closed subprescheme of Y'' (4.1.10). □

Definition (9.5.3). — Whenever there exists a smallest closed subprescheme Y' of Y such that f factors through the canonical injection $j : Y' \to Y$, we say that Y' is the *closed image* prescheme of X under the morphism f.

Proposition (9.5.4). — *If $f_*(\mathscr{O}_X)$ is a quasi-coherent $\mathscr{O}_Y$-module, then the underlying space of the closed image of X under f is the closure $\overline{f(X)}$ in Y.*

Proof. As the support of $f_*(\mathscr{O}_X)$ is contained in $\overline{f(X)}$, we have (with the notation of (9.5.2)) $\mathscr{J}_y = \mathscr{O}_y$ for $y \notin \overline{f(X)}$, thus the support of $\mathscr{O}_Y/\mathscr{J}$ is contained in $\overline{f(X)}$. In addition, this support is closed and contains $f(X)$: indeed, if $y \in f(X)$, the unit element of the ring $(\psi_*(\mathscr{O}_X))_y$ is not zero, being the germ at y of the section
$$1 \in \Gamma(X, \mathscr{O}_X) = \Gamma(Y, \psi_*(\mathscr{O}_X));$$
since it is the image under θ of the unit element of $\mathscr{O}_y$, the latter does not belong to $\mathscr{J}_y$, hence $\mathscr{O}_y/\mathscr{J}_y \neq 0$; this finishes the proof. □

Proposition (9.5.5). — (Transitivity of closed images). *Let $f : X \to Y$ and $g : Y \to Z$ be two morphisms of preschemes; we suppose that the closed image Y' of X under f exists, and that, if g' is the restriction of g to Y', then the closed image Z' of Y' under g' exists. Then the closed image of X under $g \circ f$ exists and is equal to Z'.*

Proof. It suffices (9.5.1) to show that Z' is the smallest closed subprescheme Z_1 of Z such that the closed subprescheme $(g \circ f)^{-1}(Z_1)$ of X (equal to $f^{-1}(g^{-1}(Z_1))$ by Corollary (4.4.2)) is equal to X; it is equivalent to say that Z' is the smallest closed subprescheme of Z such that f factors through the injection $g^{-1}(Z_1) \to Y$ (4.4.1). By virtue of the existence of the closed image Y', every Z_1 with this property is such that $g^{-1}(Z_1)$ factors through Y', which is equivalent to saying that $j^{-1}(g^{-1}(Z_1)) = g'^{-1}(Z_1) = Y'$, denoting by j the injection $Y' \to Y$. By the definition of Z', we indeed conclude that Z' is the smallest closed subprescheme of Z satisfying the preceding condition. □

Corollary (9.5.6). — *Let $f : X \to Y$ be an S-morphism such that Y is the closed image of X under f. Let Z be an S-scheme; if two S-morphisms g_1, g_2 from Y to Z are such that $g_1 \circ f = g_2 \circ f$, then $g_1 = g_2$.*

Proof. Let $h = (g_1, g_2)_S : Y \to Z \times_S Z$; since the diagonal $T = \Delta_Z(Z)$ is a closed subprescheme of $Z \times_S Z$, $Y' = h^{-1}(T)$ is a closed subprescheme of Y (4.4.1). Let $u = g_1 \circ f = g_2 \circ f$; we then have, by definition of the product, $h' = h \circ f = (u, u)_S$, so $h \circ f = \Delta_Z \circ u$; since $\Delta_Z^{-1}(T) = Z$, we have

$h'^{-1}(T) = u^{-1}(Z) = X$, so $f^{-1}(Y') = X$. From this, we conclude (4.4.1) that f factors through the canonical injection $Y' \to Y$, so $Y' = Y$ by hypothesis; it then follows (4.4.1) that h factors as $\Delta_Z \circ v$, where v is a morphism $Y \to Z$, which implies that $g_1 = g_2 = v$. □

Remark (9.5.7). — If X and Y are S-schemes, Proposition (9.5.6) implies that, when Y is the closed image of X under f, f is an *epimorphism* in the category of *S-schemes* (T, 1.1). We will show in Chapter V that, conversely, if the closed image Y' of X under f exists and if f is an epimorphism of S-schemes, then we necessarily have that $Y' = Y$. I | 178

Proposition (9.5.8). — *Suppose that the hypotheses of (9.5.1) are satisfied, and let Y' be the closed image of X under f. For every open V of Y, let $f_V : f^{-1}(V) \to V$ be the restriction of f; then the closed image of $f^{-1}(V)$ under f_V in V exists and is equal to the prescheme induced by Y' on the open $V \cap Y'$ of Y'* (in other words, to the subprescheme $\inf(V, Y')$ of Y (4.4.3)).

Proof. Let $X' = f^{-1}(V)$; since the direct image of $\mathscr{O}_{X'}$ by f_V is exactly the restriction of $f_*(\mathscr{O}_X)$ to V, it is clear that the kernel $\mathscr{J}'$ of the homomorphism $\mathscr{O}_V \to (f_V)_*(\mathscr{O}_{X'})$ is the restriction of $\mathscr{J}$ to V, from which the proposition quickly follows. □

We will see that this result can be understood as saying that taking the closed image commutes with an extension $Y_1 \to Y$ of the base prescheme, which is an *open immersion*. We will see in Chapter IV that it is the same for an extension $Y_1 \to Y$ which is a *flat* morphism, provided that f is separated and quasi-compact.

Proposition (9.5.9). — *Let $f : X \to Y$ be a morphism such that the closed image Y' of X under f exists.*

(i) *If X is reduced, then so too is Y'.*
(ii) *If the hypotheses of Proposition (9.5.1) are satisfied and X is irreducible (resp. integral), then so too is Y'.*

Proof. By hypothesis, the morphism f factors as $X \xrightarrow{g} Y' \xrightarrow{j} Y$, where j is the canonical injection. Since X is reduced, g factors as $X \xrightarrow{h} Y'_{\text{red}} \xrightarrow{j'} Y'$, where j' is the canonical injection (5.2.2), and it then follows from the definition of Y' that $Y'_{\text{red}} = Y'$. If, moreover, the conditions of Proposition (9.5.1) are satisfied, then it follows from (9.5.4) that $f(X)$ is dense in Y'; if X is irreducible, then so is Y' (**0**, 2.1.5). The claim about integral preschemes follows from the conjunction of the two others. □

Proposition (9.5.10). — *Let Y be a subprescheme of a prescheme X, such that the canonical injection $i : Y \to X$ is a quasi-compact morphism. Then there exists a smallest closed subprescheme $\overline{Y}$ of X containing Y; its underlying space is the closure of that of Y; the latter is open in its closure, and the prescheme Y is induced on this open by $\overline{Y}$.*

Proof. It suffices to apply Proposition (9.5.1) to the injection i[30], which is separated (5.5.1) and quasi-compact by hypothesis; (9.5.1) thus proves the existence of $\overline{Y}$, and (9.5.4) shows that its underlying space is the closure of Y in X; since Y is locally closed in X, it is open in $\overline{Y}$, and the last claim comes from (9.5.8) applied to an open subset V of X such that Y is closed in V. □

With the above notation, if the injection $V \to X$ is quasi-compact, and if $\mathscr{J}$ is the quasi-coherent sheaf of ideals of $\mathscr{O}_X|V$ defining the closed subprescheme Y of V, it follows from Proposition (9.5.1) that the quasi-coherent sheaf of ideals of $\mathscr{O}_X$ defining $\overline{Y}$ is the canonical extension (9.4.1) $\overline{\mathscr{J}}$ of $\mathscr{J}$, because it is clearly the largest quasi-coherent subsheaf of ideals of $\mathscr{O}_X$ inducing $\mathscr{J}$ on V.

I | 179

Corollary (9.5.11). — *Under the hypotheses of Proposition (9.5.10), every section of $\mathscr{O}_{\overline{Y}}$ over an open V of $\overline{Y}$ that is zero on $V \cap Y$ is zero.*

Proof. By Proposition (9.5.8), we can reduce to the case where $V = \overline{Y}$. If we take into account that the sections of $\mathscr{O}_{\overline{Y}}$ over $\overline{Y}$ canonically correspond to the $\overline{Y}$-sections of $\overline{Y} \otimes_{\mathbb{Z}} \mathbb{Z}[T]$ (3.3.15) and that the latter is separated over $\overline{Y}$, then the corollary appears as a specific case of (9.5.6). □

When there exists a smallest closed subprescheme Y' of X containing a subprescheme Y of X, we say that Y' is the *closure* of Y in X, when this causes no confusion.

[30] *[Trans.] The French source prints j here, but the proposition defines the canonical injection as $i : Y \to X$.*

9.6. Quasi-coherent sheaves of algebras; change of structure sheaf

Proposition (9.6.1). — *Let X be a prescheme, and $\mathscr{B}$ a quasi-coherent $\mathscr{O}_X$-algebra (**0**, 5.1.3). For a $\mathscr{B}$-module $\mathscr{F}$ to be quasi-coherent (on the ringed space $(X, \mathscr{B})$) it is necessary and sufficient that $\mathscr{F}$ be a quasi-coherent $\mathscr{O}_X$-module.*

Proof. Since the question is local, we can assume X to be affine, given by some ring A, and thus $\mathscr{B} = \widetilde{B}$, where B is an A-algebra (1.4.3). If $\mathscr{F}$ is quasi-coherent on the ringed space $(X, \mathscr{B})$ then we can also assume that $\mathscr{F}$ is the cokernel of a $\mathscr{B}$-homomorphism $\mathscr{B}^{(I)} \to \mathscr{B}^{(J)}$; since this homomorphism is also an $\mathscr{O}_X$-homomorphism of $\mathscr{O}_X$-modules, and $\mathscr{B}^{(I)}$ and $\mathscr{B}^{(J)}$ are quasi-coherent $\mathscr{O}_X$-modules (1.3.9, ii), $\mathscr{F}$ is also a quasi-coherent $\mathscr{O}_X$-module (1.3.9, i).

Conversely, if $\mathscr{F}$ is a quasi-coherent $\mathscr{O}_X$-module, then $\mathscr{F} = \widetilde{M}$, where M is a B-module (1.4.3); M is isomorphic to the cokernel of a B-homomorphism $B^{(I)} \to B^{(J)}$, so $\mathscr{F}$ is a $\mathscr{B}$-module isomorphic to the cokernel of the corresponding homomorphism $\mathscr{B}^{(I)} \to \mathscr{B}^{(J)}$ (1.3.13), which finishes the proof. □

In particular, if $\mathscr{F}$ and $\mathscr{G}$ are two quasi-coherent $\mathscr{B}$-modules, then $\mathscr{F} \otimes_{\mathscr{B}} \mathscr{G}$ is a quasi-coherent $\mathscr{B}$-module; similarly for $\mathscr{H}om_{\mathscr{B}}(\mathscr{F}, \mathscr{G})$ whenever we further suppose that $\mathscr{F}$ admits a finite presentation (1.3.13).

(9.6.2). Given a prescheme X, we say that a quasi-coherent $\mathscr{O}_X$-algebra $\mathscr{B}$ is of *finite type* if, for all $x \in X$, there exists an open *affine* neighbourhood U of x such that $\Gamma(U, \mathscr{B}) = B$ is an algebra of finite type over $\Gamma(U, \mathscr{O}_X) = A$. We then have that $\mathscr{B}|U = \widetilde{B}$ and, for all $f \in A$, the induced $(\mathscr{O}_X|D(f))$-algebra $\mathscr{B}|D(f)$ is of finite type, because it is isomorphic to $(B_f)^{\sim}$, and $B_f = B \otimes_A A_f$ is clearly an algebra of finite type over A_f. Since the $D(f)$ form a basis for the topology of U, we thus conclude that if $\mathscr{B}$ is a quasi-coherent $\mathscr{O}_X$-algebra of finite type then, for every open V of X, $\mathscr{B}|V$ is a quasi-coherent $(\mathscr{O}_X|V)$-algebra of finite type.

Proposition (9.6.3). — *Let X be a locally Noetherian prescheme. Then every quasi-coherent $\mathscr{O}_X$-algebra $\mathscr{B}$ of finite type is a coherent sheaf of rings (**0**, 5.3.7).*

Proof. We can once again restrict to the case where X is an affine scheme given by a Noetherian ring A, and where $\mathscr{B} = \widetilde{B}$, with B being an A-algebra of finite type; B is then a Noetherian ring. With this, it remains to prove that the kernel $\mathscr{N}$ of a $\mathscr{B}$-homomorphism $\mathscr{B}^m \to \mathscr{B}$ is a $\mathscr{B}$- module of finite type; but it is isomorphic (as a $\mathscr{B}$-module) to $\widetilde{N}$, where N is the kernel of the corresponding homomorphism of B-modules $B^m \to B$ (1.3.13). Since B is Noetherian, the submodule N of B^m is a B-module of finite type, so there exists a homomorphism $B^p \to B^m$ with image N; since the sequence $B^p \to B^m \to B$ is exact, so too is the corresponding sequence $\mathscr{B}^p \to \mathscr{B}^m \to \mathscr{B}$ (1.3.5), and since $\mathscr{N}$ is the image of $\mathscr{B}^p \to \mathscr{B}^m$ (1.3.9, i), this proves the proposition. □ **I** | 180

Corollary (9.6.4). — *Under the hypotheses of (9.6.3), for a $\mathscr{B}$-module $\mathscr{F}$ to be coherent, it is necessary and sufficient that it be a quasi-coherent $\mathscr{O}_X$-module and a $\mathscr{B}$-module of finite type. If this is the case, and if $\mathscr{G}$ is a $\mathscr{B}$-submodule or a quotient $\mathscr{B}$-module of $\mathscr{F}$, then in order for $\mathscr{G}$ to be a coherent $\mathscr{B}$-module, it is necessary and sufficient that it be a quasi-coherent $\mathscr{O}_X$-module.*

Proof. Taking (9.6.1) into account, the conditions on $\mathscr{F}$ are clearly necessary; we will show that they are sufficient. We can restrict to the case where X is affine, given by some Noetherian ring A, where $\mathscr{B} = \widetilde{B}$, with B an A-algebra of finite type, where $\mathscr{F} = \widetilde{M}$, with M a B-module, and where there exists a surjective $\mathscr{B}$-homomorphism $\mathscr{B}^m \to \mathscr{F} \to 0$. We then have the corresponding exact sequence $B^m \to M \to 0$, so M is a B-module of finite type; further, the kernel P of the homomorphism $B^m \to M$ is then a B-module of finite type, since B is Noetherian. We thus conclude (1.3.13) that $\mathscr{F}$ is the cokernel of a $\mathscr{B}$-homomorphism $\mathscr{B}^n \to \mathscr{B}^m$, and is thus coherent, since $\mathscr{B}$ is a coherent sheaf of rings (**0**, 5.3.4). The same reasoning shows that a quasi-coherent $\mathscr{B}$-submodule (resp. a quotient $\mathscr{B}$-module) of $\mathscr{F}$ is of finite type, from whence the second part of the corollary. □

Proposition (9.6.5). — *Let X be a quasi-compact scheme, or a prescheme whose underlying space is Noetherian. For every quasi-coherent $\mathscr{O}_X$-algebra $\mathscr{B}$ of finite type, there exists a quasi-coherent $\mathscr{O}_X$-submodule $\mathscr{E}$ of $\mathscr{B}$ of finite type such that $\mathscr{E}$ generates (**0**, 4.1.4) the $\mathscr{O}_X$-algebra $\mathscr{B}$.*

Proof. In fact, by hypothesis, there exists a finite cover (U_i) of X consisting of affine opens such that $\Gamma(U_i, \mathscr{B}) = B_i$ is an algebra of finite type over $\Gamma(U_i, \mathscr{O}_X) = A_i$; let E_i be an A_i-submodule of B_i of finite type that generates the A_i-algebra B_i; thanks to (9.4.7), there exists an $\mathscr{O}_X$-submodule $\mathscr{E}_i$ of $\mathscr{B}$, quasi-coherent and of finite type, such that $\mathscr{E}_i|U_i = \widetilde{E}_i$. It is clear that the sum $\mathscr{E}$ of the $\mathscr{E}_i$ is the desired object. □

Proposition (9.6.6). — *Let X be a prescheme whose underlying space is locally Noetherian, or a quasi-compact scheme. Then every quasi-coherent $\mathscr{O}_X$-algebra $\mathscr{B}$ is the inductive limit of its quasi-coherent $\mathscr{O}_X$-subalgebras of finite type.*

Proof. In fact, it follows from (9.4.9) that $\mathscr{B}$ is the inductive limit (as an $\mathscr{O}_X$-module) of its quasi-coherent $\mathscr{O}_X$-submodules of finite type; the latter generate quasi-coherent $\mathscr{O}_X$-*subalgebras* of $\mathscr{B}$ of finite type (1.3.14), and so $\mathscr{B}$ is *a fortiori* their inductive limit. □

§10. Formal schemes

10.1. Formal affine schemes

(10.1.1). Let A be an *admissible* topological ring (**0**, 7.1.2); for each ideal of definition $\mathfrak{J}$ of A, $\operatorname{Spec}(A/\mathfrak{J})$ can be identified with the closed subspace $V(\mathfrak{J})$ of $\operatorname{Spec}(A)$ (1.1.11), the set of *open* prime ideals of A; this topological space does not depend on the ideal of definition $\mathfrak{J}$ considered; we denote this topological space by $\mathfrak{X}$. Let $(\mathfrak{J}_\lambda)$ be a fundamental system of neighbourhoods of 0 in A, consisting of ideals of definition, and for each λ, let $\mathscr{O}_\lambda$ be the structure sheaf of $\operatorname{Spec}(A/\mathfrak{J}_\lambda)$; this sheaf is induced on $\mathfrak{X}$ by $\widetilde{A}/\widetilde{\mathfrak{J}_\lambda}$ (which is zero outside of $\mathfrak{X}$). For $\mathfrak{J}_\mu \subset \mathfrak{J}_\lambda$, the canonical homomorphism $A/\mathfrak{J}_\mu \to A/\mathfrak{J}_\lambda$ thus defines a homomorphism $u_{\lambda\mu} : \mathscr{O}_\mu \to \mathscr{O}_\lambda$ of sheaves of rings (1.6.1), and $(\mathscr{O}_\lambda)$ is a *projective system of sheaves of rings* for these homomorphisms. Since the topology of $\mathfrak{X}$ admits a basis consisting of quasi-compact open subsets, we can associate to each $\mathscr{O}_\lambda$ a *pseudo-discrete sheaf of topological rings* (**0**, 3.8.1) which has $\mathscr{O}_\lambda$ as the underlying sheaf of rings (without topologies), and which we also denote by $\mathscr{O}_\lambda$; and the $\mathscr{O}_\lambda$ give again a *projective system of sheaves of topological rings* (**0**, 3.8.2). We denote by $\mathscr{O}_\mathfrak{X}$ the *sheaf of topological rings* on $\mathfrak{X}$, the projective limit of the system $(\mathscr{O}_\lambda)$; for each *quasi-compact* open subset U of $\mathfrak{X}$, $\Gamma(U, \mathscr{O}_\mathfrak{X})$ is a topological ring, the projective limit of the system of *discrete* rings $\Gamma(U, \mathscr{O}_\lambda)$ (**0**, 3.2.6). I | 181

Definition (10.1.2). — Given an admissible topological ring A, we define the formal spectrum of A, denoted by $\operatorname{Spf}(A)$, to be the closed subspace $\mathfrak{X}$ of $\operatorname{Spec}(A)$ consisting of the open prime ideals of A. We say that a topologically ringed space is a formal affine scheme if it is isomorphic to a formal spectrum $\operatorname{Spf}(A) = \mathfrak{X}$ equipped with a sheaf of topological rings $\mathscr{O}_\mathfrak{X}$ which is the projective limit of sheaves of pseudo-discrete topological rings $(\widetilde{A}/\widetilde{\mathfrak{J}_\lambda})|\mathfrak{X}$, where $\mathfrak{J}_\lambda$ varies over the filtered set of ideals of definition of A.

When we speak of a *formal spectrum* $\mathfrak{X} = \operatorname{Spf}(A)$ as a formal affine scheme, it will always be as the topologically ringed space $(\mathfrak{X}, \mathscr{O}_\mathfrak{X})$ where $\mathscr{O}_\mathfrak{X}$ is defined as above.

We note that every *affine scheme* $X = \operatorname{Spec}(A)$ can be considered as a formal affine scheme in only one way, by considering A as a discrete topological ring: the topological rings $\Gamma(U, \mathscr{O}_X)$ are then discrete whenever U is quasi-compact (but not, in general, when U is an arbitrary open subset of X).

Proposition (10.1.3). — *If $\mathfrak{X} = \operatorname{Spf}(A)$, where A is an admissible ring, then $\Gamma(\mathfrak{X}, \mathscr{O}_\mathfrak{X})$ is topologically isomorphic to A.*

Proof. Indeed, since $\mathfrak{X}$ is closed in $\operatorname{Spec}(A)$, it is quasi-compact, and so $\Gamma(\mathfrak{X}, \mathscr{O}_\mathfrak{X})$ is topologically isomorphic to the projective limit of the discrete rings $\Gamma(\mathfrak{X}, \mathscr{O}_\lambda)$; but $\Gamma(\mathfrak{X}, \mathscr{O}_\lambda)$ is isomorphic to $A/\mathfrak{J}_\lambda$ (1.3.7); since A is separated and complete, it is topologically isomorphic to $\varprojlim A/\mathfrak{J}_\lambda$ (**0**, 7.2.1), whence the proposition. □

Proposition (10.1.4). — *Let A be an admissible ring, $\mathfrak{X} = \operatorname{Spf}(A)$, and, for every $f \in A$, let $\mathfrak{D}(f) = D(f) \cap \mathfrak{X}$; then the topologically ringed space $(\mathfrak{D}(f), \mathscr{O}_\mathfrak{X}|\mathfrak{D}(f))$ is isomorphic to the formal affine spectrum* $\operatorname{Spf}(A_{\{f\}})$ (**0**, 7.6.15).

Proof. For every ideal of definition $\mathfrak{J}$ of A, the discrete ring $S_f^{-1}A/S_f^{-1}\mathfrak{J}$ is canonically identified with $A_{\{f\}}/\mathfrak{J}_{\{f\}}$ (**0**, 7.6.9), so, by (1.2.5) and (1.2.6), the topological space $\mathrm{Spf}(A_{\{f\}})$ is canonically identified with $\mathfrak{D}(f)$. Further, for every quasi-compact open subset U of $\mathfrak{X}$ contained in $\mathfrak{D}(f)$, $\Gamma(U, \mathscr{O}_\lambda)$ can be identified with the module of sections of the structure sheaf of $\mathrm{Spec}(S_f^{-1}A/S_f^{-1}\mathfrak{J}_\lambda)$ over U (1.3.6), so, setting $\mathfrak{Y} = \mathrm{Spf}(A_{\{f\}})$, $\Gamma(U, \mathscr{O}_\mathfrak{X})$ can be identified with the module of sections $\Gamma(U, \mathscr{O}_\mathfrak{Y})$, which proves the proposition. □

I | 182

(10.1.5). As a sheaf of rings *without topology*, the structure sheaf $\mathscr{O}_\mathfrak{X}$ of $\mathrm{Spf}(A)$ admits, for every $x \in \mathfrak{X}$, a fibre which, by (10.1.4), can be identified with the inductive limit $\varinjlim A_{\{f\}}$ for the $f \notin \mathfrak{j}_x$. Then, by (**0**, 7.6.17) and (**0**, 7.6.18):

Proposition (10.1.6). — *For every $x \in \mathfrak{X} = \mathrm{Spf}(A)$, the fibre $\mathscr{O}_x$ is a local ring whose residue field is isomorphic to $k(x) = A_x/\mathfrak{j}_x A_x$. If, further, A is adic and Noetherian, then $\mathscr{O}_x$ is a Noetherian ring.*

Since $k(x)$ is not the zero ring, we conclude from this that the *support* of the sheaf of rings $\mathscr{O}_\mathfrak{X}$ is *equal to* $\mathfrak{X}$.

10.2. Morphisms of formal affine schemes

(10.2.1). Let A, B be two admissible rings, and let $\phi : B \to A$ be a *continuous* homomorphism. The continuous map ${}^a\phi : \mathrm{Spec}(A) \to \mathrm{Spec}(B)$ (1.2.1) then maps $\mathfrak{X} = \mathrm{Spf}(A)$ to $\mathfrak{Y} = \mathrm{Spf}(B)$, since the inverse image under ϕ of an open prime ideal of A is an open prime ideal of B. On the other hand, for all $g \in B$, ϕ defines a continuous homomorphism $\Gamma(\mathfrak{D}(g), \mathscr{O}_\mathfrak{Y}) \to \Gamma(\mathfrak{D}(\phi(g)), \mathscr{O}_\mathfrak{X})$ according to (10.1.4), (10.1.3), and (**0**, 7.6.7); since these homomorphisms satisfy the compatibility conditions for the restrictions corresponding to the change from g to a multiple of g, and since $\mathfrak{D}(\phi(g)) = {}^a\phi^{-1}(\mathfrak{D}(g))$, they define a *continuous* homomorphism of sheaves of topological rings $\mathscr{O}_\mathfrak{Y} \to {}^a\phi_*(\mathscr{O}_\mathfrak{X})$ (**0**, 3.2.5) that we denote by $\widetilde{\phi}$; we have thus defined a morphism $\Phi = ({}^a\phi, \widetilde{\phi})$ of topologically ringed spaces $\mathfrak{X} \to \mathfrak{Y}$. We note that, as a homomorphism of sheaves of rings without topology, $\widetilde{\phi}$ defines a homomorphism $\widetilde{\phi}_x^\sharp : \mathscr{O}_{{}^a\phi(x)} \to \mathscr{O}_x$ on the stalks, for all $x \in \mathfrak{X}$.

Proposition (10.2.2). — *Let A and B be admissible topological rings, and let $\mathfrak{X} = \mathrm{Spf}(A)$ and $\mathfrak{Y} = \mathrm{Spf}(B)$. For a morphism $u = (\psi, \theta) : \mathfrak{X} \to \mathfrak{Y}$ of topologically ringed spaces to be of the form $({}^a\phi, \widetilde{\phi})$, where ϕ is a continuous ring homomorphism $B \to A$, it is necessary and sufficient that $\theta_x^\sharp$ be a local homomorphism $\mathscr{O}_{\psi(x)} \to \mathscr{O}_x$ for all $x \in \mathfrak{X}$.*

Proof. The condition is necessary: let $\mathfrak{p} = \mathfrak{j}_x \in \mathrm{Spf}(A)$, and let $\mathfrak{q} = \phi^{-1}(\mathfrak{j}_x)$; if $g \notin \mathfrak{q}$, then we have $\phi(g) \notin \mathfrak{p}$, and it is immediate that the homomorphism $B_{\{g\}} \to A_{\{\phi(g)\}}$ induced by ϕ (**0**, 7.6.7) sends $\mathfrak{q}_{\{g\}}$ to a subset of $\mathfrak{p}_{\{\phi(g)\}}$; by passing to the inductive limit, we see (taking (10.1.5) and (**0**, 7.6.17) into account) that $\widetilde{\phi}_x^\sharp$ is a local homomorphism.

Conversely, let (ψ, θ) be a morphism satisfying the condition of the proposition; by (10.1.3), θ defines a continuous ring homomorphism

$$\phi = \Gamma(\theta) : B = \Gamma(\mathfrak{Y}, \mathscr{O}_\mathfrak{Y}) \longrightarrow \Gamma(\mathfrak{X}, \mathscr{O}_\mathfrak{X}) = A.$$

By virtue of the hypothesis on θ, for the section $\phi(g)$ of $\mathscr{O}_\mathfrak{X}$ over $\mathfrak{X}$ to be an invertible germ at the point x, it is necessary and sufficient that g be an invertible germ at the point $\psi(x)$. But, by (**0**, 7.6.17), the sections of $\mathscr{O}_\mathfrak{X}$ (resp. $\mathscr{O}_\mathfrak{Y}$) over $\mathfrak{X}$ (resp. $\mathfrak{Y}$) that have a non-invertible germ at the point x (resp. $\psi(x)$) are exactly the elements of $\mathfrak{j}_x$ (resp. $\mathfrak{j}_{\psi(x)}$); the above remark thus shows that ${}^a\phi = \psi$. Finally, I | 183
for all $g \in B$ the diagram

$$\begin{tikzcd} B = \Gamma(\mathfrak{Y}, \mathscr{O}_\mathfrak{Y}) \arrow[r, "\phi"] \arrow[d] & \Gamma(\mathfrak{X}, \mathscr{O}_\mathfrak{X}) = A \arrow[d] \\ B_{\{g\}} = \Gamma(\mathfrak{D}(g), \mathscr{O}_\mathfrak{Y}) \arrow[r, "\Gamma(\theta_{\mathfrak{D}(g)})"'] & \Gamma(\mathfrak{D}(\phi(g)), \mathscr{O}_\mathfrak{X}) = A_{\{\phi(g)\}} \end{tikzcd}$$

is commutative; by the universal property of completed rings of fractions (**0**, 7.6.6), $\theta_{\mathfrak{D}(g)}$ is equal to $\widetilde{\phi}_{\mathfrak{D}(g)}$ for all $g \in B$, and so (**0**, 3.2.5) we have $\theta = \widetilde{\phi}$. □

We say that a morphism (ψ, θ) of topologically ringed spaces satisfying the condition of Proposition (10.2.2) is a *morphism of formal affine schemes*. We can say that the functors $A \mapsto \mathrm{Spf}(A)$ and $\mathfrak{X} \mapsto \Gamma(\mathfrak{X}, \mathscr{O}_{\mathfrak{X}})$ define an *equivalence* between the category of admissible rings and the opposite category of formal affine schemes (T, I, 1.2).

(10.2.3). As a particular case of (10.2.2), note that, for $f \in A$, the canonical injection of the formal affine scheme induced by $\mathfrak{X}$ on $\mathfrak{D}(f)$ corresponds to the continuous canonical homomorphism $A \to A_{\{f\}}$. Under the hypotheses of Proposition (10.2.2), let h be an element of B, and g an element of A that is a multiple of $\phi(h)$; we then have $\psi(\mathfrak{D}(g)) \subset \mathfrak{D}(h)$; the restriction of u to $\mathfrak{D}(g)$, considered as a morphism from $\mathfrak{D}(g)$ to $\mathfrak{D}(h)$, is the unique morphism v making the diagram

$$\begin{tikzcd} \mathfrak{D}(g) \arrow[r, "v"] \arrow[d] & \mathfrak{D}(h) \arrow[d] \\ \mathfrak{X} \arrow[r, "u"'] & \mathfrak{Y} \end{tikzcd}$$

commute.

This morphism corresponds to the unique continuous homomorphism $\phi' : B_{\{h\}} \to A_{\{g\}}$ (0, 7.6.7) making the diagram

$$\begin{tikzcd} A \arrow[d] & B \arrow[l, "\phi"'] \arrow[d] \\ A_{\{g\}} & B_{\{h\}} \arrow[l, "\phi'"'] \end{tikzcd}$$

commute.

10.3. Ideals of definition for a formal affine scheme

(10.3.1). Let A be an admissible ring, $\mathfrak{J}$ an open ideal of A, and $\mathfrak{X}$ the formal affine scheme $\mathrm{Spf}(A)$. Let $(\mathfrak{J}_\lambda)$ be the set of those ideals of definition for A that are contained in $\mathfrak{J}$; then $\widetilde{\mathfrak{J}}/\widetilde{\mathfrak{J}}_\lambda$ is a sheaf of ideals of $\widetilde{A}/\widetilde{\mathfrak{J}}_\lambda$. Denote by $\mathfrak{J}^\Delta$ the projective limit of the sheaves on $\mathfrak{X}$ induced by $\widetilde{\mathfrak{J}}/\widetilde{\mathfrak{J}}_\lambda$, which is identified with a *sheaf of ideals* of $\mathscr{O}_{\mathfrak{X}}$ (0, 3.2.6). For every $f \in A$, $\Gamma(\mathfrak{D}(f), \mathfrak{J}^\Delta)$ is the projective limit of the $S_f^{-1}\mathfrak{J}/S_f^{-1}\mathfrak{J}_\lambda$, or, in other words, can be identified with the open ideal $\mathfrak{J}_{\{f\}}$ of the ring $A_{\{f\}}$ (0, 7.6.9), and, in particular, $\Gamma(\mathfrak{X}, \mathfrak{J}^\Delta) = \mathfrak{J}$; we conclude (the $\mathfrak{D}(f)$ forming a basis for the topology of $\mathfrak{X}$) that

(10.3.1.1) $$\mathfrak{J}^\Delta | \mathfrak{D}(f) = (\mathfrak{J}_{\{f\}})^\Delta.$$

I | 184

(10.3.2). With the notation of (10.3.1), for all $f \in A$, the canonical map from $A_{\{f\}} = \Gamma(\mathfrak{D}(f), \mathscr{O}_{\mathfrak{X}})$ to $\Gamma(\mathfrak{D}(f), (\widetilde{A}/\widetilde{\mathfrak{J}})|\mathfrak{X}) = S_f^{-1}A/S_f^{-1}\mathfrak{J}$ is *surjective* and has $\Gamma(\mathfrak{D}(f), \mathfrak{J}^\Delta) = \mathfrak{J}_{\{f\}}$ as its kernel (0, 7.6.9); these maps thus define a *surjective* continuous homomorphism, said to be *canonical*, from the sheaf of topological rings $\mathscr{O}_{\mathfrak{X}}$ to the sheaf of discrete rings $(\widetilde{A}/\widetilde{\mathfrak{J}})|\mathfrak{X}$, whose kernel is $\mathfrak{J}^\Delta$; this homomorphism is none other than $\widetilde{\phi}$ (10.2.1), where ϕ is the continuous homomorphism $A \to A/\mathfrak{J}$; the morphism $({}^a\phi, \widetilde{\phi}) : \mathrm{Spec}(A/\mathfrak{J}) \to \mathfrak{X}$ of formal affine schemes (where ${}^a\phi$ is the identity homeomorphism from $\mathfrak{X}$ to itself) is also said to be *canonical*. We thus have, according to the above, a *canonical isomorphism*

(10.3.2.1) $$\mathscr{O}_{\mathfrak{X}}/\mathfrak{J}^\Delta \simeq (\widetilde{A}/\widetilde{\mathfrak{J}})|\mathfrak{X}.$$

It is clear (since $\Gamma(\mathfrak{X}, \mathfrak{J}^\Delta) = \mathfrak{J}$) that the map $\mathfrak{J} \to \mathfrak{J}^\Delta$ is *strictly increasing*; according to the above, for $\mathfrak{J} \subset \mathfrak{J}'$, the sheaf $\mathfrak{J}'^\Delta/\mathfrak{J}^\Delta$ is canonically isomorphic to $\widetilde{\mathfrak{J}}'/\widetilde{\mathfrak{J}} = (\mathfrak{J}'/\mathfrak{J})^\sim$.

(10.3.3). The hypotheses and notation being the same as in (10.3.1), we say that a sheaf of ideals $\mathscr{J}$ of $\mathscr{O}_{\mathfrak{X}}$ is a *sheaf of ideals of definition* for $\mathfrak{X}$ (or an *ideal sheaf of definition* for $\mathfrak{X}$) if, for all $x \in \mathfrak{X}$, there exists an open neighbourhood of x of the form $\mathfrak{D}(f)$, where $f \in A$, such that $\mathscr{J}|\mathfrak{D}(f)$ is of the form $\mathfrak{H}^\Delta$, where $\mathfrak{H}$ is an ideal of definition for $A_{\{f\}}$.

Proposition (10.3.4). — *For all $f \in A$, each sheaf of ideals of definition for $\mathfrak{X}$ induces a sheaf of ideals of definition for $\mathfrak{D}(f)$.*

Proof. This follows from (10.3.1.1). □

Proposition (10.3.5). — *If A is an admissible ring, then every sheaf of ideals of definition for $\mathfrak{X} = \mathrm{Spf}(A)$ is of the form $\mathfrak{J}^\Delta$, where $\mathfrak{J}$ is a uniquely determined ideal of definition for A.*

Proof. Let $\mathscr{J}$ be a sheaf of ideals of definition of $\mathfrak{X}$; by hypothesis, and since $\mathfrak{X}$ is quasi-compact, there are finitely many elements $f_i \in A$ such that the $\mathfrak{D}(f_i)$ cover $\mathfrak{X}$ and such that $\mathscr{J}|\mathfrak{D}(f_i) = \mathfrak{H}_i^\Delta$, where $\mathfrak{H}_i$ is an ideal of definition for $A_{\{f_i\}}$. For each i, there exists an open ideal $\mathfrak{K}_i$ of A such that $(\mathfrak{K}_i)_{\{f_i\}} = \mathfrak{H}_i$ (**0**, 7.6.9); let $\mathfrak{K}$ be an ideal of definition for A contained in all the $\mathfrak{K}_i$. The canonical image of $\mathscr{J}/\mathfrak{K}^\Delta$ in the structure sheaf $(A/\mathfrak{K})^\sim$ of $\mathrm{Spec}(A/\mathfrak{K})$ (10.3.2) is thus such that its restriction to $\mathfrak{D}(f_i)$ is equal to the restriction of $(\mathfrak{K}_i/\mathfrak{K})^\sim$; we conclude that this canonical image is a *quasi-coherent* sheaf on $\mathrm{Spec}(A/\mathfrak{K})$, and so is of the form $(\mathfrak{J}/\mathfrak{K})^\sim$, where $\mathfrak{J}$ is an ideal of A containing $\mathfrak{K}$ (1.4.1), whence $\mathscr{J} = \mathfrak{J}^\Delta$ (10.3.2); in addition, since for each i there exists an integer n_i such that $\mathfrak{H}_i^{n_i} \subset \mathfrak{K}_{\{f_i\}}$, we will have, by setting n to be the largest of the n_i, that $(\mathscr{J}/\mathfrak{K}^\Delta)^n = 0$, and, as a result (10.3.2), that $((\mathfrak{J}/\mathfrak{K})^\sim)^n = 0$, whence finally that $(\mathfrak{J}/\mathfrak{K})^n = 0$ (1.3.13), which proves that $\mathfrak{J}$ is an ideal of definition for A (**0**, 7.1.4). □

Proposition (10.3.6). — *Let A be an adic ring, and $\mathfrak{J}$ an ideal of definition for A such that $\mathfrak{J}/\mathfrak{J}^2$ is an $(A/\mathfrak{J})$-module of finite type. For any integer $n > 0$, we then have $(\mathfrak{J}^\Delta)^n = (\mathfrak{J}^n)^\Delta$.*

Proof. For all $f \in A$, we have (since $\mathfrak{J}^n$ is an open ideal)

$$(\Gamma(\mathfrak{D}(f), \mathfrak{J}^\Delta))^n = (\mathfrak{J}_{\{f\}})^n = (\mathfrak{J}^n)_{\{f\}} = \Gamma(\mathfrak{D}(f^n), (\mathfrak{J}^n)^\Delta)$$

by (10.3.1.1) and (**0**, 7.6.12). The result then follows from the fact that $(\mathfrak{J}^\Delta)^n$ is associated to the **I** | 185
presheaf $U \mapsto (\Gamma(U, \mathfrak{J}^\Delta))^n$ (**0**, 4.1.6), since the $\mathfrak{D}(f)$ form a basis for the topology of $\mathfrak{X}$. □

(10.3.7). We say that a family $(\mathscr{J}_\lambda)$ of sheaves of ideals of definition for $\mathfrak{X}$ is a *fundamental system of sheaves of ideals of definition* if each sheaf of ideals of definition for $\mathfrak{X}$ contains one of the $\mathscr{J}_\lambda$; since $\mathscr{J}_\lambda = \mathfrak{J}_\lambda^\Delta$, it is equivalent to say that the $\mathfrak{J}_\lambda$ form a *fundamental system of neighbourhoods of* 0 in A. Let (f_α) be a family of elements of A such that the $\mathfrak{D}(f_\alpha)$ cover $\mathfrak{X}$. If $(\mathscr{J}_\lambda)$ is a filtered decreasing family of sheaves of ideals of $\mathscr{O}_\mathfrak{X}$ such that, for each α, the family $(\mathscr{J}_\lambda|\mathfrak{D}(f_\alpha))$ is a fundamental system of sheaves of ideals of definition for $\mathfrak{D}(f_\alpha)$, then $(\mathscr{J}_\lambda)$ is a fundamental system of sheaves of ideals of definition for $\mathfrak{X}$. Indeed, for each sheaf of ideals of definition $\mathscr{J}$ for $\mathfrak{X}$, there is a finite cover of $\mathfrak{X}$ by $\mathfrak{D}(f_i)$ such that, for each i, $\mathscr{J}_{\lambda_i}|\mathfrak{D}(f_i)$ is a sheaf of ideals of definition for $\mathfrak{D}(f_i)$ that is contained in $\mathscr{J}|\mathfrak{D}(f_i)$. If μ is an index such that $\mathscr{J}_\mu \subset \mathscr{J}_{\lambda_i}$ for all i, then it follows from (10.3.3) that $\mathscr{J}_\mu$ is a sheaf of ideals of definition for $\mathfrak{X}$, evidently contained in $\mathscr{J}$, whence our claim.

10.4. Formal preschemes and morphisms of formal preschemes

(10.4.1). Given a topologically ringed space $\mathfrak{X}$, we say that an open $U \subset \mathfrak{X}$ is a *formal affine open* (resp. a *formal adic affine open*, resp. a *formal Noetherian affine open*) if the topologically ringed space induced on U by $\mathfrak{X}$ is a formal affine scheme (resp. a scheme whose ring is adic, resp. adic and Noetherian).

Definition (10.4.2). — A *formal prescheme* is a topologically ringed space $\mathfrak{X}$ which admits a formal affine open neighbourhood for each point. We say that the formal prescheme $\mathfrak{X}$ is adic (resp. locally Noetherian) if each point of $\mathfrak{X}$ admits a formal adic affine (resp. formal Noetherian affine) open neighbourhood. We say that $\mathfrak{X}$ is Noetherian if it is locally Noetherian and its underlying space is quasi-compact (and hence Noetherian).

Proposition (10.4.3). — *If $\mathfrak{X}$ is a formal prescheme (resp. a locally Noetherian formal prescheme), then the formal affine (resp. Noetherian affine) open sets form a basis for the topology of $\mathfrak{X}$.*

Proof. This follows from Definition (10.4.2) and Proposition (10.1.4) by taking into account that, if A is an adic Noetherian ring, then so too is $A_{\{f\}}$ for all $f \in A$ (**0**, 7.6.11). □

Corollary (10.4.4). — *If $\mathfrak{X}$ is a formal prescheme (resp. a locally Noetherian formal prescheme, resp. a Noetherian formal prescheme), then the topologically ringed space induced on each open set of $\mathfrak{X}$ is also a formal prescheme (resp. a locally Noetherian formal prescheme, resp. a Noetherian formal prescheme).*

Definition (10.4.5). — Given two formal preschemes $\mathfrak{X}$ and $\mathfrak{Y}$, a morphism (of formal preschemes) from $\mathfrak{X}$ to $\mathfrak{Y}$ is a morphism (ψ, θ) of topologically ringed spaces such that, for all $x \in \mathfrak{X}$, $\theta_x^\sharp$ is a local homomorphism $\mathscr{O}_{\psi(x)} \to \mathscr{O}_x$.

It is immediate that the composition of any two morphisms of formal preschemes is again a morphism of formal preschemes; the formal preschemes thus form a *category*, and we denote by $\mathrm{Hom}(\mathfrak{X}, \mathfrak{Y})$ the set of morphisms from a formal prescheme $\mathfrak{X}$ to a formal prescheme $\mathfrak{Y}$.

If U is an open subset of $\mathfrak{X}$, then the canonical injection into $\mathfrak{X}$ of the formal prescheme induced **I** | 186
on U by $\mathfrak{X}$ is a morphism of formal preschemes (and in fact a *monomorphism* of topologically ringed spaces (**0**, 4.1.1)).

Proposition (10.4.6). — *Let $\mathfrak{X}$ be a formal prescheme, and $\mathfrak{S} = \mathrm{Spf}(A)$ a formal affine scheme. There exists a canonical bijective correspondence between the morphisms from the formal prescheme $\mathfrak{X}$ to the formal prescheme $\mathfrak{S}$ and the continuous homomorphisms from the ring A to the topological ring $\Gamma(\mathfrak{X}, \mathscr{O}_{\mathfrak{X}})$.*

Proof. The proof is the same as that of (2.2.4), by replacing "homomorphism" with "continuous homomorphism", "affine open" with "formal affine open", and by using Proposition (10.2.2) instead of Theorem (1.7.3); we leave the details to the reader. □

(10.4.7). Given a formal prescheme $\mathfrak{S}$, we say that the datum of a formal prescheme $\mathfrak{X}$ and a morphism $\phi : \mathfrak{X} \to \mathfrak{S}$ defines a formal prescheme $\mathfrak{X}$ *over* $\mathfrak{S}$ or a *formal $\mathfrak{S}$-prescheme*, ϕ being called the *structure morphism* of the $\mathfrak{S}$-prescheme $\mathfrak{X}$. If $\mathfrak{S} = \mathrm{Spf}(A)$, where A is an admissible ring, then we also say that the formal $\mathfrak{S}$-prescheme $\mathfrak{X}$ is a *formal A-prescheme* or a formal prescheme *over A*. An arbitrary formal prescheme can be considered as a formal prescheme over $\mathbf{Z}$ (equipped with the discrete topology).

If $\mathfrak{X}$ and $\mathfrak{Y}$ are formal $\mathfrak{S}$-preschemes, then we say that a morphism $u : \mathfrak{X} \to \mathfrak{Y}$ is a $\mathfrak{S}$-*morphism* if the diagram

$$\begin{tikzcd} \mathfrak{X} \arrow[rr, "u"] \arrow[dr] & & \mathfrak{Y} \arrow[dl] \\ & \mathfrak{S} & \end{tikzcd}$$

(where the oblique arrows are the structure morphisms) is commutative. With this definition, the formal $\mathfrak{S}$-preschemes (for fixed $\mathfrak{S}$) form a *category*. We denote by $\mathrm{Hom}_{\mathfrak{S}}(\mathfrak{X}, \mathfrak{Y})$ the set of $\mathfrak{S}$-morphisms from a formal $\mathfrak{S}$-prescheme $\mathfrak{X}$ to a formal $\mathfrak{S}$-prescheme $\mathfrak{Y}$. When $\mathfrak{S} = \mathrm{Spf}(A)$, we also say *$A$-morphism* instead of *$\mathfrak{S}$-morphism*.

(10.4.8). Since every affine scheme can be considered as a formal affine scheme (10.1.2), every (usual) prescheme can be considered as a formal prescheme. In addition, it follows from Definition (10.4.5) that, for the *usual* preschemes, the morphisms (resp. S-morphisms) of *formal* preschemes coincide with the morphisms (resp. S-morphisms) defined in §2.

10.5. Sheaves of ideals of definition for formal preschemes

(10.5.1). Let $\mathfrak{X}$ be a formal prescheme; we say that an $\mathscr{O}_{\mathfrak{X}}$-ideal $\mathscr{J}$ is a *sheaf of ideals of definition* (or an *ideal sheaf of definition*) for $\mathfrak{X}$ if every $x \in \mathfrak{X}$ has a formal affine open neighbourhood U such that $\mathscr{J}|U$ is a sheaf of ideals of definition for the formal affine scheme induced on U by $\mathfrak{X}$ (10.3.3); by (10.3.1.1) and Proposition (10.4.3), for each open $V \subset \mathfrak{X}$, $\mathscr{J}|V$ is then a sheaf of ideals of definition for the formal prescheme induced on V by $\mathfrak{X}$.

We say that a family $(\mathscr{J}_\lambda)$ of sheaves of ideals of definition for $\mathfrak{X}$ is a *fundamental system of sheaves* **I** | 187
of ideals of definition if there exists a cover (U_α) of $\mathfrak{X}$ by formal affine open sets such that, for each α, the family of the $\mathscr{J}_\lambda|U_\alpha$ is a fundamental system of sheaves of ideals of definition (10.3.6) for the formal affine scheme induced on U_α by $\mathfrak{X}$. It follows from the last remark of (10.3.7) that, when $\mathfrak{X}$ is a formal affine scheme, this definition coincides with the definition given in (10.3.7). For an open subset V of $\mathfrak{X}$, the restrictions $\mathscr{J}_\lambda|V$ then form a fundamental system of sheaves of ideals of definition for the formal prescheme induced on V, according to (10.3.1.1). If $\mathfrak{X}$ is a *locally Noetherian* formal prescheme, and $\mathscr{J}$ is a sheaf of ideals of definition for $\mathfrak{X}$, then it follows from Proposition (10.3.6) that the powers $\mathscr{J}^n$ form a fundamental system of sheaves of ideals of definition for $\mathfrak{X}$.

(10.5.2). Let $\mathfrak{X}$ be a formal prescheme, and $\mathscr{J}$ a sheaf of ideals of definition for $\mathfrak{X}$. Then the ringed space $(\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{J})$ is a (usual) *prescheme*, which is affine (resp. locally Noetherian, resp. Noetherian) when $\mathfrak{X}$ is a formal affine scheme (resp. a locally Noetherian formal prescheme, resp. a Noetherian formal prescheme); we can reduce to the affine case, and then the proposition has already been proved in (10.3.2). In addition, if $\theta : \mathscr{O}_{\mathfrak{X}} \to \mathscr{O}_{\mathfrak{X}}/\mathscr{J}$ is the canonical homomorphism, then $u = (1_{\mathfrak{X}}, \theta)$ is a *morphism* (said to be *canonical*) of formal preschemes $(\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{J}) \to (\mathfrak{X}, \mathscr{O}_{\mathfrak{X}})$, because, again, this was proved in the affine case (10.3.2), to which it is immediately reduced.

Proposition (10.5.3). — *Let $\mathfrak{X}$ be a formal prescheme, and $(\mathscr{J}_\lambda)$ a fundamental system of sheaves of ideals of definition for $\mathfrak{X}$. Then the sheaf of topological rings $\mathscr{O}_{\mathfrak{X}}$ is the projective limit of the pseudo-discrete sheaves of rings (**0**, 3.8.1) $\mathscr{O}_{\mathfrak{X}}/\mathscr{J}_\lambda$.*

Proof. Since the topology of $\mathfrak{X}$ admits a basis of formal quasi-compact affine open sets (10.4.3), we reduce to the affine case, where the proposition is a consequence of Proposition (10.3.5), (10.3.2), and Definition (10.1.1). □

It is not certain that every formal prescheme admits a sheaf of ideals of definition. However:

Proposition (10.5.4). — *Let $\mathfrak{X}$ be a locally Noetherian formal prescheme. There exists a largest sheaf of ideals of definition $\mathscr{T}$ for $\mathfrak{X}$; this is the unique sheaf of ideals of definition $\mathscr{J}$ such that the prescheme $(\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{J})$ is reduced. If $\mathscr{J}$ is a sheaf of ideals of definition for $\mathfrak{X}$, then $\mathscr{T}$ is the inverse image under $\mathscr{O}_{\mathfrak{X}} \to \mathscr{O}_{\mathfrak{X}}/\mathscr{J}$ of the nilradical of $\mathscr{O}_{\mathfrak{X}}/\mathscr{J}$.*

Proof. Suppose first that $\mathfrak{X} = \mathrm{Spf}(A)$, where A is an adic Noetherian ring. The existence and the properties of $\mathscr{T}$ follow immediately from Propositions (10.3.5) and (5.1.1), taking into account the **Err**$_{\mathrm{II}}$
existence and the properties of the largest ideal of definition for A ((**0**, 7.1.6) and (**0**, 7.1.7)).

To prove the existence and the properties of $\mathscr{T}$ in the general case, it suffices to show that, if $U \supset V$ are two Noetherian formal affine open subsets of $\mathfrak{X}$, then the largest sheaf of ideals of definition $\mathscr{T}_U$ for U induces the largest sheaf of ideals of definition $\mathscr{T}_V$ for V; but as $(V, (\mathscr{O}_{\mathfrak{X}}|V)/(\mathscr{T}_U|V))$ is reduced, this follows from the above. □

We denote by $\mathfrak{X}_{\mathrm{red}}$ the (usual) reduced prescheme $(\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{T})$.

Corollary (10.5.5). — *Let $\mathfrak{X}$ be a locally Noetherian formal prescheme, and $\mathscr{T}$ the largest sheaf of ideals of definition for $\mathfrak{X}$; for each open subset V of $\mathfrak{X}$, $\mathscr{T}|V$ is the largest sheaf of ideals of definition for the formal prescheme induced on V by $\mathfrak{X}$.*

I | 188

Proposition (10.5.6). — *Let $\mathfrak{X}$ and $\mathfrak{Y}$ be formal preschemes, $\mathscr{J}$ (resp. $\mathscr{K}$) be a sheaf of ideals of definition for $\mathfrak{X}$ (resp. $\mathfrak{Y}$), and $f : \mathfrak{X} \to \mathfrak{Y}$ a morphism of formal preschemes.*

(i) *If $f^*(\mathscr{K})\mathscr{O}_{\mathfrak{X}} \subset \mathscr{J}$, then there exists a unique morphism $f' : (\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{J}) \to (\mathfrak{Y}, \mathscr{O}_{\mathfrak{Y}}/\mathscr{K})$ of usual preschemes making the diagram*

(10.5.6.1)
$$\begin{tikzcd}
(\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}) \arrow[r, "f"] & (\mathfrak{Y}, \mathscr{O}_{\mathfrak{Y}}) \\
(\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{J}) \arrow[u] \arrow[r, "f'"'] & (\mathfrak{Y}, \mathscr{O}_{\mathfrak{Y}}/\mathscr{K}) \arrow[u]
\end{tikzcd}$$

commute, where the vertical arrows are the canonical morphisms.

(ii) *Suppose that $\mathfrak{X} = \mathrm{Spf}(A)$ and $\mathfrak{Y} = \mathrm{Spf}(B)$ are formal affine schemes, $\mathscr{J} = \mathfrak{J}^\Delta$ and $\mathscr{K} = \mathfrak{K}^\Delta$, where $\mathfrak{J}$ (resp. $\mathfrak{K}$) is an ideal of definition for A (resp. B), and $f = ({}^a\phi, \widetilde{\phi})$, where $\phi : B \to A$ is a continuous homomorphism; for $f^*(\mathscr{K})\mathscr{O}_{\mathfrak{X}} \subset \mathscr{J}$ to hold, it is necessary and sufficient that $\phi(\mathfrak{K}) \subset \mathfrak{J}$, and, in this case, f' is then the morphism $({}^a\phi', \widetilde{\phi'})$, where $\phi' : B/\mathfrak{K} \to A/\mathfrak{J}$ is the homomorphism induced from ϕ by passing to quotients.*

Proof.

(i) If $f = (\psi, \theta)$, then the hypotheses imply that the image under $\theta^\sharp : \psi^*(\mathscr{O}_\mathfrak{Y}) \to \mathscr{O}_\mathfrak{X}$ of the sheaf of ideals $\psi^*(\mathscr{K})$ of $\psi^*(\mathscr{O}_\mathfrak{Y})$ is contained in $\mathscr{J}$ (**0**, 4.3.5). By passing to quotients, we thus obtain from $\theta^\sharp$ a homomorphism of sheaves of rings

$$\omega : \psi^*(\mathscr{O}_\mathfrak{Y}/\mathscr{K}) = \psi^*(\mathscr{O}_\mathfrak{Y})/\psi^*(\mathscr{K}) \longrightarrow \mathscr{O}_\mathfrak{X}/\mathscr{J};$$

furthermore, since, for all $x \in \mathfrak{X}$, $\theta_x^\sharp$ is a *local* homomorphism, so too is ω_x. The morphism of ringed spaces $(\psi, \omega^\flat)$ is thus (2.2.1) the unique morphism f' of ringed spaces whose existence was claimed.

(ii) The canonical functorial correspondence between morphisms of formal affine schemes and continuous homomorphisms of rings (10.2.2) shows that, in the case considered, the relation $f^*(\mathscr{K})\mathscr{O}_\mathfrak{X} \subset \mathscr{J}$ implies that we have $f' = ({}^a\phi', \widetilde{\phi'})$, where $\phi' : B/\mathfrak{K} \to A/\mathfrak{J}$ is the unique homomorphism making the diagram

(10.5.6.2)
$$\begin{tikzcd} B \arrow[r, "\phi"] \arrow[d] & A \arrow[d] \\ B/\mathfrak{K} \arrow[r, "\phi'"'] & A/\mathfrak{J} \end{tikzcd}$$

commute. The existence of ϕ' thus implies that $\phi(\mathfrak{K}) \subset \mathfrak{J}$. Conversely, if this condition is satisfied, then, denoting by ϕ' the unique homomorphism making the diagram (10.5.6.2) commute and setting $f' = ({}^a\phi', \widetilde{\phi'})$, it is clear that the diagram (10.5.6.1) is commutative; considering the homomorphisms ${}^a\phi^*(\mathscr{O}_\mathfrak{Y}) \to \mathscr{O}_\mathfrak{X}$ and ${}^a\phi'^*(\mathscr{O}_\mathfrak{Y}/\mathscr{K}) \to \mathscr{O}_\mathfrak{X}/\mathscr{J}$ corresponding to f and f' respectively then leads to the fact that this implies the relation $f^*(\mathscr{K})\mathscr{O}_\mathfrak{X} \subset \mathscr{J}$. □

It is clear that the correspondence $f \mapsto f'$ defined above is *functorial*.

10.6. Formal preschemes as inductive limits of preschemes

(10.6.1). Let $\mathfrak{X}$ be a formal prescheme, and $(\mathscr{J}_\lambda)$ a fundamental system of sheaves of ideals of definition for $\mathfrak{X}$; for each λ, let f_λ be the canonical morphism $(\mathfrak{X}, \mathscr{O}_\mathfrak{X}/\mathscr{J}_\lambda) \to \mathfrak{X}$ (10.5.2); for $\mathscr{J}_\mu \subset \mathscr{J}_\lambda$, the canonical morphism $\mathscr{O}_\mathfrak{X}/\mathscr{J}_\mu \to \mathscr{O}_\mathfrak{X}/\mathscr{J}_\lambda$ defines a canonical morphism $f_{\mu\lambda}$: **I** | 189
$(\mathfrak{X}, \mathscr{O}_\mathfrak{X}/\mathscr{J}_\lambda) \to (\mathfrak{X}, \mathscr{O}_\mathfrak{X}/\mathscr{J}_\mu)$ of (usual) preschemes such that $f_\lambda = f_\mu \circ f_{\mu\lambda}$. The preschemes $X_\lambda = (\mathfrak{X}, \mathscr{O}_\mathfrak{X}/\mathscr{J}_\lambda)$ and the morphisms $f_{\mu\lambda}$ thus form (by (10.4.8)) an *inductive system* in the category of formal preschemes.

