(iii) For every α *and every* $t \in \Gamma(X_{f_\alpha}, \mathscr{O}_X)$, *there exists an integer* $m > 0$ *and some* $s \in S_{mn_\alpha}$ *such that* $t = (\psi^\flat(s)|X_{f_\alpha})(f_\alpha|X_{f_\alpha})^{-m}$.

For $r_{\mathscr{L},\psi}$ *to be everywhere defined and an open immersion, it is necessary and sufficient that there exists a family* (s_α) *satisfying conditions (i), (ii), and (iii) above, as well as:*

(iv) For all $n > 0$ *and every* $s \in S_{nn_\alpha}$ *such that* $\psi^\flat(s)|X_{f_\alpha} = 0$, *there exists an integer* $k > 0$ *such that* $s^k_\alpha = 0$.

For $r_{\mathscr{L},\psi}$ *to be everywhere defined and a closed immersion, it is necessary and sufficient that there exists a family* (s_α) *satisfying conditions (i), (ii), and (iii) above, as well as:*

(v) *The* $D_+(s_\alpha)$ *form a cover of* $P = \mathrm{Proj}(S)$.

Proof. For r to be an immersion (resp. a closed immersion), it is necessary and sufficient that there exists a cover of $r(G(\psi))$ (resp. of P) by the $D_+(s_\alpha)$, such that, if we set $V_\alpha = r^{-1}(D_+(s_\alpha))$, then the restriction of r to V_α is a *closed* immersion of V_α into $D_+(s_\alpha)$ (**I**, 4.2.4). Condition (i) says that r is everywhere defined and also that the $D_+(s_\alpha)$ cover $r(X)$, by (3.7.3.1); since $D_+(s_\alpha)$ is affine, conditions (ii) and (iii) say that the restriction of r to X_{f_α} is a closed immersion into $D_+(s_\alpha)$, by (**I**, 4.2.3); finally, since conditions (iii) and (iv) say that $\psi^\flat_{(s_\alpha)}$ is bijective (using the notation of (3.7.3.2)), conditions (ii), (iii), and (iv) say that the restriction of r to X_{f_α} is an isomorphism to $D_+(s_\alpha)$ for all α, and so conditions (i), (ii), (iii), and (iv) together say that r is an open immersion. □

Corollary (3.8.3). — *Under the hypotheses of* (3.7.6), *if* $r_{\mathscr{L},\psi'}$ *is everywhere defined and an immersion, then so too is* $r_{\mathscr{L},\psi}$. *If we further suppose that* u *is* (**TN**)*-surjective, then if* $r_{\mathscr{L},\psi'}$ *is an open (resp. closed) immersion, so too is* $r_{\mathscr{L},\psi}$.

Proof. By (3.8.2), there exists a family $s'_\alpha \in S'_{n_\alpha}$ such that, if we set $f_\alpha = \psi'^\flat(s'_\alpha)$, conditions (i), (ii), and (iii) are satisfied. But if we set $s_\alpha = u(s'_\alpha)$, then we also have that $f_\alpha = \psi^\flat(s_\alpha)$, and if $t = (\psi'^\flat(s')|X_{f_\alpha})(f_\alpha|X_{f_\alpha})^{-m}$, then also $t = (\psi^\flat(s)|X_{f_\alpha})(f_\alpha|X_{f_\alpha})^{-m}$ by setting $s = u(s')$, whence the first claim. The second claim follows immediately from the fact that $\mathrm{Proj}(u)$ is a closed immersion. □

Proposition (3.8.4). — *Suppose that the hypotheses of* (3.7.7) *are satisfied, and further that* $q : X \to Y$ *is a morphism of finite type. Then, for* $r_{\mathscr{L},\psi}$ *to be everywhere defined and an immersion, it is necessary and sufficient that there exist some* λ *such that* $r_{\mathscr{L},\psi_\lambda}$ *is everywhere defined and an immersion; in this case,* $r_{\mathscr{L},\psi_\mu}$ *is also everywhere defined and an immersion for all* $\mu \geqslant \lambda$.

II | 70

Proof. Taking (3.8.3) into account, it suffices to show that, if $r_{\mathscr{L},\psi}$ is everywhere defined and an immersion, then so too is $r_{\mathscr{L},\psi_\lambda}$ for at least one λ. By the same argument as in (3.7.7), using the quasi-compactness of Y, we first reduce to the case where $Y = \mathrm{Spec}(A)$ is affine. Since X is quasi-compact, (3.8.2) then shows the existence of a *finite* family $(s_i \in S_{n_i})$ of elements of S satisfying conditions (i), (ii), and (iii). The morphism $X_{f_i} \to Y$ (where $f_i = \psi^\flat(s_i)$) is of finite type: it is a morphism of affine schemes, and is thus quasi-compact (**I**, 6.6.1), and also locally of finite type, since q is of finite type (**I**, 6.3.2), and the conclusion then follows from (**I**, 6.6.3). The ring B_i of X_{f_i} is thus an A-algebra of finite type (**I**, 6.3.3); let (t_{ij}) be a family of generators of this algebra. By hypothesis, there exist elements $s'_{ij} \in S_{m_{ij}n_i}$ such that

$$t_{ij} = (\psi^\flat(s'_{ij})|X_{f_i})(\psi^\flat(s_i)|X_{f_i})^{-m_{ij}}.$$

Also by hypothesis, there exists some λ and elements $s_{i\lambda} \in S^\lambda_{n_i}$ and $s'_{ij\lambda} \in S^\lambda_{m_{ij}n_i}$ whose images under ϕ_λ are s_i and s'_{ij}, respectively; it is clear that $r_{\mathscr{L},\psi_\lambda}$ satisfies conditions (i), (ii), and (iii) of (3.8.2). □

Proposition (3.8.5). — *Let* Y *be a quasi-compact scheme, or a prescheme whose underlying space is Noetherian,* $q : X \to Y$ *a morphism* of finite type, $\mathscr{L}$ *an invertible* $\mathscr{O}_X$*-module,* $\mathscr{S}$ *a quasi-coherent graded* $\mathscr{O}_Y$*-algebra, and* $\psi : q^*(\mathscr{S}) \to \bigoplus_{n\geqslant 0} \mathscr{L}^{\otimes n}$ *a homomorphism of graded algebras. For* $r_{\mathscr{L},\psi}$ *to be everywhere defined and an immersion, it is necessary and sufficient that there exist an integer* $n > 0$ *and a quasi-coherent sub-*$\mathscr{O}_Y$*-module* of finite type $\mathscr{E}$ *of* $\mathscr{S}_n$ *such that*

a) *the homomorphism* $\psi_n \circ q^*(j_n) : q^*(\mathscr{E}) \to \mathscr{L}^{\otimes n}$ *(where* $j_n : \mathscr{E} \to \mathscr{S}$ *is the canonical injection) is surjective; and*

b) *if we denote by* $\mathscr{S}'$ *the (graded) sub-*$\mathscr{O}_Y$*-algebra of* $\mathscr{S}$ *generated by* $\mathscr{E}$*, and by* ψ' *the homomorphism* $\psi \circ q^*(j')$ *(where* j' *is the injection of* $\mathscr{S}'$ *into* $\mathscr{S}$*),* $r_{\mathscr{L},\psi'}$ *is everywhere defined and an immersion.*

If this is the case, then every quasi-coherent sub-$\mathscr{O}_Y$*-module* $\mathscr{E}'$ *of* $\mathscr{S}_n$ *that contains* $\mathscr{E}$ *also possesses the same property, as does the image of* $\otimes^k\mathscr{E}$ *in* $\mathscr{S}_{kn}$ *for all* $k > 0$.

Proof. The fact that the condition is sufficient, and the last two claims, are particular cases of (3.8.3), taking into account the canonical isomorphism between $\mathrm{Proj}(\mathscr{S})$ and $\mathrm{Proj}(\mathscr{S}^{(k)})$ (3.1.8).

Let (U_i) be a finite cover of Y by affine opens, and set $A_i = A(U_i)$. Since $q^{-1}(U_i)$ is quasi-compact, the hypothesis that $r_{\mathscr{L},\psi}$ be everywhere defined and an immersion implies, along with (3.8.2), the existence of a finite family $(s_{ij} \in S^{(i)}_{n_{ij}})$ of elements of $S^{(i)} = \Gamma(U_i, \mathscr{S})$ satisfying conditions (i), (ii), and (iii). We see, as in the proof of (3.8.4), that the morphism $X_{f_{ij}} \to U_i$ (where $f_{ij} = \psi^\flat(s_{ij})$) is of finite type, and that the ring B_{ij} of $X_{f_{ij}}$ is thus an A_i-algebra of finite type, having a system of generators of the form $(\psi^\flat(t_{ijk})|X_{f_{ij}})(f_{ij}|X_{f_{ij}})^{-m_{ijk}}$, where $t_{ijk} \in S^{(i)}_{m_{ijk}n_{ij}}$. Let n be a common multiple of the $m_{ijk}n_{ij}$; replacing (for each (i,j,k)) s_{ij} by some power s^ρ_{ij} such that $\rho m_{ijk} n_{ij} = n$, and multiplying t_{ijk} by $s^{\rho - m_{ijk}}_{ij}$, we can assume that, for each i, the s_{ij} and t_{ijk} belong to $S^{(i)}_n$ and that $m_{ijk} = 1$. Let E_i be the sub-A_i-module of $S^{(i)}$ generated by these elements (for fixed i). Then there exists a coherent sub-$\mathscr{O}_Y$-module $\mathscr{E}_i$ of $\mathscr{S}_n$ of finite type such that $\mathscr{E}_i|U_i = (E_i)^\sim$ (I, 9.4.7). It is clear that the sub-$\mathscr{O}_Y$-module $\mathscr{E}$ of $\mathscr{S}_n$ given by the sum of the $\mathscr{E}_i$ is the desired object (since each section f_{ij} is such that, for all $x \in X_{f_{ij}}$, there exists an affine neighbourhood $V \subset X_{f_{ij}}$ of x such that $f_{ij}|V$ is a basis for $\Gamma(V, \mathscr{L}^{\otimes n})$). □ II | 71

§4. Projective bundles; ample sheaves

4.1. Definition of projective bundles

Definition (4.1.1). — Let Y be a prescheme, $\mathscr{E}$ a quasi-coherent $\mathscr{O}_Y$-module, and $\mathbf{S}_{\mathscr{O}_Y}(\mathscr{E})$ the symmetric $\mathscr{O}_Y$-algebra of $\mathscr{E}$ (1.7.4), which is quasi-coherent (1.7.7). We define the *projective bundle on Y defined by $\mathscr{E}$*, denoted $\mathbf{P}(\mathscr{E})$, to be the Y-scheme $P = \operatorname{Proj}(\mathbf{S}_{\mathscr{O}_Y}(\mathscr{E}))$. The $\mathscr{O}_P$-module $\mathscr{O}_P(1)$ is called the *fundamental sheaf on P*.

When Y is affine of ring A, then we have $\mathscr{E} = \widetilde{E}$ for some A-module E, and we then write $\mathbf{P}(E)$ instead of $\mathbf{P}(\widetilde{E})$.

When we take $\mathscr{E} = \mathscr{O}^n_Y$, we write $\mathbf{P}^{n-1}_Y$ instead of $\mathbf{P}(\mathscr{E})$; if, further, Y is affine of ring A, then we also write $\mathbf{P}^{n-1}_A$ instead of $\mathbf{P}^{n-1}_Y$. Since $\mathbf{S}_{\mathscr{O}_Y}(\mathscr{O}_Y)$ is canonically identified with $\mathscr{O}_Y[T]$ (1.7.4), $\mathbf{P}^0_Y$ is canonically identified with Y (3.1.7); Example (2.4.3) is then exactly $\mathbf{P}^1_K$.

(4.1.2). Let $\mathscr{E}$ and $\mathscr{F}$ be quasi-coherent $\mathscr{O}_Y$-modules; let $u : \mathscr{E} \to \mathscr{F}$ be an $\mathscr{O}_Y$-homomorphism; there is a corresponding canonical homomorphism $\mathbf{S}(u) : \mathbf{S}_{\mathscr{O}_Y}(\mathscr{E}) \to \mathbf{S}_{\mathscr{O}_Y}(\mathscr{F})$ of graded $\mathscr{O}_Y$-algebras (1.7.4). If u is *surjective*, then so too is $\mathbf{S}(u)$, and thus (3.6.2, (i)) $\operatorname{Proj}(\mathbf{S}(u))$ is a *closed immersion* $\mathbf{P}(\mathscr{F}) \to \mathbf{P}(\mathscr{E})$, which we denote by $\mathbf{P}(u)$. We can thus say that $\mathbf{P}(\mathscr{E})$ is a *contravariant functor* in $\mathscr{E}$, with the condition that we only consider *surjective* morphisms of quasi-coherent $\mathscr{O}_Y$-modules.