Proposition (10.6.2). — *With the notation of (10.6.1), the formal prescheme $\mathfrak{X}$ and the morphisms f_λ form an inductive limit (T, I, 1.8) of the system $(X_\lambda, f_{\mu\lambda})$ in the category of formal preschemes.*

Proof. Let $\mathfrak{Y}$ be a formal prescheme, and, for each index λ, let

$$g_\lambda = (\psi_\lambda, \theta_\lambda) : X_\lambda \longrightarrow \mathfrak{Y}$$

be a morphism such that $g_\lambda = g_\mu \circ f_{\mu\lambda}$ for $\mathscr{J}_\mu \subset \mathscr{J}_\lambda$. This latter condition and the definition of the X_λ imply first of all that the ψ_λ are identical to a single continuous map $\psi : \mathfrak{X} \to \mathfrak{Y}$ of the underlying spaces; in addition, the homomorphisms $\theta_\lambda^\sharp : \psi^*(\mathscr{O}_\mathfrak{Y}) \to \mathscr{O}_{X_\lambda} = \mathscr{O}_\mathfrak{X}/\mathscr{J}_\lambda$ form a *projective system* of homomorphisms of sheaves of rings. By passing to the projective limit, there is an induced homomorphism $\omega : \psi^*(\mathscr{O}_\mathfrak{Y}) \to \varprojlim \mathscr{O}_\mathfrak{X}/\mathscr{J}_\lambda = \mathscr{O}_\mathfrak{X}$, and it is clear that the morphism $g = (\psi, \omega^\flat)$ of *ringed spaces* is the *unique* morphism making the diagrams

(10.6.2.1)
$$\begin{tikzcd} X_\lambda \arrow[rr, "g_\lambda"] \arrow[dr, "f_\lambda"'] & & \mathfrak{Y} \\ & \mathfrak{X} \arrow[ur, "g"'] & \end{tikzcd}$$

commutative. It remains to prove that g is a morphism of *formal preschemes*; the question is local on $\mathfrak{X}$ and $\mathfrak{Y}$, so we can assume that $\mathfrak{X} = \mathrm{Spf}(A)$ and $\mathfrak{Y} = \mathrm{Spf}(B)$, with A and B admissible rings, and with $\mathscr{J}_\lambda = \mathfrak{J}_\lambda^\Delta$, where $(\mathfrak{J}_\lambda)$ is a fundamental system of ideals of definition for A (10.3.5); since $A = \varprojlim A/\mathfrak{J}_\lambda$, the existence of a morphism g of formal affine schemes making the diagrams

(10.6.2.1) commute then follows from the bijective correspondence (10.2.2) between morphisms of formal affine schemes and continuous ring homomorphisms, and from the definition of the projective limit. But the uniqueness of g as a morphism of ringed spaces shows that it coincides with the morphism in the beginning of the proof. □

The following proposition establishes, under certain additional conditions, the existence of the inductive limit of a given inductive system of (usual) preschemes in the category of formal preschemes:

Proposition (10.6.3). — *Let $\mathfrak{X}$ be a topological space, and $(\mathscr{O}_i, u_{ji})$ a projective system of sheaves of rings on $\mathfrak{X}$, with $\mathbf{N}$ for its set of indices. Let $\mathscr{J}_i$ be the kernel of $u_{0i} : \mathscr{O}_i \to \mathscr{O}_0$. Suppose that:*

(a) *the ringed space $(\mathfrak{X}, \mathscr{O}_i)$ is a prescheme X_i;*
(b) *for all $x \in \mathfrak{X}$ and all i, there exists an open neighbourhood U_i of x in $\mathfrak{X}$ such that the restriction $\mathscr{J}_i|U_i$ is nilpotent; and* **Err$_{\text{II}}$**
(c) *the homomorphisms u_{ji} are surjective.*

Let $\mathscr{O}_{\mathfrak{X}}$ be the sheaf of topological rings given by the projective limit of the pseudo-discrete sheaves of rings $\mathscr{O}_i$, and let $u_i : \mathscr{O}_{\mathfrak{X}} \to \mathscr{O}_i$ be the canonical homomorphism. Then the topologically ringed space $(\mathfrak{X}, \mathscr{O}_{\mathfrak{X}})$ is a formal prescheme; the homomorphisms u_i are surjective; their kernels $\mathscr{J}^{(i)}$ form a fundamental system of sheaves of ideals of definition for $\mathfrak{X}$, and $\mathscr{J}^{(0)}$ is the projective limit of the sheaves of ideals $\mathscr{J}_i$. **I | 190**

Proof. We first note that, on each stalk, u_{ji} is a surjective homomorphism and *a fortiori* a local homomorphism; thus $v_{ij} = (1_{\mathfrak{X}}, u_{ji})$ is a morphism of preschemes $X_j \to X_i$ ($i \geqslant j$) (2.2.1). Suppose first that each X_i is an affine scheme of ring A_i. There exists a *ring* homomorphism $\phi_{ji} : A_i \to A_j$ such that $u_{ji} = \widetilde{\phi_{ji}}$ (1.7.3); as a result (1.6.3), the sheaf $\mathscr{O}_j$ is a quasi-coherent $\mathscr{O}_i$-module over X_i (for the external law defined by u_{ji}), associated to A_j considered as an A_i-module by means of ϕ_{ji}. For all $f \in A_i$, let $f' = \phi_{ji}(f)$; by hypothesis, the open sets $D(f)$ and $D(f')$ are identical in $\mathfrak{X}$, and the homomorphism from $\Gamma(D(f), \mathscr{O}_i) = (A_i)_f$ to $\Gamma(D(f), \mathscr{O}_j) = (A_j)_{f'}$ corresponding to u_{ji} is exactly $(\phi_{ji})_f$ (1.6.1). But when we consider A_j as an A_i-module, $(A_j)_{f'}$ is the $(A_i)_f$-module $(A_j)_f$, so we also have $u_{ji} = \widetilde{\phi_{ji}}$, where ϕ_{ji} is now considered as a homomorphism of A_i-*modules*. Then, since u_{ji} is surjective, we conclude that ϕ_{ji} is also surjective (1.3.9), and if $\mathfrak{J}_{ji}$ is the kernel of ϕ_{ji}, then the kernel of u_{ji} is a quasi-coherent $\mathscr{O}_i$-module equal to $\widetilde{\mathfrak{J}_{ji}}$. In particular, we have $\mathscr{J}_i = \widetilde{\mathfrak{J}_i}$, where $\mathfrak{J}_i$ is the kernel of $\phi_{0i} : A_i \to A_0$. Hypothesis (b) implies that $\mathscr{J}_i$ is *nilpotent*: indeed, since $\mathfrak{X}$ is quasi-compact, we can cover $\mathfrak{X}$ by a finite number of open sets U_k such that $(\mathscr{J}_i|U_k)^{n_k} = 0$, and, by setting n to be the largest of the n_k, we have $\mathscr{J}_i^n = 0$. We thus conclude that $\mathfrak{J}_i$ is nilpotent (1.3.13). Then the ring $A = \varprojlim A_i$ is admissible (**0**, 7.2.2), the canonical homomorphism $\phi_i : A \to A_i$ is surjective, and its kernel $\mathfrak{J}^{(i)}$ is equal to the projective limit of the $\mathfrak{J}_{ik}$ for $k \geqslant i$; the $\mathfrak{J}^{(i)}$ form a fundamental system of neighbourhoods of 0 in A. The claims of Proposition (10.6.3) follow in this case from (10.1.1) and (10.3.2), with $(\mathfrak{X}, \mathscr{O}_{\mathfrak{X}})$ being $\operatorname{Spf}(A)$.

Again, in this particular case, we note that, if $f = (f_i)$ is an element of the projective limit $A = \varprojlim A_i$, then all the open sets $D(f_i)$ (which are affine open sets in X_i) can be identified with the open subset $\mathfrak{D}(f)$ of $\mathfrak{X}$, and the prescheme induced on $\mathfrak{D}(f)$ by X_i thus being identified with the affine scheme $\operatorname{Spec}((A_i)_{f_i})$.

In the general case, we remark first that, for every quasi-compact open subset U of $\mathfrak{X}$, each of the $\mathscr{J}_i|U$ is nilpotent, as shown by the above reasoning. We will show that, for every $x \in \mathfrak{X}$, there exists an open neighbourhood U of x in $\mathfrak{X}$ which is an *affine open set* for *all* the X_i. Indeed, we take U to be an affine open set for X_0, and observe that $\mathscr{O}_{X_0} = \mathscr{O}_{X_i}/\mathscr{J}_i$. Since, by the above, $\mathscr{J}_i|U$ is nilpotent, U is also an affine open set for each X_i, by Proposition (5.1.9). This being so, for each U satisfying the preceding conditions, the study of the affine case as above shows that $(U, \mathscr{O}_{\mathfrak{X}}|U)$ is a formal prescheme whose $\mathscr{J}^{(i)}|U$ form a fundamental system of sheaves of ideals of definition, and $\mathscr{J}^{(0)}|U$ is the projective limit of the $\mathscr{J}_i|U$; whence the conclusion. □

Corollary (10.6.4). — *Suppose that, for $i \geqslant j$, the kernel of u_{ji} is $\mathscr{J}_i^{j+1}$ and that $\mathscr{J}_1/\mathscr{J}_1^2$ is of finite type over $\mathscr{O}_0 = \mathscr{O}_1/\mathscr{J}_1$. Then $\mathfrak{X}$ is an adic formal prescheme, and if $\mathscr{J}^{(n)}$ is the kernel of $\mathscr{O}_{\mathfrak{X}} \to \mathscr{O}_n$, then $\mathscr{J}^{(n)} = \mathscr{J}^{n+1}$ and $\mathscr{J}/\mathscr{J}^2$ is isomorphic to $\mathscr{J}_1$. If, in addition, X_0 is locally Noetherian (resp. Noetherian), then $\mathfrak{X}$ is locally Noetherian (resp. Noetherian).* **I | 191**

Proof. Since the underlying spaces of $\mathfrak{X}$ and X_0 are the same, the question is local, and we can suppose that all the X_i are affine; taking into account the fact that $\mathscr{J}_{ij} = \widetilde{\mathfrak{J}_{ji}}$ (with the notation of Proposition (10.6.3)), we can immediately reduce the problem to the corresponding claims of Proposition (**0**, 7.2.7) and Corollary (**0**, 7.2.8), by noting that $\mathfrak{J}_1/\mathfrak{J}_1^2$ is then an A_0-module of finite type (1.3.9). □

In particular, *every locally Noetherian formal prescheme* $\mathfrak{X}$ is the inductive limit of a sequence (X_n) of locally Noetherian (usual) preschemes satisfying the conditions of Proposition (10.6.3) and Corollary (10.6.4): it suffices to consider a sheaf of ideals of definition $\mathscr{J}$ for $\mathfrak{X}$ (10.5.4) and to take $X_n = (\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{J}^{n+1})$ ((10.5.1) and Proposition (10.6.2)).

Corollary (10.6.5). — *Let A be an admissible ring. For the formal affine scheme $\mathfrak{X} = \operatorname{Spf}(A)$ to be Noetherian, it is necessary and sufficient for A to be adic and Noetherian.*

Proof. The condition is evidently sufficient. Conversely, suppose that $\mathfrak{X}$ is Noetherian, and let $\mathfrak{J}$ be an ideal of definition for A, and $\mathscr{J} = \mathfrak{J}^\Delta$ the corresponding sheaf of ideals of definition for $\mathfrak{X}$. The (usual) preschemes $X_n = (\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{J}^{n+1})$ are then affine and Noetherian, so the rings $A_n = A/\mathfrak{J}^{n+1}$ are Noetherian (6.1.3), whence we conclude that $\mathfrak{J}/\mathfrak{J}^2$ is an $A/\mathfrak{J}$-module of finite type. Since the $\mathscr{J}^n$ form a fundamental system of sheaves of ideals of definition for $\mathfrak{X}$ (10.5.1), we have $\mathscr{O}_{\mathfrak{X}} = \varprojlim \mathscr{O}_{\mathfrak{X}}/\mathscr{J}^n$ (10.5.3); we thus conclude (10.1.3) that A is topologically isomorphic to $\varprojlim A/\mathfrak{J}^n$, which is adic and Noetherian (**0**, 7.2.8). □

Remark (10.6.6). — With the notation of Proposition (10.6.3), let $\mathscr{F}_i$ be an $\mathscr{O}_i$-module, and suppose we are given, for $i \geqslant j$, a v_{ij}-morphism $\theta_{ji} : \mathscr{F}_i \to \mathscr{F}_j$ such that $\theta_{kj} \circ \theta_{ji} = \theta_{ki}$ for $k \leqslant j \leqslant i$. Since the underlying continuous map of v_{ij} is the identity, θ_{ji} is a homomorphism of sheaves of abelian groups on the space $\mathfrak{X}$; in addition, if $\mathscr{F}$ is the projective limit of the projective system $(\mathscr{F}_i)$ of sheaves of abelian groups, then the fact that the θ_{ji} are v_{ij}-morphisms lets us define an $\mathscr{O}_{\mathfrak{X}}$-module structure on $\mathscr{F}$ by passing to the projective limit; when equipped with this structure, we say that $\mathscr{F}$ is the *projective limit* (with respect to the θ_{ji}) of the system of $\mathscr{O}_i$-modules $(\mathscr{F}_i)$. In the particular case where $v_{ij}^*(\mathscr{F}_i) = \mathscr{F}_j$ and θ_{ji} is the *identity*, we say that $\mathscr{F}$ is the projective limit of a system $(\mathscr{F}_i)$ such that $v_{ij}^*(\mathscr{F}_i) = \mathscr{F}_j$ for $j \leqslant i$ (without mentioning the θ_{ji}).

(10.6.7). Let $\mathfrak{X}$ and $\mathfrak{Y}$ be formal preschemes, $\mathscr{J}$ (resp. $\mathscr{K}$) a sheaf of ideals of definition for $\mathfrak{X}$ (resp. $\mathfrak{Y}$), and $f : \mathfrak{X} \to \mathfrak{Y}$ a morphism such that $f^*(\mathscr{K})\mathscr{O}_{\mathfrak{X}} \subset \mathscr{J}$. We then have, for every integer $n > 0$, that $f^*(\mathscr{K}^n)\mathscr{O}_{\mathfrak{X}} = (f^*(\mathscr{K})\mathscr{O}_{\mathfrak{X}})^n \subset \mathscr{J}^n$; f thus induces (10.5.6) a morphism of (usual) preschemes $f_n : X_n \to Y_n$ by setting $X_n = (\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{J}^{n+1})$ and $Y_n = (\mathfrak{Y}, \mathscr{O}_{\mathfrak{Y}}/\mathscr{K}^{n+1})$, and it immediately follows from the definitions that the diagrams

(10.6.7.1)
$$\begin{tikzcd} X_m \arrow[r, "f_m"] \arrow[d] & Y_m \arrow[d] \\ X_n \arrow[r, "f_n"'] & Y_n \end{tikzcd}$$

commute for $m \leqslant n$; in other words, (f_n) is an *inductive system* of morphisms. **I** | 192

(10.6.8). Conversely, let (X_n) (resp. (Y_n)) be an inductive system of (usual) preschemes satisfying conditions (b) and (c) of Proposition (10.6.3), and let $\mathfrak{X}$ (resp. $\mathfrak{Y}$) be its inductive limit. By definition of the inductive limit, every sequence (f_n) of morphisms $X_n \to Y_n$ forming an inductive system admits an *inductive limit* $f : \mathfrak{X} \to \mathfrak{Y}$, which is the unique morphism of formal preschemes that makes the diagrams

$$\begin{tikzcd} X_n \arrow[r, "f_n"] \arrow[d] & Y_n \arrow[d] \\ \mathfrak{X} \arrow[r, "f"'] & \mathfrak{Y} \end{tikzcd}$$

commute.

Proposition (10.6.9). — *Let $\mathfrak{X}$ and $\mathfrak{Y}$ be locally Noetherian formal preschemes, and $\mathscr{J}$ (resp. $\mathscr{K}$) be a sheaf of ideals of definition for $\mathfrak{X}$ (resp. $\mathfrak{Y}$); the map $f \mapsto (f_n)$ defined in (10.6.7) is a bijection from the set of morphisms $f : \mathfrak{X} \to \mathfrak{Y}$ such that $f^*(\mathscr{K})\mathscr{O}_{\mathfrak{X}} \subset \mathscr{J}$ to the set of sequences (f_n) of morphisms that make the diagrams (10.6.7.1) commute.*

Proof. If f is the inductive limit of this sequence, then it remains to show that $f^*(\mathscr{K})\mathscr{O}_{\mathfrak{X}} \subset \mathscr{J}$. The statement, being local on $\mathfrak{X}$ and $\mathfrak{Y}$, can be reduced to the case where $\mathfrak{X} = \operatorname{Spf}(A)$ and $\mathfrak{Y} = \operatorname{Spf}(B)$ are affine, with A and B adic Noetherian rings, and with $\mathscr{J} = \mathfrak{J}^\Delta$ and $\mathscr{K} = \mathfrak{K}^\Delta$, where $\mathfrak{J}$ (resp. $\mathfrak{K}$) is an ideal of definition for A (resp. B). We then have $X_n = \operatorname{Spec}(A_n)$ and $Y_n = \operatorname{Spec}(B_n)$, with $A_n = A/\mathfrak{J}^{n+1}$ and $B_n = B/\mathfrak{K}^{n+1}$, by Proposition (10.3.6) and (10.3.2); we have $f_n = ({}^a\phi_n, \widetilde{\phi_n})$, where the homomorphisms $\phi_n : B_n \to A_n$ form a projective system, and hence $f = ({}^a\phi, \widetilde{\phi})$, where $\phi = \varprojlim \phi_n$. The commutativity of the diagram (10.6.7.1) for $m = 0$ then gives the condition $\phi_n(\mathfrak{K}/\mathfrak{K}^{n+1}) \subset \mathfrak{J}/\mathfrak{J}^{n+1}$ for all n, so, by passing to the projective limit, we have $\phi(\mathfrak{K}) \subset \mathfrak{J}$, which implies that $f^*(\mathscr{K})\mathscr{O}_{\mathfrak{X}} \subset \mathscr{J}$ (10.5.6, ii). □

Corollary (10.6.10). — *Let $\mathfrak{X}$ and $\mathfrak{Y}$ be locally Noetherian formal preschemes, and $\mathscr{T}$ the largest sheaf of ideals of definition for $\mathfrak{X}$ (10.5.4).*

(i) *For every sheaf of ideals of definition $\mathscr{K}$ for $\mathfrak{Y}$ and every morphism $f : \mathfrak{X} \to \mathfrak{Y}$, we have $f^*(\mathscr{K})\mathscr{O}_{\mathfrak{X}} \subset \mathscr{T}$.*

(ii) *There is a canonical bijective correspondence between $\operatorname{Hom}(\mathfrak{X}, \mathfrak{Y})$ and the set of sequences (f_n) of morphisms making the diagrams (10.6.7.1) commute, where $X_n = (\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{T}^{n+1})$ and $Y_n = (\mathfrak{Y}, \mathscr{O}_{\mathfrak{Y}}/\mathscr{K}^{n+1})$.*

Proof. (ii) follows immediately from (i) and Proposition (10.6.9). To prove (i), we can reduce to the case where $\mathfrak{X} = \operatorname{Spf}(A)$ and $\mathfrak{Y} = \operatorname{Spf}(B)$, with A and B Noetherian, and with $\mathscr{T} = \mathfrak{T}^\Delta$ and $\mathscr{K} = \mathfrak{K}^\Delta$, where $\mathfrak{T}$ is the largest ideal of definition for A and $\mathfrak{K}$ is an ideal of definition for B. Let $f = ({}^a\phi, \widetilde{\phi})$, where $\phi : B \to A$ is a continuous homomorphism; since the elements of $\mathfrak{K}$ are topologically nilpotent (**0**, 7.1.4, ii), so too are those of $\phi(\mathfrak{K})$, and so $\phi(\mathfrak{K}) \subset \mathfrak{T}$, since $\mathfrak{T}$ is the set of topologically nilpotent elements of A (**0**, 7.1.6); hence, by Proposition (10.5.6, ii), we are done. □

Corollary (10.6.11). — *Let $\mathfrak{S}$, $\mathfrak{X}$, $\mathfrak{Y}$ be locally Noetherian formal preschemes, and $f : \mathfrak{X} \to \mathfrak{S}$ and $g : \mathfrak{Y} \to \mathfrak{S}$ the morphisms that make $\mathfrak{X}$ and $\mathfrak{Y}$ formal $\mathfrak{S}$-preschemes. Let $\mathscr{J}$ (resp. $\mathscr{K}$, $\mathscr{L}$) be a sheaf of ideals of definition for $\mathfrak{S}$ (resp. $\mathfrak{X}$, $\mathfrak{Y}$), and suppose that $f^*(\mathscr{J})\mathscr{O}_{\mathfrak{X}} \subset \mathscr{K}$ and $g^*(\mathscr{J})\mathscr{O}_{\mathfrak{Y}} = \mathscr{L}$; set $S_n = (\mathfrak{S}, \mathscr{O}_{\mathfrak{S}}/\mathscr{J}^{n+1})$, $X_n = (\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{K}^{n+1})$, and $Y_n = (\mathfrak{Y}, \mathscr{O}_{\mathfrak{Y}}/\mathscr{L}^{n+1})$. Then there exists a canonical bijective correspondence between $\operatorname{Hom}_{\mathfrak{S}}(\mathfrak{X}, \mathfrak{Y})$ and the set of sequences (u_n) of S_n-morphisms $u_n : X_n \to Y_n$ making the diagrams (10.6.7.1) commute.* **I** | 193

Proof. For each $\mathfrak{S}$-morphism $u : \mathfrak{X} \to \mathfrak{Y}$, we have by definition that $f = g \circ u$, whence

$$u^*(\mathscr{L})\mathscr{O}_{\mathfrak{X}} = u^*(g^*(\mathscr{J})\mathscr{O}_{\mathfrak{Y}})\mathscr{O}_{\mathfrak{X}} = f^*(\mathscr{J})\mathscr{O}_{\mathfrak{X}} \subset \mathscr{K},$$

and the corollary then follows from Proposition (10.6.9). □

We note that, for $m \leqslant n$, the data of a morphism $f_n : X_n \to Y_n$ determines a unique morphism $f_m : X_m \to Y_m$ making the diagram (10.6.7.1) commute, since we immediately see that we can reduce to the affine case; we have thus defined a map $\phi_{mn} : \operatorname{Hom}_{S_n}(X_n, Y_n) \to \operatorname{Hom}_{S_m}(X_m, Y_m)$, and the $\operatorname{Hom}_{S_n}(X_n, Y_n)$ form, with the ϕ_{mn}, a *projective system of sets*; Corollary (10.6.11) then says that there is a canonical bijection

$$\operatorname{Hom}_{\mathfrak{S}}(\mathfrak{X}, \mathfrak{Y}) \simeq \varprojlim_n \operatorname{Hom}_{S_n}(X_n, Y_n).$$

10.7. Products of formal preschemes

(10.7.1). Let $\mathfrak{S}$ be a formal prescheme; formal $\mathfrak{S}$-preschemes form a category, and we can define a notion of a *product* of formal $\mathfrak{S}$-preschemes.

Proposition (10.7.2). — *Let $\mathfrak{X} = \operatorname{Spf}(B)$ and $\mathfrak{Y} = \operatorname{Spf}(C)$ be formal affine schemes over a formal affine scheme $\mathfrak{S} = \operatorname{Spf}(A)$. Let $\mathfrak{Z} = \operatorname{Spf}(B\widehat{\otimes}_A C)$, and let p_1 and p_2 be the $\mathfrak{S}$-morphisms corresponding (10.2.2) to the canonical (continuous) A-homomorphisms $\rho : B \to B\widehat{\otimes}_A C$ and $\sigma : C \to B\widehat{\otimes}_A C$; then $(\mathfrak{Z}, p_1, p_2)$ is a product of the formal affine $\mathfrak{S}$-schemes $\mathfrak{X}$ and $\mathfrak{Y}$.*

Proof. By Proposition (10.4.6), it suffices to check that, if we associate, to each continuous A-homomorphism $\phi : B\widehat{\otimes}_A C \to D$ (where D is an admissible ring which is a topological A-algebra), the pair $(\phi \circ \rho, \phi \circ \sigma)$, then this defines a bijection

$$\operatorname{Hom}_A(B\widehat{\otimes}_A C, D) \simeq \operatorname{Hom}_A(B, D) \times \operatorname{Hom}_A(C, D),$$

which is exactly the universal property of the completed tensor product (**0**, 7.7.6). □

Proposition (10.7.3). — *Given formal $\mathfrak{S}$-preschemes $\mathfrak{X}$ and $\mathfrak{Y}$, their product $\mathfrak{X} \times_{\mathfrak{S}} \mathfrak{Y}$ exists.*

Proof. The proof is similar to that of Theorem (3.2.6), replacing affine schemes (resp. affine open sets) by formal affine schemes (resp. formal affine open sets), and replacing Proposition (3.2.2) by Proposition (10.7.2). □

All the formal properties of the product of preschemes ((3.2.7) and (3.2.8), (3.3.1) through (3.3.12)) hold true without any modification for the product of formal preschemes.

(10.7.4). Let $\mathfrak{S}$, $\mathfrak{X}$, and $\mathfrak{Y}$ be formal preschemes, and let $f : \mathfrak{X} \to \mathfrak{S}$ and $g : \mathfrak{Y} \to \mathfrak{S}$ be morphisms. Suppose that there exist, in $\mathfrak{S}$, $\mathfrak{X}$, and $\mathfrak{Y}$ respectively, three fundamental systems of sheaves of ideals of definition $(\mathscr{J}_\lambda)$, $(\mathscr{K}_\lambda)$, and $(\mathscr{L}_\lambda)$, all having the same set I of indices, and such that $f^*(\mathscr{J}_\lambda)\mathscr{O}_{\mathfrak{X}} \subset \mathscr{K}_\lambda$ and $g^*(\mathscr{J}_\lambda)\mathscr{O}_{\mathfrak{Y}} \subset \mathscr{L}_\lambda$ for all λ. Set $S_\lambda = (\mathfrak{S}, \mathscr{O}_{\mathfrak{S}}/\mathscr{J}_\lambda)$, $X_\lambda = (\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{K}_\lambda)$, and $Y_\lambda = (\mathfrak{Y}, \mathscr{O}_{\mathfrak{Y}}/\mathscr{L}_\lambda)$; for $\mathscr{J}_\mu \subset \mathscr{J}_\lambda$, $\mathscr{K}_\mu \subset \mathscr{K}_\lambda$, and $\mathscr{L}_\mu \subset \mathscr{L}_\lambda$, note that S_λ (resp. X_λ, Y_λ) is a closed subprescheme of S_μ (resp. X_μ, Y_μ) that has the *same* underlying space (10.6.1). Since $S_\lambda \to S_\mu$ is a monomorphism of preschemes, we see that the products $X_\lambda \times_{S_\lambda} Y_\lambda$ and $X_\lambda \times_{S_\mu} Y_\lambda$ are identical (3.2.4), since $X_\lambda \times_{S_\mu} Y_\lambda$ can be identified with a closed subprescheme of $X_\mu \times_{S_\mu} Y_\mu$ that has the *same* underlying space (4.3.1). With this in mind, the product $\mathfrak{X} \times_{\mathfrak{S}} \mathfrak{Y}$ is the *inductive limit* of the usual preschemes $X_\lambda \times_{S_\lambda} Y_\lambda$: indeed, as we see in Proposition (10.6.2), we can reduce to the case where $\mathfrak{S}$, $\mathfrak{X}$, and $\mathfrak{Y}$ are formal affine schemes. Taking into account both Proposition (10.5.6, ii) and the hypotheses on the fundamental systems of sheaves of ideals of definition for $\mathfrak{S}$, $\mathfrak{X}$, and $\mathfrak{Y}$, we immediately see that our claim follows from the definition of the completed tensor product of two algebras (**0**, 7.7.1). **I** | 194

Furthermore, let $\mathfrak{Z}$ be a formal $\mathfrak{S}$-prescheme, $(\mathscr{M}_\lambda)$ a fundamental system of ideals of definition for $\mathfrak{Z}$ having I for its set of indices, and let $u : \mathfrak{Z} \to \mathfrak{X}$ and $v : \mathfrak{Z} \to \mathfrak{Y}$ be $\mathfrak{S}$-morphisms such that $u^*(\mathscr{K}_\lambda)\mathscr{O}_{\mathfrak{Z}} \subset \mathscr{M}_\lambda$ and $v^*(\mathscr{L}_\lambda)\mathscr{O}_{\mathfrak{Z}} \subset \mathscr{M}_\lambda$ for all λ. If we set $Z_\lambda = (\mathfrak{Z}, \mathscr{O}_{\mathfrak{Z}}/\mathscr{M}_\lambda)$, and if $u_\lambda : Z_\lambda \to X_\lambda$ and $v_\lambda : Z_\lambda \to Y_\lambda$ are the S_λ-morphisms corresponding to u and v (10.5.6), then we immediately have that $(u, v)_{\mathfrak{S}}$ is the inductive limit of the S_λ-morphisms $(u_\lambda, v_\lambda)_{S_\lambda}$.

The ideas of this section apply, in particular, to the case where $\mathfrak{S}$, $\mathfrak{X}$, and $\mathfrak{Y}$ are locally Noetherian, taking the systems consisting of the powers of a sheaf of ideals of definition (10.5.1) as the fundamental systems of sheaves of ideals of definition. However, we note that $\mathfrak{X} \times_{\mathfrak{S}} \mathfrak{Y}$ is not necessarily locally Noetherian (see however (10.13.5)).

10.8. Formal completion of a prescheme along a closed subset

(10.8.1). Let X be a *locally Noetherian* (usual) prescheme, and X' a closed subset of the underlying space of X; we denote by Φ the set of *coherent* sheaves of ideals $\mathscr{J}$ of $\mathscr{O}_X$ such that the support of $\mathscr{O}_X/\mathscr{J}$ is X'. The set Φ is nonempty ((5.2.1), (4.1.4), (6.1.1)); we order it by the relation $\supset$.

Lemma (10.8.2). — *The ordered set Φ is filtered; if X is Noetherian, then, for all $\mathscr{J}_0 \in \Phi$, the set of powers $\mathscr{J}_0^n$ $(n > 0)$ is cofinal in Φ.*

Proof. If $\mathscr{J}_1$ and $\mathscr{J}_2$ are in Φ, and if we set $\mathscr{J} = \mathscr{J}_1 \cap \mathscr{J}_2$, then $\mathscr{J}$ is coherent since $\mathscr{O}_X$ is coherent ((6.1.1) and (**0**, 5.3.4)), and we have $\mathscr{J}_x = (\mathscr{J}_1)_x \cap (\mathscr{J}_2)_x$ for all $x \in X$, whence $\mathscr{J}_x = \mathscr{O}_x$ for $x \notin X'$, and $\mathscr{J}_x \neq \mathscr{O}_x$ for $x \in X'$, which proves that $\mathscr{J} \in \Phi$. On the other hand, if X is Noetherian and if $\mathscr{J}_0$ and $\mathscr{J}$ are in Φ, then there exists an integer $n > 0$ such that $\mathscr{J}_0^n(\mathscr{O}_X/\mathscr{J}) = 0$ (9.3.4), which implies that $\mathscr{J}_0^n \subset \mathscr{J}$. □

(10.8.3). Now let $\mathscr{F}$ be a *coherent* $\mathscr{O}_X$-module; for all $\mathscr{J} \in \Phi$, we have that $\mathscr{F} \otimes_{\mathscr{O}_X} (\mathscr{O}_X/\mathscr{J})$ is a coherent $\mathscr{O}_X$-module (9.1.1) with support contained in X', and we will usually identify it with its restriction to X'. When $\mathscr{J}$ varies over Φ, these sheaves form a *projective system* of sheaves of abelian groups.

Definition (10.8.4). — Given a closed subset X' of a locally Noetherian prescheme X and a coherent $\mathscr{O}_X$-module $\mathscr{F}$, we define the *completion of $\mathscr{F}$ along X'*, denoted by $\mathscr{F}_{/X'}$ (or $\widehat{\mathscr{F}}$ when there is little chance of confusion), to be the restriction to X' of the sheaf $\varprojlim_{\Phi}(\mathscr{F} \otimes_{\mathscr{O}_X} (\mathscr{O}_X/\mathscr{J}))$; we say that its sections over X' are the *formal sections of $\mathscr{F}$ along X'*. I | 195

It is immediate that, for every open $U \subset X$, we have $(\mathscr{F}|U)_{/(U\cap X')} = (\mathscr{F}_{/X'})|(U \cap X')$.

By passing to the projective limit, it is clear that $(\mathscr{O}_X)_{/X'}$ is a sheaf of rings, and that $\mathscr{F}_{/X'}$ can be considered as an $(\mathscr{O}_X)_{/X'}$-module. In addition, since there exists a basis for the topology of X' consisting of quasi-compact open sets, we can consider $(\mathscr{O}_X)_{/X'}$ (resp. $\mathscr{F}_{/X'}$) as a *sheaf of topological rings* (resp. of *topological groups*), the projective limit of the *pseudo-discrete* sheaves of rings (resp. groups) $\mathscr{O}_X/\mathscr{J}$ (resp. $\mathscr{F} \otimes_{\mathscr{O}_X} (\mathscr{O}_X/\mathscr{J}) = \mathscr{F}/\mathscr{J}\mathscr{F}$), and, by passing to the projective limit, $\mathscr{F}_{/X'}$ then becomes a *topological $(\mathscr{O}_X)_{/X'}$-module* ((**0**, 3.8.1) and (**0**, 3.8.2)); recall that, for every *quasi-compact* open $U \subset X$, $\Gamma(U \cap X', (\mathscr{O}_X)_{/X'})$ (resp. $\Gamma(U \cap X', \mathscr{F}_{/X'})$) is then the projective limit of the discrete rings (resp. groups) $\Gamma(U, \mathscr{O}_X/\mathscr{J})$ (resp. $\Gamma(U, \mathscr{F}/\mathscr{J}\mathscr{F})$).

Now, if $u : \mathscr{F} \to \mathscr{G}$ is a homomorphism of $\mathscr{O}_X$-modules, then there are canonically induced homomorphisms $u_{\mathscr{J}} : \mathscr{F} \otimes_{\mathscr{O}_X} (\mathscr{O}_X/\mathscr{J}) \to \mathscr{G} \otimes_{\mathscr{O}_X} (\mathscr{O}_X/\mathscr{J})$ for all $\mathscr{J} \in \Phi$, and these homomorphisms form a projective system. By passing to the projective limit and restricting to X', these give a continuous $(\mathscr{O}_X)_{/X'}$-homomorphism $\mathscr{F}_{/X'} \to \mathscr{G}_{/X'}$, denoted $u_{/X'}$ or $\widehat{u}$, and called the *completion* of the homomorphism u along X'. It is clear that, if $v : \mathscr{G} \to \mathscr{H}$ is a second homomorphism of $\mathscr{O}_X$-modules, then we have $(v \circ u)_{/X'} = (v_{/X'}) \circ (u_{/X'})$, hence $\mathscr{F}_{/X'}$ is a *covariant additive functor* in $\mathscr{F}$ from the category of coherent $\mathscr{O}_X$-modules to the category of topological $(\mathscr{O}_X)_{/X'}$-modules.

Proposition (10.8.5). — *The support of $(\mathscr{O}_X)_{/X'}$ is X'; the topologically ringed space $(X', (\mathscr{O}_X)_{/X'})$ is a locally Noetherian formal prescheme, and, if $\mathscr{J} \in \Phi$, then $\mathscr{J}_{/X'}$ is a sheaf of ideals of definition for this formal prescheme. If $X = \operatorname{Spec}(A)$ is an affine scheme with Noetherian ring A, $\mathscr{J} = \widetilde{\mathfrak{J}}$ for some ideal $\mathfrak{J}$ of A, and $X' = V(\mathfrak{J})$, then $(X', (\mathscr{O}_X)_{/X'})$ is canonically identified with* $\operatorname{Spf}(\widehat{A})$, *where $\widehat{A}$ is the separated completion of A with respect to the $\mathfrak{J}$-preadic topology.*

Proof. We can evidently reduce to proving the latter claim. We know (**0**, 7.3.3) that the separated completion $\widehat{\mathfrak{J}}$ of $\mathfrak{J}$ with respect to the $\mathfrak{J}$-preadic topology can be identified with the ideal $\mathfrak{J}\widehat{A}$ of $\widehat{A}$, where $\widehat{A}$ is the Noetherian $\widehat{\mathfrak{J}}$-adic ring such that $\widehat{A}/\widehat{\mathfrak{J}}^n = A/\mathfrak{J}^n$ (**0**, 7.2.6). This latter equation shows that the open prime ideals of $\widehat{A}$ are the ideals $\widehat{\mathfrak{p}} = \mathfrak{p}\widehat{A}$, where $\mathfrak{p}$ is a prime ideal of A containing $\mathfrak{J}$, and that we have $\widehat{\mathfrak{p}} \cap A = \mathfrak{p}$, and hence $\operatorname{Spf}(\widehat{A}) = X'$. Since $\mathscr{O}_X/\mathscr{J}^n = (A/\mathfrak{J}^n)^\sim$, the proposition follows immediately from the definitions. □

We say that the formal prescheme defined above is the *completion of X along X'*, and we denote it by $X_{/X'}$ or $\widehat{X}$ when there is little chance of confusion. When we take $X' = X$, we can set $\mathscr{J} = 0$, and we thus have $X_{/X} = X$.

It is clear that, if U is a subprescheme induced on an open subset of X, then $U_{/(U\cap X')}$ is canonically identified with the formal subprescheme induced on $X_{/X'}$ by the open subset $U \cap X'$ of X'.

Corollary (10.8.6). — *The (usual) prescheme $\widehat{X}_{\text{red}}$ is the unique reduced subprescheme of X having X' as its underlying space (5.2.1). For $\widehat{X}$ to be Noetherian, it is necessary and sufficient for $\widehat{X}_{\text{red}}$ to be Noetherian, and it suffices that X be Noetherian.*

I | 196

Proof. Since $\widehat{X}_{\text{red}}$ is determined locally (10.5.4), we can assume that X is an affine scheme of some Noetherian ring A; with the notation of Proposition (10.8.5), the ideal $\mathfrak{T}$ of topologically nilpotent elements of $\widehat{A}$ is the inverse image under the canonical map $\widehat{A} \to \widehat{A}/\widehat{\mathfrak{J}} = A/\mathfrak{J}$ of the nilradical of $A/\mathfrak{J}$ (**0**, 7.1.3), so $\widehat{A}/\mathfrak{T}$ is isomorphic to the quotient of $A/\mathfrak{J}$ by its nilradical. The first claim then follows from Propositions (10.5.4) and (5.1.1). If $\widehat{X}_{\text{red}}$ is Noetherian, then so too is its underlying space X', and so the $X'_n = \operatorname{Spec}(\mathscr{O}_X/\mathscr{J}^n)$ are Noetherian (6.1.2), and thus so too is $\widehat{X}$ (10.6.4); the converse is immediate, by Proposition (6.1.2). □

(10.8.7). The canonical homomorphisms $\mathscr{O}_X \to \mathscr{O}_X/\mathscr{J}$ (for $\mathscr{J} \in \Phi$) form a projective system, and give, by passing to the projective limit, a homomorphism of sheaves of rings $\theta : \mathscr{O}_X \to \psi_*((\mathscr{O}_X)_{/X'}) = \varprojlim_\Phi(\mathscr{O}_X/\mathscr{J})$, where ψ denotes the canonical injection $X' \to X$ of the underlying spaces. We denote by i (or i_X) the morphism (said to be *canonical*)

$$(\psi,\theta) : X_{/X'} \longrightarrow X$$

of ringed spaces.

By taking tensor products, for every coherent $\mathscr{O}_X$-module $\mathscr{F}$, the canonical homomorphisms $\mathscr{O}_X \to \mathscr{O}_X/\mathscr{J}$ give homomorphisms $\mathscr{F} \to \mathscr{F} \otimes_{\mathscr{O}_X} (\mathscr{O}_X/\mathscr{J})$ of $\mathscr{O}_X$-modules which form a projective system, and thus give, by passing to the projective limit, a canonical functorial homomorphism $\gamma : \mathscr{F} \to \psi_*(\mathscr{F}_{/X'})$ of $\mathscr{O}_X$-modules.

Proposition (10.8.8). —

(i) *The functor $\mathscr{F}_{/X'}$ (in $\mathscr{F}$) is exact.*
(ii) *The functorial homomorphism $\gamma^\sharp : i^*(\mathscr{F}) \to \mathscr{F}_{/X'}$ of $(\mathscr{O}_X)_{/X'}$-modules is an isomorphism.*

Proof.

(i) It suffices to prove that, if $0 \to \mathscr{F}' \to \mathscr{F} \to \mathscr{F}'' \to 0$ is an exact sequence of coherent $\mathscr{O}_X$-modules, and if U is an affine open subset of X with Noetherian ring A, then the sequence

$$0 \longrightarrow \Gamma(U\cap X', \mathscr{F}'_{/X'}) \longrightarrow \Gamma(U\cap X', \mathscr{F}_{/X'}) \longrightarrow \Gamma(U\cap X', \mathscr{F}''_{/X'}) \longrightarrow 0$$

is exact. We have that $\mathscr{F}|U = \widetilde{M}$, $\mathscr{F}'|U = \widetilde{M'}$, and $\mathscr{F}''|U = \widetilde{M''}$, where M, M', and M'' are three A-modules of finite type such that the sequence $0 \to M' \to M \to M'' \to 0$ is exact ((1.5.1) and (1.3.11)); let $\mathscr{J} \in \Phi$, and let $\mathfrak{J}$ be an ideal of A such that $\mathscr{J}|U = \widetilde{\mathfrak{J}}$. We then have

$$\Gamma(U\cap X', \mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{O}_X/\mathscr{J}^n) = M \otimes_A (A/\mathfrak{J}^n)$$

(1.3.12); so, by definition of the projective limit, we have

$$\Gamma(U\cap X', \mathscr{F}_{/X'}) = \varprojlim_n (M \otimes_A (A/\mathfrak{J}^n)) = \widehat{M},$$

the separated completion of M with respect to the $\mathfrak{J}$-preadic topology, and similarly

$$\Gamma(U\cap X', \mathscr{F}'_{/X'}) = \widehat{M'},\ \Gamma(U\cap X', \mathscr{F}''_{/X'}) = \widehat{M''};$$

our claim then follows, since A is Noetherian, and since the functor $\widehat{M}$ in M is exact on the category of A-modules of finite type (**0**, 7.3.3). **I** | 197

(ii) The question is local, so we can assume that we have an exact sequence $\mathscr{O}_X^m \to \mathscr{O}_X^n \to \mathscr{F} \to 0$ (**0**, 5.3.2); since $\gamma^\sharp$ is functorial, and the functors $i^*(\mathscr{F})$ and $\mathscr{F}_{/X'}$ are right exact (by (i) and (**0**, 4.3.1)), we have the commutative diagram

(10.8.8.1)
$$\begin{tikzcd} i^*(\mathscr{O}_X^m) \arrow[r] \arrow[d, "\gamma^\sharp"'] & i^*(\mathscr{O}_X^n) \arrow[r] \arrow[d, "\gamma^\sharp"'] & i^*(\mathscr{F}) \arrow[r] \arrow[d, "\gamma^\sharp"'] & 0 \\ (\mathscr{O}_X^m)_{/X'} \arrow[r] & (\mathscr{O}_X^n)_{/X'} \arrow[r] & \mathscr{F}_{/X'} \arrow[r] & 0 \end{tikzcd}$$

whose rows are exact. Furthermore, the functors $i^*(\mathscr{F})$ and $\mathscr{F}_{/X'}$ commute with finite direct sums ((**0**, 3.2.6) and (**0**, 4.3.2)), and we thus reduce to proving our claim for $\mathscr{F} = \mathscr{O}_X$. We have $i^*(\mathscr{O}_X) = (\mathscr{O}_X)_{/X'} = \mathscr{O}_{\widehat{X}}$ (**0**, 4.3.4), and that $\gamma^\sharp$ is a homomorphism of $\mathscr{O}_{\widehat{X}}$*-modules*; so it suffices to check that $\gamma^\sharp$ sends the unit section of $\mathscr{O}_{\widehat{X}}$ over an open subset of X' to itself, which is immediate, and shows, in this case, that $\gamma^\sharp$ is the identity.

□

Corollary (10.8.9). — *The morphism $i : X_{/X'} \to X$ of ringed spaces is flat.*

Proof. This follows from (**0**, 6.7.3) and Proposition (10.8.8, i). □

Corollary (10.8.10). — *If $\mathscr{F}$ and $\mathscr{G}$ are coherent $\mathscr{O}_X$-modules, then there exist canonical functorial (in $\mathscr{F}$ and $\mathscr{G}$) isomorphisms*

(10.8.10.1)
$$(\mathscr{F}_{/X'}) \otimes_{(\mathscr{O}_X)_{/X'}} (\mathscr{G}_{/X'}) \simeq (\mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{G})_{/X'},$$

(10.8.10.2)
$$(\mathscr{H}om_{\mathscr{O}_X}(\mathscr{F}, \mathscr{G}))_{/X'} \simeq \mathscr{H}om_{(\mathscr{O}_X)_{/X'}}(\mathscr{F}_{/X'}, \mathscr{G}_{/X'}).$$

Proof. This follows from the canonical identification of $i^*(\mathscr{F})$ with $\mathscr{F}_{/X'}$; the existence of the first isomorphism is then a result which holds for all morphisms of ringed spaces (**0**, 4.3.3.1), and the second is a result which holds for all flat morphisms (**0**, 6.7.6), by Corollary (10.8.9). □

Proposition (10.8.11). — *For every coherent $\mathscr{O}_X$-module $\mathscr{F}$, the kernel of the canonical homomorphism $\Gamma(X, \mathscr{F}) \to \Gamma(X', \mathscr{F}_{/X'})$ induced by $\mathscr{F} \to \mathscr{F}_{/X'}$ consists of the sections that vanish in some neighbourhood of X'.*

Proof. It follows from the definition of $\mathscr{F}_{/X'}$ that the canonical image of such a section is zero. Conversely, if $s \in \Gamma(X, \mathscr{F})$ has a zero image in $\Gamma(X', \mathscr{F}_{/X'})$, then it suffices to see that every $x \in X'$ admits a neighbourhood in X in which s is zero, and we can thus reduce to the case where $X = \operatorname{Spec}(A)$ is affine, A Noetherian, $X' = V(\mathfrak{J})$ for some ideal $\mathfrak{J}$ of A, and $\mathscr{F} = \widetilde{M}$ for some A-module M of finite type. Then $\Gamma(X', \mathscr{F}_{/X'})$ is the separated completion $\widehat{M}$ of M for the $\mathfrak{J}$-preadic topology, and the homomorphism $\Gamma(X, \mathscr{F}) \to \Gamma(X', \mathscr{F}_{/X'})$ is the canonical homomorphism $M \to \widehat{M}$. We know (**0**, 7.3.7) that the kernel of this homomorphism is the set of the $z \in M$ killed by an element of $1 + \mathfrak{J}$. So we have $(1 + f)s = 0$ for some $f \in \mathfrak{J}$; for every $x \in X'$ we have $(1_x + f_x)s_x = 0$, and, since $1_x + f_x$ is invertible in $\mathscr{O}_x$ ($\mathfrak{J}_x\mathscr{O}_x$ being contained in the maximal ideal of $\mathscr{O}_x$), we have $s_x = 0$, which proves the proposition. □

Corollary (10.8.12). — *The support of $\mathscr{F}_{/X'}$ is equal to* $\operatorname{Supp}(\mathscr{F}) \cap X'$.

Proof. It is clear that $\mathscr{F}_{/X'}$ is an $(\mathscr{O}_X)_{/X'}$-module of finite type ((10.8.8, ii) and (**0**, 5.2.4)), so its support is closed (**0**, 5.2.2) and evidently contained in $\operatorname{Supp}(\mathscr{F}) \cap X'$. To show that it is equal to the latter set, we immediately reduce to proving that the equation $\Gamma(X', \mathscr{F}_{/X'}) = 0$ implies that $\operatorname{Supp}(\mathscr{F}) \cap X' = \varnothing$; this follows from Proposition (10.8.11) and Theorem (1.4.1). □ **I** | 198

Corollary (10.8.13). — *Let $u : \mathscr{F} \to \mathscr{G}$ be a homomorphism of coherent $\mathscr{O}_X$-modules. For $u_{/X'} : \mathscr{F}_{/X'} \to \mathscr{G}_{/X'}$ to be zero, it is necessary and sufficient for u to be zero on a neighbourhood of X'.*

Proof. By Proposition (10.8.8, ii), $u_{/X'}$ can be identified with $i^*(u)$, so, if we consider u as a section over X of the sheaf $\mathscr{H} = \mathscr{H}om_{\mathscr{O}_X}(\mathscr{F}, \mathscr{G})$, then $u_{/X'}$ is the section over X' of $i^*(\mathscr{H}) = \mathscr{H}_{/X'}$ to which it canonically corresponds ((10.8.10.2) and (**0**, 4.4.6)). It thus suffices to apply Proposition (10.8.11) to the coherent $\mathscr{O}_X$-module $\mathscr{H}$. □

Corollary (10.8.14). — *Let $u : \mathscr{F} \to \mathscr{G}$ be a homomorphism of coherent $\mathscr{O}_X$-modules. For $u_{/X'}$ to be a monomorphism (resp. an epimorphism), it is necessary and sufficient for u to be a monomorphism (resp. an epimorphism) on a neighbourhood of X'.*

Proof. Let $\mathscr{P}$ and $\mathscr{N}$ be the cokernel and kernel (respectively) of u, so that we have the exact sequence $0 \to \mathscr{N} \xrightarrow{v} \mathscr{F} \xrightarrow{u} \mathscr{G} \xrightarrow{w} \mathscr{P} \to 0$, hence (10.8.8, i) the exact sequence

$$0 \longrightarrow \mathscr{N}_{/X'} \xrightarrow{v_{/X'}} \mathscr{F}_{/X'} \xrightarrow{u_{/X'}} \mathscr{G}_{/X'} \xrightarrow{w_{/X'}} \mathscr{P}_{/X'} \longrightarrow 0.$$

If $u_{/X'}$ is a monomorphism (resp. an epimorphism), then we have $v_{/X'} = 0$ (resp. $w_{/X'} = 0$), so there exists a neighbourhood of X' on which $v = 0$ (resp. $w = 0$) by Corollary (10.8.13). □

10.9. Extension of morphisms to completions

(10.9.1). Let X and Y be locally Noetherian (usual) preschemes, $f : X \to Y$ a morphism, and X' (resp. Y') a closed subset of the underlying space X (resp. Y) such that $f(X') \subset Y'$. Let $\mathscr{J}$ (resp. $\mathscr{K}$) be a sheaf of ideals of $\mathscr{O}_X$ (resp. $\mathscr{O}_Y$) such that the support of $\mathscr{O}_X/\mathscr{J}$ (resp. $\mathscr{O}_Y/\mathscr{K}$) is X' (resp. Y') and $f^*(\mathscr{K})\mathscr{O}_X \subset \mathscr{J}$; we note that there always exist such sheaves of ideals, since, for example, we can take $\mathscr{J}$ to be the largest sheaf of ideals of $\mathscr{O}_X$ defining a subprescheme of X with underlying space X' (5.2.1), and the hypothesis $f(X') \subset Y'$ implies that $f^*(\mathscr{K})\mathscr{O}_X \subset \mathscr{J}$ (5.2.4). For every integer $n > 0$ we have $f^*(\mathscr{K}^n)\mathscr{O}_X \subset \mathscr{J}^n$ (**0**, 4.3.5); as a result (4.4.6), if we set $X'_n = (X', \mathscr{O}_X/\mathscr{J}^{n+1})$ and $Y'_n = (Y', \mathscr{O}_Y/\mathscr{K}^{n+1})$, then f induces a morphism $f_n : X'_n \to Y'_n$, and it is immediate that the f_n form an inductive system. We denote its inductive limit (10.6.8) by $\widehat{f} : X_{/X'} \to Y_{/Y'}$, and we say (by abuse of language) that $\widehat{f}$ is the *extension of f to the completions of X and Y along X' and Y'*. It can be checked immediately that this morphism does not depend on the choice of sheaves of ideals $\mathscr{J}$ and $\mathscr{K}$ satisfying the above conditions. It suffices to consider the case where X and Y are Noetherian affine schemes with rings A and B (respectively); then $\mathscr{J} = \widetilde{\mathfrak{J}}$ and $\mathscr{K} = \widetilde{\mathfrak{K}}$, where $\mathfrak{J}$ (resp. $\mathfrak{K}$) is an ideal of A (resp. B), f corresponds to a ring homomorphism $\phi : B \to A$ such that $\phi(\mathfrak{K}) \subset \mathfrak{J}$ ((4.4.6) and (1.7.4)); *$\widehat{f}$ is then the morphism corresponding* (10.2.2) *to the continuous homomorphism $\widehat{\phi} : \widehat{B} \to \widehat{A}$*, where $\widehat{A}$ (resp. $\widehat{B}$) is the separated completion of A (resp. B) with respect to the $\mathfrak{J}$-preadic (resp. $\mathfrak{K}$-preadic) topology (10.6.8); we know that, if we replace $\mathscr{J}$ by another sheaf of ideals $\mathscr{J}' = \widetilde{\mathfrak{J}'}$ **I** | 199
such that the support of $\mathscr{O}_X/\mathscr{J}'$ is X', then the $\mathfrak{J}$-preadic and $\mathfrak{J}'$-preadic topologies on A are the same (10.8.2).

We note that, by definition, the continuous map $X' \to Y'$ of the underlying spaces of $X_{/X'}$ and $Y_{/Y'}$ corresponding to $\widehat{f}$ is exactly the restriction to X' of f.

(10.9.2). It follows immediately from the above definition that the diagram of morphisms of ringed spaces

$$\begin{tikzcd} \widehat{X} \arrow[r, "\widehat{f}"] \arrow[d, "i_X"'] & \widehat{Y} \arrow[d, "i_Y"] \\ X \arrow[r, "f"'] & Y \end{tikzcd}$$

commutes, with the vertical arrows being the canonical morphisms (10.8.7).

(10.9.3). Let Z be a third prescheme, $g : Y \to Z$ a morphism, and Z' a closed subset of Z such that $g(Y') \subset Z'$. If $\widehat{g}$ denotes the completion of the morphism g along Y' and Z', then it immediately follows from (10.9.1) that we have $(g \circ f)^\wedge = \widehat{g} \circ \widehat{f}$.

Proposition (10.9.4). — *Let X and Y be locally Noetherian S-preschemes, with Y of finite type over S. Let f and g be S-morphisms from X to Y such that $f(X') \subset Y'$ and $g(X') \subset Y'$. For $\widehat{f} = \widehat{g}$ to hold, it is necessary and sufficient for f and g to coincide on a neighbourhood of X'.*

Proof. The condition is evidently sufficient (even without the finiteness hypothesis on Y). To see that it is necessary, we remark first that the hypothesis $\widehat{f} = \widehat{g}$ implies that $f(x) = g(x)$ for all $x \in X'$. Also, since the question is local, we can assume that X and Y are affine open neighbourhoods of x and $y = f(x) = g(x)$ respectively (with Noetherian rings), that S is affine, and that $\Gamma(Y, \mathscr{O}_Y)$ is a $\Gamma(S, \mathscr{O}_S)$-algebra of finite type (6.3.3). Then f and g correspond to $\Gamma(S, \mathscr{O}_S)$-homomorphisms ρ and

σ (respectively) from $\Gamma(Y, \mathscr{O}_Y)$ to $\Gamma(X, \mathscr{O}_X)$ (1.7.3), and, by hypothesis, the extensions by continuity of these homomorphisms to the separated completion of $\Gamma(Y, \mathscr{O}_Y)$ are the same. We conclude from Proposition (10.8.11) that, for every section $s \in \Gamma(Y, \mathscr{O}_Y)$, the sections $\rho(s)$ and $\sigma(s)$ coincide on a neighbourhood (depending on s) of X'; since $\Gamma(Y, \mathscr{O}_Y)$ is an algebra of finite type over $\Gamma(S, \mathscr{O}_S)$, we have that there exists a neighbourhood V of X' such that $\rho(s)$ and $\sigma(s)$ coincide on V for *every* section $s \in \Gamma(Y, \mathscr{O}_Y)$. If $h \in \Gamma(X, \mathscr{O}_X)$ is such that $D(h)$ is a neighbourhood of x contained in V, then we conclude from the above and from Theorem (1.4.1, d) that f and g coincide on $D(h)$. □

Proposition (10.9.5). — *Under the hypotheses of (10.9.1), for every coherent $\mathscr{O}_Y$-module $\mathscr{G}$, there exists a canonical functorial isomorphism of $(\mathscr{O}_X)_{/X'}$-modules*

$$(f^*(\mathscr{G}))_{/X'} \simeq \widehat{f}^*(\mathscr{G}_{/Y'}).$$

Proof. If we canonically identify $(f^*(\mathscr{G}))_{/X'}$ with $i_X^*(f^*(\mathscr{G}))$, and $\widehat{f}^*(\mathscr{G}_{/Y'})$ with $\widehat{f}^*(i_Y^*(\mathscr{G}))$ (10.8.8), then the proposition follows immediately from the commutativity of the diagram in (10.9.2). □

(10.9.6). Now let $\mathscr{F}$ be a coherent $\mathscr{O}_X$-module, and let $\mathscr{G}$ be a coherent $\mathscr{O}_Y$-module. If $u : \mathscr{G} \to \mathscr{F}$ is an f-morphism, then it corresponds to an $\mathscr{O}_X$-homomorphism $u^\sharp : f^*(\mathscr{G}) \to \mathscr{F}$, thus, by completion, to a continuous $(\mathscr{O}_X)_{/X'}$-homomorphism $(u^\sharp)_{/X'} : (f^*(\mathscr{G}))_{/X'} \to \mathscr{F}_{/X'}$, and, by Proposition (10.9.5), there exists a unique $\widehat{f}$-morphism $v : \mathscr{G}_{/Y'} \to \mathscr{F}_{/X'}$ such that $v^\sharp = (u^\sharp)_{/X'}$. If we consider the triples $(\mathscr{F}, X, X')$ ($\mathscr{F}$ being a coherent $\mathscr{O}_X$-module, and X' a closed subset of X) as a *category*, with the morphisms $(\mathscr{F}, X, X') \to (\mathscr{G}, Y, Y')$ consisting of a morphism of preschemes $f : X \to Y$ such that $f(X') \subset Y'$ and an f-morphism $u : \mathscr{G} \to \mathscr{F}$, then we can say that $(X_{/X'}, \mathscr{F}_{/X'})$ is a *functor* in $(\mathscr{F}, X, X')$ with values in the category of pairs $(\mathfrak{Z}, \mathscr{H})$ consisting of a locally Noetherian formal prescheme $\mathfrak{Z}$ and an $\mathscr{O}_\mathfrak{Z}$-module $\mathscr{H}$, with the morphisms of the latter category being the pairs consisting of a morphism g of formal preschemes and a g-morphism. I | 200

Proposition (10.9.7). — *Let S, X, and Y be locally Noetherian preschemes, $g : X \to S$ and $h : Y \to S$ morphisms, S' a closed subset of S, and X' (resp. Y') a closed subset of X (resp. Y) such that $g(X') \subset S'$ (resp. $h(Y') \subset S'$); let $Z = X \times_S Y$; suppose that Z is locally Noetherian, and let $Z' = p^{-1}(X') \cap q^{-1}(Y')$, where p and q are the projections of $X \times_S Y$. With these conditions, the completion $Z_{/Z'}$ can be identified with the product $(X_{/X'}) \times_{S_{/S'}} (Y_{/Y'})$ of formal $S_{/S'}$-preschemes, where the structure morphisms are identified with $\widehat{g}$ and $\widehat{h}$, and the projections with $\widehat{p}$ and $\widehat{q}$.*

Proof. It is immediate that the question is local for S, X, and Y, and we thus reduce to the case where $S = \operatorname{Spec}(A)$, $X = \operatorname{Spec}(B)$, $Y = \operatorname{Spec}(C)$, $S' = V(\mathfrak{J})$, $X' = V(\mathfrak{K})$, and $Y' = V(\mathfrak{L})$, with $\mathfrak{J}$, $\mathfrak{K}$, and $\mathfrak{L}$ ideals such that $\phi(\mathfrak{J}) \subset \mathfrak{K}$ and $\psi(\mathfrak{J}) \subset \mathfrak{L}$, where we denote by ϕ and ψ the homomorphisms $A \to B$ and $A \to C$ which correspond to g and h (respectively). We know that $Z = \operatorname{Spec}(B \otimes_A C)$ and that $Z' = V(\mathfrak{M})$, where $\mathfrak{M}$ is the ideal $\operatorname{Im}(\mathfrak{K} \otimes_A C) + \operatorname{Im}(B \otimes_A \mathfrak{L})$. The conclusion follows (10.7.2) from the fact that the completed tensor product $(\widehat{B} \otimes_{\widehat{A}} \widehat{C})^\wedge$ (where $\widehat{A}$, $\widehat{B}$, and $\widehat{C}$ are, respectively, the separated completions of A, B, and C with respect to the $\mathfrak{J}$-, $\mathfrak{K}$-, and $\mathfrak{L}$-preadic topologies) is the separated completion of the tensor product $B \otimes_A C$ with respect to the $\mathfrak{M}$-preadic topology (**0**, 7.7.2). □

In addition, we note that, if T is a locally Noetherian S-prescheme, $u : T \to X$ and $v : T \to Y$ both S-morphisms, and T' a closed subset of T such that $u(T') \subset X'$ and $v(T') \subset Y'$, then the extension to the completion $((u, v)_S)^\wedge$ can be identified with $(\widehat{u}, \widehat{v})_{S_{/S'}}$.

Corollary (10.9.8). — *Let X and Y be locally Noetherian S-preschemes such that $X \times_S Y$ is locally Noetherian; let S' be a closed subset of S, and X' (resp. Y') a closed subset of X (resp. Y) whose image in S is contained in S'. For every S-morphism $f : X \to Y$ such that $f(X') \subset Y'$, the graph morphism $\Gamma_{\widehat{f}}$ can be identified with the extension $(\Gamma_f)^\wedge$ of the graph morphism of f.*

Corollary (10.9.9). — *Let X and Y be locally Noetherian preschemes, $f : X \to Y$ a morphism, Y' a closed subset of Y, and $X' = f^{-1}(Y')$. Then the formal prescheme $X_{/X'}$ can be identified, by the commutative* *diagram*

$$\begin{tikzcd} X & X_{/X'} \arrow[l] \arrow[d, "\widehat{f}"] \\ Y \arrow[from=u, "f"'] & Y_{/Y'} \arrow[l] \end{tikzcd}$$

with the product $X \times_Y (Y_{/Y'})$ of formal preschemes.

Proof. It suffices to apply Proposition (10.9.7), replacing S and S' by Y, and X and X' by X. □

Remark (10.9.10). — If X is the sum $X_1 \sqcup X_2$ (3.1), X' the union $X'_1 \cup X'_2$, where X'_i is a closed subset of X_i ($i = 1, 2$), then we have $X_{/X'} = X_{1/X'_1} \sqcup X_{2/X'_2}$. I | 201

10.10. Application to coherent sheaves on formal affine schemes

(10.10.1). In this paragraph, A denotes an *adic Noetherian ring*, and $\mathfrak{J}$ an ideal of definition for A. Let $X = \operatorname{Spec}(A)$, and $\mathfrak{X} = \operatorname{Spf}(A)$, which can be identified with the closed subset $V(\mathfrak{J})$ of X (10.1.2). In addition, Definitions (10.1.2) and (10.8.4) show that the *formal affine scheme* $\mathfrak{X}$ is identical to the completion $X_{/\mathfrak{X}}$ of the affine scheme X along the closed subset $\mathfrak{X}$ of its underlying space. To every coherent $\mathscr{O}_X$-module $\mathscr{F}$ corresponds an $\mathscr{O}_{\mathfrak{X}}$-module of finite type $\mathscr{F}_{/\mathfrak{X}}$, which is a sheaf of topological modules over the sheaf of topological rings $\mathscr{O}_{\mathfrak{X}}$. Every coherent $\mathscr{O}_X$-module $\mathscr{F}$ is of the form $\widetilde{M}$, where M is an A-module of finite type (1.5.1); we set $(\widetilde{M})_{/\mathfrak{X}} = M^{\Delta}$. In addition, if $u : M \to N$ is an A-homomorphism of A-modules of finite type, then it corresponds to a homomorphism $\widetilde{u} : \widetilde{M} \to \widetilde{N}$, and, as a result, to a continuous homomorphism $\widetilde{u}_{/\mathfrak{X}} : (\widetilde{M})_{/\mathfrak{X}} \to (\widetilde{N})_{/\mathfrak{X}}$, which we denote by u^{Δ}. It is immediate that $(v \circ u)^{\Delta} = v^{\Delta} \circ u^{\Delta}$; we have thus defined a *covariant additive functor* M^{Δ} from the category of A-modules of finite type to the category of $\mathscr{O}_{\mathfrak{X}}$-modules of finite type. When A is a *discrete* ring, we have $M^{\Delta} = \widetilde{M}$.

Proposition (10.10.2). —

(i) *M^{Δ} is an exact functor in M, and there exists a canonical functorial isomorphism of A-modules $\Gamma(\mathfrak{X}, M^{\Delta}) \simeq M$.*

(ii) *If M and N are A-modules of finite type, then there exist canonical functorial isomorphisms*

(10.10.2.1) $$(M \otimes_A N)^{\Delta} \simeq M^{\Delta} \otimes_{\mathscr{O}_{\mathfrak{X}}} N^{\Delta},$$

(10.10.2.2) $$(\operatorname{Hom}_A(M, N))^{\Delta} \simeq \mathscr{H}\!om_{\mathscr{O}_{\mathfrak{X}}}(M^{\Delta}, N^{\Delta}).$$

(iii) *The map $u \mapsto u^{\Delta}$ is a functorial isomorphism*

(10.10.2.3) $$\operatorname{Hom}_A(M, N) \simeq \operatorname{Hom}_{\mathscr{O}_{\mathfrak{X}}}(M^{\Delta}, N^{\Delta}).$$

Proof. The exactness of M^{Δ} follows from the exactness of the functors $\widetilde{M}$ (1.3.5) and $\mathscr{F}_{/\mathfrak{X}}$ (10.8.8). By definition, $\Gamma(\mathfrak{X}, M^{\Delta})$ is the separated completion of the A-module $\Gamma(X, \widetilde{M}) = M$ with respect to the $\mathfrak{J}$-preadic topology; but, since A is complete and M is of finite type, we know (**0**, 7.3.6) that M is separated and complete, which proves (i). The isomorphism (10.10.2.1) (resp. (10.10.2.2)) comes from the composition of the isomorphisms (1.3.12, i) and (10.8.10.1) (resp. (1.3.12, ii) and (10.8.10.2)). Finally, since $\operatorname{Hom}_A(M, N)$ is an A-module of finite type, we can apply (i), which identifies $\Gamma(\mathfrak{X}, (\operatorname{Hom}_A(M, N))^{\Delta})$ with $\operatorname{Hom}_A(M, N)$, and we can use (10.10.2.2), which proves that the homomorphism (10.10.2.3) is an isomorphism. □

We deduce from Proposition (10.10.2) a series of results analogous to those of Theorem (1.3.7) and Corollary (1.3.12), whose formulation we leave to the reader.

We note that the exactness property of M^{Δ}, applied to the exact sequence $0 \to \mathfrak{J} \to A \to A/\mathfrak{J} \to 0$, shows that the sheaf of ideals of $\mathscr{O}_{\mathfrak{X}}$ denoted here by $\mathfrak{J}^{\Delta}$ coincides with the one denoted also by $\mathfrak{J}^{\Delta}$ in (10.3.1), by (10.3.2). I | 202

Proposition (10.10.3). — *Under the hypotheses of (10.10.1), $\mathscr{O}_{\mathfrak{X}}$ is a coherent sheaf of rings.*

Proof. If $f \in A$, then we know that $A_{\{f\}}$ is an adic Noetherian ring (**0**, 7.6.11), and, since the question is local, we reduce (10.1.4) to proving that the kernel of the homomorphism $v : \mathscr{O}_{\mathfrak{X}}^n \to \mathscr{O}_{\mathfrak{X}}$ is an $\mathscr{O}_{\mathfrak{X}}$-module of finite type. We then have $v = u^{\Delta}$, where u is an A-homomorphism $A^n \to A$ (10.10.2); since A is Noetherian, the kernel of u is of finite type, or, equivalently, we have a homomorphism $A^m \xrightarrow{w} A^n$ such that the sequence $A^m \xrightarrow{w} A^n \xrightarrow{u} A$ is exact. We conclude (10.10.2) that the sequence $\mathscr{O}_{\mathfrak{X}}^m \xrightarrow{w^{\Delta}} \mathscr{O}_{\mathfrak{X}}^n \xrightarrow{v} \mathscr{O}_{\mathfrak{X}}$ is exact, which proves that the kernel of v is of finite type. □

(10.10.4). With the above notation, set $A_n = A/\mathfrak{J}^{n+1}$, and let X_n be the affine scheme $\operatorname{Spec}(A_n) = (\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{J}^{n+1})$, with $\mathscr{J} = \mathfrak{J}^{\Delta}$ the sheaf of ideals of definition for $\mathscr{O}_{\mathfrak{X}}$ corresponding to the ideal $\mathfrak{J}$. Let u_{mn} be the morphism of preschemes $X_m \to X_n$ corresponding to the canonical homomorphism $A_n \to A_m$ for $m \leqslant n$; the formal scheme $\mathfrak{X}$ is the inductive limit of the X_n with respect to the u_{mn} (10.6.3).

Proposition (10.10.5). — *Under the hypothesis of (10.10.1), let $\mathscr{F}$ be an $\mathscr{O}_{\mathfrak{X}}$-module. The following conditions are equivalent:*

(a) *$\mathscr{F}$ is a coherent $\mathscr{O}_{\mathfrak{X}}$-module;*
(b) *$\mathscr{F}$ is isomorphic to the projective limit (10.6.6) of a sequence $(\mathscr{F}_n)$ of coherent $\mathscr{O}_{X_n}$-modules such that $u_{mn}^*(\mathscr{F}_n) = \mathscr{F}_m$; and*
(c) *there exists an A-module M of finite type (determined up to canonical isomorphism by Proposition (10.10.2, i)) such that $\mathscr{F}$ is isomorphic to M^{Δ}.*

Proof. We first show that (b) implies (c). We have $\mathscr{F}_n = \widetilde{M_n}$, where M_n is an A_n-module of finite type, and the hypotheses imply that $M_m = M_n \otimes_{A_n} A_m$ for $m \leqslant n$ (1.6.5); the M_n thus form a projective system for the canonical di-homomorphisms $M_n \to M_m$ ($m \leqslant n$), and it follows immediately from the definition of the A_n that this projective system satisfies the conditions of (**0**, 7.2.9); as a result, its projective limit M is an A-module of finite type such that $M_n = M \otimes_A A_n$ for all n. We deduce that $\mathscr{F}_n$ is induced over X_n by $\widetilde{M} \otimes_{\mathscr{O}_X} (\mathscr{O}_X/\widetilde{\mathfrak{J}}^{n+1})$, and so $\mathscr{F} = M^{\Delta}$ by Definition (10.8.4).

Conversely, (c) implies (b); indeed, if u_n is the immersion morphism $X_n \to X$, then $u_n^*(\widetilde{M}) = (M \otimes_A A_n)^{\sim}$ is induced over X_n by $\widetilde{M} \otimes_{\mathscr{O}_X} (\mathscr{O}_X/\widetilde{\mathfrak{J}}^{n+1})$, and $M^{\Delta} = \varprojlim u_n^*(\widetilde{M})$ by Definition (10.8.4); since $u_m = u_n \circ u_{mn}$ for $m \leqslant n$, the $\mathscr{F}_n = u_n^*(\widetilde{M})$ satisfy the conditions of (b), whence our claim.

We now show that (c) implies (a): indeed, we have, by definition, that $\mathscr{O}_{\mathfrak{X}} = A^{\Delta}$; since M is the cokernel of a homomorphism $A^m \to A^n$, it follows from Proposition (10.10.2) that M^{Δ} is the cokernel of a homomorphism $\mathscr{O}_{\mathfrak{X}}^m \to \mathscr{O}_{\mathfrak{X}}^n$, and, since the sheaf of rings $\mathscr{O}_{\mathfrak{X}}$ is coherent (10.10.3), so too is M^{Δ} (**0**, 5.3.4).

Finally, (a) implies (b). Considered as an $\mathscr{O}_{\mathfrak{X}}$-module, we have that $\mathscr{O}_{X_n} = \mathscr{O}_{\mathfrak{X}}/\mathscr{J}^{n+1} = A_n^{\Delta}$; **I** | 203
but $\mathscr{F}_n = \mathscr{F} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{O}_{X_n}$ is a coherent $\mathscr{O}_{\mathfrak{X}}$-module (**0**, 5.3.5), and, since it is also an $\mathscr{O}_{X_n}$-module, and $\mathscr{J}^{n+1}$ is coherent, we conclude that $\mathscr{F}_n$ is a coherent $\mathscr{O}_{X_n}$-module (**0**, 5.3.10), and it is immediate that $u_{mn}^*(\mathscr{F}_n) = \mathscr{F}_m$ for $m \leqslant n$ (recalling that the continuous map $X_m \to X_n$ of the underlying spaces is the identity on $\mathfrak{X}$). The sheaf $\mathscr{G} = \varprojlim \mathscr{F}_n$ is thus a coherent $\mathscr{O}_{\mathfrak{X}}$-module, since we have seen that (b) implies (a). The canonical homomorphisms $\mathscr{F} \to \mathscr{F}_n$ form a projective system, which, by passing to the limit, gives a canonical homomorphism $w : \mathscr{F} \to \mathscr{G}$, and it remains only to prove that w is bijective. The question is now *local*, so we can reduce to the case where $\mathscr{F}$ is the cokernel of a homomorphism $\mathscr{O}_{\mathfrak{X}}^p \to \mathscr{O}_{\mathfrak{X}}^q$; since this homomorphism is of the form v^{Δ}, where v is a homomorphism $A^p \to A^q$ (10.10.2), $\mathscr{F}$ is isomorphic to M^{Δ}, where $M = \operatorname{Coker} v$ (10.10.2). We then have, by Proposition (10.10.2), that $\mathscr{F}_n = M^{\Delta} \otimes_{\mathscr{O}_{\mathfrak{X}}} A_n^{\Delta} = (M \otimes_A A_n)^{\Delta}$, and, since the $\mathfrak{J}$-adic topology on $M \otimes_A A_n$ is discrete, we have $(M \otimes_A A_n)^{\Delta} = (M \otimes_A A_n)^{\sim}$ (as an $\mathscr{O}_{X_n}$-module); we have seen above that $M^{\Delta} = \varprojlim \mathscr{F}_n$, and w is thus the identity in this case. □

Corollary (10.10.6). — *If $\mathscr{F}$ satisfies condition* (b) *of Proposition (10.10.5), then the projective system $(\mathscr{F}_n)$ is isomorphic to the system of the $\mathscr{F} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{O}_{X_n}$.*

(10.10.7). Now let A and B be adic Noetherian rings, and $\phi : B \to A$ a continuous homomorphism; we denote by $\mathfrak{J}$ (resp. $\mathfrak{K}$) an ideal of definition for A (resp. B) such that $\phi(\mathfrak{K}) \subset \mathfrak{J}$, and we set $X = \operatorname{Spec}(A)$, $Y = \operatorname{Spec}(B)$, $\mathfrak{X} = \operatorname{Spf}(A)$, and $\mathfrak{Y} = \operatorname{Spf}(B)$. Let $f : X \to Y$ be the morphism of preschemes corresponding to ϕ (1.6.1), and $\widehat{f} : \mathfrak{X} \to \mathfrak{Y}$ its extension to the completions (10.9.1), which is also a morphism of formal preschemes that corresponds to ϕ (10.2.2).

Proposition (10.10.8). — *For every B-module N of finite type, there exists a canonical functorial isomorphism of $\mathscr{O}_{\mathfrak{X}}$-modules*

$$\widehat{f}^*(N^\Delta) \simeq (N \otimes_B A)^\Delta.$$

Proof. Denoting by $i_X : \mathfrak{X} \to X$ and $i_Y : \mathfrak{Y} \to Y$ the canonical morphisms, we have (10.8.8), up to canonical functorial isomorphisms, $N^\Delta = i_Y^*(\widetilde{N})$ and

$$(N \otimes_B A)^\Delta = i_X^*((N \otimes_B A)^\sim) = i_X^*(f^*(\widetilde{N}))$$

(1.6.5); the proposition then follows from the commutativity of the diagram in (10.9.2). □

Corollary (10.10.9). — *For every ideal $\mathfrak{b}$ of B, we have $\widehat{f}^*(\mathfrak{b}^\Delta)\mathscr{O}_{\mathfrak{X}} = (\mathfrak{b}A)^\Delta$.*

Proof. Let j be the canonical injection $\mathfrak{b} \to B$, to which corresponds the canonical injection $j^\Delta : \mathfrak{b}^\Delta \to \mathscr{O}_{\mathfrak{Y}}$ of sheaves of $\mathscr{O}_{\mathfrak{Y}}$-modules; by definition, $\widehat{f}^*(\mathfrak{b}^\Delta)\mathscr{O}_{\mathfrak{X}}$ is the image of the homomorphism $\widehat{f}^*(j^\Delta) : \widehat{f}^*(\mathfrak{b}^\Delta) \to \mathscr{O}_{\mathfrak{X}} = \widehat{f}^*(\mathscr{O}_{\mathfrak{Y}})$; but this homomorphism can be identified with $(j \otimes 1)^\Delta : (\mathfrak{b} \otimes_B A)^\Delta \to \mathscr{O}_{\mathfrak{X}} = (B \otimes_B A)^\Delta$ by Proposition (10.10.8). Since the image of $j \otimes 1$ is the ideal $\mathfrak{b}A$ of A, the image of $(j \otimes 1)^\Delta$ is thus $(\mathfrak{b}A)^\Delta$, by Proposition (10.10.2), whence the conclusion. □

10.11. Coherent sheaves on formal preschemes

Proposition (10.11.1). — *If $\mathfrak{X}$ is a locally Noetherian formal prescheme, then the sheaf of rings $\mathscr{O}_{\mathfrak{X}}$ is coherent, and every sheaf of ideals of definition for $\mathfrak{X}$ is coherent.* **I** | 204

Proof. The question is local, so we can reduce to the case of a Noetherian affine formal scheme, and the proposition then follows from Propositions (10.10.3) and (10.10.5). □

(10.11.2). Let $\mathfrak{X}$ be a locally Noetherian formal prescheme, $\mathscr{J}$ a sheaf of ideals of definition for $\mathfrak{X}$, and X_n the locally Noetherian (usual) prescheme $(\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{J}^{n+1})$, so that $\mathfrak{X}$ is the *inductive limit* of the sequence (X_n) with respect to the canonical morphisms $u_{mn} : X_m \to X_n$ (10.6.3). With this notation:

Theorem (10.11.3). — *For an $\mathscr{O}_{\mathfrak{X}}$-module $\mathscr{F}$ to be coherent, it is necessary and sufficient for it to be isomorphic to a projective limit of a sequence $(\mathscr{F}_n)$, where the $\mathscr{F}_n$ are coherent $\mathscr{O}_{X_n}$-modules such that $u_{mn}^*(\mathscr{F}_n) = \mathscr{F}_m$ for $m \leqslant n$ (10.6.6). The projective system $(\mathscr{F}_n)$ is then isomorphic to the system of the $u_n^*(\mathscr{F}) = \mathscr{F} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{O}_{X_n}$, where u_n is the canonical morphism $X_n \to \mathfrak{X}$.*

Proof. The question is local, so we can reduce to the case where $\mathfrak{X}$ is a Noetherian affine formal scheme, and the theorem then is a consequence of Proposition (10.10.5) and Corollary (10.10.6). □

We can thus say that *the data of a coherent $\mathscr{O}_{\mathfrak{X}}$-module is equivalent to the data of a projective system $(\mathscr{F}_n)$ of coherent $\mathscr{O}_{X_n}$-modules such that $u_{mn}^*(\mathscr{F}_n) = \mathscr{F}_m$ for $m \leqslant n$.*

Corollary (10.11.4). — *If $\mathscr{F}$ and $\mathscr{G}$ are coherent $\mathscr{O}_{\mathfrak{X}}$-modules, then we can (with the notation of Theorem (10.11.3)) define a canonical functorial isomorphism*

(10.11.4.1) $$\operatorname{Hom}_{\mathscr{O}_{\mathfrak{X}}}(\mathscr{F}, \mathscr{G}) \simeq \varprojlim_n \operatorname{Hom}_{\mathscr{O}_{X_n}}(\mathscr{F}_n, \mathscr{G}_n).$$

Proof. The projective limit on the right-hand side is understood to be taken with respect to the maps $\theta_n \mapsto u_{mn}^*(\theta_n)$ ($m \leqslant n$) from $\operatorname{Hom}_{\mathscr{O}_{X_n}}(\mathscr{F}_n, \mathscr{G}_n)$ to $\operatorname{Hom}_{\mathscr{O}_{X_m}}(\mathscr{F}_m, \mathscr{G}_m)$. The homomorphism (10.11.4.1) sends an element $\theta \in \operatorname{Hom}_{\mathscr{O}_{\mathfrak{X}}}(\mathscr{F}, \mathscr{G})$ to the sequence $(u_n^*(\theta))$; we can define its inverse by sending a projective system $(\theta_n) \in \varprojlim_n \operatorname{Hom}_{\mathscr{O}_{X_n}}(\mathscr{F}_n, \mathscr{G}_n)$ to its projective limit in $\operatorname{Hom}_{\mathscr{O}_{\mathfrak{X}}}(\mathscr{F}, \mathscr{G})$, taking into account Theorem (10.11.3). □

Corollary (10.11.5). — *For a homomorphism $\theta : \mathscr{F} \to \mathscr{G}$ to be surjective, it is necessary and sufficient for the corresponding homomorphism $\theta_0 = u_0^*(\theta) : \mathscr{F}_0 \to \mathscr{G}_0$ to be surjective.*

Proof. The question is local, so we reduce to the case where $\mathfrak{X} = \operatorname{Spf}(A)$ with A an adic Noetherian ring, $\mathscr{F} = M^\Delta$, $\mathscr{G} = N^\Delta$, and $\theta = u^\Delta$, where M and N are A-modules of finite type, and u is a homomorphism $M \to N$; we then have that $\theta_0 = \widetilde{u_0}$, where u_0 is the homomorphism $u \otimes 1 : M \otimes_A A/\mathfrak{J} \to N \otimes_A A/\mathfrak{J}$; the conclusion follows from the fact θ and u (resp. θ_0 and u_0) are simultaneously surjective ((1.3.9) and (10.10.2)) and that u and u_0 are simultaneously surjective (**0**, 7.1.14). □

(10.11.6). Theorem (10.11.3) shows that we can consider every coherent $\mathscr{O}_{\mathfrak{X}}$-module $\mathscr{F}$ as a *topological $\mathscr{O}_{\mathfrak{X}}$-module*, considering it as a projective limit of *pseudo-discrete* sheaves of groups $\mathscr{F}_n$ (**0**, 3.8.1). It then follows from Corollary (10.11.4) that every homomorphism $u : \mathscr{F} \to \mathscr{G}$ of coherent $\mathscr{O}_{\mathfrak{X}}$-modules is automatically *continuous* (**0**, 3.8.2). Furthermore, if $\mathscr{H}$ is a coherent $\mathscr{O}_{\mathfrak{X}}$-submodule of a coherent $\mathscr{O}_{\mathfrak{X}}$-module $\mathscr{F}$, then, for every open $U \subset \mathfrak{X}$, $\Gamma(U, \mathscr{H})$ is a *closed* subgroup of the topological group $\Gamma(U, \mathscr{F})$, since the functor Γ is left exact, and $\Gamma(U, \mathscr{H})$ is the kernel of the homomorphism $\Gamma(U, \mathscr{F}) \to \Gamma(U, \mathscr{F}/\mathscr{H})$, which is *continuous* by the above, since $\mathscr{F}/\mathscr{H}$ is coherent (**0**, 5.3.4); our claim follows from the fact that $\Gamma(U, \mathscr{F}/\mathscr{H})$ is a separated topological group. **I** | 205

Proposition (10.11.7). — *Let $\mathscr{F}$ and $\mathscr{G}$ be coherent $\mathscr{O}_{\mathfrak{X}}$-modules. We can define (with the notation of Theorem* (10.11.3)*) canonical functorial isomorphisms of topological $\mathscr{O}_{\mathfrak{X}}$-modules* (10.11.6)

(10.11.7.1)
$$\mathscr{F} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{G} \simeq \varprojlim_n (\mathscr{F}_n \otimes_{\mathscr{O}_{X_n}} \mathscr{G}_n),$$

(10.11.7.2)
$$\mathscr{H}om_{\mathscr{O}_{\mathfrak{X}}}(\mathscr{F}, \mathscr{G}) \simeq \varprojlim_n \mathscr{H}om_{\mathscr{O}_{X_n}}(\mathscr{F}_n, \mathscr{G}_n).$$

Proof. The existence of the isomorphism (10.11.7.1) follows from the formula

$$\mathscr{F}_n \otimes_{\mathscr{O}_{X_n}} \mathscr{G}_n = (\mathscr{F} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{O}_{X_n}) \otimes_{\mathscr{O}_{X_n}} (\mathscr{G} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{O}_{X_n}) = (\mathscr{F} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{G}) \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{O}_{X_n}$$

and from Theorem (10.11.3). The isomorphism (10.11.7.2), where both sides are considered as sheaves of modules without topology, follows from the definition of the sections of $\mathscr{H}om_{\mathscr{O}_{\mathfrak{X}}}(\mathscr{F}, \mathscr{G})$ and $\mathscr{H}om_{\mathscr{O}_{X_n}}(\mathscr{F}_n, \mathscr{G}_n)$, and from the existence of the isomorphism (10.11.4.1), applied to the formal prescheme induced on an arbitrary Noetherian affine formal open subset of $\mathfrak{X}$. It remains to prove that the isomorphism (10.11.7.2) is bicontinuous over a quasi-compact set, and we can thus reduce to the case where $\mathfrak{X} = \mathrm{Spf}(A)$ with A an adic Noetherian ring, and hence (10.10.5) to the case where $\mathscr{F} = M^\Delta$ and $\mathscr{G} = N^\Delta$, with M and N both A-modules of finite type; taking (10.10.2.1), (10.10.2.3), and Corollary (1.3.12, ii) into account, we reduce to showing that the canonical isomorphism $\mathrm{Hom}_A(M, N) \simeq \varprojlim_n \mathrm{Hom}_{A_n}(M_n, N_n)$ (with $M_n = M \otimes_A A_n$ and $N_n = N \otimes_A A_n$) is continuous, which has already been proved in (**0**, 7.8.2). □

(10.11.8). Since $\mathrm{Hom}_{\mathscr{O}_{\mathfrak{X}}}(\mathscr{F}, \mathscr{G})$ is the group of sections of the sheaf of topological groups $\mathscr{H}om_{\mathscr{O}_{\mathfrak{X}}}(\mathscr{F}, \mathscr{G})$, it is equipped with a group topology. If $\mathfrak{X}$ is *Noetherian*, then it follows from (10.11.7.2) that the subgroups $\mathrm{Hom}_{\mathscr{O}_{\mathfrak{X}}}(\mathscr{F}, \mathscr{J}^n\mathscr{G})$ (for arbitrary n) form a fundamental system of neighbourhoods of 0 in this group.

Proposition (10.11.9). — *Let $\mathfrak{X}$ be a Noetherian formal prescheme, and $\mathscr{F}$ and $\mathscr{G}$ coherent $\mathscr{O}_{\mathfrak{X}}$-modules. In the topological group* $\mathrm{Hom}_{\mathscr{O}_{\mathfrak{X}}}(\mathscr{F}, \mathscr{G})$*, the surjective (resp. injective, bijective) homomorphisms form an open set.*

Proof. By Corollary (10.11.5), the set of surjective homomorphisms in $\mathrm{Hom}_{\mathscr{O}_{\mathfrak{X}}}(\mathscr{F}, \mathscr{G})$ is the inverse image under the continuous map $\mathrm{Hom}_{\mathscr{O}_{\mathfrak{X}}}(\mathscr{F}, \mathscr{G}) \to \mathrm{Hom}_{\mathscr{O}_{X_0}}(\mathscr{F}_0, \mathscr{G}_0)$ of a subset of the discrete group $\mathrm{Hom}_{\mathscr{O}_{X_0}}(\mathscr{F}_0, \mathscr{G}_0)$, whence the first claim. To show the second, we cover $\mathfrak{X}$ by a finite number of Noetherian affine formal open subsets U_i. For $\theta \in \mathrm{Hom}_{\mathscr{O}_{\mathfrak{X}}}(\mathscr{F}, \mathscr{G})$ to be injective, it is necessary and sufficient for all of the images under the (continuous) restriction maps $\mathrm{Hom}_{\mathscr{O}_{\mathfrak{X}}}(\mathscr{F}, \mathscr{G}) \to \mathrm{Hom}_{\mathscr{O}_{\mathfrak{X}}|U_i}(\mathscr{F}|U_i, \mathscr{G}|U_i)$ to be injective; we can thus reduce to the affine case, and then this has already been proved in (**0**, 7.8.3). □

10.12. Adic morphisms of formal preschemes

(10.12.1). Let $\mathfrak{X}$ and $\mathfrak{S}$ be *locally Noetherian* formal preschemes; we say that a morphism $f : \mathfrak{X} \to \mathfrak{S}$ is *adic* if there exists an ideal of definition $\mathscr{J}$ of $\mathfrak{S}$ such that $\mathscr{K} = f^*(\mathscr{J})\mathscr{O}_{\mathfrak{X}}$ is an ideal of definition of $\mathfrak{X}$; we then also say that $\mathfrak{X}$ is an *adic* $\mathfrak{S}$*-prescheme* (for f). Whenever this is the case, for *every* ideal of definition $\mathscr{J}_1$ of $\mathfrak{S}$, $\mathscr{K}_1 = f^*(\mathscr{J}_1)\mathscr{O}_{\mathfrak{X}}$ is an ideal of definition of $\mathfrak{X}$. Indeed, since the question is local, we can assume that $\mathfrak{X}$ and $\mathfrak{S}$ are Noetherian and affine; there then exists an integer n such that $\mathscr{J}^n \subset \mathscr{J}_1$ and $\mathscr{J}_1^n \subset \mathscr{J}$ ((10.3.6) and (**0**, 7.1.4)), whence $\mathscr{K}^n \subset \mathscr{K}_1$ and $\mathscr{K}_1^n \subset \mathscr{K}$. The first of these relations shows that $\mathscr{K}_1 = \mathfrak{K}_1^\Delta$, where $\mathfrak{K}_1$ is an open ideal of $A = \Gamma(\mathfrak{X}, \mathscr{O}_{\mathfrak{X}})$, and the second shows that $\mathfrak{K}_1$ is an ideal of definition of A (**0**, 7.1.4), whence our claim. I | 206

It follows immediately from the above that, if $\mathfrak{X}$ and $\mathfrak{Y}$ are adic $\mathfrak{S}$-preschemes, then *every* $\mathfrak{S}$*-morphism* $u : \mathfrak{X} \to \mathfrak{Y}$ *is adic*: indeed, if $f : \mathfrak{X} \to \mathfrak{S}$ and $g : \mathfrak{Y} \to \mathfrak{S}$ are the structure morphisms, and $\mathscr{J}$ is an ideal of definition of $\mathfrak{S}$, then we have $f = g \circ u$, and so $u^*(g^*(\mathscr{J})\mathscr{O}_{\mathfrak{Y}})\mathscr{O}_{\mathfrak{X}} = f^*(\mathscr{J})\mathscr{O}_{\mathfrak{X}}$ is an ideal of definition of $\mathfrak{X}$, and, by hypothesis, $g^*(\mathscr{J})\mathscr{O}_{\mathfrak{Y}}$ is an ideal of definition of $\mathfrak{Y}$.

(10.12.2). In what follows, we suppose that we have some fixed locally Noetherian formal prescheme $\mathfrak{S}$, and some ideal of definition $\mathscr{J}$ of $\mathfrak{S}$; we set $S_n = (\mathfrak{S}, \mathscr{O}_{\mathfrak{S}}/\mathscr{J}^{n+1})$. The (locally Noetherian) adic $\mathfrak{S}$-preschemes clearly form a *category*. We say that an inductive system (X_n) of locally Noetherian (usual) S_n-preschemes is an *adic inductive* (S_n)*-system* if the structure morphisms $f_n : X_n \to S_n$ are such that, for $m \leqslant n$, the diagrams

(10.12.2.1)
$$\begin{tikzcd} X_n \arrow[d, "f_n"'] & X_m \arrow[l] \arrow[d, "f_m"] \\ S_n & S_m \arrow[l] \end{tikzcd}$$

commute and *identify* X_m *with the product* $X_n \times_{S_n} S_m = (X_n)_{(S_m)}$. The adic inductive systems form a *category*: it suffices in fact to define a morphism $(X_n) \to (Y_n)$ of such systems to be an *inductive system of* S_n*-morphisms* $u_n : X_n \to Y_n$ such that u_m is identified with $(u_n)_{(S_m)}$ for $m \leqslant n$. With this in mind:

Theorem (10.12.3). — *There is a canonical equivalence between the category of adic* $\mathfrak{S}$*-preschemes and the category of adic inductive* (S_n)*-systems.*

The equivalence in question is obtained in the following way: if $\mathfrak{X}$ is an adic $\mathfrak{S}$-prescheme, and $f : \mathfrak{X} \to \mathfrak{S}$ is the structure morphism, then $\mathscr{K} = f^*(\mathscr{J})\mathscr{O}_{\mathfrak{X}}$ is an ideal of definition of $\mathfrak{X}$, and we associate to $\mathfrak{X}$ the inductive system of the $X_n = (\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{K}^{n+1})$, with the structure morphism $f_n : X_n \to S_n$ corresponding to f (10.5.6). We first show that (X_n) is an *adic inductive system*: if $f = (\psi, \theta)$, then $\psi^*(\mathscr{J})\mathscr{O}_{\mathfrak{X}} = \mathscr{K}$, so $\psi^*(\mathscr{J}^n)\mathscr{O}_{\mathfrak{X}} = \mathscr{K}^n$ for all n, and (by exactness of the functor ψ^*) $\mathscr{K}^{m+1}/\mathscr{K}^{n+1} = \psi^*(\mathscr{J}^{m+1}/\mathscr{J}^{n+1})(\mathscr{O}_{\mathfrak{X}}/\mathscr{K}^{n+1})$ for $m \leqslant n$; our conclusion thus follows from (4.4.5). Furthermore, it can be immediately verified that a $\mathfrak{S}$-morphism $u : \mathfrak{X} \to \mathfrak{Y}$ of adic $\mathfrak{S}$-preschemes corresponds (with the obvious notation) to an inductive system of S_n-morphisms I | 207
$u_n : X_n \to Y_n$ such that u_m is identified with $(u_n)_{(S_m)}$ for $m \leqslant n$.

The fact that this equivalence is well defined will follow from the more-precise following proposition.

Proposition (10.12.3.1). — *Let* (X_n) *be an inductive system of* S_n*-preschemes; suppose that the structure morphisms* $f_n : X_n \to S_n$ *are such that the diagrams in* (10.12.2.1) *commute and identify* X_m *with* $X_n \times_{S_n} S_m$ *for* $m \leqslant n$*. Then the inductive system* (X_n) *satisfies conditions* (b) *and* (c) *of* (10.6.3)*; let* $\mathfrak{X}$ *be the inductive limit, and* $f : \mathfrak{X} \to \mathfrak{S}$ *the morphism given by the inductive limit of the inductive system* (f_n)*. Then, if* X_0 *is locally Noetherian,* $\mathfrak{X}$ *is locally Noetherian, and* f *is an adic morphism.*

Proof. Since the sheaf of ideals of $\mathscr{O}_{S_n}$ that defines the subprescheme S_m of S_n is nilpotent, by (4.4.5), so too is the sheaf of ideals of $\mathscr{O}_{X_n}$ that defines the subprescheme X_m of X_n, and so the conditions of (10.6.3) are satisfied. Since the question is local on $\mathfrak{X}$ and $\mathfrak{S}$, we can assume that $\mathfrak{S} = \operatorname{Spf}(A)$, $\mathscr{J} = \mathfrak{J}^\Delta$ (with A a Noetherian $\mathfrak{J}$-adic ring), and $X_n = \operatorname{Spec}(B_n)$; if $A_n = A/\mathfrak{J}^{n+1}$, then the hypothesis implies that B_0 is Noetherian, and if we set $\mathfrak{J}_n = \mathfrak{J}/\mathfrak{J}^{n+1}$, then $B_m = B_n/\mathfrak{J}_n^{m+1}B_n$. The kernel of $B_n \to B_0$ is thus $\mathfrak{K}_n = \mathfrak{J}_n B_n$, and the kernel of $B_n \to B_m$ is $\mathfrak{K}_n^{m+1}$ for $m \leqslant n$; further, since A_1 is Noetherian, $\mathfrak{J}_1$ is of finite type over A_1, and so $\mathfrak{K}_1/\mathfrak{K}_1^2$ is of finite type over B_1, and *a fortiori* of finite type over $B_0 = B_1/\mathfrak{K}_1$; the fact that $\mathfrak{X}$ is Noetherian then follows from (10.6.4); if $B = \varprojlim B_n$, then we have $\mathfrak{X} = \mathrm{Spf}(B)$, and, if $\mathfrak{K}$ is the kernel of $B \to B_0$, then $B_n = B/\mathfrak{K}^{n+1}$. If $\rho_n : A/\mathfrak{J}^{n+1} \to B/\mathfrak{K}^{n+1}$ is the homomorphism corresponding to f_n, then we have that

$$\mathfrak{K}/\mathfrak{K}^{n+1} = (B/\mathfrak{K}^{n+1})\rho_n(\mathfrak{J}/\mathfrak{J}^{n+1})$$

Since the homomorphism $\rho : A \to B$ corresponding to f is equal to $\varprojlim \rho_n$, the ideal $\mathfrak{J}B$ of B is dense in $\mathfrak{K}$; since every ideal of B is closed (**0**, 7.3.5), we also have $\mathfrak{K} = \mathfrak{J}B$. If $\mathscr{K} = \mathfrak{K}^\Delta$, the equality $f^*(\mathscr{J})\mathscr{O}_{\mathfrak{X}} = \mathscr{K}$ then follows from (10.10.9), and finishes the proof. □

(10.12.3.2). The above equivalence gives, for adic $\mathfrak{S}$-preschemes $\mathfrak{X}$ and $\mathfrak{Y}$, a *canonical bijection*

$$\mathrm{Hom}_{\mathfrak{S}}(\mathfrak{X}, \mathfrak{Y}) \simeq \varprojlim_n \mathrm{Hom}_{S_n}(X_n, Y_n)$$

where the projective limit is relative to the maps $u_n \to (u_n)_{(S_m)}$ for $m \leqslant n$.

10.13. Morphisms of finite type

Proposition (10.13.1). — *Let $\mathfrak{Y}$ be a locally Noetherian formal prescheme, $\mathscr{K}$ an ideal of definition of $\mathfrak{Y}$, and $f : \mathfrak{X} \to \mathfrak{Y}$ a morphism of formal preschemes. Then the following conditions are equivalent.*

(a) *$\mathfrak{X}$ is locally Noetherian, f is an adic morphism* (10.12.1), *and, if we set $\mathscr{J} = f^*(\mathscr{K})\mathscr{O}_{\mathfrak{X}}$, then the morphism $f_0 : (\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{J}) \to (\mathfrak{Y}, \mathscr{O}_{\mathfrak{Y}}/\mathscr{K})$ induced by f is of finite type.*

(b) *$\mathfrak{X}$ is locally Noetherian, and is the inductive limit of an adic inductive (Y_n)-system (X_n) such that the morphism $X_0 \to Y_0$ is of finite type.* **I** | 208

(c) *Every point of $\mathfrak{Y}$ has a Noetherian formal affine open neighbourhood V which satisfies the following property:*

*(**Q**) $f^{-1}(V)$ is a finite union of Noetherian formal affine open subsets U_i such that the Noetherian adic ring $\Gamma(U_i, \mathscr{O}_{\mathfrak{X}})$ is topologically isomorphic to the quotient of an algebra of restricted formal series* (**0**, 7.5.1) *over $\Gamma(V, \mathscr{O}_{\mathfrak{Y}})$ by an ideal (which is necessarily closed).*

Proof. It is immediate that (a) implies (b), by (10.12.3). To show that (b) implies (c), we can, since the question is local on $\mathfrak{Y}$, assume that $\mathfrak{Y} = \mathrm{Spf}(B)$, where B is Noetherian and adic; let $\mathscr{K} = \mathfrak{K}^\Delta$, with $\mathfrak{K}$ an ideal of definition of B. Since, by hypothesis, X_0 is of finite type over Y_0, X_0 is a finite union of affine open subsets U_i such that the ring A_{i0} of the affine scheme induced by X_0 on U_i is an algebra of finite type over the ring $B/\mathfrak{K}$ of Y_0 (6.3.2). By (5.1.9), U_i is also an affine open subset in each of the Noetherian preschemes X_n, and, if A_{in} is the ring of the affine scheme induced by X_n on U_i, then hypothesis (b) implies, for $m \leqslant n$, that A_{im} is isomorphic to $A_{in}/\mathfrak{K}^{m+1}A_{in}$. Consequently, the formal prescheme induced by $\mathfrak{X}$ on U_i is isomorphic to $\mathrm{Spf}(A_i)$, where $A_i = \varprojlim_n A_{in}$ (10.6.4); A_i is a $\mathfrak{K}A_i$-adic ring, and $A_i/\mathfrak{K}A_i$, being isomorphic to A_{i0}, is an algebra of finite type over $B/\mathfrak{K}$. We thus conclude (**0**, 7.5.5) that A_i is topologically isomorphic to a quotient of an algebra of restricted formal series over B (by a necessarily closed ideal, because such an algebra is Noetherian (**0**, 7.5.4)).

To show that (c) implies (a), we can restrict to the case where $\mathfrak{X} = \mathrm{Spf}(A)$ is also affine, with A a Noetherian adic ring isomorphic to a quotient of an algebra of restricted formal series over B by a closed ideal. Then (**0**, 7.5.5) $A/\mathfrak{K}A$ is an algebra of finite type over $B/\mathfrak{K}$, and $\mathfrak{K}A = \mathfrak{J}$ is an ideal of definition of A, and so, by (10.10.9), the conditions of (a) are satisfied. □

We note that, if the conditions of Proposition (10.13.1) are satisfied, then property (a) holds true for *any* ideal of definition $\mathscr{K}$ of $\mathfrak{Y}$ (by *(c)*), and so, in property (b), *all* the f_n are morphisms of finite type.

Corollary (10.13.2). — *If the conditions of* (10.13.1) *are satisfied, then every Noetherian formal affine open subset V of $\mathfrak{Y}$ has property (**Q**), and, if $\mathfrak{Y}$ is Noetherian, then so too is $\mathfrak{X}$.*

Proof. This follows immediately from (10.13.1) and (6.3.2). □

Definition (10.13.3). — When the equivalent properties (a), (b), and (c) of (10.13.1) are satisfied, we say that the morphism f is of finite type, or that $\mathfrak{X}$ is a formal $\mathfrak{Y}$-prescheme of finite type, or a formal prescheme of finite type over $\mathfrak{Y}$.

Corollary (10.13.4). — *Let $\mathfrak{X} = \operatorname{Spf}(A)$ and $\mathfrak{Y} = \operatorname{Spf}(B)$ be Noetherian formal affine schemes; for $\mathfrak{X}$ to be of finite type over $\mathfrak{Y}$, it is necessary and sufficient for the Noetherian adic ring A to be isomorphic to the quotient of an algebra of restricted formal series over B by some closed ideal.*

Proof. With the notation of (10.13.1), if $\mathfrak{X}$ is of finite type over $\mathfrak{Y}$, then $A/\mathfrak{K}A$ is a $(B/\mathfrak{K})$-algebra of finite type by (6.3.3), and $\mathfrak{K}A$ is an ideal of definition of A (10.10.9). We are then done, by (**0**, 7.5.5). □

Proposition (10.13.5). —

(i) *The composition of any two morphisms (of formal preschemes) of finite type is again of finite type.* I | 209

(ii) *Let $\mathfrak{X}$, $\mathfrak{S}$, and $\mathfrak{S}'$ be locally Noetherian (resp. Noetherian) formal preschemes, and let $f : \mathfrak{X} \to \mathfrak{S}$ and $g : \mathfrak{S}' \to \mathfrak{S}$ be morphisms. If f is of finite type, then $\mathfrak{X} \times_{\mathfrak{S}} \mathfrak{S}'$ is locally Noetherian (resp. Noetherian) and of finite type over $\mathfrak{S}'$.*

(iii) *Let $\mathfrak{S}$ be a locally Noetherian formal prescheme, and let $\mathfrak{X}'$ and $\mathfrak{Y}'$ be locally Noetherian formal $\mathfrak{S}$-preschemes; suppose that $\mathfrak{X}' \times_{\mathfrak{S}} \mathfrak{Y}'$ is locally Noetherian. If $\mathfrak{X}$ and $\mathfrak{Y}$ are locally Noetherian formal $\mathfrak{S}$-preschemes, and $f : \mathfrak{X} \to \mathfrak{X}'$ and $g : \mathfrak{Y} \to \mathfrak{Y}'$ are $\mathfrak{S}$-morphisms of finite type, then $\mathfrak{X} \times_{\mathfrak{S}} \mathfrak{Y}$ is locally Noetherian, and $f \times_{\mathfrak{S}} g$ is a $\mathfrak{S}$-morphism of finite type.*

Proof. By the formal argument of (3.5.1), (iii) follows from (i) and (ii), so it suffices to prove (i) and (ii).

Let $\mathfrak{X}$, $\mathfrak{Y}$, and $\mathfrak{Z}$ be locally Noetherian formal preschemes, and $f : \mathfrak{X} \to \mathfrak{Y}$ and $g : \mathfrak{Y} \to \mathfrak{Z}$ morphisms of finite type. If $\mathscr{L}$ is an ideal of definition of $\mathfrak{Z}$, then $\mathscr{K} = g^*(\mathscr{L})\mathscr{O}_{\mathfrak{Y}}$ is an ideal of definition of $\mathfrak{Y}$, and $\mathscr{J} = f^*(g^*(\mathscr{L}))\mathscr{O}_{\mathfrak{X}}$ is an ideal of definition for $\mathfrak{X}$. Let $X_0 = (\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{J})$, $Y_0 = (\mathfrak{Y}, \mathscr{O}_{\mathfrak{Y}}/\mathscr{K})$, and $Z_0 = (\mathfrak{Z}, \mathscr{O}_{\mathfrak{Z}}/\mathscr{L})$, and let $f_0 : X_0 \to Y_0$ and $g_0 : Y_0 \to Z_0$ be the morphisms corresponding to f and g (respectively). Since, by hypothesis, f_0 and g_0 are of finite type, so too is $g_0 \circ f_0$ (6.3.4), which corresponds to $g \circ f$; thus $g \circ f$ is of finite type, by (10.13.1).

Under the conditions of (ii), $\mathfrak{S}$ (resp. $\mathfrak{X}$, $\mathfrak{S}'$) is the inductive limit of a sequence (S_n) (resp. (X_n), (S'_n)) of locally Noetherian preschemes, and we can assume (10.13.1) that $X_m = X_n \times_{S_n} S_m$ for $m \leqslant n$. The formal prescheme $\mathfrak{X} \times_{\mathfrak{S}} \mathfrak{S}'$ is then the inductive limit of the preschemes $X_n \times_{S_n} S'_n$ (10.7.4), and we have that

$$X_m \times_{S_m} S'_m = (X_n \times_{S_n} S_m) \times_{S_m} S'_m = (X_n \times_{S_n} S'_n) \times_{S'_n} S'_m.$$

Furthermore, $X_0 \times_{S_0} S'_0$ is locally Noetherian, since X_0 is of finite type over S_0 (6.3.8). We thus conclude (10.12.3.1), first of all, that $\mathfrak{X} \times_{\mathfrak{S}} \mathfrak{S}'$ is locally Noetherian; then, since $X_0 \times_{S_0} S'_0$ is of finite type over S'_0 (6.3.8), it follows from (10.12.3.1) and (10.13.1) that $\mathfrak{X} \times_{\mathfrak{S}} \mathfrak{S}'$ is of finite type over $\mathfrak{S}'$, which proves (ii) (the claim about Noetherian preschemes being an immediate consequence of (6.3.8)). □

Corollary (10.13.6). — *Under the hypotheses of (10.9.9), if f is a morphism of finite type, then so too is its extension $\widehat{f}$ to the completions.*

10.14. Closed subpreschemes of formal preschemes

Proposition (10.14.1). — *Let $\mathfrak{X}$ be a locally Noetherian formal prescheme, and $\mathscr{A}$ a coherent sheaf of ideals of $\mathscr{O}_{\mathfrak{X}}$. If $\mathfrak{Y}$ is the (closed) support of $\mathscr{O}_{\mathfrak{X}}/\mathscr{A}$, then the topologically ringed space $(\mathfrak{Y}, (\mathscr{O}_{\mathfrak{X}}/\mathscr{A})|\mathfrak{Y})$ is a locally Noetherian formal prescheme that is Noetherian if $\mathfrak{X}$ is.*

Proof. Note that $\mathscr{O}_{\mathfrak{X}}/\mathscr{A}$ is coherent by (10.10.3) and (**0**, 5.3.4), so its support $\mathfrak{Y}$ is closed (**0**, 5.2.2). Let $\mathscr{J}$ be an ideal of definition of $\mathfrak{X}$, and let $X_n = (\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{J}^{n+1})$; the sheaf of rings $\mathscr{O}_{\mathfrak{X}}/\mathscr{A}$ is the projective limit of the sheaves $\mathscr{O}_{\mathfrak{X}}/(\mathscr{A} + \mathscr{J}^{n+1}) = (\mathscr{O}_{\mathfrak{X}}/\mathscr{A}) \otimes_{\mathscr{O}_{\mathfrak{X}}} (\mathscr{O}_{\mathfrak{X}}/\mathscr{J}^{n+1})$ (10.11.3), all of which have support $\mathfrak{Y}$. The sheaf $(\mathscr{A} + \mathscr{J}^{n+1})/\mathscr{J}^{n+1}$ is a coherent $\mathscr{O}_{\mathfrak{X}}$-module, since $\mathscr{J}^{n+1}$ is coherent, and so $(\mathscr{A} + \mathscr{J}^{n+1})/\mathscr{J}^{n+1}$ is also a coherent $(\mathscr{O}_{\mathfrak{X}}/\mathscr{J}^{n+1})$-module (**0**, 5.3.10); if Y_n is the closed subprescheme of X_n defined by this sheaf of ideals, it is immediate that $(\mathfrak{Y}, (\mathscr{O}_{\mathfrak{X}}/\mathscr{A})|\mathfrak{Y})$ is I | 210
the formal prescheme given by the inductive limit of the Y_n, and, since the conditions of (10.6.4) are satisfied, this proves that this formal prescheme is locally Noetherian, and further Noetherian if $\mathfrak{X}$ is (since then Y_0 is, by (6.1.4)). □

Definition (10.14.2). — We define a closed subprescheme of a formal prescheme $\mathfrak{X}$ to be any formal prescheme of the form $(\mathfrak{Y}, (\mathscr{O}_{\mathfrak{X}}/\mathscr{A})|\mathfrak{Y})$ with $\mathscr{A}$ a coherent ideal of $\mathscr{O}_{\mathfrak{X}}$; we say that this prescheme Err$_{\text{II}}$
is the subprescheme defined by $\mathscr{A}$.

It is clear that the correspondence thus defined between coherent ideals of $\mathscr{O}_{\mathfrak{X}}$ and closed subpreschemes of $\mathfrak{X}$ is bijective. **Err$_{\text{II}}$**

The morphism of topologically ringed spaces $j = (\psi, \theta) : \mathfrak{Y} \to \mathfrak{X}$, where ψ is the injection $\mathfrak{Y} \to \mathfrak{X}$ and $\theta^\sharp$ the canonical homomorphism $\mathscr{O}_{\mathfrak{X}} \to \mathscr{O}_{\mathfrak{X}}/\mathscr{A}$, is evidently (10.4.5) a morphism of formal preschemes, and we call it the *canonical injection* from $\mathfrak{Y}$ to $\mathfrak{X}$. Note that, if $\mathfrak{X} = \operatorname{Spf}(A)$, where A is Noetherian and adic, then $\mathscr{A} = \mathfrak{a}^\Delta$, where $\mathfrak{a}$ is an ideal of A (10.10.5), and it then follows immediately from the above that $\mathfrak{Y} = \operatorname{Spf}(A/\mathfrak{a})$, up to isomorphism, and that j corresponds (10.2.2) to the canonical homomorphism $A \to A/\mathfrak{a}$.

We say that a morphism $f : \mathfrak{Z} \to \mathfrak{X}$ of locally Noetherian formal preschemes is a *closed immersion* if it factors as $\mathfrak{Z} \xrightarrow{g} \mathfrak{Y} \xrightarrow{j} \mathfrak{X}$, where g is an isomorphism from $\mathfrak{Z}$ to a closed subprescheme $\mathfrak{Y}$ of $\mathfrak{X}$, and j is the canonical injection. Since j is a monomorphism of ringed spaces, g and $\mathfrak{Y}$ are necessarily *unique*.

Proposition (10.14.3). — *A closed immersion is a morphism of finite type.*

Proof. We can immediately restrict to the case where $\mathfrak{X}$ is a formal affine scheme $\operatorname{Spf}(A)$, and $\mathfrak{Y} = \operatorname{Spf}(A/\mathfrak{a})$; the proposition then follows from Proposition (10.13.1, *c*). □

Lemma (10.14.4). — *Let $f : \mathfrak{Y} \to \mathfrak{X}$ be a morphism of locally Noetherian formal preschemes, and let (U_α) be a cover of $f(\mathfrak{Y})$ by Noetherian formal affine open subsets of $\mathfrak{X}$ such that the $f^{-1}(U_\alpha)$ are Noetherian formal affine open subsets of $\mathfrak{Y}$. For f to be a closed immersion, it is necessary and sufficient for $f(\mathfrak{Y})$ to be a closed subset of $\mathfrak{X}$ and, for all α, for the restriction of f to $f^{-1}(U_\alpha)$ to correspond* (10.4.6) *to a surjective homomorphism $\Gamma(U_\alpha, \mathscr{O}_{\mathfrak{X}}) \to \Gamma(f^{-1}(U_\alpha), \mathscr{O}_{\mathfrak{Y}})$.*

Proof. The conditions are clearly necessary. Conversely, if the conditions are satisfied, and if we denote by $\mathfrak{a}_\alpha$ the kernel of $\Gamma(U_\alpha, \mathscr{O}_{\mathfrak{X}}) \to \Gamma(f^{-1}(U_\alpha), \mathscr{O}_{\mathfrak{Y}})$, then we can define a coherent sheaf of ideals $\mathscr{A}$ of $\mathscr{O}_{\mathfrak{X}}$ by setting $\mathscr{A}|U_\alpha = \mathfrak{a}_\alpha^\Delta$ and taking $\mathscr{A}$ to be $\mathscr{O}_{\mathfrak{X}}$ on the complement of the union of the U_α.[31] Since $f(\mathfrak{Y})$ is closed, and since the support of the quotient $(\mathscr{O}_{\mathfrak{X}}|U_\alpha)/\mathfrak{a}_\alpha^\Delta$ is $U_\alpha \cap f(\mathfrak{Y})$, everything reduces to proving that $\mathfrak{a}_\alpha^\Delta$ and $\mathfrak{a}_\beta^\Delta$ induce the same sheaf on any Noetherian formal affine open subset $V \subset U_\alpha \cap U_\beta$. But the restriction to $f^{-1}(U_\alpha)$ of f is a closed immersion of this formal prescheme into U_α, $f^{-1}(V)$ is a Noetherian formal affine open subset of $f^{-1}(U_\alpha)$, and the restriction of f to $f^{-1}(V)$ is a closed immersion; if $\mathfrak{b}$ is the kernel of the surjective homomorphism $\Gamma(V, \mathscr{O}_{\mathfrak{X}}) \to \Gamma(f^{-1}(V), \mathscr{O}_{\mathfrak{Y}})$ corresponding to this restriction, then it is immediate (10.10.2) that $\mathfrak{a}_\alpha^\Delta$ induces $\mathfrak{b}^\Delta$ on V. The sheaf of ideals $\mathscr{A}$ being thus defined, it is then clear that $f = j \circ g$,[32] where $j : \mathfrak{Z} \to \mathfrak{X}$ is the canonical injection of the closed subprescheme $\mathfrak{Z}$ of $\mathfrak{X}$ defined by $\mathscr{A}$, and that g is an isomorphism from $\mathfrak{Y}$ to $\mathfrak{Z}$. □

Proposition (10.14.5). —

(i) *If $f : \mathfrak{Z} \to \mathfrak{Y}$ and $g : \mathfrak{Y} \to \mathfrak{X}$ are closed immersions of locally Noetherian formal preschemes, then $g \circ f$ is a closed immersion.* **I | 211**

(ii) *Let $\mathfrak{X}$, $\mathfrak{Y}$, and $\mathfrak{S}$ be locally Noetherian formal preschemes, $f : \mathfrak{X} \to \mathfrak{S}$ a closed immersion, and $g : \mathfrak{Y} \to \mathfrak{S}$ a morphism. Then the morphism $\mathfrak{X} \times_{\mathfrak{S}} \mathfrak{Y} \to \mathfrak{Y}$ is a closed immersion.*

(iii) *Let $\mathfrak{S}$ be a locally Noetherian formal prescheme, and let $\mathfrak{X}'$ and $\mathfrak{Y}'$ be locally Noetherian formal $\mathfrak{S}$-preschemes; suppose that $\mathfrak{X}' \times_{\mathfrak{S}} \mathfrak{Y}'$ is locally Noetherian. If $\mathfrak{X}$ and $\mathfrak{Y}$ are locally Noetherian formal $\mathfrak{S}$-preschemes, and $f : \mathfrak{X} \to \mathfrak{X}'$ and $g : \mathfrak{Y} \to \mathfrak{Y}'$ are $\mathfrak{S}$-morphisms that are closed immersions, then $f \times_{\mathfrak{S}} g$ is a closed immersion.*

Proof. By (3.5.1), it again suffices to prove (i) and (ii).