Still supposing that u is surjective, and letting $P = \mathbf{P}(\mathscr{E})$, $Q = \mathbf{P}(\mathscr{F})$, and $j = \mathbf{P}(u)$, we have, up to isomorphism, that

$$j^*(\mathscr{O}_P(n)) = \mathscr{O}_Q(n) \qquad \text{for all } n \in \mathbf{Z} \tag{4.1.2.1}$$

by (3.6.3).

(4.1.3). Now let $\psi : Y' \to Y$ be a morphism, and let $\mathscr{E}' = \psi^*(\mathscr{E})$; then $\mathbf{S}_{\mathscr{O}_{Y'}}(\mathscr{E}') = \psi^*(\mathbf{S}_{\mathscr{O}_Y}(\mathscr{E}))$ (1.7.5); thus (3.5.3)

$$\mathbf{P}(\psi^*(\mathscr{E})) = \mathbf{P}(\mathscr{E}) \times_Y Y' \tag{4.1.3.1}$$

up to canonical isomorphism; furthermore, we clearly have that

$$\psi^*((\mathbf{S}_{\mathscr{O}_Y}(\mathscr{E}))(n)) = (\mathbf{S}_{\mathscr{O}_{Y'}}(\mathscr{E}'))(n)$$

for all $n \in \mathbf{Z}$, whence, letting $P = \mathbf{P}(\mathscr{E})$ and $P' = \mathbf{P}(\mathscr{E}')$, we have (3.5.4), up to isomorphism, that

$$\mathscr{O}_{P'}(n) = \mathscr{O}_P(n) \otimes_Y \mathscr{O}_{Y'} \qquad \text{for all } n \in \mathbf{Z}. \tag{4.1.3.2}$$

II | 72

Proposition (4.1.4). — *Let $\mathscr{L}$ be an invertible $\mathscr{O}_Y$-module. For every quasi-coherent $\mathscr{O}_Y$-module $\mathscr{E}$, there exists a canonical Y-isomorphism $i_{\mathscr{L}} : \mathbf{P}(\mathscr{E}) \xrightarrow{\sim} \mathbf{P}(\mathscr{E} \otimes \mathscr{L})$; furthermore, if we let $P = \mathbf{P}(\mathscr{E})$ and $Q = \mathbf{P}(\mathscr{E} \otimes \mathscr{L})$, then $i^*_{\mathscr{L}}(\mathscr{O}_Q(n))$ is canonically isomorphic to $\mathscr{O}_P(n) \otimes_Y \mathscr{L}^{\otimes n}$ for all $n \in \mathbf{Z}$.*

Proof. First note that, if A is a ring, E an A-module, and L a *free rank-one* A-module, then we can canonically define a homomorphism of A-modules

$$\mathbf{S}_n(E \otimes L) \longrightarrow \mathbf{S}_n(E) \otimes L^{\otimes n}$$

by sending $(x_1 \otimes y_1) \ldots (x_n \otimes y_n)$ to the element

$$(x_1 x_2 \ldots x_n) \otimes (y_1 \otimes y_2 \otimes \ldots \otimes y_n) \qquad (x_i \in E, y_i \in L, \text{for } 1 \leqslant i \leqslant n);$$

we can immediately see (by restricting to the case where $L = A$) that this homomorphism is in fact an isomorphism. We thus obtain a canonical isomorphism of graded A-algebras $\mathbf{S}_A(E \otimes L) \xrightarrow{\sim} \bigoplus_{n \geqslant 0} \mathbf{S}_n(E) \otimes L^{\otimes n}$. Returning to the setting of (4.1.4), the preceding remarks allow us to define a canonical isomorphism of graded $\mathscr{O}_Y$-algebras

$$\mathbf{S}_{\mathscr{O}_Y}(\mathscr{E} \otimes_{\mathscr{O}_Y} \mathscr{L}) \xrightarrow{\sim} \bigoplus_{n \geqslant 0} \mathbf{S}_n(\mathscr{E}) \otimes_{\mathscr{O}_Y} \mathscr{L}^{\otimes n} \tag{4.1.4.1}$$

by defining this isomorphism as an isomorphism of presheaves, and taking into account (1.7.4), (**I**, 1.3.9), and (**I**, 1.3.12). The proposition then follows from (3.1.8, (iii)) and (3.2.10). □

(4.1.5). With the hypotheses of (4.1.1), let $P = \mathbf{P}(\mathscr{E})$, and denote by p the structure morphism $P \to Y$. Since, by definition, $\mathscr{E} = (\mathbf{S}_{\mathscr{O}_Y}(\mathscr{E}))_1$, we have a canonical homomorphism $\alpha_1 : \mathscr{E} \to p_*(\mathscr{O}_P(1))$ (3.3.2.2), and thus (**0**, 4.4.3) also a canonical homomorphism

$$\alpha_1^\sharp : p^*(\mathscr{E}) \longrightarrow \mathscr{O}_P(1). \tag{4.1.5.1}$$

Proposition (4.1.6). — *The canonical homomorphism* (4.1.5.1) *is surjective.*

Proof. We have seen, in (3.3.2), that $\alpha_1^\sharp$ corresponds functorially to the canonical homomorphism $\mathscr{E} \otimes_{\mathscr{O}_Y} \mathbf{S}_{\mathscr{O}_Y}(\mathscr{E}) \to (\mathbf{S}_{\mathscr{O}_Y}(\mathscr{E}))(1)$; since, by definition, $\mathscr{E}$ generates $\mathbf{S}_{\mathscr{O}_Y}(\mathscr{E})$, this homomorphism is surjective, whence the conclusion, by (3.2.4). □

4.2. Morphisms from a prescheme to a projective bundle

(4.2.1). Keeping the notation of (4.1.5), let X be a Y-prescheme, $q : X \to Y$ the structure morphism, and let $r : X \to P$ be a Y-*morphism* such that the following diagram commutes:

$$\begin{tikzcd} P \arrow[d, "p"'] & X \arrow[l, "r"'] \arrow[dl, "q"] \\ Y & \end{tikzcd}$$

Since the functor r^* is right exact (**0**, 4.3.1), we obtain, from the surjective homomorphism in **II** | 73
(4.1.5.1), a surjective homomorphism

$$r^*(\alpha_1^\sharp) : r^*(p^*(\mathscr{E})) \longrightarrow r^*(\mathscr{O}_P(1)).$$

But $r^*(p^*(\mathscr{E})) = q^*(\mathscr{E})$, and $r^*(\mathscr{O}_P(1))$ is locally isomorphic to $r^*(\mathscr{O}_P) = \mathscr{O}_X$; in other words, it is an *invertible* $\mathscr{O}_X$-module $\mathscr{L}_r$. Thus, from r, we have defined a canonical surjective $\mathscr{O}_X$-homomorphism

$$\phi_r : q^*(\mathscr{E}) \longrightarrow \mathscr{L}_r. \tag{4.2.1.1}$$

When $Y = \operatorname{Spec}(A)$ is affine and $\mathscr{E} = \widetilde{E}$, we can describe this homomorphism more explicitly as follows. given $f \in E$, it follows from (2.6.3) that

$$r^{-1}(D_+(f)) = X_{\phi_r^\flat(f)}. \tag{4.2.1.2}$$

Now let V be an affine open subset of X contained in $r^{-1}(D_+(f))$, and let B be its ring, which is an A-algebra; let $S = \mathbf{S}_A(E)$; the restriction of r to V corresponds to an A-homomorphism $\omega : S_{(f)} \to B$, and we have $q^*(\mathscr{E})|V = (E \otimes_A B)^\sim$ and $\mathscr{L}_r|V = \widetilde{L_r}$, whence $L_r = (S(1))_{(f)} \otimes_{S_{(f)}} B_{[\omega]}$ (**I**, 1.6.5). The restriction of ϕ_r to $q^*(\mathscr{E})|V$ corresponds to the B-homomorphism $u : E \otimes_A B \to L_r$, which sends $x \otimes 1$ to $(x/1) \otimes f = (f/1) \otimes \omega(x/f)$. The canonical extension of ϕ_r to a homomorphism of $\mathscr{O}_X$-algebras

$$\psi_r : q^*(\mathbf{S}(\mathscr{E})) = \mathbf{S}(q^*(\mathscr{E})) \longrightarrow \mathbf{S}(\mathscr{L}_r) = \bigoplus_{n \geqslant 0} \mathscr{L}_r^{\otimes n}$$

is therefore such that its restriction to $q^*(\mathbf{S}_n(\mathscr{E}))|V$ corresponds to the homomorphism $\mathbf{S}_n(E \otimes_A B) = \mathbf{S}_n(E) \otimes_A B \to L_r^{\otimes n}$ that sends $s \otimes 1$ to $(f/1)^{\otimes n} \otimes \omega(s/f^n)$.

(4.2.2). Conversely, suppose that we are given a morphism $q : X \to Y$, an invertible $\mathscr{O}_X$-module $\mathscr{L}$, and a quasi-coherent $\mathscr{O}_Y$-module $\mathscr{E}$; every homomorphism $\phi : q^*(\mathscr{E}) \to \mathscr{L}$ canonically determines a homomorphism of quasi-coherent $\mathscr{O}_X$-algebras

$$\psi : \mathbf{S}(q^*(\mathscr{E})) = q^*(\mathbf{S}(\mathscr{E})) \longrightarrow \bigoplus_{n \geqslant 0} \mathscr{L}^{\otimes n}$$

and thus (3.7.1) a Y-morphism $r_{\mathscr{L},\psi} : G(\psi) \to \operatorname{Proj}(\mathbf{S}(\mathscr{E})) = \mathbf{P}(\mathscr{E})$, which we denote by $r_{\mathscr{L},\phi}$. If ϕ is *surjective*, then so too is ψ, and thus (3.7.4) $r_{\mathscr{L},\phi}$ is *everywhere defined*. Furthermore, with the notation of (4.2.1) and (4.2.2):

Proposition (4.2.3). — *Given a morphism $q : X \to Y$ and a quasi-coherent $\mathscr{O}_Y$-module $\mathscr{E}$, the assignments $r \mapsto (\mathscr{L}_r, \phi_r)$ and $(\mathscr{L}, \phi) \mapsto r_{\mathscr{L},\phi}$ give a bijective correspondence between the set of Y-morphisms $r : X \to \mathbf{P}(\mathscr{E})$ and the set of equivalence classes of pairs $(\mathscr{L}, \phi)$ consisting of an invertible $\mathscr{O}_X$-module $\mathscr{L}$ and a surjective homomorphism $\phi : q^*(\mathscr{E}) \to \mathscr{L}$, where two pairs $(\mathscr{L}, \phi)$ and $(\mathscr{L}', \phi')$ are equivalent if there exists an $\mathscr{O}_X$-isomorphism $\tau : \mathscr{L} \xrightarrow{\sim} \mathscr{L}'$ such that $\phi' = \tau \circ \phi$.*

Proof. Start first with a Y-morphism $r : X \to \mathbf{P}(\mathscr{E})$, and construct $\mathscr{L}_r$ and ϕ_r (4.2.1), and let $r' = r_{\mathscr{L}_r,\phi_r}$; it follows immediately from (4.2.1) and (3.7.2) that the morphisms r and r' are identical (by taking the generator of $\mathscr{L}_r$ to be the element $(f/1) \otimes 1$ to define the homomorphisms v_n of (3.7.2)). Conversely, take a pair $(\mathscr{L}, \phi)$ and construct $r'' = r_{\mathscr{L},\phi}$, and then $\mathscr{L}_{r''}$ and $\phi_{r''}$; we will show that there exists **II | 74**
a canonical isomorphism $\tau : \mathscr{L}_{r''} \xrightarrow{\sim} \mathscr{L}$ such that $\phi = \tau \circ \phi_{r''}$; to define it, we can restrict to the case where $Y = \operatorname{Spec}(A)$ and $X = \operatorname{Spec}(B)$ are affine, and (with the notation of (4.2.1) and (3.7.2)) associate to each element $(x/1) \otimes 1$ of $L_{r''}$ (where $x \in E$) the element $v_1(x)c$ of L. We immediately see that τ does not depend on the chosen generator c of L; since v_1 is surjective by hypothesis, to prove that τ is an isomorphism it suffices to show that, if $x/1 = 0$ in $(S(1))_{(f)}$, then $v_1(x)/1 = 0$ in B_g; but the first equality implies that $f^n x = 0$ in $\mathbf{S}_{n+1}(E)$ for some n, and this implies that $v_{n+1}(f^n x) = g^n v_1(x) = 0$ in B, whence the conclusion. Finally, it is immediate that, for any two equivalent pairs $(\mathscr{L}, \phi)$ and $(\mathscr{L}', \phi')$, we have $r_{\mathscr{L},\phi} = r_{\mathscr{L}',\phi'}$. □

In particular, for $X = Y$:

Theorem (4.2.4). — *The set of Y-sections of $\mathbf{P}(\mathscr{E})$ is in canonical bijective correspondence with the set of quasi-coherent sub-$\mathscr{O}_Y$-modules $\mathscr{F}$ of $\mathscr{E}$ such that $\mathscr{E}/\mathscr{F}$ is invertible.*

We note that this property corresponds to the classical definition of "projective space" as the set of hyperplanes of a vector space (the classical case corresponding to $Y = \operatorname{Spec}(K)$, where K is a field, and $\mathscr{E} = \widetilde{E}$, where E is a finite-dimensional K-vector space; the $\mathscr{F}$ having the property described in (4.2.4) then correspond to the hyperplanes of E, and we already know that the Y-sections of $\mathbf{P}(\mathscr{E})$ are then the *K-rational points of* $\mathbf{P}(\mathscr{E})$ (**I**, 3.4.5)).