To prove (i), we can assume that $\mathfrak{Y}$ (resp. $\mathfrak{Z}$) is a closed subprescheme of $\mathfrak{X}$ (resp. $\mathfrak{Y}$) defined by a coherent sheaf $\mathscr{J}$ (resp. $\mathscr{K}$) of ideals of $\mathscr{O}_{\mathfrak{X}}$ (resp. $\mathscr{O}_{\mathfrak{Y}}$); if ψ is the injection $\mathfrak{Y} \to \mathfrak{X}$ of underlying spaces, then $\psi_*(\mathscr{K})$ is a coherent sheaf of ideals of $\psi_*(\mathscr{O}_{\mathfrak{Y}}) = \mathscr{O}_{\mathfrak{X}}/\mathscr{J}$ (**0**, 5.3.12), and thus also a coherent $\mathscr{O}_{\mathfrak{X}}$-module (**0**, 5.3.10); the kernel $\mathscr{K}_1$ of $\mathscr{O}_{\mathfrak{X}} \to (\mathscr{O}_{\mathfrak{X}}/\mathscr{J})/\psi_*(\mathscr{K})$ is thus a coherent sheaf of

[31] *[Trans.] The French text prints that $\mathscr{A}$ is zero on this complement and, in the next sentence, that $\mathfrak{a}_\alpha^\Delta$ itself has support $U_\alpha \cap f(\mathfrak{Y})$. The defining ideal instead equals the unit ideal off $f(\mathfrak{Y})$, while its quotient has that support; these two corrections are required for the sheaves to glue to the closed subprescheme with underlying space $f(\mathfrak{Y})$.*

[32] *[Trans.] The French source prints $f = g \circ j$; with $g : \mathfrak{Y} \to \mathfrak{Z}$ and $j : \mathfrak{Z} \to \mathfrak{X}$, the type-correct composite is $j \circ g$.*

ideals of $\mathscr{O}_{\mathfrak{X}}$ (**0**, 5.3.4), and $\mathscr{O}_{\mathfrak{X}}/\mathscr{K}_1$ is isomorphic to $\psi_*(\mathscr{O}_{\mathfrak{Y}}/\mathscr{K})$, which proves that $\mathfrak{Z}$ is isomorphic to a closed subprescheme of $\mathfrak{X}$.

To prove (ii), we can immediately restrict to the case where $\mathfrak{S} = \mathrm{Spf}(A)$, $\mathfrak{X} = \mathrm{Spf}(B)$, and $\mathfrak{Y} = \mathrm{Spf}(C)$, with A a Noetherian $\mathfrak{J}$-adic ring, $B = A/\mathfrak{a}$ (where $\mathfrak{a}$ is an ideal of A), and C a Noetherian topological adic A-algebra. Everything then reduces to proving that the homomorphism $C \to C\widehat{\otimes}_A(A/\mathfrak{a})$ is *surjective*: but $A/\mathfrak{a}$ is an A-module of finite type, and its topology is the $\mathfrak{J}$-adic topology; it then follows from (**0**, 7.7.8) that $C\widehat{\otimes}_A(A/\mathfrak{a})$ can be identified with $C \otimes_A (A/\mathfrak{a}) = C/\mathfrak{a}C$, whence our claim. □

Corollary (10.14.6). — *Under the hypotheses of (10.14.5, ii), let $p : \mathfrak{X} \times_{\mathfrak{S}} \mathfrak{Y} \to \mathfrak{X}$ and $q : \mathfrak{X} \times_{\mathfrak{S}} \mathfrak{Y} \to \mathfrak{Y}$ be the projections, so that the diagram*

$$\begin{tikzcd} \mathfrak{X} \arrow[d, "f"'] & \mathfrak{X} \times_{\mathfrak{S}} \mathfrak{Y} \arrow[l, "p"'] \arrow[d, "q"] \\ \mathfrak{S} & \mathfrak{Y} \arrow[l, "g"] \end{tikzcd}$$

commutes. For every coherent $\mathscr{O}_{\mathfrak{X}}$-module $\mathscr{F}$, we then have a canonical isomorphism of $\mathscr{O}_{\mathfrak{Y}}$-modules

(10.14.6.1) $$u : g^* f_*(\mathscr{F}) \simeq q_* p^*(\mathscr{F}).$$

Proof. We know that defining a homomorphism $g^* f_*(\mathscr{F}) \to q_* p^*(\mathscr{F})$ is equivalent to defining a homomorphism $f_*(\mathscr{F}) \to g_* q_* p^*(\mathscr{F}) = f_* p_* p^*(\mathscr{F})$ (**0**, 4.4.3): we take for u the homomorphism corresponding under this adjunction to $f_*(\rho)$,[33] where ρ is the canonical homomorphism $\mathscr{F} \to p_* p^*(\mathscr{F})$ (**0**, 4.4.3). To see that u is an isomorphism, we can immediately restrict to the case where $\mathfrak{S}$, $\mathfrak{X}$, and $\mathfrak{Y}$ are formal spectra of Noetherian adic rings A, B, and C (respectively), satisfying the conditions in (10.14.5, ii) above; we then have $\mathscr{F} = M^\Delta$, where M is an $(A/\mathfrak{a})$-module of finite type (10.10.5), and the two sides of (10.14.6.1) can then be identified, respectively, by (10.10.8), with $(C \otimes_A M)^\Delta$ and $((C/\mathfrak{a}C) \otimes_{A/\mathfrak{a}} M)^\Delta$, whence the corollary, since $(C/\mathfrak{a}C) \otimes_{A/\mathfrak{a}} M = (C \otimes_A (A/\mathfrak{a})) \otimes_{A/\mathfrak{a}} M$ is canonically identified with $C \otimes_A M$. □

I | 212

Corollary (10.14.7). — *Let X be a locally Noetherian usual prescheme, Y a closed subprescheme of X, j the canonical injection $Y \to X$, X' a closed subset of X, and $Y' = Y \cap X'$; then $\widehat{j} : Y_{/Y'} \to X_{/X'}$ is a closed immersion, and, for every coherent $\mathscr{O}_Y$-module $\mathscr{F}$, we have*

$$\widehat{j}_*(\mathscr{F}_{/Y'}) = (j_*(\mathscr{F}))_{/X'}.$$

Proof. Since $Y' = j^{-1}(X')$, it suffices to use (10.9.9) and to apply (10.14.5) and (10.14.6). □

10.15. Separated formal preschemes

Definition (10.15.1). — Let $\mathfrak{S}$ be a formal prescheme, $\mathfrak{X}$ a formal $\mathfrak{S}$-prescheme, and $f : \mathfrak{X} \to \mathfrak{S}$ the structure morphism. We define the diagonal morphism $\Delta_{\mathfrak{X}|\mathfrak{S}} : \mathfrak{X} \to \mathfrak{X} \times_{\mathfrak{S}} \mathfrak{X}$ (also denoted by $\Delta_{\mathfrak{X}}$) to be the morphism $(1_{\mathfrak{X}}, 1_{\mathfrak{X}})_{\mathfrak{S}}$. We say that $\mathfrak{X}$ is separated over $\mathfrak{S}$, or is a formal $\mathfrak{S}$-scheme, or that f is a separated morphism, if the image of the underlying space of $\mathfrak{X}$ under $\Delta_{\mathfrak{X}}$ is a closed subset of the underlying space of $\mathfrak{X} \times_{\mathfrak{S}} \mathfrak{X}$. We say that a formal prescheme $\mathfrak{X}$ is separated, or is a formal scheme, if it is separated over $\mathbf{Z}$.

Proposition (10.15.2). — *Suppose that the formal preschemes $\mathfrak{S}$ and $\mathfrak{X}$ are inductive limits of sequences (S_n) and (X_n) (respectively) of usual preschemes, and that the morphism $f : \mathfrak{X} \to \mathfrak{S}$ is the inductive limit of a sequence of morphisms $f_n : X_n \to S_n$. For f to be separated, it is necessary and sufficient for the morphism $f_0 : X_0 \to S_0$ to be separated.*

Proof. Indeed, $\Delta_{\mathfrak{X}|\mathfrak{S}}$ is then the inductive limit of the sequence of morphisms $\Delta_{X_n|S_n}$ (10.7.4); the underlying spaces of $\mathfrak{X}$ and $\mathfrak{X} \times_{\mathfrak{S}} \mathfrak{X}$ are respectively identical to those of X_0 and $X_0 \times_{S_0} X_0$, and, under these identifications, the image of $\mathfrak{X}$ under $\Delta_{\mathfrak{X}|\mathfrak{S}}$ is identical to the image of X_0 under $\Delta_{X_0|S_0}$; whence the conclusion. □

---

[33] *[Trans.] The French source writes $u = f_*(\rho)$; these maps live on different spaces and have different source and target sheaves, with $f_*(\rho)$ the adjoint of u.*

Proposition (10.15.3). — *Suppose that all the formal preschemes (resp. morphisms of formal preschemes) in what follows are inductive limits of sequences of usual preschemes (resp. of morphisms of usual preschemes).*

(i) *The composition of any two separated morphisms is separated.*

(ii) *If $f : \mathfrak{X} \to \mathfrak{X}'$ and $g : \mathfrak{Y} \to \mathfrak{Y}'$ are separated $\mathfrak{S}$-morphisms, then $f \times_{\mathfrak{S}} g$ is separated.*

(iii) *If $f : \mathfrak{X} \to \mathfrak{Y}$ is a separated $\mathfrak{S}$-morphism, then the $\mathfrak{S}'$-morphism $f_{(\mathfrak{S}')}$ is separated for every extension $\mathfrak{S}' \to \mathfrak{S}$ of the base formal prescheme.*

(iv) *If the composition $g \circ f$ of two morphisms is separated, then f is separated.*

(In the above, it is implicit that if the same formal prescheme $\mathfrak{Z}$ is mentioned more than once in the same proposition, we consider it as the inductive limit of the *same* sequence (Z_n) of usual preschemes wherever it is mentioned, and the morphisms from $\mathfrak{Z}$ to another formal prescheme (resp. from a formal prescheme to $\mathfrak{Z}$) as inductive limits of morphisms from Z_n to some usual preschemes (resp. from some usual preschemes to Z_n)).

Proof. With the notation of (10.15.2), we have, in fact, that $(g \circ f)_0 = g_0 \circ f_0$ and $(f \times_{\mathfrak{S}} g)_0 = f_0 \times_{S_0} g_0$; the claims of (10.15.3) are then immediate consequences of (10.15.2) and the corresponding claims in (5.5.1) for usual preschemes. □

We leave it to the reader to state, for the same type of formal preschemes and morphisms as in (10.15.3), the propositions corresponding to (5.5.5), (5.5.9), and (5.5.10) (by replacing "affine open subset" by "formal affine open subset satisfying condition (b) of (10.6.3)"). **I** | 213

A similar argument also shows that every *Noetherian* formal affine scheme is separated, which justifies the terminology.

Proposition (10.15.4). — *Let $\mathfrak{S}$ be a locally Noetherian formal prescheme, and $\mathfrak{X}$ and $\mathfrak{Y}$ locally Noetherian formal $\mathfrak{S}$-preschemes such that $\mathfrak{X}$ or $\mathfrak{Y}$ is of finite type over $\mathfrak{S}$ (so that $\mathfrak{X} \times_{\mathfrak{S}} \mathfrak{Y}$ is locally Noetherian) and such that $\mathfrak{Y}$ is separated over $\mathfrak{S}$. Let $f : \mathfrak{X} \to \mathfrak{Y}$ be an $\mathfrak{S}$-morphism; then the graph morphism $\Gamma_f = (1_{\mathfrak{X}}, f)_{\mathfrak{S}} : \mathfrak{X} \to \mathfrak{X} \times_{\mathfrak{S}} \mathfrak{Y}$ is a closed immersion.*

Proof. We can assume that $\mathfrak{S}$ is the inductive limit of a sequence (S_n) of locally Noetherian preschemes, $\mathfrak{X}$ (resp. $\mathfrak{Y}$) the inductive limit of a sequence (X_n) (resp. (Y_n)) of S_n-preschemes, and f the inductive limit of a sequence $(f_n : X_n \to Y_n)$ of S_n-morphisms; then $\mathfrak{X} \times_{\mathfrak{S}} \mathfrak{Y}$ is the inductive limit of the sequence $(X_n \times_{S_n} Y_n)$, and Γ_f the inductive limit of the sequence (Γ_{f_n}) (10.7.4); by hypothesis, Y_0 is separated over S_0 (10.15.2), so the space $\Gamma_{f_0}(X_0)$ is a closed subspace of $X_0 \times_{S_0} Y_0$; since the underlying spaces of $\mathfrak{X} \times_{\mathfrak{S}} \mathfrak{Y}$ (resp. $\Gamma_f(\mathfrak{X})$) and $X_0 \times_{S_0} Y_0$ (resp. $\Gamma_{f_0}(X_0)$) are identical, we already see that $\Gamma_f(\mathfrak{X})$ is a *closed* subspace of $\mathfrak{X} \times_{\mathfrak{S}} \mathfrak{Y}$. Now note that, when (U, V) runs over the set of pairs consisting of a Noetherian formal affine open subset U (resp. V) of $\mathfrak{X}$ (resp. $\mathfrak{Y}$) such that $f(U) \subset V$, the open subsets $U \times_{\mathfrak{S}} V$ form a cover of $\Gamma_f(\mathfrak{X})$ in $\mathfrak{X} \times_{\mathfrak{S}} \mathfrak{Y}$, and, if $f_U : U \to V$ is the restriction of f to U, then $\Gamma_{f_U} : U \to U \times_{\mathfrak{S}} V$ is the restriction of Γ_f to U. If we show that Γ_{f_U} is a closed immersion, then Γ_f will be a closed immersion (10.14.4), or, in other words, we are led to consider the case where $\mathfrak{S} = \mathrm{Spf}(A)$, $\mathfrak{X} = \mathrm{Spf}(B)$, and $\mathfrak{Y} = \mathrm{Spf}(C)$ are affine (with A, B, and C Noetherian adic rings), with f corresponding to a continuous A-homomorphism $\phi : C \to B$; then Γ_f corresponds to the unique continuous homomorphism $\omega : B \widehat{\otimes}_A C \to B$ which, when composed with the canonical homomorphisms $B \to B \widehat{\otimes}_A C$ and $C \to B \widehat{\otimes}_A C$, gives the identity and ϕ (respectively). But it is clear that ω is *surjective*, whence our claim. □

Corollary (10.15.5). — *Let $\mathfrak{S}$ be a locally Noetherian formal prescheme, and $\mathfrak{X}$ an $\mathfrak{S}$-prescheme of finite type; for $\mathfrak{X}$ to be separated over $\mathfrak{S}$, it is necessary and sufficient for the diagonal morphism $\mathfrak{X} \to \mathfrak{X} \times_{\mathfrak{S}} \mathfrak{X}$ to be a closed immersion.*

Proposition (10.15.6). — *A closed immersion $j : \mathfrak{Y} \to \mathfrak{X}$ of locally Noetherian formal preschemes is a separated morphism.*

Proof. With the notation of (10.14.2), $j_0 : Y_0 \to X_0$ is a closed immersion, thus a separated morphism, and so it suffices to apply (10.15.2). □

Proposition (10.15.7). — *Let X be a locally Noetherian (usual) prescheme, X' a closed subset of X, and $\widehat{X} = X_{/X'}$. For $\widehat{X}$ to be separated, it is necessary and sufficient that $\widehat{X}_{\mathrm{red}}$ be separated, and it is sufficient that X be separated.*

Proof. With the notation of (10.8.5), for $\widehat{X}$ to be separated, it is necessary and sufficient for X'_0 to be separated (10.15.2), and since $\widehat{X}_{\text{red}} = (X'_0)_{\text{red}}$, it is equivalent to ask for $\widehat{X}_{\text{red}}$ to be separated (5.5.1, vi). $\square$

Chapter 0

Chapter I

Terminological Index

The order of entries follows the French source index; English translations therefore do not always appear in English alphabetical order.

Terminological note. The source uses "adic" only for rings or modules that are separated and complete; this differs somewhat from customary usage.

EGA II

Elementary global study of some classes of morphisms

Alexander Grothendieck and Jean Dieudonné

Complete English reader

Summary

The various classes of morphisms studied in this chapter are treated without making much use **II | 5** of cohomological methods; a deeper study making use of those methods will be carried out in Chapter III, where we shall use chiefly §§2, 4, and 5 of Chapter II. §8 may be omitted on a first reading: it gives some supplements to the formalism developed in §§1 through 3, reducing to easy applications of that formalism, and we shall use it less consistently than the other results of this chapter.

§1. Affine morphisms

Most of the results in this section are the "global" counterparts of those in Chapter I, §1; they are therefore not essentially new and merely provide convenient language for what follows.

1.1. S-preschemes and $\mathscr{O}_S$-algebras

(1.1.1). Let S be a prescheme, X an S-prescheme, and $f : X \to S$ its structure morphism. We know (**0**, 4.2.4) that the direct image $f_*(\mathscr{O}_X)$ is an $\mathscr{O}_S$-algebra, which we denote $\mathscr{A}(X)$ when there is little **II | 6** chance of confusion; if U is an open subset of S, then we have

$$\mathscr{A}(f^{-1}(U)) = \mathscr{A}(X)|U.$$

Similarly, for every $\mathscr{O}_X$-module $\mathscr{F}$ (resp. every $\mathscr{O}_X$-algebra $\mathscr{B}$), we write $\mathscr{A}(\mathscr{F})$ (resp. $\mathscr{A}(\mathscr{B})$) for the direct image $f_*(\mathscr{F})$ (resp. $f_*(\mathscr{B})$) which is an $\mathscr{A}(X)$-module (resp. an $\mathscr{A}(X)$-algebra) and not only an $\mathscr{O}_S$-module (resp. an $\mathscr{O}_S$-algebra).

(1.1.2). Let Y be a second S-prescheme, $g : Y \to S$ its structure morphism, and $h : X \to Y$ an S-morphism; we then have the commutative diagram

(1.1.2.1)
$$\begin{tikzcd} X \arrow[rr, "h"] \arrow[dr, "f"'] & & Y \arrow[dl, "g"] \\ & S. & \end{tikzcd}$$

We have by definition $h = (\psi, \theta)$, where $\theta : \mathscr{O}_Y \to h_*(\mathscr{O}_X) = \psi_*(\mathscr{O}_X)$ is a homomorphism of sheaves of rings; we thus obtain (**0**, 4.2.2) a homomorphism of $\mathscr{O}_S$-algebras $g_*(\theta) : g_*(\mathscr{O}_Y) \to g_*(h_*(\mathscr{O}_X)) = f_*(\mathscr{O}_X)$, in other words, a homomorphism of $\mathscr{O}_S$-algebras $\mathscr{A}(Y) \to \mathscr{A}(X)$, which we denote by $\mathscr{A}(h)$. If $h' : Y \to Z$ is a second S-morphism, then it is immediate that $\mathscr{A}(h' \circ h) = \mathscr{A}(h) \circ \mathscr{A}(h')$. We have thus defined a *contravariant functor* $X \mapsto \mathscr{A}(X)$ on the category of S-preschemes, with values in the category of $\mathscr{O}_S$-algebras.

Now let $\mathscr{F}$ be an $\mathscr{O}_X$-module, $\mathscr{G}$ an $\mathscr{O}_Y$-module, and $u : \mathscr{G} \to \mathscr{F}$ an h-morphism, that is (**0**, 4.4.1) a homomorphism of $\mathscr{O}_Y$-modules $\mathscr{G} \to h_*(\mathscr{F})$. Then $g_*(u) : g_*(\mathscr{G}) \to g_*(h_*(\mathscr{F})) = f_*(\mathscr{F})$ is a homomorphism $\mathscr{A}(\mathscr{G}) \to \mathscr{A}(\mathscr{F})$ of $\mathscr{O}_S$-modules, which we denote by $\mathscr{A}(u)$; in addition, the pair $(\mathscr{A}(h), \mathscr{A}(u))$ forms a *di-homomorphism* from the $\mathscr{A}(Y)$-module $\mathscr{A}(\mathscr{G})$ to the $\mathscr{A}(X)$-module $\mathscr{A}(\mathscr{F})$.

(1.1.3). If we fix the prescheme S, then we can consider the pairs $(X, \mathscr{F})$, where X is an S-prescheme and $\mathscr{F}$ is an $\mathscr{O}_X$-module, as forming a *category*, by defining a *morphism* $(X, \mathscr{F}) \to (Y, \mathscr{G})$ as a pair (h, u), where $h : X \to Y$ is an S-morphism and $u : \mathscr{G} \to \mathscr{F}$ is an h-morphism. We can then say that $(X, \mathscr{F}) \mapsto (\mathscr{A}(X), \mathscr{A}(\mathscr{F}))$ is a *contravariant functor* with values in the category whose objects are pairs consisting of an $\mathscr{O}_S$-algebra and a module over that algebra, and whose morphisms are the di-homomorphisms.

1.2. Affine preschemes over a prescheme

Definition (1.2.1). — Let X be an S-prescheme, and $f : X \to S$ its structure morphism. We say that X is *affine over* S if there exists a cover (S_α) of S by affine open sets such that for all α, the prescheme induced by X on the open set $f^{-1}(S_\alpha)$ is affine.

Example (1.2.2). — Every closed subprescheme of S is an affine S-prescheme over S ((**I**, 4.2.3) and (**I**, 4.2.4)).

Remark (1.2.3). — An affine prescheme X over S is not necessarily an affine scheme, as the example $X = S$ shows (1.2.2). On the other hand, if an affine scheme X is an S-prescheme, then X is not necessarily affine over S (see Example (1.3.3)). However, recall that if S is a *scheme*, then every **II** | 7
S-prescheme which is an affine scheme is affine over S (**I**, 5.5.10).

Proposition (1.2.4). — *Every S-prescheme which is affine over S is separated over S (in other words, it is an S-scheme).*

Proof. This follows immediately from (**I**, 5.5.5) and (**I**, 5.5.8). ☐

Proposition (1.2.5). — *Let X be an S-scheme affine over S, and $f : X \to S$ its structure morphism. For every open $U \subset S$, $f^{-1}(U)$ is affine over U.*

Proof. By Definition (1.2.1), we can reduce to the case where $S = \operatorname{Spec}(A)$ and $X = \operatorname{Spec}(B)$ are affine; then $f = ({}^a\phi, \widetilde{\phi})$, where $\phi : A \to B$ is a homomorphism. As the $D(g)$ for $g \in A$ form a basis for S, we reduce to the case where $U = D(g)$; but we then know that $f^{-1}(U) = D(\phi(g))$ (**I**, 1.2.2.2), hence the proposition. ☐

Proposition (1.2.6). — *Let X be an S-scheme affine over S, and $f : X \to S$ its structure morphism. For every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$, $f_*(\mathscr{F})$ is a quasi-coherent $\mathscr{O}_S$-module.*

Proof. Taking into account Proposition (1.2.4), this follows from (**I**, 9.2.2, a). ☐

In particular, the $\mathscr{O}_S$-algebra $\mathscr{A}(X) = f_*(\mathscr{O}_X)$ is *quasi-coherent*.

Proposition (1.2.7). — *Let X be an S-scheme affine over S. For every S-prescheme Y, the map $h \mapsto \mathscr{A}(h)$ from the set* $\operatorname{Hom}_S(Y, X)$ *to the set* $\operatorname{Hom}(\mathscr{A}(X), \mathscr{A}(Y))$ (1.1.2) *is bijective.*

Proof. Let $f : X \to S$ and $g : Y \to S$ be the structure morphisms. First, suppose that $S = \operatorname{Spec}(A)$ and $X = \operatorname{Spec}(B)$ are affine; we must prove that for every homomorphism $\omega : f_*(\mathscr{O}_X) \to g_*(\mathscr{O}_Y)$ of $\mathscr{O}_S$-algebras, there exists a unique S-morphism $h : Y \to X$ such that $\mathscr{A}(h) = \omega$. By definition, for every open $U \subset S$, ω defines a homomorphism $\omega_U = \Gamma(U, \omega) : \Gamma(f^{-1}(U), \mathscr{O}_X) \to \Gamma(g^{-1}(U), \mathscr{O}_Y)$ of $\Gamma(U, \mathscr{O}_S)$-algebras. In particular, for $U = S$, this gives a homomorphism $\phi : \Gamma(X, \mathscr{O}_X) \to \Gamma(Y, \mathscr{O}_Y)$ of $\Gamma(S, \mathscr{O}_S)$-algebras, to which corresponds a well-defined S-morphism $h : Y \to X$, since X is affine (**I**, 2.2.4). It remains to prove that $\mathscr{A}(h) = \omega$, or, in other words, that, for every open set U of a basis for S, ω_U coincides with the homomorphism of algebras ϕ_U corresponding to the S-morphism $g^{-1}(U) \to f^{-1}(U)$, a restriction of h. We can reduce to the case where $U = D(\lambda)$, with $\lambda \in A$; then, if $f = ({}^a\rho, \widetilde{\rho})$, where $\rho : A \to B$ is a ring homomorphism, we have $f^{-1}(U) = D(\mu)$, where $\mu = \rho(\lambda)$, and $\Gamma(f^{-1}(U), \mathscr{O}_X)$ is the ring of fractions B_μ; the diagram

$$\begin{tikzcd} B \arrow[r, "\phi"] \arrow[d] & \Gamma(Y, \mathscr{O}_Y) \arrow[d] \\ B_\mu \arrow[r, "\phi_U"'] & \Gamma(g^{-1}(U), \mathscr{O}_Y) \end{tikzcd}$$

is commutative, and so is the analogous diagram where ϕ_U is replaced by ω_U; the equality $\phi_U = \omega_U$ then follows from the universal property of rings of fractions (**0**, 1.2.4).

We now pass to the general case; let (S_α) be a cover of S by affine open sets such that the $f^{-1}(S_\alpha)$ are affine. Then every homomorphism $\omega : \mathscr{A}(X) \to \mathscr{A}(Y)$ of $\mathscr{O}_S$-algebras gives by restriction a family of homomorphisms **II | 8**

$$\omega_\alpha : \mathscr{A}(f^{-1}(S_\alpha)) \longrightarrow \mathscr{A}(g^{-1}(S_\alpha))$$

of $\mathscr{O}_{S_\alpha}$-algebras, hence a family of S_α-morphisms $h_\alpha : g^{-1}(S_\alpha) \to f^{-1}(S_\alpha)$ by the above. It remains to see that for every affine open set of a basis for $S_\alpha \cap S_\beta$, the restrictions of h_α and h_β to $g^{-1}(U)$ coincide, which is evident since by the above, these restrictions both correspond to the homomorphism $\mathscr{A}(X)|U \to \mathscr{A}(Y)|U$, a restriction of ω. □

Corollary (1.2.8). — *Let X and Y be two S-schemes which are affine over S. For an S-morphism $h : Y \to X$ to be an isomorphism, it is necessary and sufficient for $\mathscr{A}(h) : \mathscr{A}(X) \to \mathscr{A}(Y)$ to be an isomorphism.*

Proof. This follows immediately from Proposition (1.2.7) and from the functorial nature of $\mathscr{A}(X)$. □

1.3. Affine preschemes over S associated to an $\mathscr{O}_S$-algebra

Proposition (1.3.1). — *Let S be a prescheme. For every quasi-coherent $\mathscr{O}_S$-algebra $\mathscr{B}$, there exists a prescheme X affine over S, defined up to unique S-isomorphism, such that $\mathscr{A}(X) = \mathscr{B}$.*

Proof. The uniqueness follows from Corollary (1.2.8); we prove the existence of X. For every affine open $U \subset S$, let X_U be the prescheme $\operatorname{Spec}(\Gamma(U, \mathscr{B}))$; as $\Gamma(U, \mathscr{B})$ is a $\Gamma(U, \mathscr{O}_S)$-algebra, X_U is an S-prescheme (**I**, 1.6.1). In addition, as $\mathscr{B}$ is quasi-coherent, the $\mathscr{O}_S$-algebra $\mathscr{A}(X_U)$ canonically identifies with $\mathscr{B}|U$ ((**I**, 1.3.7), (**I**, 1.3.13), (**I**, 1.6.3)). Let V be a second affine open subset of S, and let $X_{U,V}$ be the prescheme induced by X_U on $f_U^{-1}(U \cap V)$, where f_U denotes the structure morphism $X_U \to S$; $X_{U,V}$ and $X_{V,U}$ are affine over $U \cap V$ (1.2.5), and by definition $\mathscr{A}(X_{U,V})$ and $\mathscr{A}(X_{V,U})$ canonically identify with $\mathscr{B}|(U \cap V)$. Hence there is (1.2.8) a canonical S-isomorphism $\theta_{U,V} : X_{V,U} \to X_{U,V}$; in addition, if W is a third affine open subset of S, and if $\theta'_{U,V}$, $\theta'_{V,W}$, and $\theta'_{U,W}$ are the restrictions of $\theta_{U,V}$, $\theta_{V,W}$, and $\theta_{U,W}$ to the inverse images of $U \cap V \cap W$ in X_V, X_W, and X_W respectively under the structure morphisms, then we have $\theta'_{U,V} \circ \theta'_{V,W} = \theta'_{U,W}$. As a result, there exists a prescheme X, a cover (T_U) of X by affine open sets, and for every U an isomorphism $\phi_U : X_U \to T_U$, such that ϕ_U maps $f_U^{-1}(U \cap V)$ to $T_U \cap T_V$, and we have $\theta_{U,V} = \phi_U^{-1} \circ \phi_V$ (**I**, 2.3.1). The morphism $g_U = f_U \circ \phi_U^{-1}$ makes T_U an S-prescheme, and the morphisms g_U and g_V coincide on $T_U \cap T_V$, hence X is an S-prescheme. In addition, it is clear by definition that X is affine over S and that $\mathscr{A}(T_U) = \mathscr{B}|U$, hence $\mathscr{A}(X) = \mathscr{B}$. □

We say that the S-scheme X defined in this way is *associated to the $\mathscr{O}_S$-algebra $\mathscr{B}$*, or is the *spectrum of $\mathscr{B}$*, and we denote it by $\operatorname{Spec}(\mathscr{B})$.

Corollary (1.3.2). — *Let X be a prescheme affine over S, $f : X \to S$ the structure morphism. For every affine open $U \subset S$, the induced prescheme on $f^{-1}(U)$ is the affine scheme with ring $\Gamma(U, \mathscr{A}(X))$.*

Proof. As we can suppose that X is associated to an $\mathscr{O}_S$-algebra by Propositions (1.2.6) and (1.3.1), the corollary follows from the construction of X described in Proposition (1.3.1). □ **II | 9**

Example (1.3.3). — Let S be the affine plane over a field K, where the point 0 has been doubled (**I**, 5.5.11); with the notation of (**I**, 5.5.11), S is the union of two affine open sets Y_1 and Y_2; if f is the open immersion $Y_1 \to S$, then $f^{-1}(Y_2) = Y_1 \cap Y_2$ is not an affine open set in Y_1 (*loc. cit.*), hence we have an example of an affine scheme which is not affine over S.

Corollary (1.3.4). — *Let S be an affine scheme; for an S-prescheme X to be affine over S, it is necessary and sufficient for X to be an affine scheme.*

Corollary (1.3.5). — *Let X be a prescheme affine over a prescheme S, and let Y be an X-prescheme. For Y to be affine over S, it is necessary and sufficient for Y to be affine over X.*

Proof. We immediately reduce to the case where S is an affine scheme, and then X is likewise an affine scheme (1.3.4); the two conditions in the statement then both express that Y is an affine scheme (1.3.4). □

(1.3.6). Let X be a prescheme affine over S. To define a prescheme Y affine *over* X, it is equivalent, by Corollary (1.3.5), to give a prescheme Y affine *over* S, and an S-morphism $g : Y \to X$; in other words (Proposition (1.3.1) and (1.2.7)), it is equivalent to give a quasi-coherent $\mathscr{O}_S$-algebra $\mathscr{B}$ and a homomorphism $\mathscr{A}(X) \to \mathscr{B}$ of $\mathscr{O}_S$-algebras (which can be considered as defining on $\mathscr{B}$ an $\mathscr{A}(X)$-algebra structure). If $f : X \to S$ is the structure morphism, then we have $\mathscr{B} = f_*(g_*(\mathscr{O}_Y))$.

Corollary (1.3.7). — *Let X be a prescheme affine over S; for X to be of finite type over S, it is necessary and sufficient for the quasi-coherent $\mathscr{O}_S$-algebra $\mathscr{A}(X)$ to be of finite type* (**I**, 9.6.2).

Proof. By definition (**I**, 9.6.2), we can reduce to the case where S is affine; then X is an affine scheme (1.3.4), and if $S = \operatorname{Spec}(A)$, $X = \operatorname{Spec}(B)$, then $\mathscr{A}(X)$ is the $\mathscr{O}_S$-algebra $\widetilde{B}$; as $\Gamma(S, \widetilde{B}) = B$, the corollary follows from (**I**, 9.6.2) and (**I**, 6.3.3). □

Corollary (1.3.8). — *Let X be a prescheme affine over S; for X to be reduced, it is necessary and sufficient for the quasi-coherent $\mathscr{O}_S$-algebra $\mathscr{A}(X)$ to be reduced* (**0**, 4.1.4).

Proof. The question is local on S; by Corollary (1.3.2), the corollary follows from (**I**, 5.1.1) and (**I**, 5.1.4). □

1.4. Quasi-coherent sheaves over an affine prescheme over S

Proposition (1.4.1). — *Let X be a prescheme affine over S, Y an S-prescheme, and $\mathscr{F}$ (resp. $\mathscr{G}$) a quasi-coherent $\mathscr{O}_X$-module (resp. an $\mathscr{O}_Y$-module). Then the map $(h, u) \mapsto (\mathscr{A}(h), \mathscr{A}(u))$ from the set of morphisms $(Y, \mathscr{G}) \to (X, \mathscr{F})$ to the set of di-homomorphisms $(\mathscr{A}(X), \mathscr{A}(\mathscr{F})) \to (\mathscr{A}(Y), \mathscr{A}(\mathscr{G}))$ ((1.1.2) and (1.1.3)) is bijective.*

Proof. The proof follows exactly as that of Proposition (1.2.7) by using (**I**, 2.2.5) and (**I**, 2.2.4), and the details are left to the reader. □

Corollary (1.4.2). — *If, in addition to the hypotheses of Proposition (1.4.1), we suppose that Y is affine over S, then for (h, u) to be an isomorphism, it is necessary and sufficient for $(\mathscr{A}(h), \mathscr{A}(u))$ to be a di-isomorphism.*

Proposition (1.4.3). — *For every pair $(\mathscr{B}, \mathscr{M})$ consisting of a quasi-coherent $\mathscr{O}_S$-algebra $\mathscr{B}$ and a quasi-coherent $\mathscr{B}$-module $\mathscr{M}$* (considered as an $\mathscr{O}_S$-module or as a $\mathscr{B}$-module, which are equivalent (**I**, 9.6.1)), *there exists a pair $(X, \mathscr{F})$ consisting of a prescheme X affine over S and of a quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$, such that $\mathscr{A}(X) = \mathscr{B}$ and $\mathscr{A}(\mathscr{F}) = \mathscr{M}$; in addition, this pair is determined up to unique isomorphism.* II | 10

Proof. The uniqueness follows from Proposition (1.4.1) and Corollary (1.4.2); the existence is proved as in Proposition (1.3.1), and we leave the details to the reader. □

We denote by $\widetilde{\mathscr{M}}$ the $\mathscr{O}_X$-module $\mathscr{F}$, and we say that it is *associated* to the quasi-coherent $\mathscr{B}$-module $\mathscr{M}$; for every affine open $U \subset S$, $\widetilde{\mathscr{M}}|p^{-1}(U)$ (where p is the structure morphism $X \to S$) is canonically isomorphic to $(\Gamma(U, \mathscr{M}))^{\sim}$.

Corollary (1.4.4). — *On the category of quasi-coherent $\mathscr{B}$-modules, $\mathscr{M} \mapsto \widetilde{\mathscr{M}}$ is an additive covariant exact functor which commutes with inductive limits and direct sums.*

Proof. We immediately reduce to the case where S is affine, and the corollary then follows from (**I**, 1.3.5), (**I**, 1.3.9), and (**I**, 1.3.11). □

Corollary (1.4.5). — *Under the hypotheses of Proposition (1.4.3), for $\widetilde{\mathscr{M}}$ to be an $\mathscr{O}_X$-module of finite type, it is necessary and sufficient for $\mathscr{M}$ to be a $\mathscr{B}$-module of finite type.*

Proof. We immediately reduce to the case where $S = \operatorname{Spec}(A)$ is an affine scheme. Then $\mathscr{B} = \widetilde{B}$, where B is an A-algebra, and $\mathscr{M} = \widetilde{M}$, where M is a B-module (**I**, 1.3.13); *over the prescheme X*, $\mathscr{O}_X$ is associated to the ring B and $\widetilde{\mathscr{M}}$ to the B-module M; for $\widetilde{\mathscr{M}}$ to be of finite type, it is therefore necessary and sufficient for M to be of finite type (**I**, 1.3.13), hence our assertion. □

Proposition (1.4.6). — *Let Y be a prescheme affine over S, X and X' two preschemes affine over Y* (hence also over S (1.3.5)). *Let $\mathscr{B} = \mathscr{A}(Y)$, $\mathscr{A} = \mathscr{A}(X)$, and $\mathscr{A}' = \mathscr{A}(X')$. Then $X \times_Y X'$ is affine over Y* (thus also over S), *and $\mathscr{A}(X \times_Y X')$ canonically identifies with $\mathscr{A} \otimes_{\mathscr{B}} \mathscr{A}'$.*

Proof. By (**I**, 9.6.1), $\mathscr{A} \otimes_{\mathscr{B}} \mathscr{A}'$ is a quasi-coherent $\mathscr{B}$-algebra, thus also a quasi-coherent $\mathscr{O}_S$-algebra (**I**, 9.6.1); let Z be the spectrum of $\mathscr{A} \otimes_{\mathscr{B}} \mathscr{A}'$ (1.3.1). The canonical $\mathscr{B}$-homomorphisms $\mathscr{A} \to \mathscr{A} \otimes_{\mathscr{B}} \mathscr{A}'$ and $\mathscr{A}' \to \mathscr{A} \otimes_{\mathscr{B}} \mathscr{A}'$ correspond (1.2.7) to Y-morphisms $p : Z \to X$ and $p' : Z \to X'$. To see that the triple (Z, p, p') is a product $X \times_Y X'$, we can reduce to the case where S is an affine scheme with ring C (**I**, 3.2.6.4). But then Y, X, and X' are affine schemes (1.3.4) whose rings B, A, and A' are C-algebras such that $\mathscr{B} = \widetilde{B}$, $\mathscr{A} = \widetilde{A}$, and $\mathscr{A}' = \widetilde{A'}$. We then know (**I**, 1.3.13) that $\mathscr{A} \otimes_{\mathscr{B}} \mathscr{A}'$ canonically identifies with the $\mathscr{O}_S$-algebra $(A \otimes_B A')^\sim$, hence the ring $A(Z)$ identifies with $A \otimes_B A'$ and the morphisms p and p' correspond to the canonical homomorphisms $A \to A \otimes_B A'$ and $A' \to A \otimes_B A'$. The proposition then follows from (**I**, 3.2.2). □

Corollary (1.4.7). — *Let $\mathscr{F}$ (resp. $\mathscr{F}'$) be a quasi-coherent $\mathscr{O}_X$-module (resp. $\mathscr{O}_{X'}$-module); then $\mathscr{A}(\mathscr{F} \otimes_Y \mathscr{F}')$ canonically identifies with $\mathscr{A}(\mathscr{F}) \otimes_{\mathscr{A}(Y)} \mathscr{A}(\mathscr{F}')$.*

Proof. We know that $\mathscr{F} \otimes_Y \mathscr{F}'$ is quasi-coherent over $X \times_Y X'$ (**I**, 9.1.2). Let $g : Y \to S$, $f : X \to Y$, and $f' : X' \to Y$ be the structure morphisms, such that the structure morphism $h : Z \to S$ is equal to $g \circ f \circ p$ and to $g \circ f' \circ p'$. We define a canonical homomorphism **II | 11**

$$\mathscr{A}(\mathscr{F}) \otimes_{\mathscr{A}(Y)} \mathscr{A}(\mathscr{F}') \longrightarrow \mathscr{A}(\mathscr{F} \otimes_Y \mathscr{F}')$$

in the following way: for every open $U \subset S$, we have canonical homomorphisms

$$\Gamma(f^{-1}(g^{-1}(U)), \mathscr{F}) \longrightarrow \Gamma(h^{-1}(U), p^*(\mathscr{F})) \text{ and } \Gamma(f'^{-1}(g^{-1}(U)), \mathscr{F}') \longrightarrow \Gamma(h^{-1}(U), p'^*(\mathscr{F}')).$$

By (**0**, 4.4.3), we therefore obtain a canonical homomorphism

$$\Gamma(f^{-1}(g^{-1}(U)), \mathscr{F}) \otimes_{\Gamma(g^{-1}(U), \mathscr{O}_Y)} \Gamma(f'^{-1}(g^{-1}(U)), \mathscr{F}') \longrightarrow \\ \Gamma(h^{-1}(U), p^*(\mathscr{F})) \otimes_{\Gamma(h^{-1}(U), \mathscr{O}_Z)} \Gamma(h^{-1}(U), p'^*(\mathscr{F}')).$$

To see that we have defined an isomorphism of $\mathscr{A}(Z)$-modules, we can reduce to the case where S (and as a result X, X', Y, and $X \times_Y X'$) are affine schemes, and (with the notation of Proposition (1.4.6)), $\mathscr{F} = \widetilde{M}$, $\mathscr{F}' = \widetilde{M'}$, where M (resp. M') is an A-module (resp. an A'-module). Then $\mathscr{F} \otimes_Y \mathscr{F}'$ identifies with the sheaf on $X \times_Y X'$ associated to the $(A \otimes_B A')$-module $M \otimes_B M'$ (**I**, 9.1.3), and the corollary follows from the canonical identification of the $\mathscr{O}_S$-modules $(M \otimes_B M')^\sim$ and $\widetilde{M} \otimes_{\widetilde{B}} \widetilde{M'}$ (where M, M', and B are considered as C-modules) ((**I**, 1.3.13) and (**I**, 1.6.3)). □

If we apply Corollary (1.4.7) in particular to the case where $X = Y$ and $\mathscr{F}' = \mathscr{O}_{X'}$, then we see that the $\mathscr{A}'$-module $\mathscr{A}(f'^*(\mathscr{F}))$ identifies with $\mathscr{A}(\mathscr{F}) \otimes_{\mathscr{B}} \mathscr{A}'$.

(1.4.8). In particular, when $X = X' = Y$ (X being affine over S), we see that if $\mathscr{F}$ and $\mathscr{G}$ are two quasi-coherent $\mathscr{O}_X$-modules, then we have

$$\mathscr{A}(\mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{G}) = \mathscr{A}(\mathscr{F}) \otimes_{\mathscr{A}(X)} \mathscr{A}(\mathscr{G}) \tag{1.4.8.1}$$

up to canonical functorial isomorphism. If in addition $\mathscr{F}$ admits a finite presentation, then it follows from (**I**, 1.6.3) and (**I**, 1.3.12) that

$$\mathscr{A}(\mathscr{H}om_X(\mathscr{F}, \mathscr{G})) = \mathscr{H}om_{\mathscr{A}(X)}(\mathscr{A}(\mathscr{F}), \mathscr{A}(\mathscr{G})) \tag{1.4.8.2}$$

up to canonical isomorphism.

Remark (1.4.9). — If X and X' are two preschemes affine over S, then the sum $X \sqcup X'$ is also affine over S, as the sum of two affine schemes is an affine scheme.

Proposition (1.4.10). — *Let S be a prescheme, $\mathscr{B}$ a quasi-coherent $\mathscr{O}_S$-algebra, and $X = \operatorname{Spec}(\mathscr{B})$. For a quasi-coherent sheaf of ideals $\mathscr{J}$ of $\mathscr{B}$, $\widetilde{\mathscr{J}}$ is a quasi-coherent sheaf of ideals of $\mathscr{O}_X$, and the closed subprescheme Y of X defined by $\widetilde{\mathscr{J}}$ is canonically isomorphic to* $\operatorname{Spec}(\mathscr{B}/\mathscr{J})$.

Proof. It follows immediately from (**I**, 4.2.3) that Y is affine over S; by Proposition (1.3.1), we reduce to the case where S is affine, and the proposition then follows immediately from (**I**, 4.1.2). □

We can also express the result of Proposition (1.4.10) by saying that if $h : \mathscr{B} \to \mathscr{B}'$ is a *surjective* homomorphism of quasi-coherent $\mathscr{O}_S$-algebras, ${}^a h : \operatorname{Spec}(\mathscr{B}') \to \operatorname{Spec}(\mathscr{B})$ is a *closed immersion*.

Proposition (1.4.11). — *Let S be a prescheme, $\mathscr{B}$ a quasi-coherent $\mathscr{O}_S$-algebra, and $X = \operatorname{Spec}(\mathscr{B})$. For every quasi-coherent sheaf of ideals $\mathscr{K}$ of $\mathscr{O}_S$, we have (denoting by f the structure morphism $X \to S$) $f^*(\mathscr{K})\mathscr{O}_X = (\mathscr{K}\mathscr{B})^\sim$ up to canonical isomorphism.* **II | 12**

Proof. Since the question is local on S, we can reduce to the case where $S = \operatorname{Spec}(A)$ is affine, and in this case the proposition is none other than (**I**, 1.6.9). □

1.5. Change of base prescheme

Proposition (1.5.1). — *Let X be a prescheme affine over S. For every extension $g : S' \to S$ of the base prescheme, $X' = X_{(S')} = X \times_S S'$ is affine over S'.*

Proof. If f' is the projection $X' \to S'$, then it suffices to prove that $f'^{-1}(U')$ is an affine open set for every affine open subset U' of S' such that $g(U')$ is contained in an affine open subset U of S (1.2.1); we can thus reduce to the case where S and S' are affine, and it suffices to prove that X' is then an affine scheme (1.3.4). But then X is an affine scheme (1.3.4), and if A, A', and B are the rings of S, S', and X respectively, then we know that X' is the affine scheme with ring $A' \otimes_A B$ (**I**, 3.2.2). □

Corollary (1.5.2). — *Under the hypotheses of Proposition (1.5.1), let $f : X \to S$ be the structure morphism, $f' : X' \to S'$ and $g' : X' \to X$ the projections, such that the diagram*

$$\begin{tikzcd} X \arrow[d] & X' \arrow[l, "g'"'] \arrow[d, "f'"] \\ S & S' \arrow[l, "g"'] \end{tikzcd}$$

is commutative. For every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$, there exists a canonical isomorphism of $\mathscr{O}_{S'}$-modules

(1.5.2.1) $$u : g^*(f_*(\mathscr{F})) \simeq f'_*(g'^*(\mathscr{F})).$$

In particular, there exists a canonical isomorphism from $\mathscr{A}(X')$ to $g^*(\mathscr{A}(X))$.

Proof. To define u, it suffices to define a homomorphism

$$v : f_*(\mathscr{F}) \longrightarrow g_*(f'_*(g'^*(\mathscr{F}))) = f_*(g'_*(g'^*(\mathscr{F})))$$

and to set $u = v^\sharp$ (**0**, 4.4.3). We take $v = f_*(\rho)$, where ρ is the canonical homomorphism $\mathscr{F} \to g'_*(g'^*(\mathscr{F}))$ (**0**, 4.4.3). To prove that u is an isomorphism, we can reduce to the case where S and S' are affine, and hence so are X and X'; with the notation of Proposition (1.5.1), we then have $\mathscr{F} = \widetilde{M}$, where M is a B-module. We then note immediately that $g^*(f_*(\mathscr{F}))$ and $f'_*(g'^*(\mathscr{F}))$ are both equal to the $\mathscr{O}_{S'}$-module associated to the A'-module $A' \otimes_A M$ (where M is considered as an A-module), and that u is the homomorphism associated to the identity ((**I**, 1.6.3), (**I**, 1.6.5), (**I**, 1.6.7)). □

Remark (1.5.3). — One must not suppose that Corollary (1.5.2) remains true when X is no longer assumed affine over S, even when $S' = \operatorname{Spec}(k(s))$ ($s \in S$) and $S' \to S$ is the canonical morphism (**I**, 2.4.5)—in which case X' is none other than the *fibre* $f^{-1}(s)$ (**I**, 3.6.2). In other words, when X is not affine over S, the operation "direct image of quasi-coherent sheaves" does not commute with the operation of "passing to fibres". However, we will see in Chapter III (**III**, 4.2.4) a result in this sense, of an "asymptotic" nature, valid for *coherent* sheaves on X when f is proper (5.4) and S is Noetherian. **II | 13**

Corollary (1.5.4). — *For every prescheme X affine over S and every $s \in S$, the fibre $f^{-1}(s)$ (where f denotes the structure morphism $X \to S$) is an affine scheme.*

Proof. It suffices to apply Proposition (1.5.1) with $S' = \operatorname{Spec}(k(s))$ and to use Corollary (1.3.4). □

Corollary (1.5.5). — *Let X be an S-prescheme and S' a prescheme affine over S; then $X' = X_{(S')}$ is a prescheme affine over X. In addition, if $f : X \to S$ is the structure morphism, then there is a canonical isomorphism of $\mathscr{O}_X$-algebras $\mathscr{A}(X') \simeq f^*(\mathscr{A}(S'))$, and for every quasi-coherent $\mathscr{A}(S')$-module $\mathscr{M}$, a canonical di-isomorphism $f^*(\mathscr{M}) \simeq \mathscr{A}(f'^*(\widetilde{\mathscr{M}}))$, denoting by $f' = f_{(S')}$ the structure morphism $X' \to S'$.*

Proof. It suffices to swap the roles of X and S' in (1.5.1) and (1.5.2). □

(1.5.6). Now let S, S' be two preschemes, $q : S' \to S$ a morphism, $\mathscr{B}$ (resp. $\mathscr{B}'$) a quasi-coherent $\mathscr{O}_S$-algebra (resp. $\mathscr{O}_{S'}$-algebra), $u : \mathscr{B} \to \mathscr{B}'$ a q-morphism (that is, a homomorphism $\mathscr{B} \to q_*(\mathscr{B}')$ of $\mathscr{O}_S$-algebras). If $X = \operatorname{Spec}(\mathscr{B})$, $X' = \operatorname{Spec}(\mathscr{B}')$, then we canonically obtain a morphism

$$v = \operatorname{Spec}(u) : X' \longrightarrow X$$

such that the diagram

(1.5.6.1)
$$\begin{tikzcd} X' \arrow[r, "v"] \arrow[d] & X \arrow[d] \\ S' \arrow[r, "q"'] & S \end{tikzcd}$$

is commutative (the vertical arrows being the structure morphisms). Indeed, the data of u is equivalent to that of a homomorphism of quasi-coherent $\mathscr{O}_{S'}$-algebras $u^\sharp : q^*(\mathscr{B}) \to \mathscr{B}'$ (**0**, 4.4.3); this thus canonically defines an S'-morphism

$$w : \operatorname{Spec}(\mathscr{B}') \longrightarrow \operatorname{Spec}(q^*(\mathscr{B}))$$

such that $\mathscr{A}(w) = u^\sharp$ (1.2.7). On the other hand, it follows from (1.5.2) that $\operatorname{Spec}(q^*(\mathscr{B}))$ canonically identifies with $X \times_S S'$; the morphism v is the composition $X' \xrightarrow{w} X \times_S S' \xrightarrow{p_1} X$ of w with the first projection, and the commutativity of (1.5.6.1) follows from the definitions. Let U (resp. U') be an affine open of S (resp. S') such that $q(U') \subset U$, $A = \Gamma(U, \mathscr{O}_S)$, $A' = \Gamma(U', \mathscr{O}_{S'})$ their rings, $B = \Gamma(U, \mathscr{B})$, $B' = \Gamma(U', \mathscr{B}')$; the restriction of u, as a $(q|U')$-morphism $\mathscr{B}|U \to \mathscr{B}'|U'$, corresponds to a di-homomorphism of algebras $B \to B'$; if V, V' are the inverse images of U, U' in X, X' respectively, under the structure morphisms, then the morphism $V' \to V$, the restriction of v, corresponds (**I**, 1.7.3) to the above di-homomorphism.

(1.5.7). Under the same hypotheses as in (1.5.6), let $\mathscr{M}$ be a quasi-coherent $\mathscr{B}$-module; there is then a canonical isomorphism of $\mathscr{O}_{X'}$-modules

(1.5.7.1)
$$v^*(\widetilde{\mathscr{M}}) \simeq (q^*(\mathscr{M}) \otimes_{q^*(\mathscr{B})} \mathscr{B}')^\sim.$$

Indeed, the canonical isomorphism (1.5.2.1) gives a canonical isomorphism from $p_1^*(\widetilde{\mathscr{M}})$ to the sheaf on $\operatorname{Spec}(q^*(\mathscr{B}))$ associated to the $q^*(\mathscr{B})$-module $q^*(\mathscr{M})$, and it then suffices to apply (1.4.7). **II** | 14

1.6. Affine morphisms

(1.6.1). We say that a morphism $f : X \to Y$ of preschemes is *affine* if it defines X as a prescheme affine over Y. The properties of preschemes affine over another translate as follows in this language:

Proposition (1.6.2). —

(i) *A closed immersion is affine.*
(ii) *The composition of two affine morphisms is affine.*
(iii) *If $f : X \to Y$ is an affine S-morphism, then $f_{(S')} : X_{(S')} \to Y_{(S')}$ is affine for every base change $S' \to S$.*
(iv) *If $f : X \to Y$ and $f' : X' \to Y'$ are two affine S-morphisms, then*

$$f \times_S f' : X \times_S X' \longrightarrow Y \times_S Y'$$

is affine.
(v) *If $f : X \to Y$ and $g : Y \to Z$ are two morphisms such that $g \circ f$ is affine and g is separated, then f is affine.*
(vi) *If f is affine, then so is f_{red}.*

Proof. By (**I**, 5.5.12), it suffices to prove (i), (ii), and (iii). But (i) is none other than Example (1.2.2), and (ii) is none other than Corollary (1.3.5); finally, (iii) follows from Proposition (1.5.1), since $X_{(S')}$ identifies with the product $X \times_Y Y_{(S')}$ (**I**, 3.3.11). □

Corollary (1.6.3). — *If X is an affine scheme and Y is a scheme, then every morphism $f : X \to Y$ is affine.*

Proposition (1.6.4). — *Let Y be a locally Noetherian prescheme, $f : X \to Y$ a morphism of finite type. For f to be affine, it is necessary and sufficient for f_{red} to be.*

Proof. By (1.6.2, vi), we need only prove the sufficiency of the condition. It suffices to prove that if Y is affine and Noetherian, then X is affine; but Y_{red} is then affine, so the same is true for X_{red} by hypothesis. Now X is Noetherian, so the conclusion follows from (**I**, 6.1.7). □

1.7. Vector bundle associated with a sheaf of modules

(1.7.1). Let A be a ring, E an A-module. Recall that the *symmetric algebra* of E, denoted by $\mathbf{S}(E)$ (or $\mathbf{S}_A(E)$), is the quotient of the tensor algebra $\mathbf{T}(E)$ by the two-sided ideal generated by the elements $x \otimes y - y \otimes x$, where x and y range over E. The algebra $\mathbf{S}(E)$ is characterized by the following universal property: if σ is the canonical map $E \to \mathbf{S}(E)$ (obtained by composing $E \to \mathbf{T}(E)$ with the canonical map $\mathbf{T}(E) \to \mathbf{S}(E)$), then every A-linear map $E \to B$, where B is a *commutative* A-algebra, factors uniquely as $E \xrightarrow{\sigma} \mathbf{S}(E) \xrightarrow{g} B$, where g is an A-homomorphism *of algebras*. We immediately deduce from this characterization that for two A-modules E and F, we have

$$\mathbf{S}(E \oplus F) = \mathbf{S}(E) \otimes \mathbf{S}(F)$$

up to canonical isomorphism; in addition, $\mathbf{S}(E)$ is a covariant functor in E, from the category of A-modules to that of commutative A-algebras; finally, the above characterization also shows that if $E = \varinjlim E_\lambda$, then we have $\mathbf{S}(E) = \varinjlim \mathbf{S}(E_\lambda)$ up to canonical isomorphism. By abuse of language, a product $\sigma(x_1)\sigma(x_2)\cdots\sigma(x_n)$, where $x_i \in E$, is often denoted by $x_1x_2\cdots x_n$ if no confusion follows. The algebra $\mathbf{S}(E)$ is *graded*, $\mathbf{S}_n(E)$ being the set of linear combinations of products of n elements of E ($n \geqslant 0$); the algebra $\mathbf{S}(A)$ is canonically isomorphic to the polynomial algebra $A[T]$ in one indeterminate, and $\mathbf{S}(A^n)$ is canonically isomorphic to the polynomial algebra $A[T_1, \ldots, T_n]$ in n indeterminates. II | 15

(1.7.2). Let ϕ be a ring homomorphism $A \to B$. If F is a B-module, then the canonical map $F \to \mathbf{S}(F)$ gives a canonical map $F_{[\phi]} \to \mathbf{S}(F)_{[\phi]}$, which thus factors as $F_{[\phi]} \to \mathbf{S}(F_{[\phi]}) \to \mathbf{S}(F)_{[\phi]}$; the canonical homomorphism $\mathbf{S}(F_{[\phi]}) \to \mathbf{S}(F)_{[\phi]}$ is surjective, but not necessarily bijective. If E is an A-module, then every di-homomorphism $E \to F$ (that is to say, every A-homomorphism $E \to F_{[\phi]}$) thus canonically gives an A-homomorphism of algebras $\mathbf{S}(E) \to \mathbf{S}(F_{[\phi]}) \to \mathbf{S}(F)_{[\phi]}$, that is to say a di-homomorphism of algebras $\mathbf{S}(E) \to \mathbf{S}(F)$.

With the same notations, for every A-module E, $\mathbf{S}(E \otimes_A B)$ canonically identifies with the algebra $\mathbf{S}(E) \otimes_A B$; this follows immediately from the universal property of $\mathbf{S}(E)$ (1.7.1).