Remark (4.2.5). — Since there is a canonical bijective correspondence between Y-morphisms from X to P and their graph morphisms, X-sections of $P \times_Y X$ (**I**, 3.3.14), we see that, conversely, (4.2.3) can be deduced from (4.2.4). Denote by $\operatorname{Hyp}_Y(X, \mathscr{E})$ the set of quasi-coherent sub-$\mathscr{O}_X$-modules $\mathscr{F}$ of $\mathscr{E} \otimes_Y \mathscr{O}_X = q^*(\mathscr{E})$ such that $q^*(\mathscr{E})/\mathscr{F}$ is an invertible $\mathscr{O}_X$-module. If $g : X' \to X$ is a Y-morphism, then the right exactness of g^* gives

$$g^*(q^*(\mathscr{E})/\mathscr{F}) = g^* q^*(\mathscr{E})/g^*(\mathscr{F}),$$

so the latter sheaf is invertible. Thus $X \mapsto \operatorname{Hyp}_Y(X, \mathscr{E})$ is a *contravariant functor* on the category of Y-preschemes. We can therefore interpret theorem (4.2.4) as defining a *canonical isomorphism* between the functors $X \mapsto \operatorname{Hom}_Y(X, \mathbf{P}(\mathscr{E}))$ and $X \mapsto \operatorname{Hyp}_Y(X, \mathscr{E})$, both contravariant in X on the category of Y-preschemes. This also gives a characterisation of the projective bundle $P = \mathbf{P}(\mathscr{E})$ by the following *universal property*, which is much closer to the geometric intuition than the constructions from §§2–3: for every morphism $q : X \to Y$ and every invertible $\mathscr{O}_X$-module $\mathscr{L}$ that is a quotient of $\mathscr{E} \otimes_{\mathscr{O}_Y} \mathscr{O}_X$, there exists a unique Y-morphism $r : X \to P$ such that $\mathscr{L} = r^*(\mathscr{O}_P(1))$.

We will see later that we can similarly define, amongst other things, "Grassmannian" schemes.

Corollary (4.2.6). — *Suppose that every invertible $\mathscr{O}_Y$-module is trivial* (**I**, 2.4.8). *Let V be the group* $\mathrm{Hom}_{\mathscr{O}_Y}(\mathscr{E}, \mathscr{O}_Y)$, *considered as a module over the ring $A = \Gamma(Y, \mathscr{O}_Y)$, and let V^* be the subset of V consisting of surjective homomorphisms. Then the set of Y-sections of $\mathbf{P}(\mathscr{E})$ is canonically identified with V^*/A^*, where A^* is the group of units of A.*

In particular: **II** | 75

(1) The corollary (4.2.6) applies whenever Y is a *local scheme* (**I**, 2.4.8). Let Y be an arbitrary prescheme, y a point of Y, and $Y' = \mathrm{Spec}(k(y))$; then the fibre $p^{-1}(y)$ of $\mathbf{P}(\mathscr{E})$ can, by (4.1.3.1), be identified with $\mathbf{P}(\mathscr{E}^y)$, where $\mathscr{E}^y = \mathscr{E}_y \otimes_{\mathscr{O}_y} k(y) = \mathscr{E}_y/\mathfrak{m}_y\mathscr{E}_y$ is considered as a vector space over $k(y)$. More generally, if K is an extension of $k(y)$, then $p^{-1}(y) \otimes_{k(y)} K$ can be identified with $\mathbf{P}(\mathscr{E}^y \otimes_{k(y)} K)$. The corollary (4.2.6) then shows that the set of *geometric points of* $\mathbf{P}(\mathscr{E})$ *with values in the extension K of $k(y)$* (**I**, 3.4.5), which we can also call the *rational geometric fibre over K of $\mathbf{P}(\mathscr{E})$ over the point y*, can be identified with the *projective space* associated to the *dual* of the K-vector space $\mathscr{E}^y \otimes_{k(y)} K$.

(2) Suppose that Y is affine of ring A, and, further, that every invertible $\mathscr{O}_Y$-module is trivial; further, take $\mathscr{E} = \mathscr{O}_Y^n$; then, in (4.2.6), V can be identified with A^n (**I**, 1.3.8), and V^* with the set of systems $(f_i)_{1 \leqslant i \leqslant n}$ of elements of A that generate the ideal A; any two such systems define the same Y-section of $\mathbf{P}_Y^{n-1} = \mathbf{P}_A^{n-1}$, or, in other words, *the same point of $\mathbf{P}_A^{n-1}$ with values in A*, if and only if one of them can be obtained from the other by multiplication by an invertible element of A.

These properties justify the terminology "projective bundle" for $\mathbf{P}(\mathscr{E})$. We note that the definition of "projective space" obtained in this way is in fact *dual* to the classical definition; this is imposed upon us by the necessity of being able to define $\mathbf{P}(\mathscr{E})$ for *arbitrary* quasi-coherent $\mathscr{O}_Y$-modules $\mathscr{E}$, and not just locally free ones.

Remark (4.2.7). — We will see, in Chapter V, that, if Y is connected and locally Noetherian, and if $\mathscr{E}$ is locally free, then, letting $P = \mathbf{P}(\mathscr{E})$, every invertible $\mathscr{O}_P$-module is isomorphic to an $\mathscr{O}_P$-module of the form $\mathscr{L}' \otimes_{\mathscr{O}_Y} \mathscr{O}_P(m)$, with $\mathscr{L}'$ some invertible $\mathscr{O}_Y$-module, well defined up to isomorphism, and m some well defined integer. In other words, $\mathrm{H}^1(P, \mathscr{O}_P^*)$ is isomorphic to $\mathbf{Z} \times \mathrm{H}^1(Y, \mathscr{O}_Y^*)$ (**0**, 5.4.7). We will also see ((**III**, 2.1.14), taking (**0**, 5.4.10) into account) that $p_*(\mathscr{L}) = 0$ if $m < 0$, and $p_*(\mathscr{L})$ is isomorphic to $\mathscr{L}' \otimes_{\mathscr{O}_Y} (\mathbf{S}_{\mathscr{O}_Y}(\mathscr{E}))_m$ if $m \geqslant 0$. If $\mathscr{F}$ is a quasi-coherent $\mathscr{O}_Y$-module, then every Y-morphism $\mathbf{P}(\mathscr{E}) \to \mathbf{P}(\mathscr{F})$ is determined by the data of an invertible $\mathscr{O}_Y$-module, an integer $m \geqslant 0$, and an $\mathscr{O}_Y$-homomorphism $\psi : \mathscr{F} \to \mathscr{L}' \otimes_{\mathscr{O}_Y} (\mathbf{S}_{\mathscr{O}_Y}(\mathscr{E}))_m$ such that the corresponding homomorphism $\psi^\sharp$ of $\mathscr{O}_{\mathbf{P}(\mathscr{F})}$-modules is surjective. We will also see that, if the Y-morphism in question is an isomorphism, then $m = 1$ and $\mathscr{F}$ is isomorphic to $\mathscr{E} \otimes_{\mathscr{O}_Y} \mathscr{L}'$ (the converse of (4.1.4)). This will allow us to determine the sheaf of germs of automorphisms of $\mathbf{P}(\mathscr{E})$ as the quotient of the sheaf of groups $\mathscr{A}ut(\mathscr{E})$ (which is locally isomorphic to $\mathbf{GL}(n, \mathscr{O}_Y)$ if $\mathscr{E}$ is of rank n) by $\mathscr{O}_Y^*$.

(4.2.8). Keeping the notation of (4.2.1), let $u : X' \to X$ be a morphism; if the Y-morphism $r : X \to P$ corresponds to the homomorphism $\phi : q^*(\mathscr{E}) \to \mathscr{L}$, then the Y-morphism $r \circ u$ corresponds to $u^*(\phi) : u^*(q^*(\mathscr{E})) \to u^*(\mathscr{L})$, as follows immediately from the definitions.

(4.2.9). Let $\mathscr{E}$ and $\mathscr{F}$ be quasi-coherent $\mathscr{O}_Y$-modules, $v : \mathscr{E} \to \mathscr{F}$ a surjective homomorphism, and $j = \mathbf{P}(v)$ the corresponding closed immersion $\mathbf{P}(\mathscr{F}) \to \mathbf{P}(\mathscr{E})$ (4.1.2). If the Y-morphism $r : X \to \mathbf{P}(\mathscr{F})$ corresponds to the homomorphism $\phi : q^*(\mathscr{F}) \to \mathscr{L}$, then the Y-morphism $j \circ r$ **II** | 76
corresponds to $q^*(\mathscr{E}) \xrightarrow{q^*(v)} q^*(\mathscr{F}) \xrightarrow{\phi} \mathscr{L}$; this again follows from the definition given in (4.2.1).

(4.2.10). Let $\psi : Y' \to Y$ be a morphism, and let $\mathscr{E}' = \psi^*(\mathscr{E})$. If the Y-morphism $r : X \to P$ corresponds to the homomorphism $\phi : q^*(\mathscr{E}) \to \mathscr{L}$, then the Y'-morphism

$$r_{(Y')} : X_{(Y')} \longrightarrow P' = \mathbf{P}(\mathscr{E}')$$

corresponds to $\phi_{(Y')} : q^*_{(Y')}(\mathscr{E}') = q^*(\mathscr{E}) \otimes_Y \mathscr{O}_{Y'} \to \mathscr{L} \otimes_Y \mathscr{O}_{Y'}$. Indeed, by (4.1.3.1), we have the commutative diagram

$$\begin{tikzcd} Y' & P' = P_{(Y')} \arrow[l, "p_{(Y')}"'] \arrow[d, "u"] & X_{(Y')} \arrow[l, "r_{(Y')}"'] \arrow[d, "v"] \\ Y \arrow[u, leftarrow] & P \arrow[l, "p"] & X \arrow[l, "r"] \end{tikzcd}$$

From (4.1.3.2), we have

$$(r_{(Y')})^*(\mathscr{O}_{P'}(1)) = (r_{(Y')})^*(u^*(\mathscr{O}_P(1))) = v^*(r^*(\mathscr{O}_P(1))) = v^*(\mathscr{L}) = \mathscr{L} \otimes_Y \mathscr{O}_{Y'};$$

we also know that $u^*(\alpha_1^\sharp)$ is exactly the canonical homomorphism $\alpha_1^\sharp : (p_{(Y')})^*(\mathscr{E}') \to \mathscr{O}_{P'}(1)$; we can see this by explicitly calculating the canonical homomorphisms $\alpha_1^\sharp$ to P and P' as in (4.1.6). Whence our claim.

4.3. The Segre morphism

(4.3.1). Let Y be a prescheme, and $\mathscr{E}$ and $\mathscr{F}$ quasi-coherent $\mathscr{O}_Y$-modules; let $P_1 = \mathbf{P}(\mathscr{E})$ and $P_2 = \mathbf{P}(\mathscr{F})$, and denote the structure morphisms by $p_1 : P_1 \to Y$ and $p_2 : P_2 \to Y$. Let $Q = P_1 \times_Y P_2$, and let $q_1 : Q \to P_1$ and $q_2 : Q \to P_2$ be the canonical projections; then the $\mathscr{O}_Q$-module $\mathscr{L} = \mathscr{O}_{P_1}(1) \otimes_Y \mathscr{O}_{P_2}(1) = q_1^*(\mathscr{O}_{P_1}(1)) \otimes_{\mathscr{O}_Q} q_2^*(\mathscr{O}_{P_2}(1))$ is invertible, since it is the tensor product of two invertible $\mathscr{O}_Q$-modules (0, 5.4.4). Also, if $r = p_1 \circ q_1 = p_2 \circ q_2$ is the structure morphism $Q \to Y$, then $r^*(\mathscr{E} \otimes_{\mathscr{O}_Y} \mathscr{F}) = q_1^*(p_1^*(\mathscr{E})) \otimes_{\mathscr{O}_Q} q_2^*(p_2^*(\mathscr{F}))$ (**0**, 4.3.3); the canonical surjective homomorphisms (4.1.5.1) $p_1^*(\mathscr{E}) \to \mathscr{O}_{P_1}(1)$ and $p_2^*(\mathscr{F}) \to \mathscr{O}_{P_2}(1)$ thus give, by taking the tensor product, a canonical homomorphism

$$s : r^*(\mathscr{E} \otimes_{\mathscr{O}_Y} \mathscr{F}) \longrightarrow \mathscr{L} \tag{4.3.1.1}$$

which is evidently surjective; from this we obtain (4.2.2) a canonical morphism, called the *Segre morphism*:

$$\varsigma : \mathbf{P}(\mathscr{E}) \times_Y \mathbf{P}(\mathscr{F}) \longrightarrow \mathbf{P}(\mathscr{E} \otimes_{\mathscr{O}_Y} \mathscr{F}). \tag{4.3.1.2}$$

We can study the morphism ς more explicitly in the case where $Y = \operatorname{Spec}(A)$ is affine, and $\mathscr{E} = \widetilde{E}$ and $\mathscr{F} = \widetilde{F}$, where E and F are A-modules, whence $\mathscr{E} \otimes_{\mathscr{O}_Y} \mathscr{F} = (E \otimes_A F)^\sim$ (**I**, 1.3.12); let $R = \mathbf{S}_A(E)$, $S = \mathbf{S}_A(F)$, and $T = \mathbf{S}_A(E \otimes_A F)$; let $f \in E$ and $g \in F$, and consider the affine open

$$D_+(f) \times_Y D_+(g) = \operatorname{Spec}(B)$$

of Q, where $B = R_{(f)} \otimes_A S_{(g)}$; the restriction of $\mathscr{L}$ to this affine open is $\widetilde{L}$, where **II** | 77

$$L = (R(1))_{(f)} \otimes_A (S(1))_{(g)}$$

and the element $c = (f/1) \otimes (g/1)$ is a generator of L considered as a free B-module (2.5.7). The homomorphism (4.3.1.1) corresponds to the homomorphism

$$(x \otimes y) \otimes b \longmapsto b((x/1) \otimes (y/1))$$

from $(E \otimes_A F) \otimes_A B$ to L. With the notation of (3.7.2), we thus have that $v_1(x \otimes y) = (x/f) \otimes (y/g)$; the restriction of ς to $D_+(f) \times_Y D_+(g)$ is a morphism from this affine scheme to $D_+(f \otimes g)$, corresponding to the ring homomorphism $\omega : T_{(f \otimes g)} \to R_{(f)} \otimes_A S_{(g)}$ defined by

$$\omega((x \otimes y)/(f \otimes g)) = (x/f) \otimes (y/g) \tag{4.3.1.3}$$

for $x \in E$ and $y \in F$.

(4.3.2). It follows from (4.2.3) that we have a canonical isomorphism

$$\tau : \varsigma^*(\mathscr{O}_P(1)) \xrightarrow{\sim} \mathscr{O}_{P_1}(1) \otimes_Y \mathscr{O}_{P_2}(1) \tag{4.3.2.1}$$

where we let $P = \mathbf{P}(\mathscr{E} \otimes_{\mathscr{O}_Y} \mathscr{F})$. We will show that, for $x \in \Gamma(Y, \mathscr{E})$ and $y \in \Gamma(Y, \mathscr{F})$, we have

$$\tau(\alpha_1(x \otimes y)) = \alpha_1(x) \otimes \alpha_1(y). \tag{4.3.2.2}$$

Indeed, we can restrict to the case where Y is affine, and we then have, with the notation of (4.3.1) and (2.6.2), that $\alpha_1^{f \otimes g}(x \otimes y) = (x \otimes y)/1$ in $(T(1))_{(f \otimes g)}$, that $\alpha_1^f(x) = x/1$ in $(R(1))_{(f)}$, and that

$\alpha_1^g(y) = y/1$ in $(S(1))_{(g)}$. The definition of τ given in (4.2.3) and the calculation of v_1 done in (4.3.1) then immediately prove the claim (4.3.2.2). From this we obtain the equation

$$\varsigma^{-1}(P_{x\otimes y}) = (P_1)_x \times_Y (P_2)_y \tag{4.3.2.3}$$

with the notation of (3.1.4). Indeed, taking (3.3.3) into account, the equation (4.3.2.2) (by restricting to the affine case, with the help of (I, 3.2.7) and (I, 3.2.3)) leaves us only to prove the following lemma:

Lemma (4.3.2.4). — *Let B and B' be A-algebras, and let $Y = \operatorname{Spec}(A)$, $Z = \operatorname{Spec}(B)$, and $Z' = \operatorname{Spec}(B')$; then $D(t \otimes t') = D(t) \times_Y D(t')$ for any $t \in B$, $t' \in B'$.*

Proof. Indeed, if $p : Z \times_Y Z' \to Z$ and $p' : Z \times_Y Z' \to Z'$ are the canonical projections, then it follows from (I, 1.2.2.2) that $p^{-1}(D(t)) = D(t \otimes 1)$ and $p'^{-1}(D(t')) = D(1 \otimes t')$; the conclusion follows from (I, 3.2.7) and (I, 1.1.9.1), since $(t \otimes 1)(1 \otimes t') = t \otimes t'$. □

Proposition (4.3.3). — *The Segre morphism is a closed immersion.*

Proof. Since the question is local on Y, we can restrict to the case where Y is affine. With the notation of (4.3.1) and (4.3.2), the $D_+(f \otimes g)$ then form a basis for the topology of P, since the $f \otimes g$ generate T when f runs over E and g runs over F. By (4.3.2.3), we also know that $\varsigma^{-1}(D_+(f \otimes g)) = D_+(f) \times_Y D_+(g)$. It thus suffices (I, 4.2.4) to prove that the restriction of ς to $D_+(f) \times_Y D_+(g)$ is a closed immersion into $D_+(f \otimes g)$. But, with the same notation, the equation (4.3.1.3) shows that ω is *surjective*, which completes the proof. □

(4.3.4). The Segre morphism is *functorial* in $\mathscr{E}$ and $\mathscr{F}$, if we consider only *surjective* homomorphisms of quasi-coherent $\mathscr{O}_Y$-modules. Indeed, we must then show that, if $\mathscr{E} \to \mathscr{E}'$ is a surjective $\mathscr{O}_Y$-homomorphism, then the diagram II | 78

$$\begin{tikzcd} \mathbf{P}(\mathscr{E}') \times_Y \mathbf{P}(\mathscr{F}) \arrow[r, "j\times 1"] \arrow[d, "\varsigma"'] & \mathbf{P}(\mathscr{E}) \times_Y \mathbf{P}(\mathscr{F}) \arrow[d, "\varsigma"] \\ \mathbf{P}(\mathscr{E}' \otimes_{\mathscr{O}_Y} \mathscr{F}) \arrow[r] & \mathbf{P}(\mathscr{E} \otimes_{\mathscr{O}_Y} \mathscr{F}) \end{tikzcd}$$

commutes, where j denotes the canonical closed immersion $\mathbf{P}(\mathscr{E}') \to \mathbf{P}(\mathscr{E})$. Let $P_1' = \mathbf{P}(\mathscr{E}')$ and keep the notation from (4.3.1); then $j \times 1$ is a closed immersion (I, 4.3.1) and, up to isomorphism,

$$(j\times 1)^*(\mathscr{O}_{P_1}(1) \otimes \mathscr{O}_{P_2}(1)) = j^*(\mathscr{O}_{P_1}(1)) \otimes \mathscr{O}_{P_2}(1) = \mathscr{O}_{P_1'}(1) \otimes \mathscr{O}_{P_2}(1)$$

by (4.1.2.1) and (I, 9.1.5); our claim then follows from (4.2.8) and (4.2.9).

(4.3.5). With the notation of (4.3.1), let $\psi : Y' \to Y$ be a morphism, and let $\mathscr{E}' = \psi^*(\mathscr{E})$ and $\mathscr{F}' = \psi^*(\mathscr{F})$; then the Segre morphism $\mathbf{P}(\mathscr{E}') \times \mathbf{P}(\mathscr{F}') \to \mathbf{P}(\mathscr{E}' \otimes \mathscr{F}')$ can be identified with $\varsigma_{(Y')}$. Indeed, keeping the notation of (4.3.1), let $P_1' = \mathbf{P}(\mathscr{E}')$ and $P_2' = \mathbf{P}(\mathscr{F}')$; we know (4.1.3.1) that P_i' can be identified with $(P_i)_{(Y')}$ $(i = 1, 2)$, and so the structure morphism $P_1' \times P_2' \to Y'$ can be identified with $r_{(Y')}$. Also $\mathscr{E}' \otimes \mathscr{F}'$ can be identified with $\psi^*(\mathscr{E} \otimes \mathscr{F})$, and so $\mathbf{P}(\mathscr{E}' \otimes \mathscr{F}')$ can be identified with $(\mathbf{P}(\mathscr{E} \otimes \mathscr{F}))_{(Y')}$ (4.1.3.1). Finally, $\mathscr{O}_{P_1'}(1) \otimes_{Y'} \mathscr{O}_{P_2'}(1) = \mathscr{L}'$ can be identified with $\mathscr{L} \otimes_Y \mathscr{O}_{Y'}$, by (4.1.3.2) and (I, 9.1.11). The canonical homomorphism $(r_{(Y')})^*(\mathscr{E}' \otimes \mathscr{F}') \to \mathscr{L}'$ can then be identified with $s_{(Y')}$, and our claim follows from (4.2.10).

Remark (4.3.6). — The prescheme given by the *sum* of $\mathbf{P}(\mathscr{E})$ and $\mathbf{P}(\mathscr{F})$ is likewise canonically isomorphic to a *closed subprescheme of* $\mathbf{P}(\mathscr{E} \oplus \mathscr{F})$. Indeed, the surjective homomorphisms $\mathscr{E} \oplus \mathscr{F} \to \mathscr{E}$ and $\mathscr{E} \oplus \mathscr{F} \to \mathscr{F}$ correspond to closed immersions $\mathbf{P}(\mathscr{E}) \to \mathbf{P}(\mathscr{E} \oplus \mathscr{F})$ and $\mathbf{P}(\mathscr{F}) \to \mathbf{P}(\mathscr{E} \oplus \mathscr{F})$; everything then reduces to showing that the underlying spaces of the closed subpreschemes of $\mathbf{P}(\mathscr{E} \oplus \mathscr{F})$ obtained in this way have empty intersection. Since the question is local on Y, we can adopt the notation of (4.3.1); but $\mathbf{S}_n(E)$ and $\mathbf{S}_n(F)$ can be identified with submodules of $\mathbf{S}_n(E \oplus F)$ with intersection consisting only of 0; if $\mathfrak{p}$ is a graded prime ideal of $\mathbf{S}(E)$ such that $\mathfrak{p} \cap \mathbf{S}_n(E) \neq \mathbf{S}_n(E)$ for any $n \geqslant 0$, then there exists a corresponding graded prime ideal of $\mathbf{S}(E \oplus F)$ whose intersection with $\mathbf{S}_n(E)$ is $\mathfrak{p} \cap \mathbf{S}_n(E)$, but which also *contains* $\mathbf{S}_+(F)$, as we immediately see; thus no point in $\operatorname{Proj}(\mathbf{S}(E))$ can have the same image in $\operatorname{Proj}(\mathbf{S}(E \oplus F))$ as any point in $\operatorname{Proj}(\mathbf{S}(F))$.

4.4. Immersions into projective bundles; very ample sheaves

Proposition (4.4.1). — *Let Y be a quasi-compact scheme, or a prescheme whose underlying space is Noetherian, $q : X \to Y$ a morphism* of finite type, *and $\mathscr{L}$ an invertible $\mathscr{O}_X$-module.*

(i) *Let $\mathscr{S}$ be a quasi-coherent positively-graded $\mathscr{O}_Y$-algebra, and $\psi : q^*(\mathscr{S}) \to \bigoplus_{n\geqslant 0} \mathscr{L}^{\otimes n}$ a homomorphism of graded algebras. For $r_{\mathscr{L},\psi}$ to be everywhere defined and an immersion, it is necessary and sufficient for there to exist an integer $n \geqslant 0$ and a quasi-coherent sub-$\mathscr{O}_Y$-module* of finite type *$\mathscr{E}$ of* II | 79 *$\mathscr{S}_n$ such that the homomorphism $\psi' = \psi_n \circ q^*(j) : q^*(\mathscr{E}) \to \mathscr{L}^{\otimes n} = \mathscr{L}'$ (where j is the injection $\mathscr{E} \to \mathscr{S}_n$) is surjective and such that the morphism $r_{\mathscr{L}',\psi'} : X \to \mathbf{P}(\mathscr{E})$ is an immersion.*

(ii) *Let $\mathscr{F}$ be a quasi-coherent $\mathscr{O}_Y$-module, and $\phi : q^*(\mathscr{F}) \to \mathscr{L}$ a surjective homomorphism. For the morphism $r_{\mathscr{L},\phi}$ to be an immersion $X \to \mathbf{P}(\mathscr{F})$, it is necessary and sufficient for there to exist a quasi-coherent sub-$\mathscr{O}_Y$-module* of finite type *$\mathscr{E}$ of $\mathscr{F}$ such that the homomorphism $\phi' = \phi \circ q^*(j) : q^*(\mathscr{E}) \to \mathscr{L}$ (where j is the canonical injection $\mathscr{E} \to \mathscr{F}$) is surjective and such that the morphism $r_{\mathscr{L},\phi'} : X \to \mathbf{P}(\mathscr{E})$ is an immersion.*

Proof.