(1.7.3). Let R be a multiplicative subset of the ring A. Applying (1.7.2) to the ring $B = R^{-1}A$ and recalling that $R^{-1}E = E \otimes_A R^{-1}A$, we obtain $\mathbf{S}(R^{-1}E) = R^{-1}\mathbf{S}(E)$ up to canonical isomorphism. In addition, if $R' \supset R$ is a second multiplicative subset of A, then the diagram

$$\begin{tikzcd} R^{-1}E \arrow[r] \arrow[d] & R'^{-1}E \arrow[d] \\ \mathbf{S}(R^{-1}E) \arrow[r] & \mathbf{S}(R'^{-1}E) \end{tikzcd}$$

is commutative.

(1.7.4). Now let $(S, \mathscr{A})$ be a ringed space, and let $\mathscr{E}$ be a $\mathscr{A}$-module over S. By associating to each open subset $U \subset S$ the $\Gamma(U, \mathscr{A})$-algebra $\mathbf{S}(\Gamma(U, \mathscr{E}))$, we obtain (by the functoriality of $\mathbf{S}$, (1.7.2)) a presheaf of algebras. Its associated sheaf, denoted by $\mathbf{S}(\mathscr{E})$ or $\mathbf{S}_{\mathscr{A}}(\mathscr{E})$, is called the *symmetric $\mathscr{A}$-algebra* of the $\mathscr{A}$-module $\mathscr{E}$. It follows immediately from (1.7.1) that $\mathbf{S}(\mathscr{E})$ is a solution to a universal problem: every homomorphism of $\mathscr{A}$-modules $\mathscr{E} \to \mathscr{B}$, where $\mathscr{B}$ is an $\mathscr{A}$-algebra, factors uniquely as $\mathscr{E} \to \mathbf{S}(\mathscr{E}) \to \mathscr{B}$, the second arrow being a homomorphism of $\mathscr{A}$-algebras. There is thus a bijective correspondence between homomorphisms $\mathscr{E} \to \mathscr{B}$ of $\mathscr{A}$-modules and homomorphisms $\mathbf{S}(\mathscr{E}) \to \mathscr{B}$ of $\mathscr{A}$-algebras. In particular, every homomorphism $u : \mathscr{E} \to \mathscr{F}$ of $\mathscr{A}$-modules defines a homomorphism $\mathbf{S}(u) : \mathbf{S}(\mathscr{E}) \to \mathbf{S}(\mathscr{F})$ of $\mathscr{A}$-algebras, and $\mathbf{S}(\mathscr{E})$ is thus a covariant functor in $\mathscr{E}$.

By (1.7.2) and the fact that $\mathbf{S}$ commutes with inductive limits, we have $(\mathbf{S}(\mathscr{E}))_x = \mathbf{S}(\mathscr{E}_x)$ for every II | 16
point $x \in S$. If $\mathscr{E}, \mathscr{F}$ are two $\mathscr{A}$-modules, then $\mathbf{S}(\mathscr{E} \oplus \mathscr{F})$ canonically identifies with $\mathbf{S}(\mathscr{E}) \otimes_{\mathscr{A}} \mathbf{S}(\mathscr{F})$, as we see for the corresponding presheaves.

We also note that $\mathbf{S}(\mathscr{E})$ is a graded $\mathscr{A}$-algebra, the infinite direct sum of the $\mathbf{S}_n(\mathscr{E})$, where the $\mathscr{A}$-module $\mathbf{S}_n(\mathscr{E})$ is the sheaf associated to the presheaf $U \mapsto \mathbf{S}_n(\Gamma(U, \mathscr{E}))$. Taking in particular

$\mathscr{E} = \mathscr{A}$, we see that $\mathbf{S}_{\mathscr{A}}(\mathscr{A})$ identifies with $\mathscr{A}[T] = \mathscr{A} \otimes_{\mathbf{Z}} \mathbf{Z}[T]$ (T an indeterminate, and $\mathbf{Z}$ regarded as a constant sheaf).

(1.7.5). Let $(T, \mathscr{B})$ be a second ringed space, f a morphism $(S, \mathscr{A}) \to (T, \mathscr{B})$. If $\mathscr{F}$ is a $\mathscr{B}$-module, then $\mathbf{S}(f^*(\mathscr{F}))$ canonically identifies with $f^*(\mathbf{S}(\mathscr{F}))$; indeed, if $f = (\psi, \theta)$, then by definition (**0**, 4.3.1),

$$\mathbf{S}(f^*(\mathscr{F})) = \mathbf{S}(\psi^*(\mathscr{F}) \otimes_{\psi^*(\mathscr{B})} \mathscr{A}) = \mathbf{S}(\psi^*(\mathscr{F})) \otimes_{\psi^*(\mathscr{B})} \mathscr{A}$$

(1.7.2); for every open U of S and every section h of $\mathbf{S}(\psi^*(\mathscr{F}))$ over U, h coincides, in a neighbourhood V of every point $s \in U$, with an element of $\mathbf{S}(\Gamma(V, \psi^*(\mathscr{F})))$; if we refer to the definition of $\psi^*(\mathscr{F})$ (**0**, 3.7.1) and take into account that every element of $\mathbf{S}(E)$ for a module E is a linear combination of a finite number of products of elements of E, then we see that there is a neighbourhood W of $\psi(s)$ in T, a section h' of $\mathbf{S}(\mathscr{F})$ over W, and a neighbourhood $V' \subset V \cap \psi^{-1}(W)$ of s such that h coincides with $t \mapsto h'(\psi(t))$ over V'; hence our assertion.

Proposition (1.7.6). — *Let A be a ring, $S = \operatorname{Spec}(A)$ its prime spectrum, $\mathscr{E} = \widetilde{M}$ the $\mathscr{O}_S$-module associated to an A-module M; then the $\mathscr{O}_S$-algebra $\mathbf{S}(\mathscr{E})$ is associated to the A-algebra $\mathbf{S}(M)$.*

Proof. For every $f \in A$, $\mathbf{S}(M_f) = (\mathbf{S}(M))_f$ (1.7.3), and the proposition thus follows from Definition (**I**, 1.3.4). □

Corollary (1.7.7). — *If S is a prescheme, $\mathscr{E}$ a quasi-coherent $\mathscr{O}_S$-module, then the $\mathscr{O}_S$-algebra $\mathbf{S}(\mathscr{E})$ is quasi-coherent. If in addition $\mathscr{E}$ is of finite type, then each of the $\mathscr{O}_S$-modules $\mathbf{S}_n(\mathscr{E})$ is of finite type.*

Proof. The first assertion is an immediate consequence of (1.7.6) and of (**I**, 1.4.1); the second follows from the fact that if E is an A-module of finite type, then $\mathbf{S}_n(E)$ is an A-module of finite type; we then apply (**I**, 1.3.13). □

Definition (1.7.8). — Let $\mathscr{E}$ be a quasi-coherent $\mathscr{O}_S$-module. We call the *vector bundle over S defined by $\mathscr{E}$* and denote by $\mathbf{V}(\mathscr{E})$ the spectrum (1.3.1) of the quasi-coherent $\mathscr{O}_S$-algebra $\mathbf{S}(\mathscr{E})$.

By (1.2.7), for every S-prescheme X, there is a canonical bijective correspondence between the S-morphisms $X \to \mathbf{V}(\mathscr{E})$ and the homomorphisms of *$\mathscr{O}_S$-algebras* $\mathbf{S}(\mathscr{E}) \to \mathscr{A}(X)$, thus also between these S-morphisms and the homomorphisms of *$\mathscr{O}_S$-modules* $\mathscr{E} \to \mathscr{A}(X) = f_*(\mathscr{O}_X)$ (where f is the structure morphism $X \to S$). In particular:

(1.7.9). Take X to be the subprescheme of S induced on an *open subset* $U \subset S$. Then the S-morphisms $U \to \mathbf{V}(\mathscr{E})$ are none other than the U-sections (**I**, 2.5.5) of the U-prescheme induced by $\mathbf{V}(\mathscr{E})$ on the open $p^{-1}(U)$ (where p is the structure morphism $\mathbf{V}(\mathscr{E}) \to S$). From what we have just seen, these U-sections correspond bijectively to homomorphisms of $\mathscr{O}_S$-modules $\mathscr{E} \to j_*(\mathscr{O}_S|U)$ (where j is the canonical injection $U \to S$), or equivalently, by (**0**, 4.4.3), to the $(\mathscr{O}_S|U)$-homomorphisms **II** | 17
$j^*(\mathscr{E}) = \mathscr{E}|U \to \mathscr{O}_S|U$. In addition, it is immediate that the restriction to an open $U' \subset U$ of an S-morphism $U \to \mathbf{V}(\mathscr{E})$ corresponds to the restriction to U' of the corresponding homomorphism $\mathscr{E}|U \to \mathscr{O}_S|U$. We conclude that *the sheaf of germs of S-sections* of $\mathbf{V}(\mathscr{E})$ is canonically identified with the *dual* $\mathscr{E}^\vee$ of $\mathscr{E}$.

In particular, if we set $X = U = S$, then the *zero* homomorphism $\mathscr{E} \to \mathscr{O}_S$ corresponds to a canonical S-section of $\mathbf{V}(\mathscr{E})$, called the *zero S-section* (cf. (8.3.3)).

(1.7.10). Now take X to be the spectrum $\{\xi\}$ of a field K; the structure morphism $f : X \to S$ then corresponds to a monomorphism $k(s) \to K$, where $s = f(\xi)$ (**I**, 2.4.6); the S-morphisms $\{\xi\} \to \mathbf{V}(\mathscr{E})$ are none other than the *geometric points of $\mathbf{V}(\mathscr{E})$ with values in the extension K of $k(s)$* (**I**, 3.4.5), lying over the points of $p^{-1}(s)$. The set of these points, which we can call *the rational geometric fibre over K* of $\mathbf{V}(\mathscr{E})$ *over the point s*, is identified by (1.7.8) with the set of homomorphisms of $\mathscr{O}_S$-modules $\mathscr{E} \to f_*(\mathscr{O}_X)$, or, equivalently (**0**, 4.4.3) with the set of homomorphisms of $\mathscr{O}_X$-modules $f^*(\mathscr{E}) \to \mathscr{O}_X = K$. But we have by definition (**0**, 4.3.1) $f^*(\mathscr{E}) = \mathscr{E}_s \otimes_{\mathscr{O}_s} K = \mathscr{E}^s \otimes_{k(s)} K$, setting $\mathscr{E}^s = \mathscr{E}_s / \mathfrak{m}_s \mathscr{E}_s$; the geometric fibre of $\mathbf{V}(\mathscr{E})$ rational over K over s thus identifies with the *dual* of the *K-vector space $\mathscr{E}^s \otimes_{k(s)} K$*; if $\mathscr{E}^s$ or K is of finite dimension over $k(s)$, then this dual also identifies with $(\mathscr{E}^s)^\vee \otimes_{k(s)} K$, denoting by $(\mathscr{E}^s)^\vee$ the dual of the $k(s)$-vector space $\mathscr{E}^s$.

Proposition (1.7.11). —

(i) $\mathbf{V}(\mathscr{E})$ *is a contravariant functor in* $\mathscr{E}$ *from the category of quasi-coherent* $\mathscr{O}_S$*-modules to the category of affine* S*-schemes.*
(ii) *If* $\mathscr{E}$ *is an* $\mathscr{O}_S$*-module of finite type, then* $\mathbf{V}(\mathscr{E})$ *is of finite type over* S.
(iii) *If* $\mathscr{E}$ *and* $\mathscr{F}$ *are two quasi-coherent* $\mathscr{O}_S$*-modules, then* $\mathbf{V}(\mathscr{E} \oplus \mathscr{F})$ *canonically identifies with* $\mathbf{V}(\mathscr{E}) \times_S \mathbf{V}(\mathscr{F})$.
(iv) *Let* $g : S' \to S$ *be a morphism; for every quasi-coherent* $\mathscr{O}_S$*-module* $\mathscr{E}$, $\mathbf{V}(g^*(\mathscr{E}))$ *canonically identifies with* $\mathbf{V}(\mathscr{E})_{(S')} = \mathbf{V}(\mathscr{E}) \times_S S'$.
(v) *A surjective homomorphism* $\mathscr{E} \to \mathscr{F}$ *of quasi-coherent* $\mathscr{O}_S$*-modules corresponds to a closed immersion* $\mathbf{V}(\mathscr{F}) \to \mathbf{V}(\mathscr{E})$.

Proof. (i) is an immediate consequence of (1.2.7), taking into account that every homomorphism of $\mathscr{O}_S$-modules $\mathscr{E} \to \mathscr{F}$ canonically defines a homomorphism of $\mathscr{O}_S$-algebras $\mathbf{S}(\mathscr{E}) \to \mathbf{S}(\mathscr{F})$. (ii) follows immediately from the definition (**I**, 6.3.1) and the fact that if E is an A-module of finite type, then $\mathbf{S}(E)$ is an A-algebra of finite type. To prove (iii), it suffices to start with the canonical isomorphism $\mathbf{S}(\mathscr{E} \oplus \mathscr{F}) \simeq \mathbf{S}(\mathscr{E}) \otimes_{\mathscr{O}_S} \mathbf{S}(\mathscr{F})$ (1.7.4) and to apply (1.4.6). Similarly, to prove (iv), it suffices to start with the canonical isomorphism $\mathbf{S}(g^*(\mathscr{E})) \simeq g^*(\mathbf{S}(\mathscr{E}))$ (1.7.5) and to apply (1.5.2). Finally, to establish (v), it suffices to remark that if the homomorphism $\mathscr{E} \to \mathscr{F}$ is surjective, then so is the corresponding homomorphism $\mathbf{S}(\mathscr{E}) \to \mathbf{S}(\mathscr{F})$ of $\mathscr{O}_S$-algebras, and the conclusion follows from (1.4.10). ☐

(1.7.12). Take in particular $\mathscr{E} = \mathscr{O}_S$; the prescheme $\mathbf{V}(\mathscr{O}_S)$ is the affine S-scheme that is the spectrum of the $\mathscr{O}_S$-algebra $\mathbf{S}(\mathscr{O}_S)$, which identifies with the $\mathscr{O}_S$-algebra $\mathscr{O}_S[T] = \mathscr{O}_S \otimes_{\mathbf{Z}} \mathbf{Z}[T]$ (T indeterminate); **II** | 18
this is evident when $S = \operatorname{Spec}(\mathbf{Z})$, by virtue of (1.7.6), and we pass from there to the general case by considering the structure morphism $S \to \operatorname{Spec}(\mathbf{Z})$ and using (1.7.11, iv). Because of this result, we set $\mathbf{V}(\mathscr{O}_S) = S[T]$, and we thus have the formula

$$S[T] = S \otimes_{\mathbf{Z}} \mathbf{Z}[T]. \tag{1.7.12.1}$$

The identification of the sheaf of germs of S-sections of $S[T]$ with $\mathscr{O}_S$, already seen in (**I**, 3.3.15), reappears here in a more general context as a special case of (1.7.9).

(1.7.13). For every S-prescheme X, we have seen (1.7.8) that $\operatorname{Hom}_S(X, S[T])$ canonically identifies with $\operatorname{Hom}_{\mathscr{O}_S}(\mathscr{O}_S, \mathscr{A}(X))$, which is canonically isomorphic to $\Gamma(S, \mathscr{A}(X))$, and is therefore equipped with a ring structure; in addition, every S-morphism $h : X \to Y$ induces a ring homomorphism $\Gamma(\mathscr{A}(h)) : \Gamma(S, \mathscr{A}(Y)) \to \Gamma(S, \mathscr{A}(X))$ (1.1.2). With the ring structure just defined on $\operatorname{Hom}_S(X, S[T])$, we may therefore regard $\operatorname{Hom}_S(X, S[T])$ as a *contravariant functor* in X, from the category of S-preschemes to that of rings. On the other hand, $\operatorname{Hom}_S(X, \mathbf{V}(\mathscr{E}))$ is likewise identified with $\operatorname{Hom}_{\mathscr{O}_S}(\mathscr{E}, \mathscr{A}(X))$ (where $\mathscr{A}(X)$ is considered as an $\mathscr{O}_S$*-module*); as a result, we can canonically equip it with a *module* structure over the ring $\operatorname{Hom}_S(X, S[T])$, and we see as above that the pair

$$(\operatorname{Hom}_S(X, S[T]), \operatorname{Hom}_S(X, \mathbf{V}(\mathscr{E})))$$

is a contravariant functor in X, with values in the category whose objects are the pairs (A, M) consisting of a ring A and an A-module M, the morphisms being di-homomorphisms.

We will interpret these facts by saying that $S[T]$ is an *S-scheme of rings* and that $\mathbf{V}(\mathscr{E})$ is an *S-scheme of modules* over the S-scheme of rings $S[T]$ (cf. Chapter 0, §8).

(1.7.14). We will see that the structure of an S-scheme of modules defined on the S-scheme $\mathbf{V}(\mathscr{E})$ allows us to reconstruct the $\mathscr{O}_S$-module $\mathscr{E}$ up to unique isomorphism: for this, we will show that $\mathscr{E}$ is canonically isomorphic to an $\mathscr{O}_S$-submodule of $\mathbf{S}(\mathscr{E}) = \mathscr{A}(\mathbf{V}(\mathscr{E}))$, defined by means of this structure. Indeed, by (1.7.4), the set $\operatorname{Hom}_{\mathscr{O}_S}(\mathbf{S}(\mathscr{E}), \mathscr{A}(X))$ of homomorphisms of *$\mathscr{O}_S$-algebras* is canonically identified with $\operatorname{Hom}_{\mathscr{O}_S}(\mathscr{E}, \mathscr{A}(X))$, the set of homomorphisms of *$\mathscr{O}_S$-modules*: if h and h' are two elements of this latter set, s_i ($1 \leqslant i \leqslant n$) sections of $\mathscr{E}$ over an open $U \subset S$, t a section of $\mathscr{A}(X)$ over U, then we have by definition

$$(h + h')(s_1 s_2 \cdots s_n) = \prod_{i=1}^{n} (h(s_i) + h'(s_i))$$

and

$$(t \cdot h)(s_1 s_2 \cdots s_n) = t^n \prod_{i=1}^{n} h(s_i).$$

This being so, if z is a section of $\mathbf{S}(\mathscr{E})$ over U, then $h \mapsto h(z)$ is a map from $\operatorname{Hom}_S(X, \mathbf{V}(\mathscr{E})) = \operatorname{Hom}_{\mathscr{O}_S}(\mathbf{S}(\mathscr{E}), \mathscr{A}(X))$ to $\Gamma(U, \mathscr{A}(X))$. We will show that $\mathscr{E}$ is identified with a submodule of $\mathbf{S}(\mathscr{E})$ **II** | 19
such that, *for every open $U \subset S$, every section z of this $\mathscr{O}_S$-submodule over U, and every S-prescheme X, the map $h \mapsto h(z)$ from $\operatorname{Hom}_{\mathscr{O}_S|U}(\mathbf{S}(\mathscr{E})|U, \mathscr{A}(X)|U)$ to $\Gamma(U, \mathscr{A}(X))$ is a homomorphism of $\Gamma(U, \mathscr{A}(X))$-modules*.

It is immediate that $\mathscr{E}$ has this property; to show the converse, we can reduce to proving that when $S = \operatorname{Spec}(A)$, $\mathscr{E} = \widetilde{M}$, a section z of $\mathbf{S}(\mathscr{E})$ over S that (for $U = S$) has the property stated above is necessarily a section of $\mathscr{E}$; we then have $z = \sum_{n=0}^{\infty} z_n$, where $z_n \in \mathbf{S}_n(M)$, and it is a question of proving that $z_n = 0$ for $n \neq 1$. Set $B = \mathbf{S}(M)$ and take for X the prescheme $\operatorname{Spec}(B[T])$, where T is an indeterminate. The set $\operatorname{Hom}_{\mathscr{O}_S}(\mathbf{S}(\mathscr{E}), \mathscr{A}(X))$ identifies with the set of ring homomorphisms $h : B \to B[T]$ (**I**, 1.3.13), and from what we saw above, we have $(T \cdot h)(z) = \sum_{n=0}^{\infty} T^n h(z_n)$: the hypothesis on z implies that we have $\sum_{n=0}^{\infty} T^n h(z_n) = T \cdot \sum_{n=0}^{\infty} h(z_n)$ for every homomorphism h. Taking h in particular to be the canonical injection, we obtain $\sum_{n=0}^{\infty} T^n z_n = T \cdot \sum_{n=0}^{\infty} z_n$, which gives the desired conclusion $z_n = 0$ for $n \neq 1$.

Proposition (1.7.15). — *Let Y be a prescheme whose underlying space is Noetherian, or a quasi-compact scheme. Every affine Y-scheme X of finite type over Y is Y-isomorphic to a closed Y-subscheme of a Y-scheme of the form $\mathbf{V}(\mathscr{E})$, where $\mathscr{E}$ is a quasi-coherent $\mathscr{O}_Y$-module of finite type.*

Proof. The quasi-coherent $\mathscr{O}_Y$-algebra $\mathscr{A}(X)$ is of finite type (1.3.7). The hypotheses imply that $\mathscr{A}(X)$ is generated by a quasi-coherent $\mathscr{O}_Y$-submodule of finite type $\mathscr{E}$ (**I**, 9.6.5); by definition, this implies that the canonical homomorphism $\mathbf{S}(\mathscr{E}) \to \mathscr{A}(X)$ canonically extending the injection $\mathscr{E} \to \mathscr{A}(X)$ is *surjective*; the conclusion then follows from (1.4.10). ☐

§2. Homogeneous prime spectra

2.1. Generalities on graded rings and modules

Notation (2.1.1). — Given a *positively graded* ring S, we denote by S_n the subset of S consisting of homogeneous elements of degree n ($n \geqslant 0$), by S_+ the (direct) sum of the S_n for $n > 0$; we have $1 \in S_0$, S_0 is a subring of S, S_+ is a graded ideal of S, and S is the direct sum of S_0 and S_+. If M is a *graded* module over S (with positive or negative degrees), we similarly denote by M_n the S_0-module consisting of homogeneous elements of M of degree n (with $n \in \mathbf{Z}$).

For every integer $d > 0$, we denote by $S^{(d)}$ the direct sum of the S_{nd}; by considering the elements of S_{nd} as homogeneous of degree n, the S_{nd} define on $S^{(d)}$ a graded ring structure.

For every integer k such that $0 \leqslant k \leqslant d-1$, we denote by $M^{(d,k)}$ the direct sum of the M_{nd+k} **II** | 20
($n \in \mathbf{Z}$); this is a graded $S^{(d)}$-module when we consider the elements of M_{nd+k} as homogeneous of degree n. We write $M^{(d)}$ in place of $M^{(d,0)}$.

With the above notation, for every integer n (positive or negative), we denote by $M(n)$ the graded S-module defined by $(M(n))_k = M_{n+k}$ for every $k \in \mathbf{Z}$. In particular, $S(n)$ will be a graded S-module such that $(S(n))_k = S_{n+k}$, by agreeing to set $S_n = 0$ for $n < 0$. We say that a graded S-module M is *free* if it is isomorphic, as a *graded* module, to a direct sum of modules of the form $S(n)$; since $S(n)$ is a cyclic S-module generated by the element 1 of S, regarded as an element of degree $-n$, this is equivalent to saying that M admits a *basis* over S consisting of *homogeneous* elements.

We say that a graded S-module M *admits a finite presentation* if there exists an exact sequence $P \to Q \to M \to 0$, where P and Q are finite direct sums of modules of the form $S(n)$ and the homomorphisms are of degree 0 (cf. (2.1.2)).

(2.1.2). Let M and N be two graded S-modules; we define on $M \otimes_S N$ a *graded* S-module structure in the following way. On the tensor product $M \otimes_{\mathbf{Z}} N$, we can define a graded $\mathbf{Z}$-module structure (where $\mathbf{Z}$ is graded by $\mathbf{Z}_0 = \mathbf{Z}$, $\mathbf{Z}_n = 0$ for $n \neq 0$) by setting $(M \otimes_{\mathbf{Z}} N)_q = \bigoplus_{m+n=q} M_m \otimes_{\mathbf{Z}} N_n$ (as M and N are respectively direct sums of the M_m and the N_n, we know that we can canonically identify $M \otimes_{\mathbf{Z}} N$ with the direct sum of all the $M_m \otimes_{\mathbf{Z}} N_n$). This being so, we have $M \otimes_S N = (M \otimes_{\mathbf{Z}} N)/P$, where P is the $\mathbf{Z}$-submodule of $M \otimes_{\mathbf{Z}} N$ generated by the elements $(xs) \otimes y - x \otimes (sy)$ for $x \in M$, $y \in N$, $s \in S$; it is clear that P is a *graded* $\mathbf{Z}$-submodule of $M \otimes_{\mathbf{Z}} N$, and we see immediately that we obtain a graded S-module structure on $M \otimes_S N$ by passing to the quotient.

For two graded S-modules M and N, recall that a homomorphism $u : M \to N$ of S-modules is said to be *of degree* k if $u(M_j) \subset N_{j+k}$ for all $j \in \mathbf{Z}$. If H_n denotes the set of all the homomorphisms of degree n from M to N, then we denote by $\mathrm{Hom}_S(M, N)$ the (direct) *sum* of the H_n ($n \in \mathbf{Z}$) in the S-module H of all the homomorphisms (of S-modules) from M to N; in general, $\mathrm{Hom}_S(M, N)$ is not equal to the latter. However, we have $H = \mathrm{Hom}_S(M, N)$ when M is *of finite type*; indeed, we can then suppose that M is generated by a finite number of homogeneous elements x_i ($1 \leqslant i \leqslant n$), and every homomorphism $u \in H$ can be written in a unique way as $\sum_{k \in \mathbf{Z}} u_k$, where for each k, $u_k(x_i)$ is equal to the homogeneous component of degree $k + \deg(x_i)$ of $u(x_i)$ ($1 \leqslant i \leqslant n$), which implies that $u_k = 0$ except for a finite number of indices; we have by definition that $u_k \in H_k$, hence the conclusion.

The elements of degree 0 of $\mathrm{Hom}_S(M, N)$ are called the *homomorphisms of graded S-modules*. It is clear that $S_m H_n \subset H_{m+n}$, so the H_n define on $\mathrm{Hom}_S(M, N)$ a graded S-module structure.

It follows immediately from these definitions that we have

$$M(m) \otimes_S N(n) = (M \otimes_S N)(m + n), \tag{2.1.2.1}$$

$$\mathrm{Hom}_S(M(m), N(n)) = (\mathrm{Hom}_S(M, N))(n - m), \tag{2.1.2.2}$$

for two graded S-modules M and N.

Let S and S' be two graded rings; a homomorphism of *graded rings* $\phi : S \to S'$ is a homomorphism of rings such that $\phi(S_n) \subset S'_n$ for all $n \in \mathbf{Z}$ (in other words, ϕ must be a homomorphism *of degree* 0 of graded $\mathbf{Z}$-modules). Such a homomorphism endows S' with a *graded* S-module structure; equipped with this structure and with its graded ring structure, S' is called a *graded S-algebra*. **II** | 21

If M is also a graded S-module, then the tensor product $M \otimes_S S'$ of *graded* S-modules is equipped in a natural way with a *graded* S'-module structure, the grading being defined as above.

Lemma (2.1.3). — *Let S be a ring graded in positive degrees. For a subset E of S_+ consisting of homogeneous elements to generate S_+ as an S-module, it is necessary and sufficient for E to generate S as an S_0-algebra.*

Proof. The condition is evidently sufficient; we show that it is necessary. Let E_n (resp. E^n) be the set of elements of E of degree equal to n (resp. of degree $\leqslant n$); it suffices to show, by induction on $n > 0$, that S_n is the S_0-module generated by the elements of degree n which are products of elements of E^n. This is evident for $n = 1$ by virtue of the hypothesis; the latter also shows that $S_n = \sum_{p=0}^{n-1} S_p E_{n-p}$, and the induction argument is then immediate. □

Corollary (2.1.4). — *For S_+ to be an ideal of finite type, it is necessary and sufficient for S to be an S_0-algebra of finite type.*

Proof. We can always assume that a finite system of generators of the S_0-algebra S (resp. of the S-ideal S_+) consists of homogeneous elements, by replacing each of the generators considered by its homogeneous components. □

Corollary (2.1.5). — *For S to be Noetherian, it is necessary and sufficient for S_0 to be Noetherian and for S to be an S_0-algebra of finite type.*

Proof. The condition is evidently sufficient; it is necessary, since S_0 is isomorphic to S/S_+ and S_+ must be an ideal of finite type (2.1.4). □

Lemma (2.1.6). — *Let S be a ring graded in positive degrees, which is an S_0-algebra of finite type. Let M be a graded S-module of finite type. Then:*

(i) *The M_n are S_0-modules of finite type, and there exists an integer n_0 such that $M_n = 0$ for $n \leqslant n_0$.*
(ii) *There exists an integer n_1 and an integer $h > 0$ such that, for every integer $n \geqslant n_1$, we have $M_{n+h} = S_h M_n$.*
(iii) *For every pair of integers (d, k) such that $d > 0$, $0 \leqslant k \leqslant d - 1$, $M^{(d,k)}$ is an $S^{(d)}$-module of finite type.*
(iv) *For every integer $d > 0$, $S^{(d)}$ is an S_0-algebra of finite type.*
(v) *There exists an integer $h > 0$ such that $S_{mh} = (S_h)^m$ for all $m > 0$.*
(vi) *For every integer $n > 0$, there exists an integer m_0 such that $S_m \subset S_+^n$ for all $m \geqslant m_0$.*

Proof. We can assume that S is generated (as an S_0-algebra) by homogeneous elements f_i, of degrees h_i ($1 \leqslant i \leqslant r$), and M is generated (as an S-module) by homogeneous elements x_j of degrees k_j ($1 \leqslant j \leqslant s$). It is clear that M_n is formed by linear combinations, with coefficients in S_0, of elements **II** | 22 $f_1^{\alpha_1} \cdots f_r^{\alpha_r} x_j$ such that the α_i are integers $\geqslant 0$ satisfying $k_j + \sum_i \alpha_i h_i = n$; for each j, there are only finitely many systems (α_i) satisfying this equation, since the h_i are > 0, hence the first assertion of (i); the second is evident. On the other hand, let h be the l.c.m. of the h_i and set $g_i = f_i^{h/h_i}$ ($1 \leqslant i \leqslant r$), so that all the g_i are of degree h; let z_μ be the elements of M of the form $f_1^{\alpha_1} \cdots f_r^{\alpha_r} x_j$ with $0 \leqslant \alpha_i < h/h_i$ for $1 \leqslant i \leqslant r$; there are finitely many of these elements, so let n_1 be the largest of their degrees. It is clear that for $n \geqslant n_1$, every element of M_{n+h} is a linear combination of the z_μ whose coefficients are monomials of positive degree in the g_i, so we have $M_{n+h} = S_h M_n$, which establishes (ii). In a similar way, we see (for all $d > 0$) that an element of $M^{(d,k)}$ is a linear combination, with coefficients in S_0, of elements of the form $g^d f_1^{\alpha_1} \cdots f_r^{\alpha_r} x_j$ with $0 \leqslant \alpha_i < d$, where g is a homogeneous element of S; hence (iii); (iv) then follows from (iii) and from Lemma (2.1.3), by taking $M = S_+$, since $(S_+)^{(d)} = (S^{(d)})_+$. The assertion of (v) is deduced from (ii) by taking $M = S$. Finally, for a given n, there are finitely many systems (α_i) such that $\alpha_i \geqslant 0$ and $\sum_i \alpha_i < n$; if m_0 is chosen strictly larger than the greatest value of $\sum_i \alpha_i h_i$ among these systems, then $S_m \subset S_+^n$ for $m \geqslant m_0$, which proves (vi). □

Corollary (2.1.7). — *If S is Noetherian, then so is $S^{(d)}$ for every integer $d > 0$.*

Proof. This follows from (2.1.5) and (2.1.6, iv). □

(2.1.8). Let $\mathfrak{p}$ be a *graded* prime ideal of the graded ring S; $\mathfrak{p}$ is thus a direct sum of the subgroups $\mathfrak{p}_n = \mathfrak{p} \cap S_n$. Suppose that $\mathfrak{p}$ *does not contain* S_+. Then if $f \in S_+$ is not in $\mathfrak{p}$, the relation $f^n x \in \mathfrak{p}$ is equivalent to $x \in \mathfrak{p}$; in particular, if $f \in S_d$ ($d > 0$), for all $x \in S_{m-nd}$, then the relation $f^n x \in \mathfrak{p}_m$ is equivalent to $x \in \mathfrak{p}_{m-nd}$.

Proposition (2.1.9). — *Let n_0 be an integer > 0; for all $n \geqslant n_0$, let $\mathfrak{p}_n$ be a subgroup of S_n. For there to exist a graded prime ideal $\mathfrak{p}$ of S not containing S_+ and such that $\mathfrak{p} \cap S_n = \mathfrak{p}_n$ for all $n \geqslant n_0$, it is necessary and sufficient for the following conditions to be satisfied:*

(1st) *$S_m \mathfrak{p}_n \subset \mathfrak{p}_{m+n}$ for all $m \geqslant 0$ and all $n \geqslant n_0$.*
(2nd) *For $m \geqslant n_0$, $n \geqslant n_0$, $f \in S_m$, $g \in S_n$, the relation $fg \in \mathfrak{p}_{m+n}$ implies $f \in \mathfrak{p}_m$ or $g \in \mathfrak{p}_n$.*
(3rd) *$\mathfrak{p}_n \neq S_n$ for at least one $n \geqslant n_0$.*

In addition, the graded prime ideal $\mathfrak{p}$ is then unique.

Proof. It is evident that the conditions (1st) and (2nd) are necessary. In addition, if $\mathfrak{p} \not\supset S_+$, then there exists at least one $k > 0$ such that $\mathfrak{p} \cap S_k \neq S_k$; if $f \in S_k$ is not in $\mathfrak{p}$, the relation $\mathfrak{p} \cap S_n = S_n$ implies $\mathfrak{p} \cap S_{n-mk} = S_{n-mk}$ according to (2.1.8); therefore, if $\mathfrak{p} \cap S_n = S_n$ for all sufficiently large n, we would have $\mathfrak{p} \supset S_+$, contrary to the hypothesis, which proves that (3rd) is necessary. Conversely, suppose that the conditions (1st), (2nd), and (3rd) are satisfied. Note that if for an integer $d \geqslant n_0$, $f \in S_d$ is not in $\mathfrak{p}_d$, then, if $\mathfrak{p}$ exists, $\mathfrak{p}_m$, for $m < n_0$, is necessarily equal to the set of the $x \in S_m$ such that $f^r x \in \mathfrak{p}_{m+rd}$, except for a finite number of values of r. This already proves that if $\mathfrak{p}$ exists, then it is unique. It remains to show that if we define the $\mathfrak{p}_m$ for $m < n_0$ by the previous condition, then $\mathfrak{p} = \sum_{n=0}^\infty \mathfrak{p}_n$ is a prime ideal. First, note that by virtue of (2nd), for $m \geqslant n_0$, $\mathfrak{p}_m$ is also defined as the set of the $x \in S_m$ such that $f^r x \in \mathfrak{p}_{m+rd}$ except for a finite number of values of r. This being **II** | 23 so, if $g \in S_m$, $x \in \mathfrak{p}_n$, then we have $f^r g x \in \mathfrak{p}_{m+n+rd}$ except for a finite number of values of r, so $gx \in \mathfrak{p}_{m+n}$, which proves that $\mathfrak{p}$ is an ideal of S. To establish that this ideal is prime, in other words that the ring $S/\mathfrak{p}$, graded by the subgroups $S_n/\mathfrak{p}_n$, is an integral domain, it suffices (by considering the highest-degree components of two elements of $S/\mathfrak{p}$) to prove that if $x \in S_m$ and $y \in S_n$ are such that $x \notin \mathfrak{p}_m$ and $y \notin \mathfrak{p}_n$, then $xy \notin \mathfrak{p}_{m+n}$. If not, for r large enough, we would have $f^{2r} xy \in \mathfrak{p}_{m+n+2rd}$; but we have $f^r y \notin \mathfrak{p}_{n+rd}$ for all $r > 0$; it then follows from (2nd) that, except for a finite number of values of r, we have $f^r x \in \mathfrak{p}_{m+rd}$, and we conclude that $x \in \mathfrak{p}_m$ contrary to the hypothesis. □

(2.1.10). We say that a subset $\mathfrak{J}$ of S_+ is an *ideal of* S_+ if it is an ideal of S, and $\mathfrak{J}$ is a *graded prime ideal of* S_+ if it is the intersection of S_+ and a graded prime ideal of S *not containing* S_+ (this prime ideal is also unique according to Proposition (2.1.9)). If $\mathfrak{J}$ is an ideal of S_+, the *radical of* $\mathfrak{J}$ *in* S_+ is the set of elements of S_+ which have a power in $\mathfrak{J}$, in other words the set $\mathfrak{r}_+(\mathfrak{J}) = \mathfrak{r}(\mathfrak{J}) \cap S_+$; in particular, the radical of 0 in S_+ is then called the *nilradical* of S_+ and denoted by $\mathfrak{N}_+$: this is the set of nilpotent elements of S_+. If $\mathfrak{J}$ is an *graded* ideal of S_+, then its radical $\mathfrak{r}_+(\mathfrak{J})$ is a *graded* ideal: by passing to the quotient ring $S/\mathfrak{J}$, we can reduce to the case $\mathfrak{J} = 0$, and it remains to see that if $x = x_h + x_{h+1} + \cdots + x_k$ is nilpotent, then so are the $x_i \in S_i$ $(1 \leqslant h \leqslant i \leqslant k)$; we can assume $x_k \neq 0$ and the component of highest degree of x^n is then x_k^n, hence x_k is nilpotent, and we then argue by induction on k. We say that the graded ring S is *essentially reduced* if $\mathfrak{N}_+ = 0$, in other words, if S_+ does not contain nilpotent elements $\neq 0$.

(2.1.11). We note that if, in the graded ring S, an element x is a zero-divisor, then so is its component of highest degree. We say that a ring S is *essentially integral* if the ring S_+ (*without a unit element*) contains no zero-divisors and is nonzero; for this, it is enough that no nonzero homogeneous element of S_+ be a zero-divisor in this ring. It is clear that if $\mathfrak{p}$ is a graded prime ideal of S_+, then $S/\mathfrak{p}$ is essentially integral.

Let S be an essentially integral graded ring, and let $x_0 \in S_0$: if there then exists *a* homogeneous element $f \neq 0$ of S_+ such that $x_0 f = 0$, then we have $x_0 S_+ = 0$, since we have $(x_0 g) f = (x_0 f) g = 0$ for all $g \in S_+$, and the hypothesis thus implies $x_0 g = 0$. For S to be integral, it is necessary and sufficient for S_0 to be integral and the annihilator of S_+ in S_0 to be 0.

2.2. Rings of fractions of a graded ring

(2.2.1). Let S be a graded ring, in positive degrees, f a *homogeneous* element of S, of degree $d > 0$; then the ring of fractions $S' = S_f$ is graded, taking for S'_n the set of the x/f^k, where $x \in S_{n+kd}$ with $k \geqslant 0$ (we observe here that n can take arbitrary negative values); we denote the subring $S'_0 = (S_f)_0$ of S' consisting of elements *of degree* 0 by the notation $S_{(f)}$.

If $f \in S_d$, then the monomials $(f/1)^h$ in S_f (h a positive or negative integer) form a *free system* over the ring $S_{(f)}$, and the set of their linear combinations is none other than the ring $(S^{(d)})_f$, which II | 24
is thus *isomorphic to* $S_{(f)}[T, T^{-1}] = S_{(f)} \otimes_{\mathbf{Z}} \mathbf{Z}[T, T^{-1}]$ (where T is an indeterminate). Indeed, if we have a relation $\sum_{h=-a}^{b} z_h (f/1)^h = 0$ with $z_h = x_h/f^m$, where the x_h are in S_{md}, then this relation is equivalent by definition to the existence of a $k \geqslant a$ such that $\sum_{h=-a}^{b} f^{h+k} x_h = 0$, and as the degrees of the terms of this sum are distinct, we have $f^{h+k} x_h = 0$ for all h, hence $z_h = 0$ for all h.

If M is a graded S-module, then $M' = M_f$ is a graded S_f-module, M'_n being the set of the z/f^k with $z \in M_{n+kd}$ $(k \geqslant 0)$; we denote by $M_{(f)}$ the set of the homogeneous elements of degree 0 of M'; it is immediate that $M_{(f)}$ is an $S_{(f)}$-module and that we have $(M^{(d)})_f = M_{(f)} \otimes_{S_{(f)}} (S^{(d)})_f$.

Lemma (2.2.2). — *Let d and e be integers > 0, $f \in S_d$, $g \in S_e$. There exists a canonical ring isomorphism*

$$S_{(fg)} \simeq (S_{(f)})_{g^d/f^e};$$

if we canonically identify these two rings, then there exists a canonical module isomorphism

$$M_{(fg)} \simeq (M_{(f)})_{g^d/f^e}.$$

Proof. Indeed, fg divides $f^e g^d$, and this latter element divides $(fg)^{de}$, so the graded rings S_{fg} and $S_{f^e g^d}$ are canonically identified; on the other hand, $S_{f^e g^d}$ also identifies with $(S_{f^e})_{g^d/1}$ (**0**, 1.4.6), and as $f^e/1$ is invertible in S_{f^e}, $S_{f^e g^d}$ also identifies with $(S_{f^e})_{g^d/f^e}$. The element g^d/f^e is of degree 0 in S_{f^e}; we immediately conclude that the subring of $(S_{f^e})_{g^d/f^e}$ consisting of elements of degree 0 is $(S_{(f^e)})_{g^d/f^e}$, and as we evidently have $S_{(f^e)} = S_{(f)}$, this proves the first part of the lemma; the second is established in a similar way. □

(2.2.3). Under the hypotheses of (2.2.2), it is clear that the canonical homomorphism $S_f \to S_{fg}$ (**0**, 1.4.1), which sends x/f^k to $g^k x/(fg)^k$, is of degree 0, thus gives by restriction a *canonical homomorphism* $S_{(f)} \to S_{(fg)}$, such that the diagram

$$\begin{tikzcd} & S_{(f)} \arrow[dl] \arrow[dr] & \\ S_{(fg)} \arrow[rr, "\sim"] & & (S_{(f)})_{g^d/f^e} \end{tikzcd}$$

is commutative. We similarly define a canonical homomorphism $M_{(f)} \to M_{(fg)}$.

Lemma (2.2.4). — *If f and g are two homogeneous elements of S_+, then the ring $S_{(fg)}$ is generated by the union of the canonical images of $S_{(f)}$ and $S_{(g)}$.*

Proof. By virtue of Lemma (2.2.2), it suffices to see that $1/(g^d/f^e) = f^{d+e}/(fg)^d$ belongs to the canonical image of $S_{(g)}$ in $S_{(fg)}$, which is evident by definition. □

Proposition (2.2.5). — *Let d be an integer > 0 and let $f \in S_d$. Then there exists a canonical ring isomorphism $S_{(f)} \simeq S^{(d)}/(f-1)S^{(d)}$; if we identify these two rings by this isomorphism, then there exists a canonical module isomorphism $M_{(f)} \simeq M^{(d)}/(f-1)M^{(d)}$.*

Proof. The first of these isomorphisms is defined by sending x/f^n, where $x \in S_{nd}$, to the element $\overline{x}$, the class of x mod. $(f-1)S^{(d)}$; this map is well-defined, because we have the congruence $f^h x \equiv x\,(\text{mod.}\,(f-1)S^{(d)})$ for all $x \in S^{(d)}$, so if $f^h x = 0$ for an $h > 0$, then we have $\overline{x} = 0$. On the other **II** | 25
hand, if $x \in S_{nd}$ is such that $x = (f-1)y$ with $y = y_{hd} + y_{(h+1)d} + \cdots + y_{kd}$ with $y_{jd} \in S_{jd}$ and $y_{hd} \neq 0$, then we necessarily have $h = n$ and $x = -y_{hd}$, as well as the relations $y_{(j+1)d} = fy_{jd}$ for $h \leqslant j \leqslant k-1$, $fy_{kd} = 0$, which ultimately gives $f^{k-n+1}x = 0$; we send every class $\overline{x}$ mod. $(f-1)S^{(d)}$ of an element $x \in S_{nd}$ to the element x/f^n of $S_{(f)}$, since the preceding remark shows that this map is well-defined. It is immediate that these two maps thus defined are ring homomorphisms, each the reciprocal of the other. We proceed exactly the same way for M. □

Corollary (2.2.6). — *If S is Noetherian, then so is $S_{(f)}$ for f homogeneous of degree > 0.*

Proof. This follows immediately from Corollary (2.1.7) and Proposition (2.2.5). □

(2.2.7). Let T be a multiplicative subset of S_+ consisting of *homogeneous* elements; $T_0 = T \cup \{1\}$ is then a multiplicative subset of S; as the elements of T_0 are homogeneous, the ring $T_0^{-1}S$ is still graded in the evident way; we denote by $S_{(T)}$ the subring of $T_0^{-1}S$ consisting of elements of degree 0, that is to say, the elements of the form x/h, where $h \in T$ and x is homogeneous of degree equal to that of h. We know from (**0**, 1.4.5) that $T_0^{-1}S$ is canonically identified with the inductive limit of the rings S_f, where f varies over T (with respect to the canonical homomorphisms $S_f \to S_{fg}$); as this identification respects the degrees, it identifies $S_{(T)}$ with the *inductive limit* of the $S_{(f)}$ for $f \in T$. For every graded S-module M, we similarly define the module $M_{(T)}$ (over the ring $S_{(T)}$) consisting of elements of degree 0 of $T_0^{-1}M$, and we see that this module is the inductive limit of the $M_{(f)}$ for $f \in T$.

If $\mathfrak{p}$ is a graded prime ideal of S_+, then we denote by $S_{(\mathfrak{p})}$ and $M_{(\mathfrak{p})}$ the ring $S_{(T)}$ and the module $M_{(T)}$ respectively, where T is the set of *homogeneous* elements of S_+ which do not belong to $\mathfrak{p}$.

2.3. Homogeneous prime spectrum of a graded ring

(2.3.1). Given a graded ring S, in positive degrees, we call the *homogeneous prime spectrum* of S and denote it by $\operatorname{Proj}(S)$ the set of graded prime ideals of S_+ (2.1.10), or equivalently the set of graded prime ideals of S *not containing* S_+; we will define a *scheme* structure having $\operatorname{Proj}(S)$ as the underlying set.

(2.3.2). For every subset E of S, let $V_+(E)$ be the set of graded prime ideals of S containing E and not containing S_+; this is thus the subset $V(E) \cap \operatorname{Proj}(S)$ of $\operatorname{Spec}(S)$. From (**I**, 1.1.2) we deduce:

(2.3.2.1) $$V_+(0) = \operatorname{Proj}(S),\ V_+(S) = V_+(S_+) = \varnothing,$$

(2.3.2.2) $$V_+\big(\textstyle\bigcup_\lambda E_\lambda\big) = \textstyle\bigcap_\lambda V_+(E_\lambda),$$

(2.3.2.3) $$V_+(EE') = V_+(E) \cup V_+(E').$$

We do not change $V_+(E)$ by replacing E with the graded ideal generated by E; in addition, if $\mathfrak{J}$ is a graded ideal of S, then we have

(2.3.2.4) $$V_+(\mathfrak{J}) = V_+\big(\textstyle\bigcup_{q \geqslant n}(\mathfrak{J} \cap S_q)\big)$$

for all $n > 0$: indeed, if $\mathfrak{p} \in \operatorname{Proj}(S)$ contains the homogeneous elements of $\mathfrak{J}$ of degree $\geqslant n$, then as by hypothesis there exists a homogeneous element $f \in S_d$ not contained in $\mathfrak{p}$, for every $m \geqslant 0$ and every $x \in S_m \cap \mathfrak{J}$, we have $f^r x \in \mathfrak{J} \cap S_{m+rd}$ for all but finitely many values of r, so $f^r x \in \mathfrak{p} \cap S_{m+rd}$, which implies that $x \in \mathfrak{p} \cap S_m$ (2.1.9). II | 26

Finally, we have, for every graded ideal $\mathfrak{J}$ of S,

(2.3.2.5) $$V_+(\mathfrak{J}) = V_+(\mathfrak{r}_+(\mathfrak{J})).$$

(2.3.3). By definition, the $V_+(E)$ are the closed subsets of $X = \operatorname{Proj}(S)$ for the topology induced by the spectral topology of $\operatorname{Spec}(S)$, which we also call the *spectral topology* on X. For all $f \in S$, we set

(2.3.3.1) $$D_+(f) = D(f) \cap \operatorname{Proj}(S) = \operatorname{Proj}(S) - V_+(f)$$

and so, for any two elements f and g of S (**I**, 1.1.9.1),

(2.3.3.2) $$D_+(fg) = D_+(f) \cap D_+(g).$$

Proposition (2.3.4). — *The $D_+(f)$, as f runs over the set of homogeneous elements of S_+, form a base for the topology of $X = \operatorname{Proj}(S)$.*

Proof. It follows from (2.3.2.2) and (2.3.2.4) that every closed subset of X is the intersection of sets of the form $V_+(f)$, where f is homogeneous of degree > 0. ☐

(2.3.5). Let f be a *homogeneous* element of S_+, of degree $d > 0$; for every graded prime ideal $\mathfrak{p}$ of S that does not contain f, we know that the set of the x/f^n, where $x \in \mathfrak{p}$ and $n \geqslant 0$, is a prime ideal of the ring of fractions S_f (**0**, 1.2.6); its intersection with $S_{(f)}$ is thus a prime ideal of $S_{(f)}$, which we denote by $\psi_f(\mathfrak{p})$: it is the set of the x/f^n for $n \geqslant 0$ and $x \in \mathfrak{p} \cap S_{nd}$. We have thus defined a map

$$\psi_f : D_+(f) \longrightarrow \operatorname{Spec}(S_{(f)});$$

furthermore, if $g \in S_e$ is another homogeneous element of S_+, then we have a commutative diagram

(2.3.5.1)
$$\begin{tikzcd} D_+(f) \arrow[r, "\psi_f"] & \operatorname{Spec}(S_{(f)}) \\ D_+(fg) \arrow[u] \arrow[r, "\psi_{fg}"'] & \operatorname{Spec}(S_{(fg)}) \arrow[u] \end{tikzcd}$$

where the vertical arrow on the left is the inclusion, and the vertical arrow on the right is the map ${}^a\omega_{fg,f}$ induced by the canonical homomorphism $\omega = \omega_{fg,f} : S_{(f)} \to S_{(fg)}$ (**I**, 1.2.1). Indeed, if $x/f^n \in \omega^{-1}(\psi_{fg}(\mathfrak{p}))$, with $fg \notin \mathfrak{p}$, then, by definition, $g^n x/(fg)^n \in \psi_{fg}(\mathfrak{p})$, so $g^n x \in \mathfrak{p}$, and so $x \in \mathfrak{p}$; the converse is evident.

Proposition (2.3.6). — *The map ψ_f is a homeomorphism from $D_+(f)$ to $\operatorname{Spec}(S_{(f)})$.*

Proof. First, ψ_f is continuous; indeed, if $h \in S_{nd}$, then $h/f^n \in \psi_f(\mathfrak{p})$ if and only if $h \in \mathfrak{p}$, and so $\psi_f^{-1}(D(h/f^n)) = D_+(hf)$; our claim then follows from (2.3.3.2). Furthermore, the $D_+(hf)$, where h runs over the sets S_{nd}, form a basis for the topology of $D_+(f)$, by (2.3.4) and (2.3.3.2); the above thus proves, taking into account the (T_0) axiom, which holds in $D_+(f)$ and in $\operatorname{Spec}(S_{(f)})$, that ψ_f is injective and that the inverse map $\psi_f(D_+(f)) \to D_+(f)$ is continuous. Finally, to see that ψ_f is surjective, we note that, if $\mathfrak{q}_0$ is a prime ideal of $S_{(f)}$, and if, for all $n > 0$, we denote by $\mathfrak{p}_n$ the set of $x \in S_n$ such that $x^d/f^n \in \mathfrak{q}_0$, then the $\mathfrak{p}_n$ satisfy the conditions of (2.1.9): if $x, y \in S_n$ are such that $x^d/f^n, y^d/f^n \in \mathfrak{q}_0$, then $(x+y)^{2d}/f^{2n} \in \mathfrak{q}_0$, whence $(x+y)^d/f^n \in \mathfrak{q}_0$, since $\mathfrak{q}_0$ is prime; this proves that the $\mathfrak{p}_n$ are subgroups of the S_n, and the verification of the other conditions of (2.1.9) is immediate, taking into account the fact that $\mathfrak{q}_0$ is prime. If $\mathfrak{p}$ is the graded prime ideal of S thus defined, then indeed $\psi_f(\mathfrak{p}) = \mathfrak{q}_0$, since, for $x \in S_{nd}$, the conditions $x/f^n \in \mathfrak{q}_0$ and $x^d/f^{nd} \in \mathfrak{q}_0$ are equivalent because $\mathfrak{q}_0$ is prime. ☐

II | 27

Corollary (2.3.7). — *To have $D_+(f) = \varnothing$, it is necessary and sufficient for f to be nilpotent.*

Proof. To have $\operatorname{Spec}(S_{(f)}) = \varnothing$, it is necessary and sufficient to have $S_{(f)} = 0$, or equivalently to have $1 = 0$ in S_f, which means, by definition, that f is nilpotent. ☐

Corollary (2.3.8). — *Let E be a subset of S_+. Then the following conditions are equivalent:*

(a) $V_+(E) = X = \mathrm{Proj}(S)$.
(b) *Every element of E is nilpotent.*
(c) *The homogeneous components of every element of E are nilpotent.*

Proof. It is clear that (c) implies (b), and that (b) implies (a). If $\mathfrak{J}$ is the graded ideal of S generated by E, then condition (a) is equivalent to requiring that $V_+(\mathfrak{J}) = X$; *a fortiori*, (a) implies that every homogeneous element $f \in \mathfrak{J}$ is such that $V_+(f) = X$, and so f is nilpotent by (2.3.7). □

Corollary (2.3.9). — *If $\mathfrak{J}$ is a graded ideal of S_+, then $\mathfrak{r}_+(\mathfrak{J})$ is the intersection of the graded prime ideals of S_+ that contain $\mathfrak{J}$.*

Proof. By considering the graded ring $S/\mathfrak{J}$, we can reduce to the case where $\mathfrak{J} = 0$. We need to prove that, if $f \in S_+$ is not nilpotent, then there exists a graded prime ideal of S that does not contain f; but at least one of the homogeneous components of f is not nilpotent, and we can thus suppose f to be homogeneous; the claim then follows from (2.3.7). □

(2.3.10). For every subset Y of $X = \mathrm{Proj}(S)$, let $\mathfrak{j}_+(Y)$ be the set of $f \in S_+$ such that $Y \subset V_+(f)$; this is equivalent to saying that $\mathfrak{j}_+(Y) = \mathfrak{j}(Y) \cap S_+$; then $\mathfrak{j}_+(Y)$ is an ideal of S_+ that is equal to its radical in S_+.

Proposition (2.3.11). — (i) *For every subset E of S_+, $\mathfrak{j}_+(V_+(E))$ is the radical in S_+ of the graded ideal of S_+ generated by E.*
(ii) *For every subset Y of X, $V_+(\mathfrak{j}_+(Y)) = \overline{Y}$, where $\overline{Y}$ is the closure of Y in X.*

Proof.

(i) If $\mathfrak{J}$ is the graded ideal of S_+ generated by E, then $V_+(E) = V_+(\mathfrak{J})$, and the claim then follows from (2.3.9).
(ii) Since $V_+(\mathfrak{J}) = \bigcap_{f \in \mathfrak{J}} V_+(f)$, having $Y \subset V_+(\mathfrak{J})$ implies that $Y \subset V_+(f)$ for every $f \in \mathfrak{J}$, and thus $\mathfrak{j}_+(Y) \supset \mathfrak{J}$, whence $V_+(\mathfrak{j}_+(Y)) \subset V_+(\mathfrak{J})$, which proves (ii) by the definition of the closed subsets.