(i) The fact that $r_{\mathscr{L},\psi}$ is everywhere defined and is an immersion is equivalent, by (3.8.5), to the existence of some $n \geqslant 0$ and $\mathscr{E}$ such that, if $\mathscr{S}'$ is the subalgebra of $\mathscr{S}$ generated by $\mathscr{E}$, the homomorphism $q^*(\mathscr{E}) \to \mathscr{L}^{\otimes n}$ is surjective and the morphism $r_{\mathscr{L}',\psi'} : X \to \operatorname{Proj}(\mathscr{S}')$ is everywhere defined and is an immersion. We already have a canonical surjective homomorphism $\mathbf{S}(\mathscr{E}) \to \mathscr{S}'$ to which there exists a corresponding closed immersion $\operatorname{Proj}(\mathscr{S}') \to \mathbf{P}(\mathscr{E})$ (3.6.2); whence the conclusion.

(ii) Since $\mathscr{F}$ is the inductive limit of its quasi-coherent submodules of finite type $\mathscr{E}_\lambda$ (**I**, 9.4.9), $\mathbf{S}(\mathscr{F})$ is the inductive limit of the $\mathbf{S}(\mathscr{E}_\lambda)$; the conclusion then follows from (3.8.4), by observing that we can take all the n_i in the proof of (3.8.4) to be equal to 1: indeed, supposing that Y is affine, if $r = r_{\mathscr{L},\phi}$ is an immersion, then $r(X)$ is a quasi-compact subspace of $\mathbf{P}(\mathscr{F})$ that we can cover by finitely many open subsets of $\mathbf{P}(\mathscr{F})$ of the form $D_+(f)$, with $f \in F$, such that $D_+(f) \cap r(X)$ is closed.

□

Definition (4.4.2). — Let Y be a prescheme, and $q : X \to Y$ a morphism. We say that an invertible $\mathscr{O}_X$-module $\mathscr{L}$ is *very ample relative to q* (or *relative to Y*, or simply *very ample*, if q is clear from the context) if there exists a quasi-coherent $\mathscr{O}_Y$-module $\mathscr{E}$ and a Y-immersion $i : X \to P = \mathbf{P}(\mathscr{E})$ such that $\mathscr{L}$ is isomorphic to $i^*(\mathscr{O}_P(1))$.

It is equivalent (4.2.3) to say that there exists a quasi-coherent $\mathscr{O}_Y$-module $\mathscr{E}$ and a *surjective* homomorphism $\phi : q^*(\mathscr{E}) \to \mathscr{L}$ such that $r_{\mathscr{L},\phi} : X \to \mathbf{P}(\mathscr{E})$ is an *immersion*.

We note that the existence of a very ample (for Y) $\mathscr{O}_X$-module implies that q is *separated* ((3.1.3) and (**I**, 5.5.1, (i) and (ii))).

Corollary (4.4.3). — *Suppose that there exists a quasi-coherent graded $\mathscr{O}_Y$-algebra $\mathscr{S}$, generated by $\mathscr{S}_1$, and a Y-immersion $i : X \to P = \operatorname{Proj}(\mathscr{S})$ such that $\mathscr{L}$ is isomorphic to $i^*(\mathscr{O}_P(1))$; then $\mathscr{L}$ is very ample relative to q.*

Proof. If $\mathscr{F} = \mathscr{S}_1$, then the canonical homomorphism $\mathbf{S}(\mathscr{F}) \to \mathscr{S}$ is surjective, and so, by composing the corresponding closed immersion $\operatorname{Proj}(\mathscr{S}) \to \mathbf{P}(\mathscr{F})$ (3.6.2) with the immersion i, we obtain an immersion $j : X \to \mathbf{P}(\mathscr{F}) = P'$ such that $\mathscr{L}$ is isomorphic to $j^*(\mathscr{O}_{P'}(1))$ (3.6.3). □

Proposition (4.4.4). — *Let $q : X \to Y$ be a quasi-compact morphism, and $\mathscr{L}$ an invertible $\mathscr{O}_X$-module. Then the following properties are equivalent:*

(a) *$\mathscr{L}$ is very ample relative to q.*

(b) *$q_*(\mathscr{L})$ is quasi-coherent, the canonical homomorphism $\sigma : q^*(q_*(\mathscr{L})) \to \mathscr{L}$ is surjective, and the morphism $r_{\mathscr{L},\sigma} : X \to \mathbf{P}(q_*(\mathscr{L}))$ is an immersion.*

Proof. Since q is quasi-compact, we know that $q_*(\mathscr{L})$ is quasi-coherent if q is separated (**I**, 9.2.2).

II | 80

We know (3.4.7) that the existence of a surjective homomorphism $\phi : q^*(\mathscr{E}) \to \mathscr{L}$ (with $\mathscr{E}$ a quasi-coherent $\mathscr{O}_Y$-module) implies that σ is surjective; furthermore, given the factorisation $q^*(\mathscr{E}) \to q^*(q_*(\mathscr{L})) \xrightarrow{\sigma} \mathscr{L}$ of ϕ, there is a canonically corresponding factorisation

$$q^*(\mathbf{S}(\mathscr{E})) \longrightarrow q^*(\mathbf{S}(q_*(\mathscr{L}))) \longrightarrow \bigoplus_{n\geqslant 0} \mathscr{L}^{\otimes n}$$

and therefore, by (3.8.3), the hypothesis that $r_{\mathscr{L},\phi}$ is an immersion implies that so too is $j = r_{\mathscr{L},\sigma}$; furthermore, by (4.2.4), $\mathscr{L}$ is isomorphic to $j^*(\mathscr{O}_{P'}(1))$, where $P' = \mathbf{P}(q_*(\mathscr{L}))$. We thus see that (a) and (b) are equivalent. □

Corollary (4.4.5). — *Suppose that q is quasi-compact. For $\mathscr{L}$ to be very ample relative to Y, it is necessary and sufficient for there to exist an open cover (U_α) of Y such that $\mathscr{L}|q^{-1}(U_\alpha)$ is very ample relative to U_α for every α.*

Proof. Indeed, condition (b) of (4.4.4) is local on Y. □

Proposition (4.4.6). — *Let Y be a quasi-compact scheme, or a prescheme whose underlying space is Noetherian, $q : X \to Y$ a morphism* of finite type*, and $\mathscr{L}$ an invertible $\mathscr{O}_X$-module. Then conditions (a) and (b) of (4.4.4) are equivalent to the following:*

- (a′) *There exists a quasi-coherent $\mathscr{O}_Y$-module $\mathscr{E}$* of finite type *and a surjective homomorphism ϕ : $q^*(\mathscr{E}) \to \mathscr{L}$ such that $r_{\mathscr{L},\phi}$ is an immersion.*
- (b′) *There exists a coherent sub-$\mathscr{O}_Y$-module $\mathscr{E}$ of $q_*(\mathscr{L})$* of finite type *that has the properties stated in condition (a′).*

Proof. It is clear that (a′) or (b′) imply (a); also (a) implies (a′), by (4.4.1), and similarly (b) implies (b′). □

Corollary (4.4.7). — *Suppose that Y is a quasi-compact scheme, or a Noetherian prescheme. If $\mathscr{L}$ is very ample for q, then there exists a quasi-coherent graded $\mathscr{O}_Y$-algebra $\mathscr{S}$ such that $\mathscr{S}_1$ is of finite type and generates $\mathscr{S}$, and also a* dominant open *Y-immersion $i : X \to P = \operatorname{Proj}(\mathscr{S})$ such that $\mathscr{L}$ is isomorphic to $i^*(\mathscr{O}_P(1))$.*

Proof. Indeed, condition (b′) of (4.4.6) is satisfied; the structure morphism $p : \mathbf{P}(\mathscr{E}) = P' \to Y$ is then separated and of finite type (3.1.3), and so P' is a quasi-compact scheme (resp. a Noetherian prescheme) if Y is a quasi-compact scheme (resp. a Noetherian prescheme). Let Z be the closure (**I**, 9.5.11) of the subprescheme X' of P' associated to the immersion $j = r_{\mathscr{L},\phi}$ from X into P'; it is clear that j factors as a dominant open immersion $i : X \to Z$ followed by the canonical injection $Z \to P'$. But Z can be identified with a prescheme $\operatorname{Proj}(\mathscr{S})$, where $\mathscr{S}$ is a graded $\mathscr{O}_Y$-algebra equal to the quotient of $\mathbf{S}(\mathscr{E})$ by a quasi-coherent graded sheaf of ideals (3.6.2), and it is clear that $\mathscr{S}_1$ is of finite type and generates $\mathscr{S}$; furthermore, $\mathscr{O}_Z(1)$ is the inverse image of $\mathscr{O}_{P'}(1)$ by the canonical injection (3.6.3), and so $\mathscr{L} = i^*(\mathscr{O}_Z(1))$. □

Proposition (4.4.8). — *Let $q : X \to Y$ be a morphism, $\mathscr{L}$ a very ample (relative to q) $\mathscr{O}_X$-module, and $\mathscr{L}'$ an invertible $\mathscr{O}_X$-module, such that there exists a quasi-coherent $\mathscr{O}_Y$-module $\mathscr{E}'$ and a surjective homomorphism $q^*(\mathscr{E}') \to \mathscr{L}'$. Then $\mathscr{L} \otimes_{\mathscr{O}_X} \mathscr{L}'$ is very ample relative to q.*

Proof. The hypothesis implies the existence of a Y-morphism $r' : X \to P' = \mathbf{P}(\mathscr{E}')$ such that $\mathscr{L}' = r'^*(\mathscr{O}_{P'}(1))$ (4.2.1). There is, by hypothesis, a quasi-coherent $\mathscr{O}_Y$-module $\mathscr{E}$ and a Y-immersion **II | 81**
$r : X \to P = \mathbf{P}(\mathscr{E})$ such that $\mathscr{L} = r^*(\mathscr{O}_P(1))$. Let $Q = \mathbf{P}(\mathscr{E} \otimes \mathscr{E}')$, and consider the Segre morphism $\varsigma : P \times_Y P' \to Q$ (4.3.1). Since r is an immersion, so too is $(r, r')_Y : X \to P \times_Y P'$ (**I**, 5.3.14); but since ς is an immersion (4.3.3), so too is $r'' : X \xrightarrow{(r,r')} P \times_Y P' \xrightarrow{\varsigma} Q$. But also (4.3.2.1) $\varsigma(\mathscr{O}_Q(1))$ is isomorphic to $\mathscr{O}_P(1) \otimes_Y \mathscr{O}_{P'}(1)$, and so (**I**, 9.1.4) $r''^*(\mathscr{O}_Q(1))$ is isomorphic to $\mathscr{L} \otimes \mathscr{L}'$, which proves the proposition. □

Corollary (4.4.9). — *Let $q : X \to Y$ be a morphism.*

1. *Let $\mathscr{L}$ be an invertible $\mathscr{O}_X$-module, and $\mathscr{K}$ an invertible $\mathscr{O}_Y$-module. For $\mathscr{L}$ to be very ample relative to q, it is necessary and sufficient for $\mathscr{L} \otimes q^*(\mathscr{K})$ to be so.*
2. *If $\mathscr{L}$ and $\mathscr{L}'$ are very ample (relative to q) $\mathscr{O}_X$-modules, then so too is $\mathscr{L} \otimes \mathscr{L}'$; in particular, $\mathscr{L}^{\otimes n}$ is very ample relative to q for all $n > 0$.*

Proof. Claim (ii) is an immediate consequence of (4.4.8), as well as the necessity of condition (i); conversely, if $\mathscr{L} \otimes q^*(\mathscr{K})$ is very ample, then so too is $(\mathscr{L} \otimes q^*(\mathscr{K})) \otimes q^*(\mathscr{K}^{-1})$, by the above, and the latter $\mathscr{O}_X$-module is isomorphic to $\mathscr{L}$ ((**0**, 5.4.3) and (**0**, 5.4.5)). ☐

Proposition (4.4.10). —

(i) *For every prescheme Y, every invertible $\mathscr{O}_Y$-module $\mathscr{L}$ is very ample relative to the identity morphism 1_Y.*

(i *bis*) *Let $f : X \to Y$ be a morphism, and $j : X' \to X$ an immersion. If $\mathscr{L}$ is a very ample (relative to f) $\mathscr{O}_X$-module, then $j^*(\mathscr{L})$ is very ample relative to $f \circ j$.*