□

Corollary (2.3.12). — *The closed subsets Y of $X = \mathrm{Proj}(S)$ are in bijective correspondence with the graded ideals of S_+ that are equal to their radical in S_+, via the inclusion-reversing maps $Y \mapsto \mathfrak{j}_+(Y)$ and $\mathfrak{J} \mapsto V_+(\mathfrak{J})$; the union $Y_1 \cup Y_2$ of two closed subsets of X corresponds to $\mathfrak{j}_+(Y_1) \cap \mathfrak{j}_+(Y_2)$, and the* **II | 28** *intersection of an arbitrary family (Y_λ) of closed subsets corresponds to the radical in S_+ of the sum of the $\mathfrak{j}_+(Y_\lambda)$.*

Corollary (2.3.13). — *Let $\mathfrak{J}$ be a graded ideal of S_+; to have $V_+(\mathfrak{J}) = \varnothing$, it is necessary and sufficient for every element f of S_+ to have a power f^n in $\mathfrak{J}$.*

The preceding corollary can also be expressed in either of the following equivalent forms:

Corollary (2.3.14). — *Let (f_α) be a family of homogeneous elements of S_+. For the $D_+(f_\alpha)$ to form a cover of $X = \mathrm{Proj}(S)$, it is necessary and sufficient for every element of S_+ to have a power in the ideal generated by the f_α.*

Corollary (2.3.15). — *Let (f_α) be a family of homogeneous elements of S_+, and f an element of S_+. Then the following are equivalent:*

(a) $D_+(f) \subset \bigcup_\alpha D_+(f_\alpha)$;
(b) $V_+(f) \supset \bigcap_\alpha V_+(f_\alpha)$;
(c) *f has a power in the ideal generated by the f_α.*

Corollary (2.3.16). — *For $X = \mathrm{Proj}(S)$ to be empty, it is necessary and sufficient for every element of S_+ to be nilpotent.*

Corollary (2.3.17). — *In the bijective correspondence described in (2.3.12), the* irreducible *closed subsets of X correspond to the graded* prime *ideals of S_+.*

Proof. If $Y = Y_1 \cup Y_2$, where Y_1 and Y_2 are proper closed subsets of Y, then

$$\mathfrak{j}_+(Y) = \mathfrak{j}_+(Y_1) \cap \mathfrak{j}_+(Y_2)$$

with the ideals $\mathfrak{j}_+(Y_1)$ and $\mathfrak{j}_+(Y_2)$ being distinct from $\mathfrak{j}_+(Y)$, and so $\mathfrak{j}_+(Y)$ is not prime. Conversely, if $\mathfrak{J}$ is a graded ideal of S_+ that is not prime, then there exist elements $f, g \in S_+$ such that $f \notin \mathfrak{J}$ and $g \notin \mathfrak{J}$, but $fg \in \mathfrak{J}$; then $V_+(f) \not\supset V_+(\mathfrak{J})$ and $V_+(g) \not\supset V_+(\mathfrak{J})$, but $V_+(\mathfrak{J}) \subset V_+(f) \cup V_+(g)$, by (2.3.2.3); we thus conclude that $V_+(\mathfrak{J})$ is the union of the closed subsets $V_+(f) \cap V_+(\mathfrak{J})$ and $V_+(g) \cap V_+(\mathfrak{J})$, which are distinct from $V_+(\mathfrak{J})$. □

2.4. The scheme structure on $\operatorname{Proj}(S)$

(2.4.1). Let f and g be homogeneous elements of S_+; consider the affine schemes $Y_f = \operatorname{Spec}(S_{(f)})$, $Y_g = \operatorname{Spec}(S_{(g)})$, and $Y_{fg} = \operatorname{Spec}(S_{(fg)})$. By (2.2.2), the morphism $w_{fg,f} = ({}^a\omega_{fg,f}, \widetilde{\omega}_{fg,f})$ from Y_{fg} to Y_f, corresponding to the canonical homomorphism $\omega_{fg,f} : S_{(f)} \to S_{(fg)}$, is an *open immersion* (**I**, 1.3.6). Using the inverse homeomorphism of $\psi_f : D_+(f) \to Y_f$ (2.3.6), we can transport the affine scheme structure of Y_f to $D_+(f)$; by the commutativity of diagram (2.3.5.1), the affine scheme $D_+(fg)$ can thus be identified with the induced scheme on the open subset $D_+(fg)$ of the underlying space of the affine scheme $D_+(f)$. It is then clear (taking (2.3.4) into account) that $X = \operatorname{Proj}(S)$ is endowed with a unique *prescheme* structure, whose restriction to each $D_+(f)$ is the affine scheme that we have just defined. Furthermore:

Proposition (2.4.2). — *The prescheme* $\operatorname{Proj}(S)$ *is a scheme.*

Proof. It suffices (**I**, 5.5.6) to show, for any homogeneous f and g in S_+, that $D_+(f) \cap D_+(g) = D_+(fg)$ is affine, and that its ring is generated by the canonical images of the rings of $D_+(f)$ and $D_+(g)$; the first point is evident by definition, and the second follows from (2.2.4). □

Whenever we speak of the homogeneous prime spectrum $\operatorname{Proj}(S)$ as a *scheme*, we always mean it with the structure just defined. **II** | 29

Example (2.4.3). — Let $S = K[T_1, T_2]$, where K is a field, T_1 and T_2 are indeterminates, and S is graded by total degree. It follows from (2.3.14) that $\operatorname{Proj}(S)$ is the union of $D_+(T_1)$ and $D_+(T_2)$; we immediately see that these affine schemes are canonically isomorphic to $\operatorname{Spec}(K[T])$, and that $\operatorname{Proj}(S)$ is obtained by gluing these two affine schemes as described in (**I**, 2.3.2) (cf. (7.4.14)).

Proposition (2.4.4). — *Let S be a positively graded ring, and let X be the scheme* $\operatorname{Proj}(S)$.

(i) *If $\mathfrak{N}_+$ is the nilradical of S_+* (2.1.10), *then the scheme X_{red} is canonically isomorphic to* $\operatorname{Proj}(S/\mathfrak{N}_+)$; *in particular, if S is essentially reduced, then* $\operatorname{Proj}(S)$ *is reduced.*
(ii) *If S is essentially reduced, then, for X to be integral, it is necessary and sufficient for S to be essentially integral.*

Proof.

(i) Let $\overline{S}$ be the graded ring $S/\mathfrak{N}_+$, and denote by $x \mapsto \overline{x}$ the canonical homomorphism $S \to \overline{S}$ of degree 0. For every $f \in S_d$ $(d > 0)$, the canonical homomorphism $S_f \to \overline{S}_{\overline{f}}$ (**0**, 1.5.1) is surjective and of degree 0, and thus gives, by restriction, a surjective homomorphism $S_{(f)} \to \overline{S}_{(\overline{f})}$; if we suppose that $f \notin \mathfrak{N}_+$, then we immediately see that $\overline{S}_{(\overline{f})}$ is reduced, and that the kernel of the above homomorphism is the nilradical of $S_{(f)}$, or, in other words, that $\overline{S}_{(\overline{f})} = (S_{(f)})_{\mathrm{red}}$. So to this homomorphism corresponds a closed immersion $D_+(\overline{f}) \to D_+(f)$ that identifies $D_+(\overline{f})$ with $(D_+(f))_{\mathrm{red}}$ (**I**, 5.1.2), and which is, in particular, a homeomorphism of the underlying spaces of these two affine schemes. Furthermore, if $g \notin \mathfrak{N}_+$ is another homogeneous element of S_+, then the diagram

$$\begin{tikzcd} S_{(f)} \arrow[r] \arrow[d] & \overline{S}_{(\overline{f})} \arrow[d] \\ S_{(fg)} \arrow[r] & \overline{S}_{(\overline{fg})} \end{tikzcd}$$

is commutative; since, furthermore, the $D_+(f)$, for homogeneous f of degree > 0 with $f \notin \mathfrak{N}_+$, form a cover of $X = \mathrm{Proj}(S)$ (2.3.7), we see that the morphisms $D_+(\overline{f}) \to D_+(f)$ are the restrictions of a closed immersion $\mathrm{Proj}(\overline{S}) \to \mathrm{Proj}(S)$ which is a homeomorphism of the underlying spaces; whence the conclusion (**I**, 5.1.2).

(ii) Suppose that S is essentially integral, or, in other words, that (0) is a graded prime ideal of S_+ that is distinct from S_+; then X is reduced, by (i), and irreducible, by (2.3.17). Conversely, suppose that S is essentially reduced and that X is integral; then, for homogeneous $f \neq 0$ in S_+, we have that $D_+(f) \neq \varnothing$ (2.3.7); the hypothesis that X is irreducible implies that $D_+(f) \cap D_+(g) \neq \varnothing$ for homogeneous $f, g \neq 0$ in S_+; thus $fg \neq 0$, by (2.3.3.2), and we thus conclude that S_+ has no zero divisors, whence the first claim.

□

(2.4.5). Given a commutative ring A, recall that we say that a graded ring S is a *graded A-algebra* if it is endowed with the structure of an A-algebra such that each of its subgroups S_n is an A-module; for this, it suffices for S_0 to be an A-algebra, or, in other words, we define the structure of a graded **II | 30**
A-algebra on S by defining the structure of an A-algebra on S_0 and setting $\alpha \cdot x = (\alpha \cdot 1)x$ for $\alpha \in A$ and $x \in S_n$.

Proposition (2.4.6). — *Suppose that S is a graded A-algebra. Then, on $X = \mathrm{Proj}(S)$, the structure sheaf $\mathscr{O}_X$ is a sheaf of A-algebras (where A is regarded as the constant sheaf on X); in other words, X is a scheme over* $\mathrm{Spec}(A)$.

Proof. It suffices to note that, for every homogeneous f in S_+, $S_{(f)}$ is an algebra over A, and that the diagram

$$\begin{tikzcd} S_{(f)} \arrow[rr] & & S_{(fg)} \\ & A \arrow[ul] \arrow[ur] & \end{tikzcd}$$

is commutative, for homogeneous f, g in S_+. □

Proposition (2.4.7). — *Let S be a positively graded ring.*

(i) *For every integer $d > 0$, there exists a canonical isomorphism from the scheme* $\mathrm{Proj}(S)$ *to the scheme* $\mathrm{Proj}(S^{(d)})$.

(ii) *Let S' be the graded ring such that $S'_0 = \mathbf{Z}$ and $S'_n = S_n$ (considered as a $\mathbf{Z}$-module) for $n > 0$. Then there exists a canonical isomorphism from the scheme* $\mathrm{Proj}(S)$ *to the scheme* $\mathrm{Proj}(S')$.

Proof.

(i) We first show that the map $\mathfrak{p} \mapsto \mathfrak{p} \cap S^{(d)}$ is a bijection from the set $\mathrm{Proj}(S)$ to the set $\mathrm{Proj}(S^{(d)})$. Indeed, suppose that we have a graded prime ideal $\mathfrak{p}' \in \mathrm{Proj}(S^{(d)})$, and let $\mathfrak{p}_{nd} = \mathfrak{p}' \cap S_{nd}$ ($n \geqslant 0$). For all $n > 0$ that are not multiples of d, define $\mathfrak{p}_n$ as the set of $x \in S_n$ such that $x^d \in \mathfrak{p}_{nd}$; if $x, y \in \mathfrak{p}_n$, then $(x+y)^{2d} \in \mathfrak{p}_{2nd}$, and so $(x+y)^d \in \mathfrak{p}_{nd}$, since $\mathfrak{p}'$ is prime; it is immediate that the $\mathfrak{p}_n$ thus defined, for $n \geqslant 0$, satisfy the conditions of (2.1.9), and so there exists a unique prime ideal $\mathfrak{p} \in \mathrm{Proj}(S)$ such that $\mathfrak{p} \cap S^{(d)} = \mathfrak{p}'$. Since, for every homogeneous f in S_+, we have that $V_+(f) = V_+(f^d)$ (2.3.2.3), we see that the above bijection is a *homeomorphism* of topological spaces. Finally, with the same notation, $S_{(f)}$ and $S^{(d)}_{(f^d)}$ are canonically identified (2.2.2), and so $\mathrm{Proj}(S)$ and $\mathrm{Proj}(S^{(d)})$ are canonically identified as *schemes*.

(ii) If, to each $\mathfrak{p} \in \mathrm{Proj}(S)$, we associate the unique prime ideal $\mathfrak{p}' \in \mathrm{Proj}(S')$ such that $\mathfrak{p}' \cap S_n = \mathfrak{p} \cap S_n$ for every $n > 0$ (2.1.9), then it is clear that we have defined a canonical homeomorphism $\mathrm{Proj}(S) \xrightarrow{\sim} \mathrm{Proj}(S')$ of the underlying spaces, since $V_+(f)$ is the same set for S and S' when f is a homogeneous element of S_+. Since, further, $S_{(f)} = S'_{(f)}$, $\mathrm{Proj}(S)$ and $\mathrm{Proj}(S')$ can be identified as *schemes*.

□

Corollary (2.4.8). — *If S is a graded A-algebra, and if S'_A is the graded A-algebra such that $(S'_A)_0 = A$ and $(S'_A)_n = S_n$ for $n > 0$, then there exists a canonical isomorphism from* $\operatorname{Proj}(S)$ *to* $\operatorname{Proj}(S'_A)$.

Proof. In fact, these two schemes are both canonically isomorphic to $\operatorname{Proj}(S')$, using the notation of (2.4.7, (ii)). ☐

2.5. The sheaf associated to a graded module

(2.5.1). Let M be a *graded* S-module. Then, for every homogeneous f in S_+, $M_{(f)}$ is an $S_{(f)}$-module, and thus has a corresponding quasi-coherent associated sheaf $(M_{(f)})^\sim$ on the affine scheme $\operatorname{Spec}(S_{(f)})$, identified with $D_+(f)$ (**I**, 1.3.4).

II | 31

Proposition (2.5.2). — *There exists on $X = \operatorname{Proj}(S)$ exactly one quasi-coherent $\mathscr{O}_X$-module $\widetilde{M}$ such that, for f homogeneous in S_+, we have $\Gamma(D_+(f), \widetilde{M}) = M_{(f)}$, with the restriction homomorphism $\Gamma(D_+(f), \widetilde{M}) \to \Gamma(D_+(fg), \widetilde{M})$, for f and g homogeneous in S_+, being the canonical homomorphism $M_{(f)} \to M_{(fg)}$* (2.2.3).

Proof. Suppose that $f \in S_d$ and $g \in S_e$. Since $D_+(fg)$ can be identified with the prime spectrum of $(S_{(f)})_{g^d/f^e}$ by (2.2.2), the restriction to $D_+(fg)$ of the sheaf $(M_{(f)})^\sim$ on $D_+(f)$ is canonically identified with the sheaf associated to the module $(M_{(f)})_{g^d/f^e}$ (**I**, 1.3.6), and thus also with $(M_{(fg)})^\sim$ (2.2.2); we thus conclude that there exists a canonical isomorphism

$$\theta_{g,f} : (M_{(f)})^\sim | D_+(fg) \xrightarrow{\sim} (M_{(g)})^\sim | D_+(fg)$$

such that, if h is a third homogeneous element of S_+, then $\theta_{f,h} = \theta_{f,g} \circ \theta_{g,h}$ in $D_+(fgh)$. Consequently (**0**, 3.3.1) there exists a quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$ on X, and, for every homogeneous f in S_+, an isomorphism η_f from $\mathscr{F}|D_+(f)$ to $(M_{(f)})^\sim$ such that $\theta_{g,f} = \eta_g \circ \eta_f^{-1}$. If we then consider the sheaf $\mathscr{G}$ associated to the presheaf (on the base for the topology of X given by the $D_+(f)$) defined by $D_+(f) \mapsto M_{(f)}$, with the canonical homomorphisms $M_{(f)} \to M_{(fg)}$ as restriction homomorphisms, then the above proves that $\mathscr{F}$ and $\mathscr{G}$ are isomorphic (taking (**I**, 1.3.7) into account); the sheaf $\mathscr{G}$ is denoted by $\widetilde{M}$, and indeed satisfies the conditions of the statement. We have, in particular, $\widetilde{S} = \mathscr{O}_X$. ☐

Definition (2.5.3). — We say that the quasi-coherent $\mathscr{O}_X$-module $\widetilde{M}$ defined in (2.5.2) is *associated* to the graded S-module M.

Recall that the graded S-modules form a category when we restrict from arbitrary homomorphisms of graded modules to homomorphisms *of degree* 0. With this convention:

Proposition (2.5.4). — *The functor $M \mapsto \widetilde{M}$ is an exact additive covariant functor from the category of graded S-modules to the category of quasi-coherent $\mathscr{O}_X$-modules, and it commutes with inductive limits and direct sums.*

Proof. Indeed, since these properties are local, it suffices to show that they are satisfied for the sheaves of the form $\widetilde{M}|D_+(f) = (M_{(f)})^\sim$; but the localization functor $M \mapsto M_f$, the degree-zero functor $N \mapsto N_0$ on graded S_f-modules, and the associated-sheaf functor $P \mapsto \widetilde{P}$ on $S_{(f)}$-modules all have these three properties: exactness and commutation with inductive limits and direct sums ((**I**, 1.3.5) and (**I**, 1.3.9)); whence the proposition. ☐

We denote by $\widetilde{u}$ the homomorphism $\widetilde{M} \to \widetilde{N}$ corresponding to a homomorphism $u : M \to N$ of degree 0. We immediately deduce from (2.5.4) that the results of (**I**, 1.3.9) and (**I**, 1.3.10) still hold for graded S-modules and homomorphisms of degree 0 (with the meaning given here to $\widetilde{M}$), since the proofs are purely formal.

Proposition (2.5.5). — *For all $\mathfrak{p} \in X = \operatorname{Proj}(S)$, we have $\widetilde{M}_\mathfrak{p} = M_{(\mathfrak{p})}$.*

Proof. By definition, $\widetilde{M}_\mathfrak{p} = \varinjlim \Gamma(D_+(f), \widetilde{M})$, where f runs over the set of homogeneous elements of S_+ such that $f \notin \mathfrak{p}$; since $\Gamma(D_+(f), \widetilde{M}) = M_{(f)}$, the proposition follows from the definition of $M_{(\mathfrak{p})}$ (2.2.7). ☐

In particular, the *local ring* $(\mathscr{O}_X)_\mathfrak{p}$ is exactly the ring $S_{(\mathfrak{p})}$, the set of fractions x/f with f homogeneous in S_+ and not belonging to $\mathfrak{p}$, and with x homogeneous of the same degree as f. II | 32

More particularly, if S is *essentially integral*, so that $\mathrm{Proj}(S) = X$ is *integral* (2.4.4), and if $\xi = (0)$ is the generic point of X, then the *field of rational functions* $R(X) = \mathscr{O}_\xi$ is the field consisting of the elements fg^{-1}, where f and g are homogeneous of the same degree in S_+ and $g \neq 0$.

Proposition (2.5.6). — *If, for all $z \in M$ and all homogeneous f in S_+, there exists a power of f that annihilates z, then $\widetilde{M} = 0$. This sufficient condition is also necessary if the S_0-algebra S is generated by the set S_1 of homogeneous elements of degree* 1.

Proof. The condition $\widetilde{M} = 0$ is equivalent to $M_{(f)} = 0$ for all homogeneous f in S_+. On the other hand, if $f \in S_d$, the equality $M_{(f)} = 0$ means that, for every homogeneous $z \in M$ whose degree is a multiple of d, there exists a power f^n such that $f^n z = 0$. If $M_{(f)} = 0$ for all $f \in S_1$, then the condition of the statement is thus satisfied for all $f \in S_1$; the condition is *a fortiori* satisfied for all homogeneous f in S_+ if S_1 generates S, since every homogeneous element of S_+ is then a linear combination of products of elements of S_1. $\square$

Proposition (2.5.7). — *Let $d > 0$ be an integer, and let $f \in S_d$. Then, for all $n \in \mathbf{Z}$, the $(\mathscr{O}_X|D_+(f))$-module $(S(nd))^\sim|D_+(f)$ is canonically isomorphic to $\mathscr{O}_X|D_+(f)$.*

Proof. Indeed, multiplication by the invertible element $(f/1)^n$ of S_f gives a bijection from $S_{(f)} = (S_f)_0$ to $(S_f)_{nd} = (S_f(nd))_0 = (S(nd)_f)_0 = S(nd)_{(f)}$; in other words, the $S_{(f)}$-modules $S_{(f)}$ and $S(nd)_{(f)}$ are canonically isomorphic, whence the proposition. $\square$

Corollary (2.5.8). — *On the open subset $U = \bigcup_{f \in S_d} D_+(f)$, the restriction of the $\mathscr{O}_X$-module $(S(nd))^\sim$ is an invertible $(\mathscr{O}_X|U)$-module* (**0**, 5.4.1).

Corollary (2.5.9). — *If the ideal S_+ of S is generated by the set S_1 of homogeneous elements of degree* 1, *then the $\mathscr{O}_X$-module $(S(n))^\sim$ is invertible for all $n \in \mathbf{Z}$.*

Proof. It suffices to remark that $X = \bigcup_{f \in S_1} D_+(f)$, by the hypothesis (2.3.14) and to apply (2.5.8) with $U = X$. $\square$

(2.5.10). We set, for the rest of this section,

$$\mathscr{O}_X(n) = (S(n))^\sim \tag{2.5.10.1}$$

for all $n \in \mathbf{Z}$, and, for every open subset U of X, and every $(\mathscr{O}_X|U)$-module $\mathscr{F}$,

$$\mathscr{F}(n) = \mathscr{F} \otimes_{\mathscr{O}_X|U} (\mathscr{O}_X(n)|U) \tag{2.5.10.2}$$

for all $n \in \mathbf{Z}$. If the ideal S_+ is generated by S_1, then the functor $\mathscr{F} \mapsto \mathscr{F}(n)$ is *exact* for every $n \in \mathbf{Z}$, since $\mathscr{O}_X(n)$ is then an *invertible* $\mathscr{O}_X$-module.

(2.5.11). Let M and N be graded S-modules. For all $f \in S_d$ ($d > 0$), we define a canonical functorial homomorphism of $S_{(f)}$-modules by

$$\lambda_f : M_{(f)} \otimes_{S_{(f)}} N_{(f)} \longrightarrow (M \otimes_S N)_{(f)} \tag{2.5.11.1}$$

by composing the homomorphism $M_{(f)} \otimes_{S_{(f)}} N_{(f)} \to M_f \otimes_{S_f} N_f$ (coming from the injections $M_{(f)} \to M_f$, $N_{(f)} \to N_f$, and $S_{(f)} \to S_f$) with the canonical isomorphism $M_f \otimes_{S_f} N_f \xrightarrow{\sim} (M \otimes_S N)_f$ (**0**, 1.3.4), and by noting that, by the definition of the tensor product of two graded modules, this latter isomorphism preserves degrees; for $x \in M_{md}$ and $y \in N_{nd}$ ($m, n \geqslant 0$), we thus have II | 33

$$\lambda_f((x/f^m) \otimes (y/f^n)) = (x \otimes y)/f^{m+n}.$$

It immediately follows from this definition that, if $g \in S_e$ ($e > 0$), then the diagram

$$\begin{tikzcd}
M_{(f)} \otimes_{S_{(f)}} N_{(f)} \arrow[r, "\lambda_f"] \arrow[d] & (M \otimes_S N)_{(f)} \arrow[d] \\
M_{(fg)} \otimes_{S_{(fg)}} N_{(fg)} \arrow[r, "\lambda_{fg}"'] & (M \otimes_S N)_{(fg)}
\end{tikzcd}$$

(where the vertical arrow on the right is the canonical homomorphism, and the one on the left comes from the canonical homomorphisms) commutes. The homomorphisms λ_f therefore induce a canonical functorial homomorphism of $\mathscr{O}_X$-modules

(2.5.11.2) $$\lambda : \widetilde{M} \otimes_{\mathscr{O}_X} \widetilde{N} \longrightarrow (M \otimes_S N)^{\sim}.$$

Consider, in particular, graded ideals $\mathfrak{J}$ and $\mathfrak{K}$ of S; since $\widetilde{\mathfrak{J}}$ and $\widetilde{\mathfrak{K}}$ are sheaves of ideals of $\mathscr{O}_X$, we have a canonical homomorphism $\widetilde{\mathfrak{J}} \otimes_{\mathscr{O}_X} \widetilde{\mathfrak{K}} \to \mathscr{O}_X$; the diagram

(2.5.11.3) $$\begin{tikzcd} \widetilde{\mathfrak{J}} \otimes_{\mathscr{O}_X} \widetilde{\mathfrak{K}} \arrow[rr, "\lambda"] \arrow[dr] & & (\mathfrak{J} \otimes_S \mathfrak{K})^{\sim} \arrow[dl] \\ & \mathscr{O}_X & \end{tikzcd}$$

then commutes. Indeed, we can reduce to verifying this on each open subset $D_+(f)$ (for f homogeneous in S_+), and this follows immediately from the definition (2.5.11.1) of λ_f and from (**I**, 1.3.13).

Finally, note that, if M, N, and P are graded S-modules, then the diagram

(2.5.11.4) $$\begin{tikzcd} \widetilde{M} \otimes_{\mathscr{O}_X} \widetilde{N} \otimes_{\mathscr{O}_X} \widetilde{P} \arrow[r, "\lambda\otimes 1"] \arrow[d, "1\otimes\lambda"'] & (M \otimes_S N)^{\sim} \otimes_{\mathscr{O}_X} \widetilde{P} \arrow[d, "\lambda"] \\ \widetilde{M} \otimes_{\mathscr{O}_X} (N \otimes_S P)^{\sim} \arrow[r, "\lambda"'] & (M \otimes_S N \otimes_S P)^{\sim} \end{tikzcd}$$

commutes. It again suffices to verify this on each open subset $D_+(f)$, and this follows immediately from the definitions and from (**I**, 1.3.13). **II** | 34

(2.5.12). Under the hypotheses of (2.5.11), we define a functorial canonical homomorphism of $S_{(f)}$-modules

(2.5.12.1) $$\mu_f : (\mathrm{Hom}_S(M, N))_{(f)} \longrightarrow \mathrm{Hom}_{S_{(f)}}(M_{(f)}, N_{(f)})$$

by sending u/f^n, where u is a homomorphism of degree nd, to the homomorphism $M_{(f)} \to N_{(f)}$ that sends x/f^m ($x \in M_{md}$) to $u(x)/f^{m+n}$. For $g \in S_e$ ($e > 0$), we again have a commutative diagram:

$$\begin{tikzcd} (\mathrm{Hom}_S(M, N))_{(f)} \arrow[r, "\mu_f"] \arrow[d] & \mathrm{Hom}_{S_{(f)}}(M_{(f)}, N_{(f)}) \arrow[d] \\ (\mathrm{Hom}_S(M, N))_{(fg)} \arrow[r, "\mu_{fg}"'] & \mathrm{Hom}_{S_{(fg)}}(M_{(fg)}, N_{(fg)}) \end{tikzcd}$$

(where the vertical arrow on the left is the canonical homomorphism, and the one on the right comes from the canonical homomorphisms). We thus again conclude (taking (**I**, 1.3.8) into account) that the μ_f define a functorial canonical homomorphism of $\mathscr{O}_X$-modules

(2.5.12.2) $$\mu : (\mathrm{Hom}_S(M, N))^{\sim} \longrightarrow \mathscr{H}om_{\mathscr{O}_X}(\widetilde{M}, \widetilde{N})$$

Proposition (2.5.13). — *Suppose that the ideal S_+ is generated by S_1. Then the homomorphism λ (2.5.11.2) is an isomorphism; so too is the homomorphism μ (2.5.12.2) if the graded S-module M admits a finite presentation (2.1.1).*

Proof. Since X is the union of the $D_+(f)$ for $f \in S_1$ (2.3.14), we are led to proving that λ_f and μ_f are isomorphisms, under the given hypotheses, whenever f is homogeneous and *of degree* 1. But we can then define a $\mathbf{Z}$-bilinear map $M_m \times N_n \to M_{(f)} \otimes_{S_{(f)}} N_{(f)}$ by sending (x, y) to the element $(x/f^m) \otimes (y/f^n)$ (if $m < 0$, we write x/f^m to mean $f^{-m}x/1$); these maps define a $\mathbf{Z}$-linear map $M \otimes_{\mathbf{Z}} N \to M_{(f)} \otimes_{S_{(f)}} N_{(f)}$, and, if $s \in S_q$, this map sends $(sx) \otimes y$ to $(s/f^q)((x/f^m) \otimes (y/f^n))$ (for $x \in M_m$ and $y \in N_n$). We thus obtain a di-homomorphism of modules $\gamma_f : M \otimes_S N \to M_{(f)} \otimes_{S_{(f)}} N_{(f)}$, with respect to the canonical homomorphism $S \to S_{(f)}$ (sending $s \in S_q$ to s/f^q). Suppose furthermore that, for an element $\sum_i (x_i \otimes y_i)$ of $M \otimes_S N$ (with x_i and y_i homogeneous of degree m_i

and n_i, respectively), we have that $f^r \sum_i (x_i \otimes y_i) = 0$, or, in other words, that $\sum_i (f^r x_i \otimes y_i) = 0$. We thus deduce, by (**0**, 1.3.4), that $\sum_i (f^r x_i / f^{m_i+r}) \otimes (y_i / f^{n_i}) = 0$, i.e. $\gamma_f(\sum_i (x_i \otimes y_i)) = 0$. Then γ_f factors as $M \otimes_S N \to (M \otimes_S N)_f \xrightarrow{\gamma'_f} M_{(f)} \otimes_{S_{(f)}} N_{(f)}$; if λ'_f is the restriction of γ'_f to $(M \otimes_S N)_{(f)}$, **II | 35**
then we can immediately show that λ_f and λ'_f are inverse $S_{(f)}$-homomorphisms, whence the first part of the proposition.

To prove the second part, suppose that M is the cokernel of a homomorphism $P \to Q$ of graded S-modules, with P and Q being direct sums of a finite number of modules of the form $S(n)$; using the left-exactness of the functor $L \mapsto \operatorname{Hom}_S(L, N)$ and the exactness of the functor $M \mapsto M_{(f)}$, we can immediately reduce to proving that μ_f is an isomorphism whenever $M = S(n)$. But, for any homogeneous z in N, let u_z be the homomorphism from $S(n)$ to N such that $u_z(1) = z$; we immediately see that $\eta : z \to u_z$ is an isomorphism of degree 0 from $N(-n)$ to $\operatorname{Hom}_S(S(n), N)$. There is a corresponding isomorphism

$$\eta_f : (N(-n))_{(f)} \longrightarrow (\operatorname{Hom}_S(S(n), N))_{(f)}.$$

Now let η'_f be the isomorphism $N_{(f)} \to \operatorname{Hom}_{S_{(f)}}(S(n)_{(f)}, N_{(f)})$ that, to any $z' \in N_{(f)}$, associates the homomorphism $v_{z'}$ that is such that $v_{z'}(s/f^k) = sz'/f^{n+k}$ (for $s \in S_{n+k} = (S(n))_k$). We easily note that the composed map

$$(N(-n))_{(f)} \xrightarrow{\eta_f} (\operatorname{Hom}_S(S(n), N))_{(f)} \xrightarrow{\mu_f} \operatorname{Hom}_{S_{(f)}}(S(n)_{(f)}, N_{(f)}) \xrightarrow{\eta'^{-1}_f} N_{(f)}$$

is the isomorphism $z/f^h \mapsto z/f^{h-n}$ from $(N(-n))_{(f)}$ to $N_{(f)}$, and thus μ_f is an isomorphism. □

If the ideal S_+ is generated by S_1, then we deduce from (2.5.13) that, for every graded ideal $\mathfrak{J}$ of S, and for every graded S-module M, we have

(2.5.13.1) $$\widetilde{\mathfrak{J}} \cdot \widetilde{M} = (\mathfrak{J} \cdot M)^\sim$$

up to canonical isomorphism; this follows from the commutativity of the diagram

$$\begin{tikzcd} \widetilde{\mathfrak{J}} \otimes_{\mathscr{O}_X} \widetilde{M} \arrow[rr, "\lambda"] \arrow[dr] & & (\mathfrak{J} \otimes_S M)^\sim \arrow[dl] \\ & \widetilde{M} & \end{tikzcd}$$

which we can verify as we did for (2.5.11.3).

Corollary (2.5.14). — *Suppose that S is generated by S_1. For any $m, n \in \mathbf{Z}$, we then have:*

(2.5.14.1) $$\mathscr{O}_X(m) \otimes_{\mathscr{O}_X} \mathscr{O}_X(n) = \mathscr{O}_X(m+n)$$

(2.5.14.2) $$\mathscr{O}_X(n) = (\mathscr{O}_X(1))^{\otimes n}$$

up to canonical isomorphism.

Proof. The first equation follows from (2.5.13) and from the existence of the canonical isomorphism $S(m) \otimes_S S(n) \xrightarrow{\sim} S(m+n)$ of degree 0 that sends the element $1 \otimes 1$ (where the first 1 is in $(S(m))_{-m}$ and the second is in $(S(n))_{-n}$) to the element $1 \in (S(m+n))_{-(m+n)}$. It then suffices to prove the second equation for $n = -1$, and, by (2.5.13), this reduces to seeing that $\operatorname{Hom}_S(S(1), S)$ is canonically isomorphic to $S(-1)$, which follows immediately from the definitions (2.1.2) and the fact that $S(1)$ is a cyclic S-module. □

II | 36

Corollary (2.5.15). — *Suppose that S is generated by S_1. Then, for every graded S-module M, and for every $n \in \mathbf{Z}$, we have*

(2.5.15.1) $$(M(n))^\sim = \widetilde{M}(n)$$

up to canonical isomorphism.

Proof. This follows from definitions (2.5.10.2) and (2.5.10.1), from Proposition (2.5.13), and from the existence of a canonical isomorphism $M(n) \xrightarrow{\sim} M \otimes_S S(n)$ of degree 0 that, to every $z \in (M(n))_h = M_{n+h}$, associates $z \otimes 1 \in M_{n+h} \otimes (S(n))_{-n} \subset (M \otimes_S S(n))_h$. □

(2.5.16). We denote by S' the graded ring such that $S'_0 = \mathbf{Z}$, and $S'_n = S_n$ for $n > 0$. Then, if $f \in S_d$ $(d > 0)$, we have that $(S(n))_{(f)} = (S'(n))_{(f)}$ for all $n \in \mathbf{Z}$, since an element of $(S'(n))_{(f)}$ is of the form x/f^k, with $x \in S'_{n+kd}$ $(k > 0)$, and we can always take k to be such that $n + kd \neq 0$. Since $X = \operatorname{Proj}(S)$ and $X' = \operatorname{Proj}(S')$ are canonically identified (2.4.7, (ii)), we see that, for all $n \in \mathbf{Z}$, $\mathscr{O}_X(n)$ and $\mathscr{O}_{X'}(n)$ are the images of one another under the above identification.

Note also that, for all $d > 0$ and all $n \in \mathbf{Z}$, we have

$$(S^{(d)}(n))_h = S_{(n+h)d} = (S(nd))_{hd}$$

for $f \in S_d$, and thus $(S^{(d)}(n))_{(f)} = (S(nd))_{(f)}$. We know that the schemes $X = \operatorname{Proj}(S)$ and $X^{(d)} = \operatorname{Proj}(S^{(d)})$ are canonically identified (2.4.7, (i)); the above shows that, if the S_0-algebra $S^{(d)}$ is generated by S_d, then $\mathscr{O}_X(nd)$ and $\mathscr{O}_{X^{(d)}}(n)$ are the images of one another under this identification, for all $n \in \mathbf{Z}$.

Proposition (2.5.17). — *Let $d > 0$ be an integer, and let $U = \bigcup_{f \in S_d} D_+(f)$. Then the restriction to U of the canonical homomorphism $\mathscr{O}_X(nd) \otimes_{\mathscr{O}_X} \mathscr{O}_X(-nd) \to \mathscr{O}_X$ is an isomorphism for every integer n.*

Proof. By (2.5.16), we can restrict to the case where $d = 1$, and the conclusion then follows from the proof of (2.5.13). □

2.6. The graded S-module associated to a sheaf on $\operatorname{Proj}(S)$ *Throughout this section, we assume that the ideal S_+ of S is generated by the set S_1 of homogeneous elements of degree* 1.

(2.6.1). The $\mathscr{O}_X$-module $\mathscr{O}_X(1)$ is *invertible* (2.5.9); we thus define, for every $\mathscr{O}_X$-module $\mathscr{F}$ (**0**, 5.4.6),

(2.6.1.1) $$\Gamma_\bullet(\mathscr{F}) = \Gamma_\bullet(\mathscr{O}_X(1), \mathscr{F}) = \bigoplus_{n \in \mathbf{Z}} \Gamma(X, \mathscr{F}(n))$$

taking (2.5.14.2) into account. Recall (**0**, 5.4.6) that $\Gamma_\bullet(\mathscr{O}_X)$ is endowed with the structure of a *graded ring*, and $\Gamma_\bullet(\mathscr{F})$ with the structure of a *graded $\Gamma_\bullet(\mathscr{O}_X)$-module*.

Since $\mathscr{O}_X(n)$ is locally free, $\Gamma_\bullet(\mathscr{F})$ is a *left exact* additive covariant functor in $\mathscr{F}$; in particular, if $\mathscr{J}$ is a sheaf of ideals of $\mathscr{O}_X$, then $\Gamma_\bullet(\mathscr{J})$ is canonically identified with a *graded ideal* of $\Gamma_\bullet(\mathscr{O}_X)$.

(2.6.2). Let M be a graded S-module; for every $f \in S_d$ $(d > 0)$, $x \mapsto x/1$ is a homomorphism of abelian groups $M_0 \to M_{(f)}$, and, since $M_{(f)}$ is canonically identified with $\Gamma(D_+(f), \widetilde{M})$, we thus **II | 37**
obtain a homomorphism of abelian groups $\alpha_0^f : M_0 \to \Gamma(D_+(f), \widetilde{M})$. It is clear that, for every $g \in S_e$ $(e > 0)$, the diagram

$$\begin{tikzcd}
 & \Gamma(D_+(f), \widetilde{M}) \arrow[dd] \\
M_0 \arrow[ur, "\alpha_0^f"] \arrow[dr, "\alpha_0^{fg}"'] & \\
 & \Gamma(D_+(fg), \widetilde{M})
\end{tikzcd}$$

commutes; this implies that, for every $x \in M_0$, the sections $\alpha_0^f(x)$ and $\alpha_0^g(x)$ of $\widetilde{M}$ agree on $D_+(f) \cap D_+(g)$, and thus there exists a unique section $\alpha_0(x) \in \Gamma(X, \widetilde{M})$ whose restriction to each $D_+(f)$ is $\alpha_0^f(x)$. We have thus defined (without using the hypothesis that S be generated by S_1) a homomorphism of abelian groups

(2.6.2.1) $$\alpha_0 : M_0 \longrightarrow \Gamma(X, \widetilde{M}).$$

Applying this result to the graded S-module $M(n)$ (for each $n \in \mathbf{Z}$), we obtain, for each $n \in \mathbf{Z}$, a homomorphism of abelian groups

(2.6.2.2) $$\alpha_n : M_n = (M(n))_0 \longrightarrow \Gamma(X, \widetilde{M}(n))$$

(taking (2.5.15) into account); whence we obtain a functorial homomorphism (of degree 0) of graded abelian groups

$$\alpha : M \longrightarrow \Gamma_\bullet(\widetilde{M}) \tag{2.6.2.3}$$

(also denoted by α_M) which, on each M_n, agrees with α_n.

If we take, in particular, $M = S$, then we immediately see (taking into account the definition (**0**, 5.4.6) of multiplication in $\Gamma_\bullet(\mathscr{O}_X)$) that $\alpha : S \to \Gamma_\bullet(\mathscr{O}_X)$ is a homomorphism of graded rings, and that, for every graded S-module M, (2.6.2.3) is a di-homomorphism of graded modules.

Proposition (2.6.3). — *For every $f \in S_d$ ($d > 0$), $D_+(f)$ is identical to the set of $\mathfrak{p} \in X$ on which the section $\alpha_d(f)$ of $\mathscr{O}_X(d)$ does not vanish* (**0**, 5.5.2).

Proof. Since $X = \bigcup_{g \in S_1} D_+(g)$ by hypothesis, it suffices to show that, for all $g \in S_1$, the set of $\mathfrak{p} \in D_+(g)$ on which $\alpha_d(f)$ does not vanish is identical to $D_+(fg)$. But the restriction of $\alpha_d(f)$ to $D_+(g)$ is, by definition, the section corresponding to the element $f/1$ of $(S(d))_{(g)}$; under the canonical isomorphism $(S(d))_{(g)} \xrightarrow{\sim} S_{(g)}$ (2.5.7), this section of $\mathscr{O}_X(d)$ over $D_+(g)$ is identified with the section of $\mathscr{O}_X$ over $D_+(g)$ that corresponds to the element f/g^d of $S_{(g)}$; to say that this section vanishes at $\mathfrak{p} \in D_+(g)$ means that $f/g^d \in \mathfrak{q}$, where $\mathfrak{q}$ is the prime ideal of $S_{(g)}$ corresponding to $\mathfrak{p}$ (2.3.6); by definition, this is equivalent to $f \in \mathfrak{p}$, whence the proposition. □

(2.6.4). Now let $\mathscr{F}$ be an $\mathscr{O}_X$-module, and set $M = \Gamma_\bullet(\mathscr{F})$; by the existence of the homomorphism of graded rings $\alpha : S \to \Gamma_\bullet(\mathscr{O}_X)$, we can consider M as a graded S-module. For every $f \in S_d$ ($d > 0$), it follows from (2.6.3) that the restriction to $D_+(f)$ of the section $\alpha_d(f)$ of $\mathscr{O}_X(d)$ is invertible; thus so too is the restriction to $D_+(f)$ of the section $\alpha_{nd}(f^n)$ of $\mathscr{O}_X(nd)$, for every $n > 0$. So let $z \in M_{nd} = \Gamma(X, \mathscr{F}(nd))$ ($n > 0$); if there exists an integer $k \geqslant 0$ such that the restriction to $D_+(f)$ of $f^k z$, i.e. the section $(z|D_+(f))(\alpha_{kd}(f^k)|D_+(f))$ of $\mathscr{F}((n+k)d)$, is zero, then, by the above remark, we also have that $z|D_+(f) = 0$. This shows that we have defined an $S_{(f)}$-homomorphism $\beta_f : M_{(f)} \to \Gamma(D_+(f), \mathscr{F})$ by sending the element z/f^n to the section $(z|D_+(f))(\alpha_{nd}(f^n)|D_+(f))^{-1}$ of $\mathscr{F}$ over $D_+(f)$. We immediately verify that the diagram II | 38

$$\begin{tikzcd} M_{(f)} \arrow[r, "\beta_f"] \arrow[d] & \Gamma(D_+(f), \mathscr{F}) \arrow[d] \\ M_{(fg)} \arrow[r, "\beta_{fg}"'] & \Gamma(D_+(fg), \mathscr{F}) \end{tikzcd} \tag{2.6.4.1}$$

commutes for $g \in S_e$ ($e > 0$). If we recall that $M_{(f)}$ is canonically identified with $\Gamma(D_+(f), \widetilde{M})$, and that the $D_+(f)$ form a base for the topology of X (2.3.4), then we see that the β_f come from a unique canonical homomorphism of $\mathscr{O}_X$-modules

$$\beta : (\Gamma_\bullet(\mathscr{F}))^\sim \longrightarrow \mathscr{F} \tag{2.6.4.2}$$

(also denoted by $\beta_{\mathscr{F}}$) which is evidently functorial.

Proposition (2.6.5). — *Let M be a graded S-module, and $\mathscr{F}$ an $\mathscr{O}_X$-module; then the composite homomorphisms*

$$\widetilde{M} \xrightarrow{\widetilde{\alpha}} (\Gamma_\bullet(\widetilde{M}))^\sim \xrightarrow{\beta} \widetilde{M} \tag{2.6.5.1}$$

$$\Gamma_\bullet(\mathscr{F}) \xrightarrow{\alpha} \Gamma_\bullet((\Gamma_\bullet(\mathscr{F}))^\sim) \xrightarrow{\Gamma_\bullet(\beta)} \Gamma_\bullet(\mathscr{F}) \tag{2.6.5.2}$$

are the identity isomorphisms.

Proof. The proof for (2.6.5.1) is local: in an open subset $D_+(f)$, it follows immediately from the definitions, along with the fact that β, applied to quasi-coherent sheaves, is determined by its action on the sections over $D_+(f)$ (**I**, 1.3.8). The assertion (2.6.5.2) is verified separately in each degree: if we set $M = \Gamma_\bullet(\mathscr{F})$, then $M_n = \Gamma(X, \mathscr{F}(n))$, and $(\Gamma_\bullet(\widetilde{M}))_n = \Gamma(X, \widetilde{M}(n)) = \Gamma(X, (M(n))^\sim)$.

But if $f \in S_1$ and $z \in M_n$, then $\alpha_n^f(z)$ is the element $z/1$ of $(M(n))_{(f)}$, equal to $(f/1)^n(z/f^n)$; it corresponds, via β_f, to the section

$$\left((\alpha_1(f))^n|D_+(f)\right)\left((z|D_+(f))((\alpha_1(f))^n|D_+(f))^{-1}\right)$$

over $D_+(f)$, i.e. the restriction of z to $D_+(f)$, which finishes the proof for (2.6.5.2). □

2.7. Finiteness conditions

Proposition (2.7.1). — (i) *If S is a graded Noetherian ring, then $X = \mathrm{Proj}(S)$ is a Noetherian scheme.*

(ii) *If S is a graded A-algebra of finite type, then $X = \mathrm{Proj}(S)$ is a scheme of finite type over $Y = \mathrm{Spec}(A)$.*

II | 39

Proof.

(i) If S is Noetherian, then the ideal S_+ admits a finite system of homogeneous generators f_i $(1 \leqslant i \leqslant p)$, thus (2.3.14) the underlying space X is the union of the $D_+(f_i) = \mathrm{Spec}(S_{(f_i)})$, and everything then reduces to showing that each of the $S_{(f_i)}$ is Noetherian, which follows from (2.2.6).

(ii) The hypothesis implies that S_0 is an A-algebra of finite type, and that S is an S_0-algebra of finite type, and so S_+ is an ideal of finite type (2.1.4). We are thus reduced, as in (i), to showing that $S_{(f)}$ is an A-algebra of finite type for all $f \in S_d$. By (2.2.5), it suffices to show that $S^{(d)}$ is an A-algebra of finite type, which follows from (2.1.6).

□

(2.7.2). In what follows, we consider the following finiteness conditions for a graded S-module M:

(TF) There exists an integer n such that the submodule $\bigoplus_{k \geqslant n} M_k$ is an S-module of finite type.

(TN) There exists an integer n such that $M_k = 0$ for $k \geqslant n$.

If M satisfies (TN), then $M_{(f)} = 0$ for all homogeneous f in S_+, and thus $\widetilde{M} = 0$.

Let M and N be graded S-modules; we say that a homomorphism $u : M \to N$ of degree 0 is (TN)-*injective* (resp. (TN)-*surjective*, (TN)-*bijective*) if there exists an integer n such that $u_k : M_k \to N_k$ is injective (resp. surjective, bijective) for $k \geqslant n$. Saying that u is (TN)-injective (resp. (TN)-surjective) thus reduces to saying that $\mathrm{Ker}\, u$ (resp. $\mathrm{Coker}\, u$) satisfies (TN). By (2.5.4), if u is (TN)-injective (resp. (TN)-surjective, (TN)-bijective), then $\widetilde{u}$ is injective (resp. surjective, bijective); if u is (TN)-bijective, then we also say that u is a (TN)-*isomorphism*.

Proposition (2.7.3). — *Let S be a graded ring such that the ideal S_+ is of finite type, and let M be a graded S-module.*

(i) *If M satisfies condition (TF) then the $\mathscr{O}_X$-module $\widetilde{M}$ is of finite type.*

(ii) *Suppose that M satisfies (TF); for $\widetilde{M} = 0$, it is necessary and sufficient for M to satisfy (TN).*

Proof. We have just seen that condition (TN) implies that $\widetilde{M} = 0$. If M satisfies (TF), then the graded submodule $M' = \bigoplus_{k \geqslant n} M_k$, which is, by hypothesis, of finite type, is such that M/M' satisfies (TN); thus $(M/M')^{\sim} = 0$, and the exactness of the functor $M \mapsto \widetilde{M}$ (2.5.4) implies that $\widetilde{M} = \widetilde{M'}$; to prove that $\widetilde{M}$ is of finite type, we can thus reduce to the case where M is *of finite type*. Since the question is local, it suffices to prove that $M_{(f)}$ is an $S_{(f)}$-module of finite type (**I**, 1.3.9); but $M^{(d)}$ is an $S^{(d)}$-module of finite type (2.1.6, iii), and our claim then follows from (2.2.5).

Now suppose that M satisfies (TF) and that $\widetilde{M} = 0$; then, with the same notation as above, we have that $\widetilde{M'} = 0$, and condition (TN) for M' is equivalent to condition (TN) for M, so to prove that $\widetilde{M} = 0$ implies that M satisfies (TN), we can again restrict to the case where M is generated by a finite number of homogeneous elements x_i $(1 \leqslant i \leqslant p)$; let $(f_j)_{1 \leqslant j \leqslant q}$ be a system of homogeneous generators of the ideal S_+. By hypothesis, $M_{(f_j)} = 0$ for all j, and so there exists an integer n such that $f_j^n x_i = 0$ for any i and j. Let n_j be the degree of f_j, and let m be the largest value of $\sum_j r_j n_j$ over the finitely many systems of nonnegative integers (r_j) such that $\sum_j r_j \leqslant nq$; it is then clear that, if **II | 40**

$k > m$, then $S_k x_i = 0$ for all i; if h is the largest of the degrees of the x_i, then we conclude that $M_k = 0$ for $k > h + m$, which finishes the proof. □

Corollary (2.7.4). — *Let S be a graded ring such that the ideal S_+ is of finite type; for $X = \mathrm{Proj}(S) = \varnothing$, it is necessary and sufficient for there to exist n such that $S_k = 0$ for $k \geqslant n$.*

Proof. The condition $X = \varnothing$ is equivalent to $\mathscr{O}_X = \widetilde{S} = 0$, and S is a cyclic S-module. □

Theorem (2.7.5). — *Suppose that the ideal S_+ is generated by a finite number of homogeneous elements of degree 1; let $X = \mathrm{Proj}(S)$. Then, for every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$, the canonical homomorphism $\beta : (\Gamma_\bullet(\mathscr{F}))^\sim \to \mathscr{F}$ (2.6.4) is an isomorphism.*

Proof. If S_+ is generated by a finite number of elements $f_i \in S_1$, then X is the union of the subspaces $\mathrm{Spec}(S_{(f_i)})$ (2.3.6), which are quasi-compact, and so X is quasi-compact; furthermore, X is a scheme (2.4.2); by (**I**, 9.3.2), (2.5.14.2), and (2.6.3), we have, for all $f \in S_d$ ($d > 0$), a canonical isomorphism $(\Gamma_\bullet(\mathscr{F}))_{(\alpha_d(f))} \xrightarrow{\sim} \Gamma(D_+(f), \mathscr{F})$; also, by definition, $(\Gamma_\bullet(\mathscr{F}))_{(\alpha_d(f))}$ (where $\Gamma_\bullet(\mathscr{F})$ is considered as a $\Gamma_\bullet(\mathscr{O}_X)$-module) is exactly $(\Gamma_\bullet(\mathscr{F}))_{(f)}$ (where $\Gamma_\bullet(\mathscr{F})$ is considered as an S-module); if we refer to the definition (**I**, 9.3.1) of the above canonical isomorphism, then we see that it agrees with the homomorphism β_f, whence the theorem. □

Remark (2.7.6). — If we suppose that the graded ring S is *Noetherian*, then the condition of (2.7.5) is satisfied *ipso facto* as soon as we suppose that the ideal S_+ is generated by the set S_1 of homogeneous elements of degree 1.

Corollary (2.7.7). — *Under the hypotheses of (2.7.5), every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$ is isomorphic to an $\mathscr{O}_X$-module of the form $\widetilde{M}$, where M is a graded S-module.*

Corollary (2.7.8). — *Under the hypotheses of (2.7.5), every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$ of finite type is isomorphic to an $\mathscr{O}_X$-module of the form $\widetilde{N}$, where N is a graded S-module of finite type.*

Proof. We can suppose that $\mathscr{F} = \widetilde{M}$, where M is a graded S-module (2.7.7). Let $(f_\lambda)_{\lambda \in L}$ be a system of homogeneous generators of M; for every finite subset H of L, let M_H be the graded submodule of M generated by the f_λ such that $\lambda \in H$; it is clear that M is the inductive limit of its submodules M_H, and so $\mathscr{F}$ is the inductive limit of its sub-$\mathscr{O}_X$-modules $\widetilde{M_H}$ (2.5.4). But, since $\mathscr{F}$ is of finite type, and since the underlying space of X is quasi-compact, it follows from (**0**, 5.2.3) that $\mathscr{F} = \widetilde{M_H}$ for some finite subset H of L. □

Corollary (2.7.9). — *Under the hypotheses of (2.7.5), let $\mathscr{F}$ be a quasi-coherent $\mathscr{O}_X$-module of finite type. Then there exists an integer n_0 such that, for all $n \geqslant n_0$, $\mathscr{F}(n)$ is isomorphic to a quotient of an $\mathscr{O}_X$-module of the form $\mathscr{O}_X^k$ (for some $k > 0$ depending on n), and is thus generated by a finite number of its sections over X (**0**, 5.1.1).*

Proof. By (2.7.8), we can suppose that $\mathscr{F} = \widetilde{M}$, where M is a quotient of a finite direct sum of S-modules of the form $S(m_i)$; by (2.5.4), we can thus restrict to the case where $M = S(m)$, and so $\mathscr{F}(n) = (S(m+n))^\sim = \mathscr{O}_X(m+n)$ (2.5.15). It thus suffices to prove

II | 41

Lemma (2.7.9.1). — *Under the hypotheses of (2.7.5), for all $n \geqslant 0$, there exists an integer k (depending on n) and a surjective homomorphism $\mathscr{O}_X^k \to \mathscr{O}_X(n)$.*

It suffices (2.7.2) to show that, for suitable k, there is a (TN)-surjective homomorphism u *of degree* 0 from the graded product S-module S^k to $S(n)$. But $(S(n))_0 = S_n$, and, by hypothesis, $S_h = S_1^h$ for all $h > 0$, and so $SS_n = S_n + S_{n+1} + \ldots$. Since S_n is an S_0-module of finite type ((2.1.5) and (2.1.6, i)), consider a system of generators $(a_i)_{1 \leqslant i \leqslant k}$ of this module; consider the homomorphism u that sends the i-th element of the canonical basis of S^k to a_i ($1 \leqslant i \leqslant k$); since $\mathrm{Coker}\, u$ can then be identified with $(S(n))_{-n} + \ldots + (S(n))_{-1}$, u is indeed the desired homomorphism. □

Corollary (2.7.10). — *Under the hypotheses of (2.7.5), let $\mathscr{F}$ be a quasi-coherent $\mathscr{O}_X$-module of finite type. Then there exists an integer n_0 such that, for all $n \geqslant n_0$, $\mathscr{F}$ is isomorphic to a quotient of an $\mathscr{O}_X$-module of the form $(\mathscr{O}_X(-n))^k$ (for some k depending on n).*

Proposition (2.7.11). — *Suppose that the hypotheses of (2.7.5) are satisfied, and let M be a graded S-module. Then:*

(i) *The canonical homomorphism $\widetilde{\alpha} : \widetilde{M} \to (\Gamma_\bullet(\widetilde{M}))^\sim$ is an isomorphism.*
(ii) *Let $\mathscr{G}$ be a quasi-coherent sub-$\mathscr{O}_X$-module of $\widetilde{M}$, and let N be the graded sub-S-module of M given by the inverse image of $\Gamma_\bullet(\mathscr{G})$ under α. Then $\widetilde{N} = \mathscr{G}$ (where $\widetilde{N}$ is identified, by (2.5.4), with a sub-$\mathscr{O}_X$-module of $\widetilde{M}$).*

Proof. Since $\beta : (\Gamma_\bullet(\widetilde{M}))^\sim \to \widetilde{M}$ is an isomorphism (by (2.7.5)), $\widetilde{\alpha}$ is the inverse isomorphism (by (2.6.5.1)), whence (i). Let P be the graded submodule $\alpha(M)$ of $\Gamma_\bullet(\widetilde{M})$; since the functor $M \mapsto \widetilde{M}$ is exact (2.5.4), the image of $\widetilde{M}$ under $\widetilde{\alpha}$ is equal to $\widetilde{P}$, and so, by (i), $\widetilde{P} = (\Gamma_\bullet(\widetilde{M}))^\sim$. Set $Q = \Gamma_\bullet(\mathscr{G}) \cap P$; by the above, and by (2.5.4), we have that $\widetilde{Q} = (\Gamma_\bullet(\mathscr{G}))^\sim$, and so the restriction of β to $\widetilde{Q}$ is an *isomorphism* from this $\mathscr{O}_X$-module to $\mathscr{G}$ by (2.7.5). But, by the definition of N, and by (2.5.4), the restriction of the isomorphism $\widetilde{\alpha}$ to $\widetilde{N}$ is an isomorphism from $\widetilde{N}$ to $\widetilde{Q}$, whence the conclusion, by (2.6.5.1). □

2.8. Functorial behaviour

(2.8.1). Let S and S' be positively graded rings, and $\phi : S' \to S$ a homomorphism of graded rings. We denote by $G(\phi)$ the open subset of $X = \operatorname{Proj}(S)$ given by the complement of $V_+(\phi(S'_+))$, or, equivalently, the union of the $D_+(\phi(f'))$ where f' runs over the set of homogeneous elements of S'_+. The restriction to $G(\phi)$ of the continuous map ${}^a\phi$ from $\operatorname{Spec}(S)$ to $\operatorname{Spec}(S')$ (**I**, 1.2.1) is thus a continuous map from $G(\phi)$ to $\operatorname{Proj}(S')$, which we again denote, with an abuse of language, by ${}^a\phi$. If $f' \in S'_+$ is homogeneous, then

$$ {}^a\phi^{-1}(D_+(f')) = D_+(\phi(f')) \tag{2.8.1.1}$$

taking into account the fact that ${}^a\phi$ sends $G(\phi)$ to $\operatorname{Proj}(S')$, as well as (**I**, 1.2.2.2). The homomorphism ϕ also canonically defines (with the same notation) a homomorphism of graded rings $S'_{f'} \to S_f$, whence, by restriction to the degree 0 elements, a homomorphism $S'_{(f')} \to S_{(f)}$, which we denote **II** | 42
by $\phi_{(f)}$; there is a corresponding (**I**, 1.6.1) morphism of affine schemes $({}^a\phi_{(f)}, \widetilde{\phi}_{(f)}) : \operatorname{Spec}(S_{(f)}) \to \operatorname{Spec}(S'_{(f')})$. If we canonically identify $\operatorname{Spec}(S_{(f)})$ with the scheme induced by $\operatorname{Proj}(S)$ on $D_+(f)$ (2.3.6), then we have defined a morphism $\Phi_f : D_+(f) \to D_+(f')$, and ${}^a\phi_{(f)}$ is identified with the restriction of ${}^a\phi$ to $D_+(f)$. It is also immediate that, if g' is another homogeneous element of S'_+, and $g = \phi(g')$, then the diagram

$$\begin{tikzcd} D_+(f) \arrow[r, "\Phi_f"] & D_+(f') \\ D_+(fg) \arrow[u] \arrow[r, "\Phi_{fg}"'] & D_+(f'g') \arrow[u] \end{tikzcd}$$

commutes, by the fact that the diagram

$$\begin{tikzcd} S'_{(f')} \arrow[r, "\phi_{(f)}"] \arrow[d, "\omega_{f'g',f'}"'] & S_{(f)} \arrow[d, "\omega_{fg,f}"] \\ S'_{(f'g')} \arrow[r, "\phi_{(fg)}"'] & S_{(fg)} \end{tikzcd}$$

commutes. Taking the definition of $G(\phi)$, along with (2.3.3.2), we thus see that:

Proposition (2.8.2). — *Given a homomorphism of graded rings $\phi : S' \to S$, there exists exactly one morphism $({}^a\phi, \widetilde{\phi})$ from the induced prescheme $G(\phi)$ to $\operatorname{Proj}(S')$ (said to be* associated *to ϕ, and denoted by $\operatorname{Proj}(\phi)$) such that, for every homogeneous element $f' \in S'_+$, the restriction of this morphism to $D_+(\phi(f'))$ agrees with the morphism associated to the homomorphism $S'_{(f')} \to S_{(\phi(f'))}$ corresponding to ϕ.*

Proof. With the above notation, if $f' \in S'_d$, then the diagram

(2.8.2.1)
$$\begin{tikzcd} S'_{(f')} \arrow[r, "\phi_{(f)}"] \arrow[d, "\sim"'] & S_{(f)} \arrow[d, "\sim"] \\ S'^{(d)}/(f'-1)S'^{(d)} \arrow[r] & S^{(d)}/(f-1)S^{(d)} \end{tikzcd}$$

commutes (the vertical arrows being the isomorphisms (2.2.5)). □

Corollary (2.8.3). — (i) *The morphism* $\mathrm{Proj}(\phi)$ *is affine.*

(ii) *If* $\mathrm{Ker}(\phi)$ *is nilpotent (and, in particular, if* ϕ *is injective), then the morphism* $\mathrm{Proj}(\phi)$ *is dominant.*

Proof. Claim (i) is an immediate consequence of (2.8.2) and (2.8.1.1). Claim (ii) follows since, if $\mathrm{Ker}(\phi)$ is nilpotent, then, for every homogeneous f' in S'_+, we immediately see that $\mathrm{Ker}(\phi_f)$ (with $f = \phi(f')$) is nilpotent, and thus so too is $\mathrm{Ker}(\phi_{(f)})$; we then apply (2.8.2) and (**I**, 1.2.7). □

We note that there are, in general, morphisms from $\mathrm{Proj}(S)$ to $\mathrm{Proj}(S')$ that are not affine, and **II** | 43
that thus do not come from homomorphisms of graded rings $S' \to S$; an example is the structure morphism $\mathrm{Proj}(S) \to \mathrm{Spec}(A)$ when A is a field ($\mathrm{Spec}(A)$ thus being identified with $\mathrm{Proj}(A[T])$, cf. (3.1.7)); indeed, this follows from (**I**, 2.3.2).