(ii) *Let Z be a quasi-compact prescheme, $f : X \to Y$ a morphism of finite type, $g : Y \to Z$ a quasi-compact morphism, $\mathscr{L}$ a very ample (relative to f) $\mathscr{O}_X$-module, and $\mathscr{K}$ a very ample (relative to g) $\mathscr{O}_Y$-module. Then there exists some integer $n_0 > 0$ such that $\mathscr{L} \otimes f^*(\mathscr{K}^{\otimes n})$ is very ample relative to $g \circ f$ for all $n \geqslant n_0$.*

(iii) *Let $f : X \to Y$ and $g : Y' \to Y$ be morphisms, and let $X' = X_{(Y')}$. If $\mathscr{L}$ is a very ample (relative to f) $\mathscr{O}_X$-module, then $\mathscr{L}' = \mathscr{L} \otimes_Y \mathscr{O}_{Y'}$ is a very ample (relative to $f_{(Y')}$) $\mathscr{O}_{X'}$-module.*

(iv) *Let $f_i : X_i \to Y_i$ ($i = 1, 2$) be S-morphisms. If $\mathscr{L}_i$ is a very ample (relative to f_i) $\mathscr{O}_{X_i}$-module ($i = 1, 2$), then $\mathscr{L}_1 \otimes_S \mathscr{L}_2$ is very ample relative to $f_1 \times_S f_2$.*

(v) *Let $f : X \to Y$ and $g : Y \to Z$ be morphisms. If an $\mathscr{O}_X$-module $\mathscr{L}$ is very ample relative to $g \circ f$, then it is also very ample relative to f.*

(vi) *Let $f : X \to Y$ be a morphism, and j the canonical injection $X_{\mathrm{red}} \to X$. If an $\mathscr{O}_X$-module $\mathscr{L}$ is very ample relative to f, then $j^*(\mathscr{L})$ is very ample relative to f_{red}.*

Proof. Property (i *bis*) follows immediately from the definition (4.4.2), and it is immediate that (vi) follows formally from (i *bis*) and (v), by an argument copied from the proof of (**I**, 5.5.12), which we leave to the reader. To prove (v), we consider, as in (**I**, 5.5.12), the factorisation $X \xrightarrow{\Gamma_f} X \times_Z Y \xrightarrow{p_2} Y$, where $p_2 = (g \circ f) \times 1_Y$. It follows from the hypothesis and from (i) and (iv) that $\mathscr{L} \otimes_{\mathscr{O}_Z} \mathscr{O}_Y$ is very ample for p_2; but also $\mathscr{L} = \Gamma_f^*(\mathscr{L} \otimes_{\mathscr{O}_Z} \mathscr{O}_Y)$ (**I**, 9.1.4), and Γ_f is an immersion (**I**, 5.3.11); we can thus apply (i *bis*).

To prove (i), we apply the definition (4.4.2) with $\mathscr{E} = \mathscr{L}$, and note that then $\mathbf{P}(\mathscr{E})$ can be identified with Y (4.1.4). **II** | 82

Now we prove (iii). There exists a quasi-coherent $\mathscr{O}_Y$-module $\mathscr{E}$ and a Y-immersion $i : X \to \mathbf{P}(\mathscr{E}) = P$ such that $\mathscr{L} = i^*(\mathscr{O}_P(1))$; if we let $\mathscr{E}' = g^*(\mathscr{E})$, then $\mathscr{E}'$ is a quasi-coherent $\mathscr{O}_{Y'}$-module, and we have that $P' = \mathbf{P}(\mathscr{E}') = P_{(Y')}$ (4.1.3.1), that $i_{(Y')}$ is an immersion from $X_{(Y')}$ into P' (**I**, 4.3.2), and that $\mathscr{L}'$ is isomorphic to $(i_{(Y')})^*(\mathscr{O}_{P'}(1))$ (4.2.10).

To prove (iv), note that there is, by hypothesis, a Y_i-immersion $r_i : X_i \to P_i = \mathbf{P}(\mathscr{E}_i)$, where $\mathscr{E}_i$ is a quasi-coherent $\mathscr{O}_{Y_i}$-module, and $\mathscr{L}_i = r_i^*(\mathscr{O}_{P_i}(1))$ ($i = 1, 2$); $r_1 \times_S r_2$ is an S-immersion of $X_1 \times_S X_2$ into $P_1 \times_S P_2$ (**I**, 4.3.1), and the inverse image of $\mathscr{O}_{P_1}(1) \otimes_S \mathscr{O}_{P_2}(1)$ under this immersion is $\mathscr{L}_1 \otimes_S \mathscr{L}_2$. Now let $T = Y_1 \times_S Y_2$, and let p_1 and p_2 be the projections from T to Y_1 and Y_2, respectively. If we let $P_i' = \mathbf{P}(p_i^*(\mathscr{E}_i))$ ($i = 1, 2$), then $P_i' = P_i \times_{Y_i} T$, by (4.1.3.1), and so

$$P_1' \times_T P_2' = (P_1 \times_{Y_1} T) \times_T (P_2 \times_{Y_2} T) = P_1 \times_{Y_1} (T \times_{Y_2} P_2) = P_1 \times_{Y_1} (Y_1 \times_S P_2) = P_1 \times_S P_2$$

up to canonical isomorphism. Similarly, $\mathscr{O}_{P_i'}(1) = \mathscr{O}_{P_i}(1) \otimes_{Y_i} \mathscr{O}_T$ (4.1.3.2), and an analogous calculation (based in particular on (**I**, 9.1.9.1) and (**I**, 9.1.2)) shows that, in the above identification, $\mathscr{O}_{P_1'}(1) \otimes_T \mathscr{O}_{P_2'}(1)$ can be identified with $\mathscr{O}_{P_1}(1) \otimes_S \mathscr{O}_{P_2}(1)$. We can thus consider $r_1 \times_S r_2$ as a T-immersion from $X_1 \times_S X_2$ into $P_1' \times_T P_2'$, with the inverse image of $\mathscr{O}_{P_1'}(1) \otimes_T \mathscr{O}_{P_2'}(1)$ under this immersion being $\mathscr{L}_1 \otimes_S \mathscr{L}_2$. We then finish the argument as in (4.4.8) by using the Segre morphism.

It remains only to prove (ii). We can first of all restrict to the case where Z is an affine scheme, since, in general, there exists a finite cover (U_i) of Z by affine opens; if the proposition were proven for $\mathscr{K}|g^{-1}(U_i)$, $\mathscr{L}|f^{-1}(g^{-1}(U_i))$, and an integer n_i, then it would suffice to take n_0 to be the largest of the n_i to prove the proposition for $\mathscr{K}$ and $\mathscr{L}$ (4.4.5). The hypothesis implies that f and g are separated morphisms, and so X and Y are quasi-compact *schemes*.

There is an immersion $r : X \to P = \mathbf{P}(\mathscr{E})$, where $\mathscr{E}$ is a quasi-coherent $\mathscr{O}_Y$-module *of finite type*, and $\mathscr{L} = r^*(\mathscr{O}_P(1))$, by (4.4.6). We will see that there exists a very ample (relative to the composed morphism $P \xrightarrow{h} Y \xrightarrow{g} Z$) $\mathscr{O}_P$-module $\mathscr{M}$ such that $\mathscr{O}_P(1)$ is isomorphic to $\mathscr{M} \otimes_Y \mathscr{K}^{\otimes(-m)}$ for some integer m. For $n \geqslant m+1$, $\mathscr{O}_P(1) \otimes_Y \mathscr{K}^{\otimes n}$ will then be very ample for Z, by hypothesis and by (iv) applied to the morphisms $h : P \to Y$ and 1_Y; since r is an immersion and $\mathscr{L} \otimes f^*(\mathscr{K}^{\otimes n}) = r^*(\mathscr{O}_P(1) \otimes_Y \mathscr{K}^{\otimes n})$, the conclusion will then follow from (i *bis*). To prove our claim concerning $\mathscr{O}_P(1)$, we will use the following lemma:

Lemma (4.4.10.1). — *Let Z be a quasi-compact scheme, or a prescheme whose underlying space is Noetherian, and let $g : Y \to Z$ be a quasi-compact morphism, $\mathscr{K}$ a very ample (with respect to g) invertible $\mathscr{O}_Y$-module, and $\mathscr{E}$ a quasi-coherent $\mathscr{O}_Y$-module of finite type. Then there exists an integer m_0 such that, for all $m \geqslant m_0$, $\mathscr{E}$ is isomorphic to a quotient of an $\mathscr{O}_Y$-module of the form $g^*(\mathscr{F}) \otimes \mathscr{K}^{\otimes(-m)}$, where $\mathscr{F}$ is a quasi-coherent $\mathscr{O}_Z$-module of finite type (depending on m).*

This lemma will be proven in (4.5.10.1); the reader can verify that (4.4.10) is not used anywhere in (4.5).

Assuming this lemma, there exists a closed immersion j_1 from P to II | 83

$$P_1 = \mathbf{P}(g^*(\mathscr{F}) \otimes \mathscr{K}^{\otimes(-m)})$$

such that $\mathscr{O}_P(1)$ is isomorphic to $j_1^*(\mathscr{O}_{P_1}(1))$ (4.1.2). Now, there exists an isomorphism from P_1 to $P_2 = \mathbf{P}(g^*(\mathscr{F}))$, sending $\mathscr{O}_{P_2}(1) \otimes_Y \mathscr{K}^{\otimes(-m)}$ to $\mathscr{O}_{P_1}(1)$ (4.1.4); we thus have a closed immersion $j_2 : P \to P_2$ such that $\mathscr{O}_P(1)$ is isomorphic to $j_2^*(\mathscr{O}_{P_2}(1)) \otimes_Y \mathscr{K}^{\otimes(-m)}$. Finally, P_2 can be identified with $P_3 \times_Z Y$, where $P_3 = \mathbf{P}(\mathscr{F})$, and $\mathscr{O}_{P_2}(1)$ with $\mathscr{O}_{P_3}(1) \otimes_Z \mathscr{O}_Y$ (4.1.3). By definition, $\mathscr{O}_{P_3}(1)$ is very ample for Z; since so too is $\mathscr{K}$, we conclude, from (iv), that $\mathscr{O}_{P_2}(1) \otimes_Y \mathscr{K}$ is very ample for Z; so too is $\mathscr{M} = j_2^*(\mathscr{O}_{P_2}(1) \otimes_Y \mathscr{K})$ by (i *bis*), and $\mathscr{O}_P(1)$ is isomorphic to $\mathscr{M} \otimes_Y \mathscr{K}^{\otimes(-m-1)}$, which finishes the proof. □

Proposition (4.4.11). — *Let $f : X \to Y$ and $f' : X' \to Y$ be morphisms, X'' the sum prescheme $X \sqcup X'$, and f'' the morphism $X'' \to Y$ that agrees with f (resp. f') on X (resp. X'). Let $\mathscr{L}$ (resp. $\mathscr{L}'$) be an invertible $\mathscr{O}_X$-module (resp. invertible $\mathscr{O}_{X'}$-module), and let $\mathscr{L}''$ be the invertible $\mathscr{O}_{X''}$-module that agrees with $\mathscr{L}$ (resp. $\mathscr{L}'$) on X (resp. X'). For $\mathscr{L}''$ to be very ample relative to f'', it is necessary and sufficient for $\mathscr{L}$ to be very ample relative to f and for $\mathscr{L}'$ to be very ample relative to f'.*

Proof. We can immediately restrict to the case where Y is affine. If $\mathscr{L}''$ is very ample then so too are $\mathscr{L}$ and $\mathscr{L}'$, by (4.4.10, (i *bis*)). Conversely, if $\mathscr{L}$ and $\mathscr{L}'$ are very ample, then it follows immediately from the definition (4.4.2) and from (4.3.6) that $\mathscr{L}''$ is very ample. □

4.5. Ample sheaves

(4.5.1). Given a prescheme X and an invertible $\mathscr{O}_X$-module $\mathscr{L}$, we define, for every $\mathscr{O}_X$-module $\mathscr{F}$ (when there will be no confusion possible over $\mathscr{L}$) $\mathscr{F}(n) = \mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{L}^{\otimes n}$ ($n \in \mathbf{Z}$); we also define $S = \bigoplus_{n \geqslant 0} \Gamma(X, \mathscr{L}^{\otimes n})$ (a graded subring of the ring $\Gamma_\bullet(\mathscr{L})$ defined in (**0**, 5.4.6)). If we consider X as a $\mathbf{Z}$-prescheme, and we denote by p the structure morphism $X \to \operatorname{Spec}(\mathbf{Z})$, then there is a bijective correspondence between homomorphisms $p^*(\widetilde{S}) \to \bigoplus_{n \geqslant 0} \mathscr{L}^{\otimes n}$ of graded $\mathscr{O}_X$-algebras and endomorphisms of the graded ring S (**I**, 2.2.5); the homomorphism $\varepsilon : p^*(\widetilde{S}) \to \bigoplus_{n \geqslant 0} \mathscr{L}^{\otimes n}$ that then corresponds to the *identity* automorphism of S is said to be *canonical*. There is a corresponding (3.7.1) morphism $G(\varepsilon) \to \operatorname{Proj}(S)$ that is also said to be *canonical*.

Theorem (4.5.2). — *Let X be a quasi-compact scheme or a prescheme whose underlying space is Noetherian, $\mathscr{L}$ an invertible $\mathscr{O}_X$-module, and S the graded ring $\bigoplus_{n \geqslant 0} \Gamma(X, \mathscr{L}^{\otimes n})$. Then the following conditions are equivalent:*

(a) *When f runs over the set of homogeneous elements of S_+, the X_f form a base for the topology of X.*
(a') *When f runs over the set of homogeneous elements of S_+, the X_f that are affine form a cover of X.*
(b) *The canonical morphism $G(\varepsilon) \to \operatorname{Proj}(S)$ (4.5.1) is everywhere defined and is a dominant open immersion.* II | 84
(b') *The canonical morphism $G(\varepsilon) \to \operatorname{Proj}(S)$ is everywhere defined and is a homeomorphism from the underlying space of X to a subspace of* $\operatorname{Proj}(S)$.
(c) *For every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$, if we denote by $\mathscr{F}_n$ the sub-$\mathscr{O}_X$-module of $\mathscr{F}(n)$ generated by the sections of $\mathscr{F}(n)$ over X, then $\mathscr{F}$ is the sum of the sub-$\mathscr{O}_X$-modules $\mathscr{F}_n(-n)$ over the integers $n > 0$.*
(c') *Property* (c) holds for every quasi-coherent sheaf of ideals of $\mathscr{O}_X$.

Furthermore, if (f_α) is a family of homogeneous elements of S_+ such that the X_{f_α} are affine, then the restriction to $\bigcup_\alpha X_{f_\alpha}$ of the canonical morphism $X \to \operatorname{Proj}(S)$ is an isomorphism from $\bigcup_\alpha X_{f_\alpha}$ to $\bigcup_\alpha (\operatorname{Proj}(S))_{f_\alpha}$.

Proof. It is clear that (b) implies (b'), and (b') implies (a) by (3.7.3.1) (taking into account the fact that $\varepsilon^\flat$ is the identity). Condition (a) implies (a'), since every $x \in X$ has an affine neighbourhood U such that $\mathscr{L}|U$ is isomorphic to $\mathscr{O}_X|U$; if $f \in \Gamma(X, \mathscr{L}^{\otimes n})$ is such that $x \in X_f \subset U$, then X_f is also the set of $x' \in U$ such that $(f|U)(x') \neq 0$, and it is thus an affine open subset (**I**, 1.3.6). To prove that (a') implies (b), it suffices to prove the last claim of the theorem, and to further prove that, if $X = \bigcup_\alpha X_{f_\alpha}$, then condition (iv) of (3.8.2) is satisfied. This latter point follows immediately from (**I**, 9.3.1, (i)). As for the last claim of (4.5.2), since X_{f_α} is the inverse image of $(\operatorname{Proj}(S))_{f_\alpha}$ under $G(\varepsilon) \to \operatorname{Proj}(S)$, it suffices to apply (**I**, 9.3.2). Thus (a), (a'), (b), and (b') are all equivalent.

To show that (a') implies (c), note that, if X_f is affine (with $f \in S_k$), then $\mathscr{F}|X_f$ is generated by its sections over X_f (**I**, 1.3.9); on the other hand (**I**, 9.3.1, (ii)), such a section s is of the form $(t|X_f) \otimes (f|X_f)^{-m}$, where $t \in \Gamma(X, \mathscr{F}(km))$; by definition, t is also a section of $\mathscr{F}_{km}$, so s is indeed a section of $\mathscr{F}_{km}(-km)$ over X_f, which proves (c). It is clear that (c) implies (c'), so it remains only to show that (c') implies (a). But let U be an open neighbourhood of $x \in X$, and let $\mathscr{J}$ be a quasi-coherent sheaf of ideals of $\mathscr{O}_X$ defining a closed subprescheme of X that has $X - U$ as its underlying space (**I**, 5.2.1). Hypothesis (c') implies that there exists an integer $n > 0$ and a section f of $\mathscr{J}(n)$ over X such that $f(x) \neq 0$. But we clearly have $f \in S_n$, and $x \in X_f \subset U$, which proves (a). □

When X is a prescheme whose underlying space is Noetherian, the equivalent conditions of (4.5.2) imply that X is a *scheme*, since it is isomorphic to a subprescheme of the scheme $\operatorname{Proj}(S)$, by (4.5.2, (b)).

Definition (4.5.3). — We say that an invertible $\mathscr{O}_X$-module $\mathscr{L}$ is *ample* if X is a quasi-compact scheme and if the equivalent conditions of (4.5.2) are satisfied.

It evidently follows from criterion (a) of (4.5.2) that, if $\mathscr{L}$ is an ample $\mathscr{O}_X$-module, then, for every open subset U of X, $\mathscr{L}|U$ is an ample $(\mathscr{O}_X|U)$-module.

It follows from the proof of (4.5.2) that the *affine* X_f form a base for the topology of X. Furthermore:

Corollary (4.5.4). — *Let $\mathscr{L}$ be an ample $\mathscr{O}_X$-module. For every finite subspace Z of X and every neighbourhood U of Z, there exists an integer n and some $f \in \Gamma(X, \mathscr{L}^{\otimes n})$ such that X_f is an affine neighbourhood of Z contained in U.*

Proof. By (4.5.2, (b)), it suffices to prove that, for every finite subset Z' of $\operatorname{Proj}(S)$ and every open neighbourhood U of Z', there exists a homogeneous element $f \in S_+$ such that $Z' \subset (\operatorname{Proj}(S))_f \subset U$ (2.4.1). But, by definition, the closed set Y, complement of U in $\operatorname{Proj}(S)$, is of the form $V_+(\mathfrak{I})$, where $\mathfrak{I}$ is a graded ideal of S that does not contain S_+ (2.3.2); also, the points of Z' are, by definition, graded prime ideals $\mathfrak{p}_i$ of S_+ that do not contain $\mathfrak{I}$ (2.3.1). There thus exists an element $f \in \mathfrak{I}$ that does not belong to any of the $\mathfrak{p}_i$ (Bourbaki, *Alg. comm.*, chap. II, §1, no. 1, prop. 2), and, since the $\mathfrak{p}_i$ are graded, the argument made *loc. cit.* shows that we can even take f to be homogeneous; this element then satisfies the claim. □ **II** | 85

Proposition (4.5.5). — *Suppose that X is a quasi-compact scheme or a prescheme whose underlying space is Noetherian. Then conditions (a) to (c') of (4.5.2) are equivalent to the following:*

- (d) *For every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$ of finite type, there exists an integer n_0 such that, for all $n \geqslant n_0$, $\mathscr{F}(n)$ is generated by its sections over X.*
- (d') *For every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$ of finite type, there exist integers $n > 0$ and $k > 0$ such that $\mathscr{F}$ is isomorphic to a quotient of the $\mathscr{O}_X$-module $\mathscr{L}^{\otimes(-n)} \otimes \mathscr{O}_X^k$.*
- (d'') *Property (d') holds for every quasi-coherent sheaf of ideals of $\mathscr{O}_X$ of finite type.*

Proof. Since X is quasi-compact, if a quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$ of finite type is such that $\mathscr{F}(n)$ (which is of finite type) is generated by its sections over X, then $\mathscr{F}(n)$ is generated by a *finite* number of these sections (**0**, 5.2.3), and so (d) implies (d'), and it is clear that (d') implies (d''). Since every quasi-coherent $\mathscr{O}_X$-module $\mathscr{G}$ is the inductive limit of its sub-$\mathscr{O}_X$-modules of finite type (**I**, 9.4.9), to satisfy condition (c') of (4.5.2), it suffices to do so for a quasi-coherent sheaf of ideals of $\mathscr{O}_X$ that is of finite type, and (d″) thus implies (c′). It remains only to show that, if $\mathscr{L}$ is ample, then property (d) is satisfied. Consider a finite cover of X by X_{f_i} ($f_i \in S_{n_i}$), that we can assume to be affine; by replacing the f_i with suitable powers (which does not alter the X_{f_i}), we can assume that all the n_i are equal to one single integer m. The sheaf $\mathscr{F}|X_{f_i}$, being of finite type, by hypothesis, is generated by a finite number of its sections h_{ij} over X_{f_i} (**I**, 1.3.13); so there exists an integer k_0 such that the section $h_{ij} \otimes f_i^{\otimes k_0}$ extends to a section of $\mathscr{F}(k_0 m)$ over X for every pair (i,j) (**I**, 9.3.1). *A fortiori*, the $h_{ij} \otimes f_i^{\otimes k}$ extend to sections of $\mathscr{F}(km)$ over X for every $k \geqslant k_0$, and, for these values of k, $\mathscr{F}(km)$ is thus generated by its sections over X. For every p such that $0 < p < m$, $\mathscr{F}(p)$ is also of finite type, and so there exists an integer k_p such that $\mathscr{F}(p)(km) = \mathscr{F}(p+km)$ is generated by its sections over X for all $k \geqslant k_p$. Taking n_0 to be the largest of the $k_p m$, we thus conclude that $\mathscr{F}(n)$ is generated by its sections over X for all $n \geqslant n_0$, since such an n is of the form $n = km + p$, with $k \geqslant k_p$ and $0 \leqslant p < m$. □

Proposition (4.5.6). — *Let X be a quasi-compact scheme, and $\mathscr{L}$ an invertible $\mathscr{O}_X$-module.*

(i) *Let $n > 0$ be an integer. For $\mathscr{L}$ to be ample, it is necessary and sufficient for $\mathscr{L}^{\otimes n}$ to be ample.*
(ii) *Let $\mathscr{L}'$ be an invertible $\mathscr{O}_X$-module such that, for all $x \in X$, there exists an integer $n > 0$ and a* **II** | 86
section s' of $\mathscr{L}'^{\otimes n}$ over X such that $s'(x) \neq 0$. Then, if $\mathscr{L}$ is ample, so too is $\mathscr{L} \otimes \mathscr{L}'$.

Proof. Property (i) is an evident consequence of criterion (a) of (4.5.2), since $X_{f^{\otimes n}} = X_f$. On the other hand, if $\mathscr{L}$ is ample, then, for every $x \in X$ and every neighbourhood U of x, there exists some $m > 0$ and $f \in \Gamma(X, \mathscr{L}^{\otimes m})$ such that $x \in X_f \subset U$ (4.5.2, (a)); if $f' \in \Gamma(X, \mathscr{L}'^{\otimes n})$ is such that $f'(x) \neq 0$, then $s(x) \neq 0$ for $s = f^{\otimes n} \otimes f'^{\otimes m} \in \Gamma(X, (\mathscr{L} \otimes \mathscr{L}')^{\otimes mn})$, and so $x \in X_s \subset X_f \subset U$, which proves that $\mathscr{L} \otimes \mathscr{L}'$ is ample (4.5.2, (a)). □

Corollary (4.5.7). — *The tensor product of two ample $\mathscr{O}_X$-modules is ample.*

Corollary (4.5.8). — *Let $\mathscr{L}$ be an ample $\mathscr{O}_X$-module, and $\mathscr{L}'$ an invertible $\mathscr{O}_X$-module; then there exists an integer $n_0 > 0$ such that $\mathscr{L}^{\otimes n} \otimes \mathscr{L}'$ is ample and generated by its sections over X for $n \geqslant n_0$.*

Proof. It follows from (4.5.5) that there exists an integer m_0 such that $\mathscr{L}^{\otimes m} \otimes \mathscr{L}'$ is generated by its sections over X for all $m \geqslant m_0$; by (4.5.6), we can then take $n_0 = m_0 + 1$. □

Remark (4.5.9). — Let $P = \mathrm{H}^1(X, \mathscr{O}_X^\times)$ be the group of classes of invertible $\mathscr{O}_X$-modules (**0**, 5.4.7), and let P^+ be the subset of P consisting of classes of ample sheaves. Suppose that P^+ is *non-empty*. Then it follows from (4.5.7) and (4.5.8) that

$$P^+ + P^+ \subset P^+ \quad \text{and} \quad P^+ - P^+ = P$$

or, in other words, $P^+ \cup \{0\}$ is the set of *positive* elements in P for a *preorder* structure on P that is compatible with its group structure, and is even *archimedean*, by (4.5.8). This is why we sometimes say "positive sheaf" instead of ample sheaf, and "negative sheaf" for the inverse of an ample sheaf (but we will not use this terminology).