(2.8.4). Let S'' be another positively graded ring, and $\phi' : S'' \to S'$ a homomorphism of graded rings, and set $\phi'' = \phi \circ \phi'$. By (2.8.1.1) and the formula ${}^a\phi'' = ({}^a\phi') \circ ({}^a\phi)$, we immediately see that $G(\phi'') \subset G(\phi)$, and that, if Φ, Φ', and Φ'' are the morphisms associated to ϕ, ϕ', and ϕ'' (respectively), then $\Phi'' = \Phi' \circ (\Phi|G(\phi''))$.

(2.8.5). Suppose that S (resp. S') is a graded A-algebra (resp. a graded A'-algebra), and let $\psi : A' \to A$ be a ring homomorphism such that the diagram

(2.8.5.1)
$$\begin{tikzcd} A' \arrow[r, "\psi"] \arrow[d] & A \arrow[d] \\ S' \arrow[r, "\phi"'] & S \end{tikzcd}$$

commutes. We can then consider $G(\phi)$ (resp. $\mathrm{Proj}(S')$) as a scheme over $\mathrm{Spec}(A)$ (resp. $\mathrm{Spec}(A')$); if Φ (resp. Ψ) is the morphism associated to ϕ (resp. ψ), then the diagram

$$\begin{tikzcd} G(\phi) \arrow[r, "\Phi"] \arrow[d] & \mathrm{Proj}(S') \arrow[d] \\ \mathrm{Spec}(A) \arrow[r, "\Psi"'] & \mathrm{Spec}(A') \end{tikzcd}$$

commutes: it suffices to prove this for the restriction of Φ to $D_+(f)$, where $f = \phi(f')$, with f' homogeneous in S'_+; this then follows from the fact that the diagram

$$\begin{tikzcd} A' \arrow[r, "\psi"] \arrow[d] & A \arrow[d] \\ S'_{(f')} \arrow[r, "\phi_{(f)}"'] & S_{(f)} \end{tikzcd}$$

commutes.

(2.8.6). Now let M be a graded S-module, and consider the S'-module $M_{[\phi]}$, which is evidently graded. Let f' be homogeneous in S'_+, and let $f = \phi(f')$; we know (**0**, 1.5.2) that there is a canonical isomorphism $(M_{[\phi]})_{f'} \xrightarrow{\sim} (M_f)_{[\phi_f]}$, and it is immediate that this isomorphism preserves degree, whence a canonical isomorphism $(M_{[\phi]})_{(f')} \xrightarrow{\sim} (M_{(f)})_{[\phi_{(f)}]}$. To this isomorphism, there canonically corresponds an isomorphism of sheaves $(M_{[\phi]})^{\sim}|D_+(f') \xrightarrow{\sim} (\Phi_f)_*(\widetilde{M}|D_+(f))$ ((2.5.2) and (**I**, 1.6.3)). Furthermore, if g' is another homogeneous element of S'_+, and $g = \phi(g')$, then the diagram **II** | 44

$$\begin{tikzcd} (M_{[\phi]})_{(f')} \arrow[r, "\sim"] \arrow[d] & (M_{(f)})_{[\phi_{(f)}]} \arrow[d] \\ (M_{[\phi]})_{(f'g')} \arrow[r, "\sim"] & (M_{(fg)})_{[\phi_{(fg)}]} \end{tikzcd}$$

commutes, whence we immediately conclude that the isomorphism

$$(M_{[\phi]})^{\sim}|D_+(f'g') \xrightarrow{\sim} (\Phi_{fg})_*(\widetilde{M}|D_+(fg))$$

is the restriction to $D_+(f'g')$ of the isomorphism $(M_{[\phi]})^{\sim}|D_+(f') \xrightarrow{\sim} (\Phi_f)_*(\widetilde{M}|D_+(f))$. Since Φ_f is the restriction to $D_+(f)$ of the morphism Φ, we see that, taking (2.8.1.1) into account, and setting $X' = \operatorname{Proj}(S')$:

Proposition (2.8.7). — *There exists a canonical functorial isomorphism from the $\mathscr{O}_{X'}$-module $(M_{[\phi]})^{\sim}$ to the $\mathscr{O}_{X'}$-module $\Phi_*(\widetilde{M}|G(\phi))$.*

We thus immediately deduce a canonical functorial map from the set of ϕ-morphisms $M' \to M$ from a graded S'-module to the graded S-module M, to the set of Φ-morphisms $\widetilde{M'} \to \widetilde{M}|G(\phi)$. With the notation of (2.8.4), if M'' is a graded S''-module, then, to the composition of a ϕ-morphism $M' \to M$ and a ϕ'-morphism $M'' \to M'$, canonically corresponds the composition of $\widetilde{M'}|G(\phi') \to \widetilde{M}|G(\phi'')$ and $\widetilde{M''} \to \widetilde{M'}|G(\phi')$.

Proposition (2.8.8). — *Under the hypotheses of (2.8.1), let M' be a graded S'-module. Then there exists a canonical functorial homomorphism ν from the $(\mathscr{O}_X|G(\phi))$-module $\Phi^*(\widetilde{M'})$ to the $(\mathscr{O}_X|G(\phi))$-module $(M' \otimes_{S'} S)^{\sim}|G(\phi)$. If the ideal S'_+ is generated by S'_1, then ν is an isomorphism.*

Proof. Indeed, for $f' \in S'_d$ ($d > 0$), we define a canonical functorial homomorphism of $S_{(f)}$-modules (where $f = \phi(f')$)

$$\nu_f : M'_{(f')} \otimes_{S'_{(f')}} S_{(f)} \longrightarrow (M' \otimes_{S'} S)_{(f)} \tag{2.8.8.1}$$

by composing the homomorphism $M'_{(f')} \otimes_{S'_{(f')}} S_{(f)} \to M'_{f'} \otimes_{S'_{f'}} S_f$ and the canonical isomorphism $M'_{f'} \otimes_{S'_{f'}} S_f \xrightarrow{\sim} (M' \otimes_{S'} S)_f$ (**0**, 1.5.4), and noting that the latter preserves degrees. We can immediately verify the compatibility of ν_f with the restriction operators from $D_+(f)$ to $D_+(fg)$ (for any $g' \in S'_+$ and $g = \phi(g')$), whence the definition of the homomorphism

$$\nu : \Phi^*(\widetilde{M'}) \longrightarrow (M' \otimes_{S'} S)^{\sim}|G(\phi)$$

taking (**I**, 1.6.5) into account. To prove the second claim, it suffices to show that ν_f is an isomorphism for all $f' \in S'_1$, since $G(\phi)$ is then a union of the $D_+(\phi(f'))$. We first define a **Z**-bilinear $M'_m \times S_n \to M'_{(f')} \otimes_{S'_{(f')}} S_{(f)}$ by sending (x', s) to the element $(x'/f'^m) \otimes (s/f^n)$ (with the convention that x'/f'^m is $f'^{-m}x'/1$ when $m < 0$). We claim that, in the proof of (2.5.13), this map gives rise to a di-homomorphism of modules **II** | 45

$$\eta_f : M' \otimes_{S'} S \longrightarrow M'_{(f')} \otimes_{S'_{(f')}} S_{(f)}.$$

Furthermore, if, for $r > 0$, we have $f^r \sum_i (x'_i \otimes s_i) = 0$, then this can also be written as $\sum_i (f'^r x'_i \otimes s_i) = 0$, whence, by (**0**, 1.5.4), $\sum_i (f'^r x'_i / f'^{m_i + r}) \otimes (s_i / f^{n_i}) = 0$, i.e. $\eta_f(\sum_i x'_i \otimes s_i) = 0$, which proves that η_f factors as $M' \otimes_{S'} S \to (M' \otimes_{S'} S)_f \xrightarrow{\eta'_f} M'_{(f')} \otimes_{S'_{(f')}} S_{(f)}$; we finally can prove that η'_f and ν_f are inverse isomorphisms to one another.

In particular, it follows from (2.1.2.1) that we have a canonical homomorphism

$$\Phi^*(\mathscr{O}_{X'}(n)) \xrightarrow{\sim} \mathscr{O}_X(n)|G(\phi) \tag{2.8.8.2}$$

for all $n \in \mathbf{Z}$. □

(2.8.9). Let A and A' be rings, and $\psi : A' \to A$ a ring homomorphism, defining a morphism $\Psi : \operatorname{Spec}(A) \to \operatorname{Spec}(A')$. Let S' be a positively graded A'-algebra, and set $S = S' \otimes_{A'} A$, which is evidently an A-algebra graded by the $S'_n \otimes_{A'} A$; the map $\phi : s' \to s' \otimes 1$ is then a graded ring homomorphism that makes the diagram (2.8.5.1) commute. Since S_+ is here the A-module generated by $\phi(S'_+)$, we have $G(\phi) = \operatorname{Proj}(S) = X$; whence, setting $X' = \operatorname{Proj}(S')$, we have the commutative diagram

(2.8.9.1)
$$\begin{tikzcd} X \arrow[r, "\Phi"] \arrow[d, "p"'] & X' \arrow[d] \\ Y \arrow[r, "\Psi"'] & Y' \end{tikzcd}$$

Now let M' be a graded S'-module, and set $M = M' \otimes_{A'} A = M' \otimes_{S'} S$. Under these conditions:

Proposition (2.8.10). — *The diagram (2.8.9.1) identifies the scheme X with the product $X' \times_{Y'} Y$; furthermore, the canonical homomorphism $\nu : \Phi^*(\widetilde{M'}) \to \widetilde{M}$ (2.8.8) is an isomorphism.*

Proof. The first claim will be proven if we show that, for every homogeneous f' in S'_+, setting $f = \phi(f')$, the restrictions of Φ and p to $D_+(f)$ identify this scheme with the product $D_+(f') \times_{Y'} Y$ (**I**, 3.2.6.2); in other words, it suffices (**I**, 3.2.2) to prove that $S_{(f)}$ is canonically identified with $S'_{(f')} \otimes_{A'} A$, which follows immediately from the canonical degree-preserving isomorphism $S_f \xrightarrow{\sim} S'_{f'} \otimes_{A'} A$ (**0**, 1.5.4). The second claim then follows from the fact that $M'_{(f')} \otimes_{S'_{(f')}} S_{(f)}$ can be identified, by the above, with $M'_{(f')} \otimes_{A'} A$, and this can be identified with $M_{(f)}$, since M_f is canonically identified with $M'_{f'} \otimes_{A'} A$ by an isomorphism that preserves degrees. □

Corollary (2.8.11). — *For every integer $n \in \mathbf{Z}$, $\widetilde{M}(n)$ can be identified with $\Phi^*(\widetilde{M'}(n)) = \widetilde{M'}(n) \otimes_{Y'} \mathscr{O}_Y$; in particular, $\mathscr{O}_X(n) = \Phi^*(\mathscr{O}_{X'}(n)) = \mathscr{O}_{X'}(n) \otimes_{Y'} \mathscr{O}_Y$.*

Proof. This follows from (2.8.10) and (2.5.15). □

II | 46

(2.8.12). Under the hypotheses of (2.8.9), for $f' \in S'_d$ $(d > 0)$ and $f = \phi(f')$, the diagram

(2.8.12.1)
$$\begin{tikzcd} M'_{(f')} \arrow[r, "\sim"] \arrow[d] & M'^{(d)}/(f'-1)M'^{(d)} \arrow[d] \\ M_{(f)} \arrow[r, "\sim"] & M^{(d)}/(f-1)M^{(d)} \end{tikzcd}$$

(cf. (2.2.5)) commutes.

(2.8.13). Keep the notation and hypotheses of (2.8.9), and let $\mathscr{F}'$ be an $\mathscr{O}_{X'}$-module; if we set $\mathscr{F} = \Phi^*(\mathscr{F}')$, then, for all $n \in \mathbf{Z}$, we have $\mathscr{F}(n) = \Phi^*(\mathscr{F}'(n))$, by (2.8.11) and (**0**, 4.3.3). Then, by (**0**, 3.7.1), we have a canonical homomorphism

$$\Gamma(\rho) : \Gamma(X', \mathscr{F}'(n)) \longrightarrow \Gamma(X, \mathscr{F}(n))$$

which gives a canonical di-homomorphism of graded modules

$$\Gamma_\bullet(\mathscr{F}') \longrightarrow \Gamma_\bullet(\mathscr{F}).$$

Suppose that the ideal S_+ is generated by S_1, and that $\mathscr{F}' = \widetilde{M'}$, thus $\mathscr{F} = \widetilde{M}$ with $M = M' \otimes_{A'} A$. If f' is homogeneous in S'_+, and $f = \phi(f')$, then we have seen that $M_{(f)} = M'_{(f')} \otimes_{A'} A$, and the diagram

$$\begin{tikzcd} M'_0 \arrow[r] \arrow[d] & M'_{(f')} \arrow[d] & = \Gamma(D_+(f'), \widetilde{M'}) \\ M_0 \arrow[r] & M_{(f)} & = \Gamma(D_+(f), \widetilde{M}) \end{tikzcd}$$

thus commutes; we immediately conclude from this remark, and from the definition of the homomorphism α (2.6.2), that the diagram

(2.8.13.1)
$$\begin{tikzcd} M' \arrow[r, "\alpha_{M'}"] \arrow[d] & \Gamma_\bullet(\widetilde{M'}) \arrow[d] \\ M \arrow[r, "\alpha_M"'] & \Gamma_\bullet(\widetilde{M}) \end{tikzcd}$$

commutes. Similarly, the diagram

(2.8.13.2)
$$\begin{tikzcd} (\Gamma_\bullet(\mathscr{F}'))^\sim \arrow[r, "\beta_{\mathscr{F}'}"] \arrow[d] & \mathscr{F}' \arrow[d] \\ (\Gamma_\bullet(\mathscr{F}))^\sim \arrow[r, "\beta_{\mathscr{F}}"'] & \mathscr{F} \end{tikzcd}$$

commutes (the vertical arrow on the right being the canonical Φ-morphism $\mathscr{F}' \to \Phi^*(\mathscr{F}') = \mathscr{F}$).

II | 47

(2.8.14). Still keeping the notation and hypotheses of (2.8.9), let N' be another graded S'-module, and let $N = N' \otimes_{A'} A$. It is immediate that the canonical di-homomorphisms $M' \to M$ and $N' \to N$ give a di-homomorphism $M' \otimes_{S'} N' \to M \otimes_S N$ (with respect to the canonical ring homomorphism $S' \to S$), and thus also an S-homomorphism $(M' \otimes_{S'} N') \otimes_{A'} A \to M \otimes_S N$ of degree 0, to which corresponds (taking (2.8.10) into account) a homomorphism of $\mathscr{O}_X$-modules

(2.8.14.1)
$$\Phi^*((M' \otimes_{S'} N')^\sim) \longrightarrow (M \otimes_S N)^\sim.$$

Furthermore, we can immediately verify that the diagram

(2.8.14.2)
$$\begin{tikzcd} \Phi^*(\widetilde{M'} \otimes_{\mathscr{O}_{X'}} \widetilde{N'}) \arrow[r, "\sim"] \arrow[d, "\Phi^*(\lambda)"'] & \widetilde{M} \otimes_{\mathscr{O}_X} \widetilde{N} \arrow[d, "\lambda"] & = \Phi^*(\widetilde{M'}) \otimes_{\mathscr{O}_X} \Phi^*(\widetilde{N'}) \\ \Phi^*((M' \otimes_{S'} N')^\sim) \arrow[r] & (M \otimes_S N)^\sim & \end{tikzcd}$$

commutes, with the first line being the canonical isomorphism (**0**, 4.3.3). If the ideal S'_+ is generated by S'_1, then it is clear that S_+ is generated by S_1, and the two vertical arrows of (2.8.14.2) are then isomorphisms (2.5.13); it is thus also the case for (2.8.14.1).

We similarly have a canonical di-homomorphism $\mathrm{Hom}_{S'}(M', N') \to \mathrm{Hom}_S(M, N)$ by sending a homomorphism u' of degree k to the homomorphism $u' \otimes 1$, which is also of degree k; from this, we again deduce a S-homomorphism of degree 0

$$(\mathrm{Hom}_{S'}(M', N')) \otimes_{A'} A \longrightarrow \mathrm{Hom}_S(M, N)$$

whence a homomorphism of $\mathscr{O}_X$-modules

(2.8.14.3)
$$\Phi^*((\mathrm{Hom}_{S'}(M', N'))^\sim) \longrightarrow (\mathrm{Hom}_S(M, N))^\sim.$$

Furthermore, the diagram

$$\begin{tikzcd} \Phi^*((\mathrm{Hom}_{S'}(M', N'))^\sim) \arrow[r] \arrow[d, "\Phi^*(\mu)"'] & (\mathrm{Hom}_S(M, N))^\sim \arrow[d, "\mu"] \\ \Phi^*(\mathscr{H}om_{\mathscr{O}_{X'}}(\widetilde{M'}, \widetilde{N'})) \arrow[r] & \mathscr{H}om_{\mathscr{O}_X}(\widetilde{M}, \widetilde{N}) \end{tikzcd}$$

commutes (the second horizontal line being the canonical homomorphism (**0**, 4.4.6)).

II | 48

(2.8.15). With the notation and hypotheses of (2.8.1), it follows from (2.4.7) that we do not change the morphism Φ, up to isomorphism, when we replace S_0 and S'_0 by $\mathbf{Z}$, and ϕ_0 by the identity map, and thus when we replace S and S' by $S^{(d)}$ and $S'^{(d)}$ (respectively) ($d > 0$), and ϕ by its restriction $\phi^{(d)}$ to $S^{(d)}$.

2.9. Closed subschemes of a scheme $\operatorname{Proj}(S)$

(2.9.1). If $\phi : S \to S'$ is a homomorphism of graded rings, then we say that ϕ is (TN)-*surjective* (resp. (TN)-*injective*, (TN)-*bijective*) if there exists an integer n such that, for $k \geqslant n$, $\phi_k : S_k \to S'_k$ is *surjective* (resp. *injective*, *bijective*). It then follows from (2.8.15) that the study of Φ may be reduced to the case where ϕ is surjective (resp. injective, bijective). Instead of saying that ϕ is (TN)-bijective, we sometimes say that it is a (TN)-*isomorphism*.

Proposition (2.9.2). — *Let S be a positively graded ring, and let $X = \operatorname{Proj}(S)$.*

(i) *If $\phi : S \to S'$ is a (TN)-surjective homomorphism of graded rings, then the corresponding morphism Φ (2.8.1) is defined on the whole of $\operatorname{Proj}(S')$, and is a closed immersion of $\operatorname{Proj}(S')$ into X. If $\mathfrak{J}$ is the kernel of ϕ, then the closed subscheme of X associated to Φ is defined by the quasi-coherent sheaf of ideals $\widetilde{\mathfrak{J}}$ of $\mathscr{O}_X$.*

(ii) *Suppose further that the ideal S_+ is generated by a finite number of homogeneous elements of degree 1. Let X' be a closed subscheme of X defined by a quasi-coherent sheaf of ideals $\mathscr{J}$ of $\mathscr{O}_X$. Let $\mathfrak{J}$ be the graded ideal of S given by the inverse image of $\Gamma_\bullet(\mathscr{J})$ under the canonical homomorphism $\alpha : S \to \Gamma_\bullet(\mathscr{O}_X)$ (2.6.2), and set $S' = S/\mathfrak{J}$. Then X' is the subscheme associated to the closed immersion $\operatorname{Proj}(S') \to X$ corresponding to the canonical homomorphism of graded rings $S \to S'$.*

Proof.

(i) We can suppose that ϕ is surjective (2.9.1). Since, by hypothesis, $\phi(S_+)$ generates S'_+, we have $G(\phi) = \operatorname{Proj}(S')$. Now, the second claim can be checked locally on X; so let f be a homogeneous element of S_+, and set $f' = \phi(f)$. Since ϕ is a surjective homomorphism of graded rings, we immediately see that $\phi_{(f')} : S_{(f)} \to S'_{(f')}$ is surjective, and that its kernel is $\mathfrak{J}_{(f)}$, which proves (i) (**I**, 4.2.3).

(ii) By (i), we are led to proving that the homomorphism $\widetilde{j} : \widetilde{\mathfrak{J}} \to \mathscr{O}_X$ induced by the canonical injection $j : \mathfrak{J} \to S$ is an isomorphism from $\widetilde{\mathfrak{J}}$ to $\mathscr{J}$, which follows from (2.7.11).

□

We note that $\mathfrak{J}$ is the *largest* of the graded ideals $\mathfrak{J}'$ of S such that $\widetilde{j}(\widetilde{\mathfrak{J}'}) = \mathscr{J}$, since we can immediately show, using the definitions (2.6.2), that this equation implies that $\alpha(\mathfrak{J}') \subset \Gamma_\bullet(\mathscr{J})$.

Corollary (2.9.3). — *Suppose that the hypotheses of (2.9.2, (i)) are satisfied, and further that the ideal S_+ is generated by S_1; then $\Phi^*((S(n))^\sim)$ is canonically isomorphic to $(S'(n))^\sim$ for all $n \in \mathbf{Z}$, and so $\Phi^*(\mathscr{F}(n))$ is canonically isomorphic to $\Phi^*(\mathscr{F})(n)$ for every $\mathscr{O}_X$-module $\mathscr{F}$.*

Proof. This is a particular case of (2.8.8), taking (2.5.10.2) into account. □

Corollary (2.9.4). — *Suppose that the hypotheses of (2.9.2, (ii)) are satisfied. For the closed sub-prescheme X' of X to be integral, it is necessary and sufficient for the graded ideal $\mathfrak{J}$ to be prime in S.*

II | 49

Proof. Since X' is isomorphic to $\operatorname{Proj}(S/\mathfrak{J})$, the condition is sufficient by (2.4.4). To see that it is necessary, consider the exact sequence $0 \to \mathscr{J} \to \mathscr{O}_X \to \mathscr{O}_X/\mathscr{J}$, which gives the exact sequence

$$0 \longrightarrow \Gamma_\bullet(\mathscr{J}) \longrightarrow \Gamma_\bullet(\mathscr{O}_X) \longrightarrow \Gamma_\bullet(\mathscr{O}_X/\mathscr{J}).$$

It suffices to prove that, if $f \in S_m$ and $g \in S_n$ are such that the image in $\Gamma_\bullet(\mathscr{O}_X/\mathscr{J})$ of $\alpha_{n+m}(fg)$ is zero, then the image of either $\alpha_m(f)$ or $\alpha_n(g)$ is zero. But, by definition, these images are sections of invertible $(\mathscr{O}_X/\mathscr{J})$-modules $\mathscr{L} = (\mathscr{O}_X/\mathscr{J})(m)$ and $\mathscr{L}' = (\mathscr{O}_X/\mathscr{J})(n)$ over the integral scheme X'; the hypothesis implies that the product of these two sections is zero in $\mathscr{L} \otimes \mathscr{L}'$ ((2.9.3) and (2.5.14.1)), and so one of them is zero by (**I**, 7.4.4). □

Corollary (2.9.5). — *Let A be a ring, M an A-module, S a graded A-algebra generated by the set S_1 of homogeneous elements of degree* 1, *$u : M \to S_1$ a surjective homomorphism of A-modules, and $\overline{u} : \mathbf{S}(M) \to S$ the homomorphism (of A-algebras) from the symmetric algebra $\mathbf{S}(M)$ of M to S that extends u. Then the morphism corresponding to $\overline{u}$ is a closed immersion of* $\operatorname{Proj}(S)$ *into* $\operatorname{Proj}(\mathbf{S}(M))$.

Proof. Indeed, $\overline{u}$ is surjective by hypothesis, and so it suffices to apply (2.9.2). □

§3. HOMOGENEOUS SPECTRUM OF A SHEAF OF GRADED ALGEBRAS

3.1. Homogeneous spectrum of a quasi-coherent graded $\mathscr{O}_Y$-algebra

(3.1.1). Let Y be a prescheme, $\mathscr{S}$ a graded $\mathscr{O}_Y$-algebra, and $\mathscr{M}$ a graded $\mathscr{S}$-module. If $\mathscr{S}$ is *quasi-coherent*, then each of its homogeneous components $\mathscr{S}_n$ is a *quasi-coherent* $\mathscr{O}_Y$-module, since they are the images of $\mathscr{S}$ under a homomorphism from $\mathscr{S}$ to itself ((**I**, 1.3.8) and (**I**, 1.3.9)); similarly, if $\mathscr{M}$ is quasi-coherent as an $\mathscr{O}_Y$-module, then its homogeneous components $\mathscr{M}_n$ are also quasi-coherent, and the converse is also true. For an integer $d > 0$, we denote by $\mathscr{S}^{(d)}$ the direct sum of the $\mathscr{O}_Y$-modules $\mathscr{S}_{nd}$ (for $n \in \mathbf{Z}$), which is quasi-coherent if $\mathscr{S}$ is quasi-coherent (**I**, 1.3.9); for every integer k such that $0 \leqslant k \leqslant d-1$, we denote by $\mathscr{M}^{(d,k)}$ (or $\mathscr{M}^{(d)}$, for $k = 0$) the direct sum of the $\mathscr{M}_{nd+k}$ (for $n \in \mathbf{Z}$), which is a graded $\mathscr{S}^{(d)}$-module, and quasi-coherent if both $\mathscr{S}$ and $\mathscr{M}$ are quasi-coherent (**I**, 9.6.1). We denote by $\mathscr{M}(n)$ the graded $\mathscr{S}$-module such that $(\mathscr{M}(n))_k = \mathscr{M}_{n+k}$ for all $k \in \mathbf{Z}$; if $\mathscr{S}$ and $\mathscr{M}$ are quasi-coherent, then $\mathscr{M}(n)$ is a quasi-coherent graded $\mathscr{S}$-module (**I**, 9.6.1).

We say that $\mathscr{M}$ is a graded $\mathscr{S}$-module *of finite type* (resp. admitting a *finite presentation*) if, for all $y \in Y$, there exists an open neighbourhood U of y, along with integers n_i (resp. integers m_i and n_j) such that there is a surjective degree 0 homomorphism $\bigoplus_{i=1}^r (\mathscr{S}(n_i)|U) \to \mathscr{M}|U$ (resp. such that $\mathscr{M}|U$ is isomorphic to the cokernel of a degree 0 homomorphism $\bigoplus_{i=1}^r (\mathscr{S}(m_i)|U) \to \bigoplus_{j=1}^s (\mathscr{S}(n_j)|U)$).

Let U be an affine open of Y, with ring $A = \Gamma(U, \mathscr{O}_Y)$; by hypothesis, the graded $(\mathscr{O}_Y|U)$-algebra $\mathscr{S}|U$ is isomorphic to $\widetilde{S}$, where $S = \Gamma(U, \mathscr{S})$ is a graded A-algebra (**I**, 1.4.3); set $X_U = \operatorname{Proj}(\Gamma(U, \mathscr{S}))$. **II** | 50
Let $U' \subset U$ be another affine open of Y, with ring A', and let $j : U' \to U$ be the canonical injection, which corresponds to the restriction homomorphism $A \to A'$; we have that $\mathscr{S}|U' = j^*(\mathscr{S}|U)$, and so $S' = \Gamma(U', \mathscr{S})$ is canonically identified with $S \otimes_A A'$ (**I**, 1.6.4). We conclude (2.8.10) that $X_{U'}$ is canonically identified with $X_U \times_U U'$, and thus also with $f_U^{-1}(U')$, where we denote by f_U the structure morphism $X_U \to U$ (**I**, 4.4.1). We denote by $\sigma_{U',U}$ the canonical isomorphism $f_U^{-1}(U') \xrightarrow{\sim} X_{U'}$ thus defined, and by $\rho_{U',U}$ the open immersion $X_{U'} \to X_U$ obtained by composing $\sigma_{U',U}^{-1}$ with the canonical injection $f_U^{-1}(U') \to X_U$. It is immediate that, if $U'' \subset U'$ is another affine open of Y, then $\rho_{U'',U} = \rho_{U',U} \circ \rho_{U'',U'}$.

Proposition (3.1.2). — *Let Y be a prescheme. For every quasi-coherent positively graded $\mathscr{O}_Y$-algebra $\mathscr{S}$, there exists exactly one (up to Y-isomorphism) prescheme X over Y satisfying the following property: if $f : X \to Y$ is the structure morphism, then, for every affine open U of Y, there exists an* isomorphism η_U *from the induced prescheme $f^{-1}(U)$ to $X_U = \operatorname{Proj}(\Gamma(U, \mathscr{S}))$ such that, if V is another affine open of Y that is contained in U, then the diagram*

(3.1.2.1)
$$\begin{tikzcd} f^{-1}(V) \arrow[r, "\eta_V"] \arrow[d] & X_V \arrow[d, "\rho_{V,U}"] \\ f^{-1}(U) \arrow[r, "\eta_U"'] & X_U \end{tikzcd}$$

commutes.

Proof. Given affine opens U and V of Y, let $X_{U,V}$ be the prescheme induced on $f_U^{-1}(U \cap V)$ by X_U; we are going to define a Y-isomorphism $\theta_{U,V} : X_{V,U} \xrightarrow{\sim} X_{U,V}$. For this, we consider an affine open $W \subset U \cap V$: by composing the isomorphisms

$$f_U^{-1}(W) \xrightarrow{\sigma_{W,U}} X_W \xrightarrow{\sigma_{W,V}^{-1}} f_V^{-1}(W),$$

we obtain an isomorphism τ_W, and we immediately see that, if $W' \subset W$ is an affine open, then $\tau_{W'}$ is the restriction of τ_W to $f_U^{-1}(W')$; the τ_W are thus indeed the restrictions of a Y-isomorphism $\theta_{V,U}$. Further, if U, V, and W are affine open subsets of Y, and $\theta'_{U,V}$, $\theta'_{V,W}$, and $\theta'_{U,W}$ the restrictions of $\theta_{U,V}$, $\theta_{V,W}$, and $\theta_{U,W}$ (respectively) to the inverse images of $U \cap V \cap W$ in X_V, X_W, and X_W (respectively), then it follows from the above definitions that we have $\theta'_{U,V} \circ \theta'_{V,W} = \theta'_{U,W}$. The existence of some X satisfying the properties in the statement thus follows from (**I**, 2.3.1); its uniqueness up to Y-isomorphism is trivial, taking (3.1.2.1) into account. □

(3.1.3). We say that the prescheme X defined in (3.1.2) is the *homogeneous spectrum* of the quasi-coherent graded $\mathscr{O}_Y$-algebra $\mathscr{S}$, and we denote it by $\operatorname{Proj}(\mathscr{S})$. It is immediate that $\operatorname{Proj}(\mathscr{S})$ is *separated over* Y ((2.4.2) and (**I**, 5.5.5)); if $\mathscr{S}$ is an $\mathscr{O}_Y$-algebra *of finite type* (**I**, 9.6.2), then $\operatorname{Proj}(\mathscr{S})$ is *of finite type* over Y ((2.7.1, (ii)) and (**I**, 6.3.1)).

If f is the structure morphism $X \to Y$, then it is immediate that, for every prescheme induced by Y on an open subset U of Y, $f^{-1}(U)$ can be identified with the homogeneous spectrum $\operatorname{Proj}(\mathscr{S}|U)$.

Proposition (3.1.4). — *Let $f \in \Gamma(Y, \mathscr{S}_d)$ for $d > 0$. Then there exists an open subset X_f of the underlying space of $X = \operatorname{Proj}(\mathscr{S})$ that satisfies the following property: for every affine open U of Y, we have $X_f \cap \phi^{-1}(U) = D_+(f|U)$ in $\phi^{-1}(U)$ identified with $X_U = \operatorname{Proj}(\Gamma(U, \mathscr{S}))$, where ϕ denotes the structure morphism $X \to Y$. Furthermore, the prescheme induced on X_f is affine over Y, and is canonically isomorphic to $\operatorname{Spec}(\mathscr{S}^{(d)}/(f-1)\mathscr{S}^{(d)})$ (1.3.1).* **II** | 51

Proof. We have $f|U \in \Gamma(U, \mathscr{S}_d) = (\Gamma(U, \mathscr{S}))_d$. If U and U' are affine opens of Y such that $U' \subset U$, then $f|U'$ is the image of $f|U$ under the restriction homomorphism

$$\Gamma(U, \mathscr{S}) \longrightarrow \Gamma(U', \mathscr{S})$$

and so $D_+(f|U')$ is equal (with the notation of (3.1.1)) to the prescheme induced on the inverse image $\rho_{U',U}^{-1}(D_+(f|U))$ in $X_{U'}$ (2.8.1); whence the first claim. Furthermore, the prescheme induced on $D_+(f|U)$ by X_U is canonically identified with $\operatorname{Spec}((\Gamma(U, \mathscr{S}))_{(f|U)})$, with these identifications being compatible with the restriction homomorphisms (2.8.1); the second claim then follows from (2.2.5) and from the commutativity of the diagram (2.8.2.1). □

We also say that X_f (as an open subset of the underlying space X) is the set of $x \in X$ where f *does not vanish*.

Corollary (3.1.5). — *If $f \in \Gamma(Y, \mathscr{S}_d)$ and $g \in \Gamma(Y, \mathscr{S}_e)$, then*

$$X_{fg} = X_f \cap X_g. \tag{3.1.5.1}$$

Proof. It suffices to consider the intersection of the two sets with a set $\phi^{-1}(U)$, where U is an affine open in Y, and to then apply formula (2.3.3.2). □

Corollary (3.1.6). — *Let (f_α) be a family of sections of $\mathscr{S}$ over Y such that $f_\alpha \in \Gamma(Y, \mathscr{S}_{d_\alpha})$; if the sheaf of ideals of $\mathscr{S}$ generated by this family* (**0**, 5.1.1) *contains all the $\mathscr{S}_n$ starting from a certain rank, then the underlying space X is the union of the X_{f_α}.*

Proof. For every affine open U of Y, $\phi^{-1}(U)$ is the union of the $X_{f_\alpha} \cap \phi^{-1}(U)$ (2.3.14). □

Corollary (3.1.7). — *Let $\mathscr{A}$ be a quasi-coherent $\mathscr{O}_Y$-algebra; set*

$$\mathscr{S} = \mathscr{A}[T] = \mathscr{A} \otimes_{\mathbf{Z}} \mathbf{Z}[T]$$

where T is an indeterminate (and $\mathbf{Z}$ and $\mathbf{Z}[T]$ are considered as simple sheaves over Y). Then $X = \operatorname{Proj}(\mathscr{S})$ is canonically identified with $\operatorname{Spec}(\mathscr{A})$. In particular, $\operatorname{Proj}(\mathscr{O}_Y[T])$ is identified with Y.

Proof. By applying (3.1.6) to the unique section $f \in \Gamma(Y, \mathscr{S})$ that is equal to T at each point of Y we see that $X_f = X$. Further, here we have $d = 1$, and $\mathscr{S}^{(1)}/(f-1)\mathscr{S}^{(1)} = \mathscr{S}/(f-1)\mathscr{S}$ is canonically isomorphic to $\mathscr{A}$, whence the corollary (1.2.2). □

Let $g \in \Gamma(Y, \mathscr{O}_Y)$; if we take $\mathscr{S} = \mathscr{O}_Y[T]$, then $g \in \Gamma(Y, \mathscr{S}_0)$; let

$$h = gT \in \Gamma(Y, \mathscr{S}_1).$$

If $X = \mathrm{Proj}(\mathscr{S})$, then the canonical identification defined in (3.1.7) identifies X_h with the open subset Y_g of Y (in the sense of (**0**, 5.5.2)): indeed, we can restrict to the case where $Y = \mathrm{Spec}(A)$ is affine, and everything then reduces (taking (2.2.5) into account) to the fact that the ring of fractions A_g is canonically identified with $A[T]/(gT-1)A[T]$ (**0**, 1.2.3).

Proposition (3.1.8). — *Let $\mathscr{S}$ be a quasi-coherent positively graded $\mathscr{O}_Y$-algebra. Then*

(i) For all $d > 0$, there exists a canonical Y-isomorphism from $\mathrm{Proj}(\mathscr{S})$ to $\mathrm{Proj}(\mathscr{S}^{(d)})$. II | 52

(ii) Let $\mathscr{S}'$ be the graded $\mathscr{O}_Y$-algebra given by the direct sum of $\mathscr{O}_Y$ with the $\mathscr{S}_n$ (for $n \geqslant 0$); then $\mathrm{Proj}(\mathscr{S}')$ and $\mathrm{Proj}(\mathscr{S})$ are canonically Y-isomorphic.

*(iii) Let $\mathscr{L}$ be an invertible $\mathscr{O}_Y$-module (**0**, 5.4.1), and let $\mathscr{S}_{(\mathscr{L})}$ be the graded $\mathscr{O}_Y$-algebra given by the direct sum of the $\mathscr{S}_d \otimes \mathscr{L}^{\otimes d}$ (for $d \geqslant 0$); then $\mathrm{Proj}(\mathscr{S})$ and $\mathrm{Proj}(\mathscr{S}_{(\mathscr{L})})$ are canonically Y-isomorphic.*

Proof. In each of the three cases, it suffices to define the isomorphism locally on Y, since the verification of compatibility with the restriction operations from one open subset to a smaller one is trivial. We can thus suppose that Y is affine, and then (i) follows from (2.4.7, (i)), and (ii) follows from (2.4.8). As for (iii), if we further suppose that $\mathscr{L}$ is isomorphic to $\mathscr{O}_Y$ (which we are allowed to do, since the question is local on Y), then the isomorphism between $\mathrm{Proj}(\mathscr{S})$ and $\mathrm{Proj}(\mathscr{S}_{(\mathscr{L})})$ is evident; to define a *canonical* isomorphism, let $Y = \mathrm{Spec}(A)$ and $\mathscr{S} = \widetilde{S}$, where S is a graded A-algebra, and let c be a generator of the free A-module L such that $\mathscr{L} = \widetilde{L}$; then, for all $n > 0$, $x_n \mapsto x_n \otimes c^{\otimes n}$ is an A-isomorphism from S_n to $S_n \otimes L^{\otimes n}$, and these A-isomorphisms define an A-isomorphism of graded algebras $\phi_c : S \to S_{(L)} = \bigoplus_{n \geqslant 0} S_n \otimes L^{\otimes n}$. So let $f \in S_+$ be homogeneous of degree d; for all $x \in S_{nd}$, we have that

$$\frac{x \otimes c^{\otimes nd}}{(f \otimes c^{\otimes d})^n} = \frac{x \otimes (\varepsilon c)^{\otimes nd}}{(f \otimes (\varepsilon c)^{\otimes d})^n}$$

for every invertible element $\varepsilon \in A$, which shows that the isomorphism $S_{(f)} \to (S_{(L)})_{(f \otimes c^{\otimes d})}$ induced from ϕ_c is *independent* of the generator c of L considered, and thus finishes the proof. □

(3.1.9). Recall ((**0**, 4.1.3) and (**I**, 1.3.14)) that, for the quasi-coherent graded $\mathscr{O}_Y$-algebra $\mathscr{S}$ to be *generated by the $\mathscr{O}_Y$-module $\mathscr{S}_1$*, it is necessary and sufficient for there to exist an affine open cover (U_α) of Y such that the graded algebra $\Gamma(U_\alpha, \mathscr{S})$ over $\Gamma(U_\alpha, \mathscr{S}_0)$ is generated by the set $\Gamma(U_\alpha, \mathscr{S}_1)$ of its homogeneous elements of degree 1. For every open V of Y, $\mathscr{S}|V$ is then generated by the $(\mathscr{O}_Y|V)$-module $\mathscr{S}_1|V$.

Proposition (3.1.10). — *Suppose that there exists a finite affine open cover (U_i) of Y such that each graded algebra $\Gamma(U_i, \mathscr{S})$ is of finite type over $\Gamma(U_i, \mathscr{O}_Y)$. Then there exists $d > 0$ such that $\mathscr{S}^{(d)}$ is generated by $\mathscr{S}_d$, with $\mathscr{S}_d$ an $\mathscr{O}_Y$-module of finite type.*

Proof. Indeed, it follows from (2.1.6, (v)) that, for each i, there exists an integer m_i such that $\Gamma(U_i, \mathscr{S}_{nm_i}) = (\Gamma(U_i, \mathscr{S}_{m_i}))^n$ for all $n > 0$; it suffices to take d to be a common multiple of all the m_i, taking (2.1.6, (i)) into account. □

Corollary (3.1.11). — *Under the hypotheses of (3.1.10), $\mathrm{Proj}(\mathscr{S})$ is Y-isomorphic to a homogeneous spectrum $\mathrm{Proj}(\mathscr{S}')$, where $\mathscr{S}'$ is a graded $\mathscr{O}_Y$-algebra generated by $\mathscr{S}'_1$, with $\mathscr{S}'_1$ an $\mathscr{O}_Y$-module of finite type.*

Proof. It suffices to take $\mathscr{S}' = \mathscr{S}^{(d)}$, where d satisfies the property of (3.1.10), and to then apply (3.1.8, (i)). □

(3.1.12). If $\mathscr{S}$ is a quasi-coherent positively-graded $\mathscr{O}_Y$-algebra, we know (**I**, 5.1.1) that its *nilradical* $\mathscr{N}$ is a quasi-coherent $\mathscr{O}_Y$-module; we say that $\mathscr{N}_+ = \mathscr{N} \cap \mathscr{S}_+$ is the *nilradical of* $\mathscr{S}_+$; this is a quasi-coherent graded $\mathscr{S}_0$-module, since we can immediately reduce to the case where Y is affine, and the proposition then follows from (2.1.10). For all $y \in Y$, $(\mathscr{N}_+)_y$ is then the nilradical of $(\mathscr{S}_+)_y = (\mathscr{S}_y)_+$ (**I**, 5.1.1). We say that the graded $\mathscr{O}_Y$-algebra $\mathscr{S}$ is *essentially reduced* if $\mathscr{N}_+ = 0$, which is equivalent to saying that $\mathscr{S}_y$ is an essentially reduced graded $\mathscr{O}_y$-algebra for all $y \in Y$. For every graded II | 53
$\mathscr{O}_Y$-algebra $\mathscr{S}$, $\mathscr{S}/\mathscr{N}_+$ is essentially reduced.

We say that $\mathscr{S}$ is *integral* if, for all $y \in Y$, $\mathscr{S}_y$ is an integral ring and, furthermore, $(\mathscr{S}_y)_+ = (\mathscr{S}_+)_y \neq 0$.

Proposition (3.1.13). — *Let $\mathscr{S}$ be a positively-graded $\mathscr{O}_Y$-algebra. If $X = \operatorname{Proj}(\mathscr{S})$, then the Y-scheme X_{red} is canonically isomorphic to $\operatorname{Proj}(\mathscr{S}/\mathscr{N}_+)$; in particular, if $\mathscr{S}$ is essentially reduced, then X is reduced.*

Proof. The fact that $X' = \operatorname{Proj}(\mathscr{S}/\mathscr{N}_+)$ is reduced follows immediately from (2.4.4, (i)), since the property is local; further, for every affine open $U \subset Y$, $\phi'^{-1}(U)$ is equal to $(\phi^{-1}(U))_{\mathrm{red}}$ (where we denote by ϕ and ϕ' the structure morphisms $X \to Y$ and $X' \to Y$, respectively); we immediately see that the canonical U-morphisms $\phi'^{-1}(U) \to \phi^{-1}(U)$ are compatible with the restriction operations, and thus define a closed immersion $X' \to X$ that is a homeomorphism of the underlying spaces; whence the conclusion (**I**, 5.1.2). □

Proposition (3.1.14). — *Let Y be an integral prescheme, and $\mathscr{S}$ a quasi-coherent graded $\mathscr{O}_Y$-algebra such that $\mathscr{S}_0 = \mathscr{O}_Y$.*

(i) *If $\mathscr{S}$ is integral (3.1.12), then $X = \operatorname{Proj}(\mathscr{S})$ is integral, and the structure morphism $\phi : X \to Y$ is dominant.*
(ii) *Suppose furthermore that $\mathscr{S}$ is essentially reduced. Then, conversely, if X is integral and ϕ is dominant, then $\mathscr{S}$ is integral.*

Proof.

(i) If (U_α) is a base of Y consisting of non-empty affine opens, then it suffices to prove the proposition in the case where Y is replaced by one of the U_α, and $\mathscr{S}$ by $\mathscr{S}|U_\alpha$: indeed, on the one hand it will follow that the underlying spaces $\phi^{-1}(U_\alpha)$ are irreducible open subsets (and thus non-empty) of X such that $\phi^{-1}(U_\alpha) \cap \phi^{-1}(U_\beta) \neq \varnothing$ for any pair of indices (since $U_\alpha \cap U_\beta$ contains some U_γ), and so X is irreducible (**0**, 2.1.4); on the other hand, X will be reduced, since this is a local property, and so X will indeed be integral, with $\phi(X)$ dense in Y.

So suppose that $Y = \operatorname{Spec}(A)$, where A is integral (**I**, 5.1.4), and that $\mathscr{S} = \widetilde{S}$, where S is a graded A-algebra; the hypothesis is that, for every $y \in Y$, $\widetilde{S}_y = S_y$ is an integral graded ring such that $(S_y)_+ \neq 0$. It suffices to prove that S is an *integral* ring, since then we will have that $S_+ \neq 0$, and we can then apply (2.4.4, (ii)). But let $f, g \neq 0$ be elements of S, and suppose that $fg = 0$; for all $y \in Y$ we then have that $(f/1)(g/1) = 0$ in S_y, and so $f/1 = 0$ or $g/1 = 0$ by hypothesis. Suppose, for example, that $f/1 = 0$ in S_y; this implies that there exists $a \in A$ such that $a \notin \mathfrak{j}_y$ and $af = 0$; we then have, for *all* $z \in Y$, that $(a/1)(f/1) = 0$ in the *integral* ring S_z, and since $a/1 \neq 0$ (since A is integral), $f/1 = 0$, which implies that $f = 0$.

(ii) Since the question is local on Y, we can again suppose that $Y = \operatorname{Spec}(A)$, with A integral, and that $\mathscr{S} = \widetilde{S}$. By hypothesis, for all $y \in Y$, $(S_y)_+$ does not contain any non-zero nilpotent elements, and the same is true of $(S_0)_y = A_y$ by hypothesis; so S_y is a reduced ring for all $y \in Y$, and we thus conclude first of all that S itself is reduced (**I**, 5.1.1). The hypothesis that X is integral implies that S is essentially integral (2.4.4, (ii)), and everything then reduces to showing that the annihilator $\mathfrak{J}$ of S_+ in $A = S_0$ is just 0 (2.1.11). If this were not the case, we would have that $(S_h)_+ = 0$ for some $h \neq 0$ in $\mathfrak{J}$, and thus (3.1.1) that $\phi^{-1}(D(h)) = \varnothing$, and $\phi(X)$ would not be dense in Y, contradicting the hypothesis (since $D(h) \neq \varnothing$, since h is not nilpotent). **II** | 54

□

3.2. Sheaf on $\operatorname{Proj}(\mathscr{S})$ associated to a graded $\mathscr{S}$-module

(3.2.1). Let Y be a prescheme, $\mathscr{S}$ a quasi-coherent positively graded $\mathscr{O}_Y$-algebra, and $\mathscr{M}$ a quasi-coherent graded $\mathscr{S}$-module (on $(Y, \mathscr{O}_Y)$ or, equivalently (**I**, 9.6.1), on the ringed space $(Y, \mathscr{S})$). With the notation of (3.1.1), we denote by $\widetilde{\mathscr{M}}_U$ the quasi-coherent $\mathscr{O}_{X_U}$-module $(\Gamma(U, \mathscr{M}))^\sim$; for $U' \subset U$, $\Gamma(U', \mathscr{M})$ is canonically identified with $\Gamma(U, \mathscr{M}) \otimes_A A'$ (**I**, 1.6.4); thus we have $\widetilde{\mathscr{M}}_{U'} = \rho^*_{U',U}(\widetilde{\mathscr{M}}_U)$ (2.8.11).

Proposition (3.2.2). — *There exists on* $\operatorname{Proj}(\mathscr{S}) = X$ *a unique quasi-coherent* $\mathscr{O}_X$*-module* $\widetilde{\mathscr{M}}$ *such that, for every affine open* U *of* Y*, we have* $\eta^*_U((\Gamma(U, \mathscr{M}))^\sim) = \widetilde{\mathscr{M}}|f^{-1}(U)$ *(where* η_U *denotes the isomorphism* $f^{-1}(U) \xrightarrow{\sim} \operatorname{Proj}(\Gamma(U, \mathscr{S}))$*), with* f *the structure morphism* $X \to Y$*.*

Proof. Since $\rho_{U',U}$ is identified with the injection morphism $f^{-1}(U') \to f^{-1}(U)$ (3.1.2.1), the proposition follows immediately from the relation $\widetilde{\mathscr{M}}_{U'} = \rho^*_{U',U}(\widetilde{\mathscr{M}}_U)$ and from the gluing principle for sheaves (**0**, 3.3.1). □

We say that $\widetilde{\mathscr{M}}$ is the $\mathscr{O}_X$-module *associated to* the quasi-coherent graded $\mathscr{S}$-module $\mathscr{M}$.

Proposition (3.2.3). — *Let* $\mathscr{M}$ *be a quasi-coherent graded* $\mathscr{S}$*-module, and let* $f \in \Gamma(Y, \mathscr{S}_d)$ *(for* $d > 0$*). If* ξ_f *is the canonical isomorphism from* X_f *to the* Y*-prescheme* $Z_f = \operatorname{Spec}(\mathscr{S}^{(d)}/(f-1)\mathscr{S}^{(d)})$ (3.1.4)*, then* $(\xi_f)_*(\widetilde{\mathscr{M}}|X_f)$ *is the* $\mathscr{O}_{Z_f}$*-module* $(\mathscr{M}^{(d)}/(f-1)\mathscr{M}^{(d)})^\sim$ (1.4.3)*.*

Proof. Since the question is local on Y, we can immediately reduce to (2.2.5), taking into account the commutativity of the diagram in (2.8.12.1). □

Proposition (3.2.4). — *The assignment* $\mathscr{M} \mapsto \widetilde{\mathscr{M}}$ *is an exact additive covariant functor from the category of quasi-coherent graded* $\mathscr{S}$*-modules to the category of quasi-coherent* $\mathscr{O}_X$*-modules, and it commutes with inductive limits and direct sums.*

Proof. Since the question is local on Y, we can reduce to (**I**, 1.3.11), (**I**, 1.3.9), and (2.5.4). □

In particular, if $\mathscr{N}$ is a quasi-coherent graded sub-$\mathscr{S}$-module of $\mathscr{M}$, then $\widetilde{\mathscr{N}}$ is canonically identified with a quasi-coherent sub-$\mathscr{O}_X$-module of $\widetilde{\mathscr{M}}$; in particular, for every quasi-coherent graded sheaf $\mathscr{J}$ of ideals of $\mathscr{S}$, $\widetilde{\mathscr{J}}$ is a quasi-coherent sheaf of ideals of $\mathscr{O}_X$.

If $\mathscr{M}$ is a quasi-coherent graded $\mathscr{S}$-module, and $\mathscr{I}$ a quasi-coherent sheaf of ideals of $\mathscr{O}_Y$, then $\mathscr{I}\mathscr{M}$ is a quasi-coherent graded sub-$\mathscr{S}$-module of $\mathscr{M}$, and we have

$$(\mathscr{I}\mathscr{M})^\sim = \mathscr{I} \cdot \widetilde{\mathscr{M}} \tag{3.2.4.1}$$

(where the right-hand side is defined as in (**0**, 4.3.5)). It suffices to verify this formula in the case where $Y = \operatorname{Spec}(A)$ is affine, $\mathscr{S} = \widetilde{S}$, with S a graded A-algebra, $\mathscr{M} = \widetilde{M}$, with M a graded S-module, and $\mathscr{I} = \mathfrak{I}$, with $\mathfrak{I}$ an ideal of A. For every homogeneous element f of S_+, the restriction **II | 55**
to $D_+(f) = \operatorname{Spec}(S_{(f)})$ of the left-hand side of (3.2.4.1) can be associated with $(\mathfrak{I}M)_{(f)} = \mathfrak{I} \cdot M_{(f)}$, and the same is true of the restriction of the right-hand side, given (**I**, 1.3.13) and (**I**, 1.6.9).

Proposition (3.2.5). — *Let* $f \in \Gamma(Y, \mathscr{S}_d)$ *(for* $d > 0$*). On the open subset* X_f*, the* $(\mathscr{O}_X|X_f)$*-module* $(\mathscr{S}(nd))^\sim|X_f$ *is canonically isomorphic to* $\mathscr{O}_X|X_f$ *for all* $n \in \mathbf{Z}$*. In particular, if the* $\mathscr{O}_Y$*-algebra* $\mathscr{S}$ *is generated by* $\mathscr{S}_1$ (3.1.9)*, then the* $\mathscr{O}_X$*-modules* $(\mathscr{S}(n))^\sim$ *are invertible for all* $n \in \mathbf{Z}$*.*

Proof. Indeed, for every affine open U of Y, we defined in (2.5.7) a canonical isomorphism from $(\mathscr{S}(nd))^\sim|(X_f \cap \phi^{-1}(U))$ to $\mathscr{O}_X|(X_f \cap \phi^{-1}(U))$, taking (3.1.4) into account (where ϕ is the structure morphism $X \to Y$); it is immediate that these isomorphisms are compatible with the restriction from U to an affine open $U' \subset U$, whence the first claim. To prove the second, it suffices to note that, if $\mathscr{S}$ is generated by $\mathscr{S}_1$, then there is a cover (U_α) of Y by affine opens such that $\Gamma(U_\alpha, \mathscr{S})$ is generated by $\Gamma(U_\alpha, \mathscr{S})_1 = \Gamma(U_\alpha, \mathscr{S}_1)$; we can then apply the result of (2.5.9), since the property of being invertible is local. □

We again set, for all $n \in \mathbf{Z}$,

$$\mathscr{O}_X(n) = (\mathscr{S}(n))^\sim \tag{3.2.5.1}$$

and, for all $\mathscr{O}_X$-modules $\mathscr{F}$,

(3.2.5.2) $$\mathscr{F}(n) = \mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{O}_X(n).$$

It follows immediately from these definitions that, for every open subset U of Y, we have

$$((\mathscr{S}|U)(n))^{\sim} = \mathscr{O}_X(n)|f^{-1}(U)$$

where f is the structure morphism $X \to Y$.

Proposition (3.2.6). — *Let $\mathscr{M}$ and $\mathscr{N}$ be quasi-coherent graded $\mathscr{S}$-modules. Then there exists a canonical functorial (in $\mathscr{M}$ and $\mathscr{N}$) homomorphism*

(3.2.6.1) $$\lambda : \widetilde{\mathscr{M}} \otimes_{\mathscr{O}_X} \widetilde{\mathscr{N}} \longrightarrow (\mathscr{M} \otimes_{\mathscr{S}} \mathscr{N})^{\sim}$$

and a canonical functorial (in $\mathscr{M}$ and $\mathscr{N}$) homomorphism

(3.2.6.2) $$\mu : (\mathscr{H}om_{\mathscr{S}}(\mathscr{M}, \mathscr{N}))^{\sim} \longrightarrow \mathscr{H}om_{\mathscr{O}_X}(\widetilde{\mathscr{M}}, \widetilde{\mathscr{N}}).$$

Furthermore, if $\mathscr{S}$ is generated by $\mathscr{S}_1$ (3.1.9), then λ is an isomorphism; if, further, $\mathscr{M}$ admits a finite presentation (3.1.1), then μ is an isomorphism.

Proof. The homomorphisms λ and μ were defined in (2.5.11.2) and (2.5.12.2) in the case where Y is affine; since these definitions are local, they transfer immediately to the general case considered here, taking (2.8.14) into account. □

Corollary (3.2.7). — *If $\mathscr{S}$ is generated by $\mathscr{S}_1$, then, for any $m, n \in \mathbf{Z}$,*

(3.2.7.1) $$\mathscr{O}_X(m) \otimes_{\mathscr{O}_X} \mathscr{O}_X(n) = \mathscr{O}_X(m+n)$$

(3.2.7.2) $$\mathscr{O}_X(n) = (\mathscr{O}_X(1))^{\otimes n}$$

up to canonical isomorphism.

II | 56

Corollary (3.2.8). — *If $\mathscr{S}$ is generated by $\mathscr{S}_1$, then, for any graded $\mathscr{S}$-module $\mathscr{M}$ and any $n \in \mathbf{Z}$,*

(3.2.8.1) $$(\mathscr{M}(n))^{\sim} = \widetilde{\mathscr{M}}(n)$$

up to canonical isomorphism.

Proof. This follows from the corresponding properties in the case where Y is affine ((2.5.14) and (2.5.15)), along with (2.8.11). □

Remarks (3.2.9). —

(1) If $\mathscr{S} = \mathscr{A}[T]$, with $\mathscr{A}$ a quasi-coherent $\mathscr{O}_Y$-algebra (3.1.7), then we immediately see that all the invertible $\mathscr{O}_X$-modules $\mathscr{O}_X(n)$ are canonically isomorphic to $\mathscr{O}_X$.

Furthermore, let $\mathscr{N}$ be a quasi-coherent $\mathscr{A}$-module, and set $\mathscr{M} = \mathscr{N} \otimes_{\mathscr{A}} \mathscr{A}[T]$. It then follows from (3.2.3) and (3.1.7) that, under the canonical identification of $X = \operatorname{Proj}(\mathscr{A}[T])$ with $X' = \operatorname{Spec}(\mathscr{A})$, the $\mathscr{O}_X$-module $\widetilde{\mathscr{M}}$ is identified with the $\mathscr{O}_{X'}$-module $\widetilde{\mathscr{N}}$ associated to $\mathscr{N}$ (in the sense of (1.4.3)).

(2) Let $\mathscr{S}$ be an arbitrary graded $\mathscr{O}_Y$-algebra, and $\mathscr{S}'$ the graded $\mathscr{O}_Y$-algebra such that $\mathscr{S}'_0 = \mathscr{O}_Y$ and $\mathscr{S}'_n = \mathscr{S}_n$ for all $n > 0$; then the canonical isomorphism from $X = \operatorname{Proj}(\mathscr{S})$ to $X' = \operatorname{Proj}(\mathscr{S}')$ (3.1.8, (ii)) identifies $\mathscr{O}_X(n)$ with $\mathscr{O}_{X'}(n)$ for all $n \in \mathbf{Z}$. This follows from the same proposition for the affine case (2.5.16) and from the fact that the identifications, for the affine opens of Y, commute with the restriction operations. Similarly, let $X^{(d)} = \operatorname{Proj}(\mathscr{S}^{(d)})$; then the canonical isomorphism from X to $X^{(d)}$ (3.1.8, (i)) identifies $\mathscr{O}_X(nd)$ with $\mathscr{O}_{X^{(d)}}(n)$ for all $n \in \mathbf{Z}$.

Proposition (3.2.10). — *Let $\mathscr{L}$ be an invertible $\mathscr{O}_Y$-module, and g the canonical isomorphism from $X_{(\mathscr{L})} = \operatorname{Proj}(\mathscr{S}_{(\mathscr{L})})$ to $X = \operatorname{Proj}(\mathscr{S})$ (3.1.8, (iii)). Then, for any $n \in \mathbf{Z}$, $g_*(\mathscr{O}_{X_{(\mathscr{L})}}(n))$ is canonically isomorphic to $\mathscr{O}_X(n) \otimes_Y \mathscr{L}^{\otimes n}$.*

Proof. Suppose first of all that Y is affine, with ring A, and that $\mathscr{L} = \widetilde{L}$, where L is a free A-module of rank one. With the notation from the proof of (3.1.8, (iii)), we define, for $f \in S_d$, an isomorphism from $(S(n))_{(f)} \otimes_A L^{\otimes n}$ to $(S_{(L)}(n))_{(f \otimes c^{\otimes d})}$ by sending $(x/f^k) \otimes c^{\otimes n}$, where $x \in S_{kd+n}$, to the element $(x \otimes c^{\otimes(n+kd)})/(f \otimes c^{\otimes d})^k$; it is immediate that this isomorphism is independent of the chosen generator c of L; further, the isomorphisms thus defined for each $f \in S_+$ are compatible with the restriction operators $D_+(f) \to D_+(fg)$. Finally, in the general case, we easily see, from the definitions (3.1.1), that the isomorphisms thus defined for each affine open U of Y are compatible with passing from U to an affine open $U' \subset U$. □

3.3. Graded $\mathscr{S}$-module associated to a sheaf on $\operatorname{Proj}(\mathscr{S})$ *Throughout this entire section we suppose that the graded $\mathscr{O}_Y$-algebra $\mathscr{S}$ is generated by $\mathscr{S}_1$ (3.1.9).* Recall that, by (3.1.8, (i)), this restrictive assumption is not essential, thanks to finiteness conditions (3.1.10).

(3.3.1). Let p be the structure morphism $X = \operatorname{Proj}(\mathscr{S}) \to Y$. For every $\mathscr{O}_X$-module $\mathscr{F}$, set

(3.3.1.1)
$$\boldsymbol{\Gamma}_*(\mathscr{F}) = \bigoplus_{n \in \mathbf{Z}} p_*(\mathscr{F}(n))$$

and, in particular, **II** | 57

(3.3.1.2)
$$\boldsymbol{\Gamma}_*(\mathscr{O}_X) = \bigoplus_{n \in \mathbf{Z}} p_*(\mathscr{O}_X(n)).$$

We know (**0**, 4.2.2) that there exists a canonical homomorphism

$$p_*(\mathscr{F}) \otimes_{\mathscr{O}_Y} p_*(\mathscr{G}) \longrightarrow p_*(\mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{G})$$

for $\mathscr{O}_X$-modules $\mathscr{F}$ and $\mathscr{G}$; we thus deduce from (3.2.7.1) that $\boldsymbol{\Gamma}_*(\mathscr{O}_X)$ is endowed with the structure of a *graded $\mathscr{O}_Y$-algebra*, and (3.2.5.2) defines the structure of a *graded $\boldsymbol{\Gamma}_*(\mathscr{O}_X)$-module* on $\boldsymbol{\Gamma}_*(\mathscr{F})$.

By (3.2.5), and by left exactness of the functor p_* (**0**, 4.2.1), the assignment $\mathscr{F} \mapsto \boldsymbol{\Gamma}_*(\mathscr{F})$ is an additive *left-exact* covariant functor from the category of $\mathscr{O}_X$-modules to the category of graded $\mathscr{O}_Y$-modules (where the morphisms are the homomorphisms of degree 0). In particular, if $\mathscr{J}$ is a sheaf of ideals of $\mathscr{O}_X$, then $\boldsymbol{\Gamma}_*(\mathscr{J})$ can be identified with a *graded sheaf of ideals* in $\boldsymbol{\Gamma}_*(\mathscr{O}_X)$.

(3.3.2). Let $\mathscr{M}$ be a quasi-coherent graded $\mathscr{S}$-module. For every affine open U of Y, we defined in (2.6.2) a homomorphism of abelian groups

$$\alpha_{0,U} : \Gamma(U, \mathscr{M}_0) \longrightarrow \Gamma(p^{-1}(U), \widetilde{\mathscr{M}}).$$

It is immediate that these homomorphisms commute with the restriction operations (2.8.13.1) and thus define (without using the hypothesis that $\mathscr{S}$ is generated by $\mathscr{S}_1$) a homomorphism of sheaves of abelian groups

(3.3.2.1)
$$\alpha_0 : \mathscr{M}_0 \longrightarrow p_*(\widetilde{\mathscr{M}}).$$

Applying this result to each of the $\mathscr{M}_n = (\mathscr{M}(n))_0$, and taking (3.2.8.1) into account, we can define a homomorphism of sheaves of abelian groups

(3.3.2.2)
$$\alpha_n : \mathscr{M}_n \longrightarrow p_*(\widetilde{\mathscr{M}}(n))$$

for all $n \in \mathbf{Z}$, whence a functorial homomorphism (of degree 0) of graded sheaves of abelian groups

(3.3.2.3)
$$\alpha : \mathscr{M} \longrightarrow \boldsymbol{\Gamma}_*(\widetilde{\mathscr{M}})$$

(also denoted $\alpha_{\mathscr{M}}$).

By taking $\mathscr{M} = \mathscr{S}$ in particular, we see that $\alpha : \mathscr{S} \to \boldsymbol{\Gamma}_*(\mathscr{O}_X)$ is a homomorphism of graded $\mathscr{O}_Y$-algebras, and that (3.3.2.3) is a semilinear homomorphism of graded modules with respect to this homomorphism of graded algebras.

We again note that to each of the α_n there corresponds (**0**, 4.4.3) a canonical homomorphism of $\mathscr{O}_X$-modules

(3.3.2.4)
$$\alpha_n^\sharp : p^*(\mathscr{M}_n) \longrightarrow \widetilde{\mathscr{M}}(n).$$

We can easily verify that this homomorphism is exactly the one which corresponds functorially (3.2.4) to the canonical homomorphism (of degree 0) of *graded* $\mathscr{O}_Y$-modules

(3.3.2.5)
$$\mathscr{M}_n \otimes_{\mathscr{O}_Y} \mathscr{S} \longrightarrow \mathscr{M}(n)$$

where the grading of the right-hand side comes naturally from that of $\mathscr{S}$. We can restrict to the case where $Y = \operatorname{Spec}(A)$ is affine, $\mathscr{M} = \widetilde{M}$, and $\mathscr{S} = \widetilde{S}$, with the graded A-algebra S being generated by S_1, so that, as f runs over S_1, the $D_+(f)$ form a cover of X. By the definitions (2.6.2), we then see, taking (**I**, 1.6.7) into account, that the restriction to $D_+(f)$ of the homomorphism (3.3.2.4) corresponds (**I**, 1.3.8) to the homomorphism of $S_{(f)}$-modules $M_n \otimes_A S_{(f)} \to (M(n))_{(f)}$ that sends $x \otimes 1$ (where $x \in M_n$) to $x/1$; this proves the claim. **II** | 58

Proposition (3.3.3). — *For every section $f \in \Gamma(Y, \mathscr{S}_d)$ (where $d > 0$), X_f is precisely the set of points of X where $\alpha_d(f)$ (considered as a section of $\mathscr{O}_X(d)$) does not vanish* (**0**, 5.5.2).

Proof. (Note that $\alpha_d(f)$ is a section of $p_*(\mathscr{O}_X(d))$ over Y, but by definition such a section is also a section of $\mathscr{O}_X(d)$ over X (**0**, 4.2.1).) The definition of X_f (3.1.4) lets us reduce to the case where Y is affine, which has already been dealt with in (2.6.3). □

(3.3.4). From now on, we suppose, in addition to the hypothesis at the start of this section, that, for every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$, the $p_*(\mathscr{F}(n))$ are *quasi-coherent* on Y, so that $\mathbf{\Gamma}_*(\mathscr{F}) = \bigoplus_{n\in\mathbf{Z}} p_*(\mathscr{F}(n))$ is also a quasi-coherent $\mathscr{O}_Y$-module ((**I**, 1.4.1) and (**I**, 1.3.9)); this will always be the case if X is *of finite type* over Y (**I**, 9.2.2). We thus conclude that $(\mathbf{\Gamma}_*(\mathscr{F}))^\sim$ is defined, and is a quasi-coherent $\mathscr{O}_X$-module. For every affine open U of Y, we have ((**I**, 1.3.9) and (**I**, 2.5.4))

$$\begin{aligned}\Big(\Gamma(U, \bigoplus_{n\in\mathbf{Z}} p_*(\mathscr{F}(n)))\Big)^\sim &= \bigoplus_{n\in\mathbf{Z}} \Big(\Gamma(U, p_*(\mathscr{F}(n)))\Big)^\sim \\ &= \bigoplus_{n\in\mathbf{Z}} \Big(\Gamma(p^{-1}(U), \mathscr{F}(n))\Big)^\sim \\ &= \Big(\bigoplus_{n\in\mathbf{Z}} \Gamma(p^{-1}(U), \mathscr{F}(n))\Big)^\sim \\ &= (\mathbf{\Gamma}_*(\mathscr{F}|p^{-1}(U)))^\sim\end{aligned}$$

and hence, by (2.6.4), we have a canonical homomorphism

$$\beta_U : \Big(\Gamma(U, \bigoplus_{n\in\mathbf{Z}} p_*(\mathscr{F}(n)))\Big)^\sim \longrightarrow \mathscr{F}|p^{-1}(U).$$

Furthermore, the commutativity of (2.8.13.2) shows that these homomorphisms commute with the restriction operations on Y; we thus obtain a canonical functorial homomorphism

$$\beta : (\mathbf{\Gamma}_*(\mathscr{F}))^\sim \longrightarrow \mathscr{F} \tag{3.3.4.1}$$

(also denoted $\beta_{\mathscr{F}}$) for quasi-coherent $\mathscr{O}_X$-modules.

Proposition (3.3.5). — *Let $\mathscr{M}$ be a quasi-coherent graded $\mathscr{S}$-module, and $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-module; then the composite homomorphisms*

$$\widetilde{\mathscr{M}} \xrightarrow{\widetilde{\alpha}} (\mathbf{\Gamma}_*(\widetilde{\mathscr{M}}))^\sim \xrightarrow{\beta} \widetilde{\mathscr{M}} \tag{3.3.5.1}$$

$$\mathbf{\Gamma}_*(\mathscr{F}) \xrightarrow{\alpha} \mathbf{\Gamma}_*((\mathbf{\Gamma}_*(\mathscr{F}))^\sim) \xrightarrow{\mathbf{\Gamma}_*(\beta)} \mathbf{\Gamma}_*(\mathscr{F}) \tag{3.3.5.2}$$

are the identity isomorphisms.

Proof. The question is local on Y, so we can reduce to (2.6.5). □

3.4. Finiteness conditions

II | 59

Proposition (3.4.1). — *Let Y be a prescheme, and $\mathscr{S}$ a quasi-coherent $\mathscr{O}_Y$-algebra generated by $\mathscr{S}_1$ (3.1.9); suppose further that $\mathscr{S}_1$ is of finite type. Then $X = \operatorname{Proj}(\mathscr{S})$ is of finite type over Y.*

Proof. Since the question is local on Y, we can suppose that Y is affine of ring A; then $\mathscr{S} = \widetilde{S}$, where $S = \Gamma(Y, \mathscr{S})$, and by hypothesis S is an A-algebra generated by $S_1 = \Gamma(Y, \mathscr{S}_1)$, where we can further suppose that S_1 is an A-module of finite type ((**I**, 1.3.9) and (**I**, 1.3.12)). Then S is a graded A-algebra of finite type, and we can reduce to (2.7.1, (ii)). □

(3.4.2). Let $\mathscr{S}$ be a quasi-coherent graded $\mathscr{O}_Y$-algebra; for a quasi-coherent graded $\mathscr{S}$-module $\mathscr{M}$, consider the following finiteness conditions:

(**TF**) There exists an integer n such that the $\mathscr{S}$-module $\bigoplus_{k \geqslant n} \mathscr{M}_k$ is of finite type.

(**TN**) There exists an integer n such that $\mathscr{M}_k = 0$ for $k \geqslant n$.

If $\mathscr{M}$ satisfies (**TN**), then $\widetilde{\mathscr{M}} = 0$, since this is a local property on Y (2.7.2).

Let $\mathscr{M}$ and $\mathscr{N}$ be quasi-coherent graded $\mathscr{S}$-modules; we say that a homomorphism $u : \mathscr{M} \to \mathscr{N}$ of degree 0 is *(**TN**)-injective* (resp. *(**TN**)-surjective*, *(**TN**)-bijective*) if there exists an integer n such that $u_k : \mathscr{M}_k \to \mathscr{N}_k$ is injective (resp. surjective, bijective) for $k \geqslant n$; then $\widetilde{u} : \widetilde{\mathscr{M}} \to \widetilde{\mathscr{N}}$ is injective (resp. surjective, bijective) by (2.7.2), since this is a local property on Y, and taking (**I**, 1.3.9) into account; if u is (**TN**)-bijective, then we also say that u is a *(**TN**)-isomorphism*.

Proposition (3.4.3). — *Let Y be a prescheme, and $\mathscr{S}$ a quasi-coherent graded $\mathscr{O}_Y$-algebra generated by $\mathscr{S}_1$, with $\mathscr{S}_1$ assumed to be of finite type. Let $\mathscr{M}$ be a quasi-coherent graded $\mathscr{S}$-module.*

*(i) If $\mathscr{M}$ satisfies (**TF**), then $\widetilde{\mathscr{M}}$ is of finite type.*

*(ii) If $\mathscr{M}$ satisfies (**TF**), then $\widetilde{\mathscr{M}} = 0$ if and only if $\mathscr{M}$ satisfies (**TN**).*

Proof. Since the questions are local on Y, we can reduce to the case where Y is affine of ring A, $\mathscr{S} = \widetilde{S}$, where S is a graded A-algebra such that the ideal S_+ is of finite type, and $\mathscr{M} = \widetilde{M}$, where M is a graded S-module; the proposition then follows from (2.7.3). □

Theorem (3.4.4). — *Let Y be a prescheme, and $\mathscr{S}$ a quasi-coherent graded $\mathscr{O}_Y$-algebra generated by $\mathscr{S}_1$, where $\mathscr{S}_1$ is assumed to be of finite type; let $X = \operatorname{Proj}(\mathscr{S})$. For every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$, the canonical homomorphism β (3.3.4) is an isomorphism.*

Proof. Note first of all that β is defined, by (3.4.1). To see that β is an isomorphism, we can reduce to the case where Y is affine of ring A, $\mathscr{S} = \widetilde{S}$, where S is a graded A-algebra generated by S_1, and S_1 is an A-module of finite type. It then suffices to apply (2.7.5). □

Corollary (3.4.5). — *Under the hypotheses of (3.4.4), every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$ is isomorphic to an $\mathscr{O}_X$-module of the form $\widetilde{\mathscr{M}}$, where $\mathscr{M}$ is a quasi-coherent graded $\mathscr{S}$-module. If, further, $\mathscr{F}$ is of finite type, and if we assume that Y is a quasi-compact scheme, or that the underlying space of Y is Noetherian, then we can take $\mathscr{M}$ to be of finite type.*

II | 60

Proof. The first claim follows immediately from (3.4.4) by taking $\mathscr{M} = \mathbf{\Gamma}_*(\mathscr{F})$. To prove the second, it suffices to show that $\mathscr{M}$ is the inductive limit of its *graded* sub-$\mathscr{S}$-modules of finite type $\mathscr{N}_\lambda$: indeed, it will follow from this that $\widetilde{\mathscr{M}}$ is the inductive limit of the $\widetilde{\mathscr{N}_\lambda}$ (3.2.4), and so $\mathscr{F}$ is the inductive limit of the $\beta(\widetilde{\mathscr{N}_\lambda})$; since X is quasi-compact ((3.4.1) and (**I**, 6.3.1)) and $\mathscr{F}$ is of finite type, $\mathscr{F}$ will necessarily be equal to one of the $\beta(\widetilde{\mathscr{N}_\lambda})$ (**0**, 5.2.3).

To define the $\mathscr{N}_\lambda$ having $\mathscr{M}$ as their inductive limit, it suffices to consider, for each $n \in \mathbf{Z}$, the quasi-coherent $\mathscr{O}_Y$-module $\mathscr{M}_n$, which is the inductive limit of its sub-$\mathscr{O}_Y$-modules $\mathscr{M}_n^{(\mu_n)}$ of finite type, by the hypotheses on Y (**I**, 9.4.9); it is immediate that $\mathscr{P}_{\mu_n} = \mathscr{S} \cdot \mathscr{M}_n^{(\mu_n)}$ is a graded $\mathscr{S}$-module of finite type, and we immediately see that taking $\mathscr{N}_\lambda$ to be the finite sums of the $\mathscr{S}$-modules of the form $\mathscr{P}_{\mu_n}$ gives the desired objects. □

Corollary (3.4.6). — *Suppose that the hypotheses of (3.4.4) are satisfied, and further that the underlying space of Y is quasi-compact; let $\mathscr{F}$ be a quasi-coherent $\mathscr{O}_X$-module of finite type. Then there exists n_0 such that, for all $n \geqslant n_0$, the canonical homomorphism $\sigma : p^*(p_*(\mathscr{F}(n))) \to \mathscr{F}(n)$ (**0**, 4.4.3) is surjective.*

Proof. For all $y \in Y$, let U be an affine open neighbourhood of y in Y. There exists an integer $n_0(U)$ such that, for all $n \geqslant n_0(U)$, $\mathscr{F}(n)|p^{-1}(U)$ is generated by a finite number of its sections over $p^{-1}(U)$ (2.7.9); but these sections are the canonical images of sections of $p^*(p_*(\mathscr{F}(n)))$ over $p^{-1}(U)$ ((**0**, 3.7.1) and (**0**, 4.4.3)), so $\mathscr{F}(n)|p^{-1}(U)$ is equal to the canonical image of $p^*(p_*(\mathscr{F}(n)))|p^{-1}(U)$. Finally, since Y is quasi-compact, there exists a finite cover of Y by affine opens U_i, and taking n_0 to be the largest of the $n_0(U_i)$ finishes the proof. □

Remarks (3.4.7). — If $p = (\psi, \theta) : X \to Y$ is a morphism of ringed spaces, and $\mathscr{F}$ an $\mathscr{O}_X$-module, the fact that the canonical homomorphism $\sigma : p^*(p_*(\mathscr{F})) \to \mathscr{F}$ is surjective can be explained in the following way (**0**, 4.4.1): for all $x \in X$, and every section s of $\mathscr{F}$ over an open neighbourhood V of x, there exists an open neighbourhood U of $p(x)$ in Y, a finite number of sections t_i (for $1 \leqslant i \leqslant m$) of $\mathscr{F}$ over $p^{-1}(U)$, a neighbourhood $W \subset V \cap p^{-1}(U)$ of x, and sections a_i (for $1 \leqslant i \leqslant m$) of $\mathscr{O}_X$ over W such that

$$s|W = \sum_{i=1}^{m} a_i \cdot (t_i|W).$$

If Y is an *affine scheme* and $p_*(\mathscr{F})$ is *quasi-coherent*, this condition is equivalent to $\mathscr{F}$ being *generated by its sections over* X (**0**, 5.5.1): indeed, if $Y = \operatorname{Spec}(A)$, we can suppose that $U = D(f)$ with $f \in A$; then there exists an integer $n > 0$ and sections s_i of $\mathscr{F}$ over X such that t_i is the restriction to $p^{-1}(U)$ of $s_i g^n$, where $g = \theta(f)$ (by applying (**I**, 1.4.1) to $p_*(\mathscr{F})$); since g is invertible over $p^{-1}(U)$, we thus have

$$s|W = \sum_i b_i \cdot (s_i|W)$$

where $b_i = a_i(g|W)^{-n}$, whence the claim. If Y is affine, then the corollary (3.4.6) recovers (2.7.9).

We thus conclude that, when Y is an arbitrary prescheme, the following three conditions, for a quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$ such that $p_*(\mathscr{F})$ is *quasi-coherent*, are equivalent: **II** | 61

a) *The canonical homomorphism* $\sigma : p^*(p_*(\mathscr{F})) \to \mathscr{F}$ *is surjective.*
b) *There exists a quasi-coherent* $\mathscr{O}_Y$*-module* $\mathscr{G}$ *and a surjective homomorphism* $p^*(\mathscr{G}) \to \mathscr{F}$.
c) *For every affine open* U *of* Y, $\mathscr{F}|p^{-1}(U)$ *is generated by its sections over* $p^{-1}(U)$.

Indeed, we have just proven the equivalence between *a)* and *c)*. It is also clear that *a)* implies *b)*, since $p_*(\mathscr{F})$ is quasi-coherent by hypothesis. Conversely, every homomorphism $u : p^*(\mathscr{G}) \to \mathscr{F}$ factors as $p^*(\mathscr{G}) \to p^*(p_*(\mathscr{F})) \xrightarrow{\sigma} \mathscr{F}$ (**0**, 3.5.4.4), so if u is surjective then so too is σ, which proves that *b)* implies *a)*.

Corollary (3.4.8). — *Suppose that the hypotheses of* (3.4.4) *are satisfied, and suppose further that* Y *is a quasi-compact scheme, or that the underlying space of* Y *is Noetherian. Let* $\mathscr{F}$ *be a quasi-coherent* $\mathscr{O}_X$*-module of finite type; then there exists an integer* n_0 *such that, for all* $n \geqslant n_0$, $\mathscr{F}$ *is isomorphic to a quotient of an* $\mathscr{O}_X$*-module of the form* $(p^*(\mathscr{G}))(-n)$, *where* $\mathscr{G}$ *is a quasi-coherent* $\mathscr{O}_Y$*-module of finite type (that depends on* n*).*

Proof. Since the structure morphism $X \to Y$ is separated and of finite type, $p_*(\mathscr{F}(n))$ is quasi-coherent (**I**, 9.2.2, b)), and thus the inductive limit of its quasi-coherent sub-$\mathscr{O}_Y$-modules of finite type, by the hypotheses on Y (**I**, 9.4.9). We thus deduce, by (3.4.6), (**0**, 4.3.2), and (**0**, 5.2.3), that $\mathscr{F}(n)$ is the canonical image of an $\mathscr{O}_X$-module of the form $p^*(\mathscr{G})$, where $\mathscr{G}$ is a quasi-coherent sub-$\mathscr{O}_Y$-module of $p_*(\mathscr{F}(n))$ of finite type; the corollary then follows from (3.2.5.2) and (3.2.7.1). □

3.5. Functorial behaviour

(3.5.1). Let Y be a prescheme, and $\mathscr{S}$ and $\mathscr{S}'$ quasi-coherent positively graded $\mathscr{O}_Y$-algebras; let $X = \operatorname{Proj}(\mathscr{S})$ and $X' = \operatorname{Proj}(\mathscr{S}')$, and let p and p' be the structure morphisms from X and X' to Y. Let $\phi : \mathscr{S}' \to \mathscr{S}$ be an $\mathscr{O}_Y$-homomorphism of graded algebras. For every affine open U of Y, let $S_U = \Gamma(U, \mathscr{S})$ and $S'_U = \Gamma(U, \mathscr{S}')$; the homomorphism ϕ defines a homomorphism $\phi_U : S'_U \to S_U$ of graded A_U-algebras, where $A_U = \Gamma(U, \mathscr{O}_Y)$. Corresponding to it are an open subset $G(\phi_U)$ of $p^{-1}(U)$ and a morphism $\Phi_U : G(\phi_U) \to p'^{-1}(U)$ (2.8.1). Furthermore, if $V \subset U$ is an affine open, then the diagram

(3.5.1.1)
$$\begin{tikzcd} S'_U \arrow[r, "\phi_U"] \arrow[d] & S_U \arrow[d] \\ S'_V \arrow[r, "\phi_V"'] & S_V \end{tikzcd}$$

commutes, and we immediately see, by definition (2.8.1), that we have

$$G(\phi_V) = G(\phi_U) \cap p^{-1}(V)$$

and that Φ_V is the restriction to $G(\phi_V)$ of Φ_U. We have thus defined an open subset $G(\phi)$ of X such that $G(\phi) \cap p^{-1}(U) = G(\phi_U)$ for every affine open $U \subset Y$, and an *affine* Y-morphism $\Phi : G(\phi) \to X'$, which we say is *associated* to ϕ, and which we denote by $\operatorname{Proj}(\phi)$. If, for all $y \in Y$, there is an affine neighbourhood U of y such that the $\Gamma(U, \mathscr{O}_Y)$-module $\Gamma(U, \mathscr{S}_+)$ is generated by $\phi(\Gamma(U, \mathscr{S}'_+))$, then $G(\phi_U) = p^{-1}(U)$, and so $G(\phi) = X$. **II** | 62

Proposition (3.5.2). —

(i) If $\mathscr{M}$ is a quasi-coherent graded $\mathscr{S}$-module, then there exists a canonical functorial isomorphism from the $\mathscr{O}_{X'}$-module $(\mathscr{M}_{[\phi]})^\sim$ to the $\mathscr{O}_{X'}$-module $\Phi_*(\widetilde{\mathscr{M}}|G(\phi))$.

(ii) If $\mathscr{M}'$ is a quasi-coherent graded $\mathscr{S}'$-module, then there exists a canonical functorial homomorphism ν from the $(\mathscr{O}_X|G(\phi))$-module $\Phi^*(\widetilde{\mathscr{M}'})$ to the $(\mathscr{O}_X|G(\phi))$-module $(\mathscr{M}' \otimes_{\mathscr{S}'} \mathscr{S})^\sim|G(\phi)$. If $\mathscr{S}'$ is generated by $\mathscr{S}'_1$, then ν is an isomorphism.

Proof. The homomorphisms in question are indeed already defined if Y is affine ((2.8.7) and (2.8.8)), and in the general case it suffices to check that they are compatible with the restriction of an affine open of Y to a smaller open, which follows immediately from the commutativity of (3.5.1.1). □

In particular, for all $n \in \mathbf{Z}$, we have a canonical homomorphism

(3.5.2.1)
$$\Phi^*(\mathscr{O}_{X'}(n)) \longrightarrow \mathscr{O}_X(n)|G(\phi).$$

Proposition (3.5.3). — *Let Y and Y' be preschemes, $\psi : Y' \to Y$ a morphism, and $\mathscr{S}$ a quasi-coherent graded $\mathscr{O}_Y$-algebra; set $\mathscr{S}' = \psi^*(\mathscr{S})$. Then the Y'-scheme $X' = \operatorname{Proj}(\mathscr{S}')$ is canonically identified with $\operatorname{Proj}(\mathscr{S}) \times_Y Y'$. Furthermore, if $\mathscr{M}$ is a quasi-coherent graded $\mathscr{S}$-module, then the $\mathscr{O}_{X'}$-module $(\psi^*(\mathscr{M}))^\sim$ can be identified with $\widetilde{\mathscr{M}} \otimes_Y \mathscr{O}_{Y'}$.*

Proof. Note first of all that $\psi^*(\mathscr{S})$ and $\psi^*(\mathscr{M})$ are quasi-coherent $\mathscr{O}_{Y'}$-modules, as are their homogeneous components (**0**, 5.1.4). Let U be an affine open of Y, $U' \subset \psi^{-1}(U)$ an affine open of Y', and A and A' the rings of U and U', respectively; then $\mathscr{S}|U = \widetilde{S}$, where S is a graded A-algebra, and $\mathscr{S}'|U'$ can be identified with $(S \otimes_A A')^\sim$ (**I**, 1.6.5); the first claim then follows from (2.8.10) and (**I**, 3.2.6.2), since we immediately see that the projection $\operatorname{Proj}(\mathscr{S}'|U') \to \operatorname{Proj}(\mathscr{S}|U)$ defined by the above identification is compatible with the restriction operations on U and U', and thus indeed defines a morphism $\operatorname{Proj}(\mathscr{S}') \to \operatorname{Proj}(\mathscr{S})$. Now let

$$q : \operatorname{Proj}(\mathscr{S}) \longrightarrow Y$$
$$q' : \operatorname{Proj}(\mathscr{S}') \longrightarrow Y'$$

be the structure morphisms; $q'^{-1}(U')$ can then be identified with $q^{-1}(U) \times_U U'$, and the two sheaves $(\psi^*(\mathscr{M}))^\sim|q'^{-1}(U')$ and $(\widetilde{\mathscr{M}} \otimes_Y \mathscr{O}_{Y'})|q'^{-1}(U')$ are then both canonically identified with $(M \otimes_A A')^\sim$, where we set $M = \Gamma(U, \mathscr{M})$, by (2.8.10) and (**I**, 1.6.5); whence the second claim, since we can again immediately see the compatibility of the above identifications with the restriction operations. □

Corollary (3.5.4). — *With the notation of (3.5.3), $\mathscr{O}_{X'}(n)$ is canonically identified with $\mathscr{O}_X(n) \otimes_Y \mathscr{O}_{Y'}$ for all $n \in \mathbf{Z}$ (where $X = \operatorname{Proj}(\mathscr{S})$).*

Proof. Indeed, with the notation of (3.5.3), it is clear that $\psi^*(\mathscr{S}(n)) = \mathscr{S}'(n)$ for all $n \in \mathbf{Z}$. ☐

(3.5.5). Keeping the above notation, denote by Ψ the canonical projection $X' \to X$, and set $\mathscr{M}' = \psi^*(\mathscr{M})$; we further suppose that $\mathscr{S}$ is generated by $\mathscr{S}_1$, and that X is of finite type over Y; it then **II** | 63
follows that $\mathscr{S}'$ is generated by $\mathscr{S}'_1$ (as can be seen by reducing to the case where Y and Y' are affine), and that X' is of finite type over Y' (**I**, 6.3.4). Let $\mathscr{F}$ be an $\mathscr{O}_X$-module, and set $\mathscr{F}' = \Psi^*(\mathscr{F})$; it then follows from (3.5.4) and (**0**, 4.3.3) that $\mathscr{F}'(n) = \Psi^*(\mathscr{F}(n))$ for all $n \in \mathbf{Z}$. We further define a canonical ψ-homomorphism $\theta_n : q_*(\mathscr{F}(n)) \to q'_*(\mathscr{F}'(n))$ in the following way: given the commutativity of the diagram

$$\begin{tikzcd} X \arrow[d, "q"'] & X' \arrow[l, "\Psi"'] \arrow[d, "q'"] \\ Y & Y' \arrow[l, "\psi"] \end{tikzcd}$$

it is enough to define a homomorphism $q_*(\mathscr{F}(n)) \to \psi_*(q'_*(\Psi^*(\mathscr{F}(n)))) = q_*(\Psi_*(\Psi^*(\mathscr{F}(n))))$, and it suffices to take the homomorphism $\theta_n = q_*(\rho_n)$, where ρ_n is the canonical homomorphism $\mathscr{F}(n) \to \Psi_*(\Psi^*(\mathscr{F}(n)))$ (**0**, 4.4.3). It is immediate that, for every affine open U of Y and every affine open U' of Y' such that $U' \subset \psi^{-1}(U)$, the homomorphism θ_n gives, on sections, the canonical homomorphism (**0**, 3.7.2) $\Gamma(q^{-1}(U), \mathscr{F}(n)) \to \Gamma(q'^{-1}(U'), \mathscr{F}'(n))$. The commutativity of (2.8.13.2) then shows that, if $\mathscr{F}$ is quasi-coherent, the diagram

$$\begin{tikzcd} \mathscr{F} \arrow[r, "\rho"] & \mathscr{F}' \\ (\mathbf{\Gamma}_*(\mathscr{F}))^\sim \arrow[u, "\beta_{\mathscr{F}}"] \arrow[r, "\widetilde{\theta}"'] & (\mathbf{\Gamma}_*(\mathscr{F}'))^\sim \arrow[u, "\beta_{\mathscr{F}'}"'] \end{tikzcd}$$

commutes (the top horizontal arrow being the canonical Ψ-morphism $\mathscr{F} \to \Psi^*(\mathscr{F})$).

Similarly, the commutativity of (2.8.13.1) shows that the diagram

$$\begin{tikzcd} \mathbf{\Gamma}_*(\widetilde{\mathscr{M}}) \arrow[r, "\theta"] & \mathbf{\Gamma}_*(\widetilde{\mathscr{M}'}) \\ \mathscr{M} \arrow[u, "\alpha_{\mathscr{M}}"] \arrow[r, "\rho"'] & \mathscr{M}' \arrow[u, "\alpha_{\mathscr{M}'}"'] \end{tikzcd}$$

commutes (the bottom horizontal arrow being the canonical ψ-morphism $\mathscr{M} \to \psi^*(\mathscr{M})$).

(3.5.6). Now consider preschemes Y and Y', a morphism $g : Y' \to Y$, a quasi-coherent graded $\mathscr{O}_Y$-algebra $\mathscr{S}$, a quasi-coherent graded $\mathscr{O}_{Y'}$-algebra $\mathscr{S}'$, and a g-morphism of graded algebras $u : \mathscr{S} \to \mathscr{S}'$, i.e. a $\mathscr{O}_Y$-homomorphism of graded algebras $\mathscr{S} \to g_*(\mathscr{S}')$; we already know that this is equivalent to giving a $\mathscr{O}_{Y'}$-homomorphism of graded algebras $u^\sharp : g^*(\mathscr{S}) \to \mathscr{S}'$. We thus canonically obtain from $u^\sharp$ a Y'-morphism $W = \operatorname{Proj}(u^\sharp) : G(u^\sharp) \to \operatorname{Proj}(g^*(\mathscr{S}))$, where $G(u^\sharp)$ is an open subset of $X' = \operatorname{Proj}(\mathscr{S}')$ (3.5.1). We also know that $X'' = \operatorname{Proj}(g^*(\mathscr{S}))$ is canonically identified with $X \times_Y Y'$, where $X = \operatorname{Proj}(\mathscr{S})$ (3.5.3); composing the first projection $p : X \times_Y Y' \to X$ with **II** | 64
$\operatorname{Proj}(u^\sharp)$, we thus obtain a morphism $v : G(u^\sharp) \to X$, which we denote by $\operatorname{Proj}(u)$, and which is such that the diagram

$$\begin{tikzcd} G(u^\sharp) \arrow[r, "v"] \arrow[d] & X \arrow[d] \\ Y' \arrow[r, "g"'] & Y \end{tikzcd}$$

commutes.

Furthermore, for every quasi-coherent graded $\mathscr{S}$-module $\mathscr{M}$, we have a canonical v-morphism

$$\nu : \widetilde{\mathscr{M}} \longrightarrow (g^*(\mathscr{M}) \otimes_{g^*(\mathscr{S})} \mathscr{S}')^\sim | G(u^\sharp). \tag{3.5.6.1}$$

Indeed, $\nu^\sharp$ is given by composing the homomorphisms

$$v^*(\widetilde{\mathscr{M}}) = W^*(p^*(\widetilde{\mathscr{M}})) \longrightarrow W^*((g^*(\mathscr{M}))^\sim) \longrightarrow (g^*(\mathscr{M}) \otimes_{g^*(\mathscr{S})} \mathscr{S}')^\sim | G(u^\sharp)$$

where the first arrow comes from the isomorphism (3.5.3) and the second is the homomorphism (3.5.2, (ii)); if $\mathscr{S}$ is generated by $\mathscr{S}_1$, then it follows from (3.5.2) that $\nu^\sharp$ is an *isomorphism*.

As a particular case of (3.5.6.1), we have, for all $n \in \mathbf{Z}$, a canonical v-morphism

$$\nu : \mathscr{O}_X(n) \longrightarrow \mathscr{O}_{X'}(n) | G(u^\sharp). \tag{3.5.6.2}$$

3.6. Closed subpreschemes of a prescheme $\mathrm{Proj}(\mathscr{S})$

(3.6.1). Let Y be a prescheme, and $\phi : \mathscr{S} \to \mathscr{S}'$ a degree 0 homomorphism of quasi-coherent graded $\mathscr{O}_Y$-algebras. We say that ϕ is *(**TN**)-surjective* (resp. *(**TN**)-injective*, *(**TN**)-bijective*) if there exists n such that, for all $k \geqslant n$, $\phi_k : \mathscr{S}_k \to \mathscr{S}'_k$ is surjective (resp. injective, bijective). If this is the case, then we can reduce the study of the corresponding morphism $\Phi : \mathrm{Proj}(\mathscr{S}') \to \mathrm{Proj}(\mathscr{S})$ to the case where ϕ is *surjective* (resp. *injective*, *bijective*). We prove this as in (2.9.1) (which is the particular case where Y is affine) by using (3.1.8). Instead of saying that ϕ is (**TN**)-bijective, we also say that it is a *(**TN**)-isomorphism*.

Proposition (3.6.2). — *Let Y be a prescheme, and $\mathscr{S}$ a quasi-coherent graded $\mathscr{O}_Y$-algebra; set $X = \mathrm{Proj}(\mathscr{S})$.*

- *(i) If $\phi : \mathscr{S} \to \mathscr{S}'$ is a (**TN**)-surjective homomorphism of graded $\mathscr{O}_Y$-algebras, then the corresponding morphism $\Phi = \mathrm{Proj}(\phi)$ (3.5.1) is defined on all of $\mathrm{Proj}(\mathscr{S}')$ and is a closed immersion of $\mathrm{Proj}(\mathscr{S}')$ into X. If $\mathscr{J}$ is the kernel of ϕ, then the closed subprescheme of X associated to Φ is defined by the quasi-coherent sheaf of ideals $\widetilde{\mathscr{J}}$ in $\mathscr{O}_X$.*
- *(ii) Suppose further that $\mathscr{S}_0 = \mathscr{O}_Y$, that $\mathscr{S}$ is generated by $\mathscr{S}_1$, and that $\mathscr{S}_1$ is of finite type. Let X' be a closed subprescheme of $X = \mathrm{Proj}(\mathscr{S})$, defined by a quasi-coherent sheaf of ideals $\mathscr{I}$ in $\mathscr{O}_X$. Let $\mathscr{J}$ be the quasi-coherent graded sheaf of ideals of $\mathscr{S}$, given by the inverse image of $\mathbf{\Gamma}_*(\mathscr{I})$ by the canonical homomorphism $\alpha : \mathscr{S} \to \mathbf{\Gamma}_*(\mathscr{O}_X)$ (3.3.2), and set $\mathscr{S}' = \mathscr{S}|\mathscr{J}$. Then X' is the subprescheme associated (I, 4.2.1) to the closed immersion $\mathrm{Proj}(\mathscr{S}') \to X$ corresponding to the canonical homomorphism $\mathscr{S} \to \mathscr{S}'$ of graded $\mathscr{O}_Y$-algebras.* II | 65

Proof.

- (i) We can assume that ϕ is surjective (3.6.1). Then, for every affine open U of Y, $\Gamma(U, \mathscr{S}) \to \Gamma(U, \mathscr{S}')$ is surjective (I, 1.3.9), so $G(\phi) = \mathrm{Proj}(\mathscr{S}')$ by (3.5.1). We can then immediately reduce to proving the proposition in the case where Y is affine, and this follows from (2.9.2, (i)).
- (ii) We can reduce to proving that the homomorphism $\widetilde{\mathscr{J}} \to \mathscr{O}_X$ induced by the canonical injection $\mathscr{J} \to \mathscr{S}$ is an isomorphism from $\widetilde{\mathscr{J}}$ to $\mathscr{I}$; since the question is local on Y, we can take Y to be affine of ring A, which implies that $\mathscr{S} = \widetilde{S}$, where S is a graded A-algebra generated by S_1, with S_1 of finite type over A. It then suffices to apply (2.9.2, (ii)).

□

Corollary (3.6.3). — *Under the conditions of (3.6.2, (i)), suppose further that $\mathscr{S}$ is generated by $\mathscr{S}_1$. Then $\Phi^*(\mathscr{O}_X(n))$ is canonically identified with $\mathscr{O}_{X'}(n)$ for all $n \in \mathbf{Z}$.*

Proof. We have defined such a canonical isomorphism when Y is affine (2.9.3); in the general case, it suffices to show that the isomorphisms thus defined for each affine open U of Y are compatible with the passage from U to an affine open $U' \subset U$, which is immediate. □

Corollary (3.6.4). — *Let Y be a prescheme, $\mathscr{S}$ a quasi-coherent graded $\mathscr{O}_Y$-algebra generated by $\mathscr{S}_1$, $\mathscr{M}$ a quasi-coherent $\mathscr{O}_Y$-module, u a surjective $\mathscr{O}_Y$-homomorphism $\mathscr{M} \to \mathscr{S}_1$, and $\overline{u} : \mathbf{S}_{\mathscr{O}_Y}(\mathscr{M}) \to \mathscr{S}$ the homomorphism of graded $\mathscr{O}_Y$-algebras that extends u (1.7.4). Then the morphism corresponding to $\overline{u}$ is a closed immersion of $\mathrm{Proj}(\mathscr{S})$ into $\mathrm{Proj}(\mathbf{S}_{\mathscr{O}_Y}(\mathscr{M}))$.*

Proof. Indeed, $\overline{u}$ is surjective by hypothesis, and we apply (3.6.2, (i)). □

3.7. Morphisms from a prescheme to a homogeneous spectrum

(3.7.1). Let $q : X \to Y$ be a morphism of preschemes, $\mathscr{L}$ an invertible $\mathscr{O}_X$-module, and $\mathscr{S}$ a quasi-coherent positively graded $\mathscr{O}_Y$-algebra; then $q^*(\mathscr{S})$ is a quasi-coherent positively graded $\mathscr{O}_X$-algebra. Consider the quasi-coherent graded $\mathscr{O}_X$-algebra $\mathscr{S}' = \bigoplus_{n \geqslant 0} \mathscr{L}^{\otimes n}$; suppose that we have an $\mathscr{O}_X$-homomorphism of graded algebras

$$\psi : q^*(\mathscr{S}) \longrightarrow \mathscr{S}' = \bigoplus_{n \geqslant 0} \mathscr{L}^{\otimes n}$$

which is equivalent to having a q-morphism of graded algebras

$$\psi^\flat : \mathscr{S} \longrightarrow q_*(\mathscr{S}').$$

We know that $\operatorname{Proj}(\mathscr{S}')$ is canonically identified with X ((3.1.7) and (3.1.8, (iii))); we thus canonically obtain from ψ an open subset $G(\psi)$ of X, and a Y-morphism

(3.7.1.1) $$r_{\mathscr{L},\psi} : G(\psi) \longrightarrow \operatorname{Proj}(\mathscr{S}) = P$$

which we call the morphism *associated to $\mathscr{L}$ and ψ*; recall (3.5.6) that this morphism is obtained by composing the Y-morphism **II** | 66

$$\tau = \operatorname{Proj}(\psi) : G(\psi) \longrightarrow \operatorname{Proj}(q^*(\mathscr{S}))$$

with the first projection $\pi : \operatorname{Proj}(q^*(\mathscr{S})) = P \times_Y X \to P$.

(3.7.2). We will explicitly describe $r = r_{\mathscr{L},\psi}$ in the case where $Y = \operatorname{Spec}(A)$ is affine, so that $\mathscr{S} = \widetilde{S}$, where S is a positively graded A-algebra. Suppose first of all that $X = \operatorname{Spec}(B)$ is also affine, and that we have $\mathscr{L} = \widetilde{L}$, where L is a free B-module of rank 1. Then $q^*(\mathscr{S}) = (S \otimes_A B)^\sim$ (**I**, 1.6.5); if c is a generator of L, then $\psi_n : q^*(\mathscr{S}_n) \to \mathscr{L}^{\otimes n}$ corresponds to a homomorphism $w_n : s \otimes b \mapsto bv_n(s)c^{\otimes n}$ from $S_n \otimes_A B$ to $L^{\otimes n}$, where $v_n : S_n \to B$ is a homomorphism of A-modules, the v_n together constituting a homomorphism of algebras $S \to B$. Let $f \in S_d$ (where $d > 0$), and set $g = v_d(f)$; we have $\pi^{-1}(D_+(f)) = D_+(f \otimes 1)$ by (2.8.10) and the identification of $D_+(f)$ with $\operatorname{Spec}(S_{(f)})$ (2.3.6); we also know, from (2.8.1.1) (taking into account the canonical identification of X with $\operatorname{Proj}(\mathscr{S}')$), that

$$\tau^{-1}(D_+(f \otimes 1)) = D(g)$$

whence

(3.7.2.1) $$r^{-1}(D_+(f)) = D(g).$$

Furthermore, the morphism $\tau = \operatorname{Proj}(\psi)$, restricted to $D(g)$, corresponds to the homomorphism that sends $(s \otimes 1)/(f \otimes 1)^n$ (where $s \in S_{nd}$) to $v_{nd}(s)/g^n$ (2.8.1), and the projection π, restricted to $D_+(f \otimes 1)$, corresponds to the homomorphism $s/f^n \mapsto (s \otimes 1)/(f \otimes 1)^n$; we thus conclude that r, restricted to $D(g)$, corresponds to the homomorphism of A-algebras $\omega : S_{(f)} \to B_g$ such that $\omega(s/f^n) = v_{nd}(s)/g^n$ (where $s \in S_{nd}$ and $n > 0$). Passing to the case where X is arbitrary (but Y still affine), we thus obtain, taking (2.8.1) into account, the following:

Proposition (3.7.3). — *If $Y = \operatorname{Spec}(A)$ is affine and $\mathscr{S} = \widetilde{S}$, where S is a graded A-algebra, then, for all $f \in S_d = \Gamma(Y, \mathscr{S}_d)$, we have*

(3.7.3.1) $$r^{-1}_{\mathscr{L},\psi}(D_+(f)) = X_{\psi^\flat(f)}$$

(where $\psi^\flat(f) \in \Gamma(X, \mathscr{L}^{\otimes d})$) and the restriction $X_{\psi^\flat(f)} \to D_+(f) = \operatorname{Spec}(S_{(f)})$ of $r_{\mathscr{L},\psi}$ corresponds (**I**, 2.2.4) *to the homomorphism of algebras*

(3.7.3.2) $$\psi^\flat_{(f)} : S_{(f)} \longrightarrow \Gamma(X_{\psi^\flat(f)}, \mathscr{O}_X)$$

such that, for $s \in S_{nd} = \Gamma(Y, \mathscr{S}_{nd})$,

(3.7.3.3) $$\psi^\flat_{(f)}(s/f^n) = (\psi^\flat(s)|X_{\psi^\flat(f)})(\psi^\flat(f)|X_{\psi^\flat(f)})^{-n}.$$

We say that $r_{\mathscr{L},\psi}$ is *everywhere defined* if $G(\psi) = X$. For this to be the case, it is evidently necessary and sufficient that $G(\psi) \cap q^{-1}(U) = q^{-1}(U)$ for every affine open $U \subset Y$; in other words, the question is *local* on Y. If Y is affine, then $G(\psi)$ is the union of the $r^{-1}(D_+(f))$ over f homogeneous in S_+ (2.8.1); by (3.7.3.1), the $X_{\psi^\flat(f)}$ must then form a *cover* of X; in other words:

Corollary (3.7.4). — *Under the hypotheses of (3.7.3), for $r_{\mathscr{L},\psi}$ to be everywhere defined, it is necessary and sufficient that, for every $x \in X$, there exist an integer $n > 0$ and a section s of $\mathscr{S}_n$ over Y such that, if we set $t = \psi^\flat(s) \in \Gamma(X, \mathscr{L}^{\otimes n})$, then $t(x) \neq 0$.*

Note that this condition is always satisfied if ψ is *(**TN**)-surjective*. **II** | 67

Similarly, the question of whether $r_{\mathscr{L},\psi}$ is *dominant* is local on Y, and we have:

Corollary (3.7.5). — *Under the hypotheses of (3.7.3), for $r_{\mathscr{L},\psi}$ to be dominant, it is necessary and sufficient that, for every integer $n > 0$, every section $s \in S_n$ such that $\psi^\flat(s) \in \Gamma(X, \mathscr{L}^{\otimes n})$ is locally nilpotent is itself nilpotent.*

Proof. We have to show that $r^{-1}_{\mathscr{L},\psi}(D_+(s))$ is nonempty whenever $D_+(s)$ is nonempty, and the corollary thus follows from (3.7.3.1) and (2.3.7). □

Proposition (3.7.6). — *Let $q : X \to Y$ be a morphism, $\mathscr{L}$ an invertible $\mathscr{O}_X$-module, $\mathscr{S}$ and $\mathscr{S}'$ quasi-coherent graded $\mathscr{O}_Y$-algebras, $u : \mathscr{S}' \to \mathscr{S}$ a homomorphism of graded algebras, and $\psi : q^*(\mathscr{S}) \to \bigoplus_{n\geqslant 0} \mathscr{L}^{\otimes n}$ a homomorphism of graded algebras; let $\psi' = \psi \circ q^*(u)$ be the composite homomorphism. If $r_{\mathscr{L},\psi'}$ is everywhere defined, then so too is $r_{\mathscr{L},\psi}$; if u is (**TN**)-surjective, then if $r_{\mathscr{L},\psi'}$ is dominant, so too is $r_{\mathscr{L},\psi}$; conversely, if u is (**TN**)-injective, then if $r_{\mathscr{L},\psi}$ is dominant, so too is $r_{\mathscr{L},\psi'}$.*

Proof. We know that $G(\psi') \subset G(\psi)$ (2.8.4), whence the first claim; if u is (**TN**)-surjective, then $\operatorname{Proj}(u) : \operatorname{Proj}(\mathscr{S}) \to \operatorname{Proj}(\mathscr{S}')$ is everywhere defined and a closed immersion; since $r_{\mathscr{L},\psi'}$ is the composition of $\operatorname{Proj}(u)$ and the restriction to $G(\psi')$ of $r_{\mathscr{L},\psi}$, we thus conclude that, if $r_{\mathscr{L},\psi'}$ is dominant, then so too is $r_{\mathscr{L},\psi}$. Finally, if u is (**TN**)-injective, then we know that $\operatorname{Proj}(u)$ is a dominant morphism from $G(u)$ to $\operatorname{Proj}(\mathscr{S}')$ (2.8.3); since $G(\psi')$ is the inverse image of $G(u)$ under $r_{\mathscr{L},\psi}$, we see that, if $r_{\mathscr{L},\psi}$ is dominant, then so too is $r_{\mathscr{L},\psi'}$. □

Proposition (3.7.7). — *Let Y be a quasi-compact prescheme, $q : X \to Y$ a quasi-compact morphism, $\mathscr{L}$ an invertible $\mathscr{O}_X$-module, and $\mathscr{S}$ a quasi-coherent graded $\mathscr{O}_Y$-algebra given by the filtered inductive limit of an inductive system $(\mathscr{S}^\lambda)$ of quasi-coherent graded $\mathscr{O}_Y$-algebras. Let $\phi_\lambda : \mathscr{S}^\lambda \to \mathscr{S}$ be the canonical homomorphism, $\psi : q^*(\mathscr{S}) \to \bigoplus_{n\geqslant 0} \mathscr{L}^{\otimes n}$ a homomorphism of graded algebras, and set $\psi_\lambda = \psi \circ q^*(\phi_\lambda)$. For $r_{\mathscr{L},\psi}$ to be everywhere defined, it is necessary and sufficient that there exist some λ such that $r_{\mathscr{L},\psi_\lambda}$ is everywhere defined; $r_{\mathscr{L},\psi_\mu}$ is then everywhere defined for $\mu \geqslant \lambda$.*

Proof. The condition is sufficient by (3.7.6). Conversely, suppose that $r_{\mathscr{L},\psi}$ is everywhere defined; we can reduce to the case where Y is affine, since, if, for every affine open $U \subset Y$ there exists $\lambda(U)$ such that the restriction of $r_{\mathscr{L},\psi_{\lambda(U)}}$ to $q^{-1}(U)$ is everywhere defined, then it will suffice (Y being quasi-compact) to cover Y by a finite number of affine opens U_i, and to take $\lambda \geqslant \lambda(U_i)$ for all indices i, by (3.7.6). If Y is affine, then the hypothesis implies that, for all $x \in X$, there exists a section $s^{(x)}$ of S_n such that, if we set $t^{(x)} = \psi^\flat(s^{(x)})$, then $t^{(x)}(x) \neq 0$ (where $t^{(x)}$ is considered as a section of $\mathscr{L}^{\otimes n}$ over X), which implies that $t^{(x)}(z) \neq 0$ for any z in a neighbourhood $V(x)$ of x. Cover X by a finite number of $V(x_i)$, and let $s^{(i)}$ be the corresponding sections of S; then there exists some λ such that the $s^{(i)}$ are all of the form $\phi_\lambda(s'^{(i)}_\lambda)$, with $s'^{(i)}_\lambda \in S^\lambda$ for all i; it then follows from (3.7.4) that $r_{\mathscr{L},\psi_\lambda}$ is everywhere defined. The final claim is a trivial consequence of (3.7.6). □

Corollary (3.7.8). — *Under the hypotheses of (3.7.7), if the $r_{\mathscr{L},\psi_\lambda}$ are dominant, then so too is $r_{\mathscr{L},\psi}$; the converse is true if the ϕ_λ are all injective.*

II | 68

Proof. The second claim is a particular case of (3.7.6); to show that $r_{\mathscr{L},\psi}$ is dominant, we can restrict to the case where Y is affine; if $s \in S$ is such that $\psi^\flat(s)$ is locally nilpotent, since we can write $s = \phi_\lambda(s_\lambda)$ for at least one λ, we conclude from the hypotheses and from (3.7.5) that s_λ is nilpotent, and thus so too is s, and the criteria of (3.7.5) then apply. □

Remarks (3.7.9). —

(i) With the notation of (3.7.1), and taking (3.2.10) into account, we have, for all $n \in \mathbf{Z}$, a canonical homomorphism

$$\theta : r^*_{\mathscr{L},\psi}(\mathscr{O}_P(n)) \longrightarrow \mathscr{L}^{\otimes n} \tag{3.7.9.1}$$

defined in a general way in (3.5.6.2). We immediately see that, under the conditions of (3.7.3), the restriction of this homomorphism to $X_{\psi^\flat(f)}$ sends s/f^k (where $s \in S_{n+kd}$) to the element $(\psi^\flat(s)|X_{\psi^\flat(f)})(\psi^\flat(f)|X_{\psi^\flat(f)})^{-k}$.

(ii) Let $\mathscr{F}$ be a quasi-coherent $\mathscr{O}_X$-module, and suppose that q is quasi-compact and separated, so that, for all $n \geqslant 0$, $q_*(\mathscr{F} \otimes \mathscr{L}^{\otimes n})$ is a quasi-coherent $\mathscr{O}_Y$-module (**I**, 9.2.2). Let $\mathscr{M}' = \bigoplus_{n \geqslant 0} \mathscr{F} \otimes \mathscr{L}^{\otimes n}$, which is a quasi-coherent graded $\mathscr{S}'$-module, and consider its image $\mathscr{M} = q_*(\mathscr{M}') = \bigoplus_{n\geqslant 0} q_*(\mathscr{F} \otimes \mathscr{L}^{\otimes n})$ (which is a quasi-coherent $\mathscr{S}$-module, via the homomorphism $\psi^\flat$). We are going to show the existence of a canonical homomorphism of $\mathscr{O}_X$-modules

$$\xi : r^*_{\mathscr{L},\psi}(\widetilde{\mathscr{M}}) \longrightarrow \mathscr{F}|G(\psi). \tag{3.7.9.2}$$

Indeed, we have already defined (3.5.6.1) a canonical homomorphism

$$r^*_{\mathscr{L},\psi}(\widetilde{\mathscr{M}}) \longrightarrow (q^*(\mathscr{M}) \otimes_{q^*(\mathscr{S})} \mathscr{S}')^\sim|G(\psi) \tag{3.7.9.3}$$

where the right-hand side is considered as a quasi-coherent sheaf on $\operatorname{Proj}(\mathscr{S}')$. We also have a canonical homomorphism

$$q^*(q_*(\mathscr{M}')) \otimes_{q^*(\mathscr{S})} \mathscr{S}' \longrightarrow \mathscr{M}' \tag{3.7.9.4}$$

for any quasi-coherent graded $\mathscr{S}'$-module $\mathscr{M}'$: for any open U of X, any section t' of $q^*(q_*(\mathscr{M}'_h))$ over U, and any section b' of $\mathscr{S}'_k$ over U, we send $t' \otimes b'$ to the section $b'\sigma(t')$ of $\mathscr{M}'_{h+k}$, where $\sigma(t')$ is the section of $\mathscr{M}'_h$ over U that corresponds canonically (**0**, 4.4.3) to t'. We thus obtain a canonical homomorphism

$$(q^*(q_*(\mathscr{M}')) \otimes_{q^*(\mathscr{S})} \mathscr{S}')^\sim|G(\psi) \longrightarrow \widetilde{\mathscr{M}'}|G(\psi) \tag{3.7.9.5}$$

and, finally, since $\widetilde{\mathscr{M}'}$ is canonically identified with $\mathscr{F}$ (3.2.9, (i)), we indeed obtain the desired canonical homomorphism.

Under the conditions of (3.7.3), the restriction of this homomorphism to $X_{\psi^\flat(f)}$ acts as follows: given a section t_{nd} of $\mathscr{F} \otimes \mathscr{L}^{\otimes nd}$ over X, if t'_{nd} is the section t_{nd} considered as a section of $q_*(\mathscr{F} \otimes \mathscr{L}^{\otimes nd})$ over Y, then it sends the element t'_{nd}/f^n to the section $(t_{nd}|X_{\psi^\flat(f)})(\psi^\flat(f)|X_{\psi^\flat(f)})^{-n}$ of $\mathscr{F}$ over $X_{\psi^\flat(f)}$.

3.8. Criteria for immersion into a homogeneous spectrum

(3.8.1). With the notation of (3.7.1), the question of whether $r_{\mathscr{L},\psi}$ is an immersion (resp. an open immersion, a closed immersion) is clearly *local on* Y.

Proposition (3.8.2). — *Under the hypotheses of* (3.7.3), *for* $r_{\mathscr{L},\psi}$ *to be everywhere defined and an immersion, it is necessary and sufficient that there exists a family of sections* $s_\alpha \in S_{n_\alpha}$ *(where* $n_\alpha > 0$*) such that, if we set* $f_\alpha = \psi^\flat(s_\alpha)$, *the following conditions are satisfied:*

(i) The X_{f_α} *form a cover of* X.

(ii) The X_{f_α} *are affine opens.*