Proposition (4.5.10). — *Let Y be an affine scheme, $q : X \to Y$ a quasi-compact separated morphism, and $\mathscr{L}$ an invertible $\mathscr{O}_X$-module.*

(i) *If $\mathscr{L}$ is very ample for q, then $\mathscr{L}$ is ample.*
(ii) *Suppose further that the morphism q is* of finite type. *Then, for $\mathscr{L}$ to be ample, it is necessary and sufficient for it to possess one of the following properties:*
   (e) *There exists $n_0 > 0$ such that, for every integer $n \geqslant n_0$, $\mathscr{L}^{\otimes n}$ is very ample for q.*
   (e′) *There exists $n > 0$ such that $\mathscr{L}^{\otimes n}$ is very ample for q.*

Proof. The first claim follows from the definition (4.4.2) of a very ample $\mathscr{O}_X$-module: if A is the ring of Y, then there exists an A-module E and a surjective homomorphism

$$\psi : q^*((\mathbf{S}(E))\tilde{}\,) \longrightarrow \bigoplus_{n \geqslant 0} \mathscr{L}^{\otimes n}$$

such that $i = r_{\mathscr{L},\psi}$ is an everywhere-defined immersion $X \to P = \mathbf{P}(\widetilde{E})$ and such that $\mathscr{L} = i^*(\mathscr{O}_P(1))$; since the $D_+(f)$ for f homogeneous in $(\mathbf{S}(E))_+$ form a base for the topology of P, and since $i^{-1}(D_+(f)) = X_{\psi^\flat(f)}$, by (3.7.3.1), we see that condition (a) of (4.5.2) is satisfied, and so $\mathscr{L}$ is ample.

Now to prove that, if q is of finite type and $\mathscr{L}$ is ample, then condition (e) is satisfied. Firstly, it follows from criterion (b) of (4.5.2) and from (4.4.1, (i)) that there exists an integer k_0 such that $\mathscr{L}^{\otimes k_0}$ **II** | 87
is very ample relative to q. Also, by (4.5.5), there exists an integer m_0 such that, for all $m \geqslant m_0$, $\mathscr{L}^{\otimes m}$ is generated by its sections over X. Let $n_0 = k_0 + m_0$; if $n \geqslant n_0$, then we can write $n = k_0 + m$ with $m \geqslant m_0$, whence $\mathscr{L}^{\otimes n} = \mathscr{L}^{\otimes k_0} \otimes \mathscr{L}^{\otimes m}$. Since $\mathscr{L}^{\otimes m}$ is generated by its sections over X, it follows from (4.4.8) and (3.4.7) that $\mathscr{L}^{\otimes n}$ is very ample relative to q. Finally, it is clear that (e) implies (e'), and (e') implies that $\mathscr{L}$ is ample by (i) and by (4.5.6, (i)).

(4.5.10.1). *[Proof of Lemma (4.4.10.1)].* Let $\mathscr{E}(n) = \mathscr{E} \otimes \mathscr{K}^{\otimes n}$; since g is separated (4.4.2), the argument of (3.4.8) applies and reduces the assertion to proving that the canonical homomorphism $g^*(g_*(\mathscr{E}(n))) \to \mathscr{E}(n)$ is surjective for all sufficiently large n. Furthermore, since Z is quasi-compact, the argument of (3.4.6) reduces us to proving the claim when Z is affine. But $\mathscr{K}$ is then ample, by (4.5.10, (i)), and the conclusion follows from (4.5.5, (d')).

□

Corollary (4.5.11). — *Let Y be an affine scheme, $q : X \to Y$ a separated morphism of finite type, $\mathscr{L}$ an ample $\mathscr{O}_X$-module, and $\mathscr{L}'$ an invertible $\mathscr{O}_X$-module. Then there exists an integer n_0 such that, for all $n \geqslant n_0$, $\mathscr{L}^{\otimes n} \otimes \mathscr{L}'$ is very ample relative to q.*

Proof. There exists m_0 such that, for $m \geqslant m_0$, $\mathscr{L}^{\otimes m} \otimes \mathscr{L}'$ is generated by its sections over X (4.5.8); there also exists k_0 such that $\mathscr{L}^{\otimes k}$ is very ample relative to q for $k \geqslant k_0$. Then $\mathscr{L}^{\otimes (k+m_0)} \otimes \mathscr{L}'$ is very ample if $k \geqslant k_0$ ((4.4.8) and (3.4.7)). □

Remark (4.5.12). — We do not know if the hypothesis that an $\mathscr{O}_X$-module $\mathscr{L}$ is such that $\mathscr{L}^{\otimes n}$ is very ample (relative to q) implies the same conclusion for $\mathscr{L}^{\otimes (n+1)}$.

Proposition (4.5.13). — *Let X be a quasi-compact prescheme, Z a closed prescheme of X defined by a* nilpotent *quasi-coherent sheaf $\mathscr{J}$ of ideals of $\mathscr{O}_X$, and j the canonical injection $Z \to X$. For an invertible $\mathscr{O}_X$-module $\mathscr{L}$ to be ample, it is necessary and sufficient for $\mathscr{L}' = j^*(\mathscr{L})$ to be an ample $\mathscr{O}_Z$-module.*

Proof. The condition is *necessary*. Indeed, for every section f of $\mathscr{L}^{\otimes n}$ over X, let f' be its canonical image $f \otimes 1$, which is a section of $\mathscr{L}'^{\otimes n} = \mathscr{L}^{\otimes n} \otimes_{\mathscr{O}_X} (\mathscr{O}_X/\mathscr{J})$ over the space Z (which is identical to X); it is clear that $X_f = Z_{f'}$, and so the criterion (a) of (4.5.2) shows that $\mathscr{L}'$ is ample.

To see that the condition is *sufficient*, note first of all that we can restrict to the case where $\mathscr{J}^2 = 0$, by considering the (finite) sequence of preschemes $X_k = (X, \mathscr{O}_X/\mathscr{J}^{k+1})$ with each prescheme being a closed subprescheme of the next, defined by a square-zero sheaf of ideals. But X is a scheme, since X_{red} is a scheme by hypothesis ((4.5.3) and (**I**, 5.5.1)). Criterion (a) of (4.5.2) shows that it suffices to prove

Lemma (4.5.13.1). — *Under the hypotheses of (4.5.13), suppose further that $\mathscr{J}$ is square-zero; with $\mathscr{L}$ being an invertible $\mathscr{O}_X$-module, let g be a section of $\mathscr{L}'^{\otimes n}$ over Z such that Z_g is affine. Then there exists an integer $m > 0$ such that $g^{\otimes m}$ is the canonical image of a section f of $\mathscr{L}^{\otimes nm}$ over X.*

We have the exact sequence of $\mathscr{O}_X$-modules

$$0 \longrightarrow \mathscr{J}(n) \longrightarrow \mathscr{O}_X(n) = \mathscr{L}^{\otimes n} \longrightarrow \mathscr{O}_Z(n) = \mathscr{L}'^{\otimes n} \longrightarrow 0$$

since $\mathscr{F}(n)$ is an exact functor in $\mathscr{F}$; from this, we have the exact sequence of cohomology **II** | 88

$$0 \longrightarrow \Gamma(X, \mathscr{J}(n)) \longrightarrow \Gamma(X, \mathscr{L}^{\otimes n}) \longrightarrow \Gamma(X, \mathscr{L}'^{\otimes n}) \xrightarrow{\partial} \mathrm{H}^1(X, \mathscr{J}(n))$$

that sends, in particular, g to an element $\partial g \in \mathrm{H}^1(X, \mathscr{J}(n))$. Note that, since $\mathscr{J}^2 = 0$, $\mathscr{J}$ can be considered as a quasi-coherent $\mathscr{O}_Z$-module, and, for all k, $\mathscr{L}'^{\otimes k} \otimes_{\mathscr{O}_Z} \mathscr{J}(n) = \mathscr{J}(n+k)$; for every section $s \in \Gamma(X, \mathscr{L}'^{\otimes k})$, tensor multiplication with s is thus a homomorphism $\mathscr{J}(n) \to \mathscr{J}(n+k)$ of $\mathscr{O}_Z$-modules, which then gives a homomorphism $\mathrm{H}^i(X, \mathscr{J}(n)) \xrightarrow{s} \mathrm{H}^i(X, \mathscr{J}(n+k))$ of cohomology groups.

With this, we will see that

$$g^{\otimes m} \otimes \partial g = 0 \tag{4.5.13.2}$$

for $m > 0$ large enough. In fact, Z_g is an *affine open* subset of Z, and so $\mathrm{H}^1(Z_g, \mathscr{J}(n)) = 0$ when $\mathscr{J}(n)$ is considered as an $\mathscr{O}_Z$*-module* (**I**, 5.1.9.2). In particular, if we set $g' = g|Z_g$, and if we consider its image under the map $\partial : \Gamma(Z_g, \mathscr{L}'^{\otimes n}) \to \mathrm{H}^1(Z_g, \mathscr{J}(n))$, then $\partial g' = 0$. To make this equation explicit, note that, in degree 1, the cohomology of a sheaf of abelian groups agrees with its Čech cohomology (G, II, 5.9); to calculate ∂g, we must thus consider a fine-enough open cover (U_α) of X, that we can suppose to be *finite* and consisting of affine opens, and take, for each α, a section $g_\alpha \in \Gamma(U_\alpha, \mathscr{L}^{\otimes n})$ whose canonical image in $\Gamma(U_\alpha, \mathscr{L}'^{\otimes n})$ is $g|U_\alpha$, and to consider the cocycle class $(g_{\alpha|\beta} - g_{\beta|\alpha})$, with $g_{\alpha|\beta}$ being the restriction of g_α to $U_\alpha \cap U_\beta$ (with this cocycle taking values in $\mathscr{J}(n)$). We can further suppose that $\partial g'$ is calculated in the same way, by means of a cover given by the $U_\alpha \cap Z_g$, and restrictions $g_\alpha|(U_\alpha \cap Z_g)$ (by replacing, if necessary, (U_α) by a finer cover); the equation $\partial g' = 0$ then implies that there exists, for each α, a section $h_\alpha \in \Gamma(U_\alpha \cap Z_g, \mathscr{J}(n))$ such that $(g_{\alpha|\beta} - g_{\beta|\alpha})|(U_\alpha \cap U_\beta \cap Z_g) = h_{\alpha|\beta} - h_{\beta|\alpha}$, where $h_{\alpha|\beta}$ denotes the restriction of h_α to $U_\alpha \cap U_\beta \cap Z_g$ (G, II, 5.11). Then there exists an integer $m > 0$ such that $g^{\otimes m} \otimes h_\alpha$ is the restriction to $U_\alpha \cap Z_g$ of a section $t_\alpha \in \Gamma(U_\alpha, \mathscr{J}(n + nm))$ for all α (**I**, 9.3.1); thus $g^{\otimes m} \otimes (g_{\alpha|\beta} - g_{\beta|\alpha}) = t_{\alpha|\beta} - t_{\beta|\alpha}$ for every pair of indices, which proves (4.5.13.2).

Now note that, if $s \in \Gamma(X, \mathscr{O}_Z(p))$ and $t \in \Gamma(X, \mathscr{O}_Z(q))$, then, in the group $\mathrm{H}^1(X, \mathscr{J}(p+q))$,

$$\partial(s \otimes t) = (\partial s) \otimes t + s \otimes (\partial t). \tag{4.5.13.3}$$

Indeed, we can again calculate the two members by considering an open cover (U_α) of X, and, for each α, a section $s_\alpha \in \Gamma(U_\alpha, \mathscr{O}_X(p))$ (resp. $t_\alpha \in \Gamma(U_\alpha, \mathscr{O}_X(q))$) whose canonical image in $\Gamma(U_\alpha, \mathscr{O}_Z(p))$ (resp. $\Gamma(U_\alpha, \mathscr{O}_Z(q))$) is $s|U_\alpha$ (resp. $t|U_\alpha$); equation (4.5.13.3) then follows from the equations

$$(s_{\alpha|\beta} \otimes t_{\alpha|\beta}) - (s_{\beta|\alpha} \otimes t_{\beta|\alpha}) = (s_{\alpha|\beta} - s_{\beta|\alpha}) \otimes t_{\alpha|\beta} + s_{\beta|\alpha} \otimes (t_{\alpha|\beta} - t_{\beta|\alpha})$$

with the same notation as above. By induction on k, we thus have

$$\partial(g^{\otimes k}) = (kg^{\otimes(k-1)}) \otimes (\partial g) \tag{4.5.13.4}$$

and we thus conclude from (4.5.13.2) and (4.5.13.4) that $\partial(g^{\otimes(m+1)}) = 0$; thus $g^{\otimes(m+1)}$ is the canonical image of a section f of $\mathscr{L}^{\otimes n(m+1)}$ over X, which proves (4.5.13). □ **II | 89**

Corollary (4.5.14). — *Let X be a Noetherian scheme, and j the canonical injection $X_{\mathrm{red}} \to X$. For an invertible $\mathscr{O}_X$-module $\mathscr{L}$ to be ample, it is necessary and sufficient for $j^*(\mathscr{L})$ to be an ample $\mathscr{O}_{X_{\mathrm{red}}}$-module.*

Proof. This follows from (**I**, 6.1.6) □

4.6. Relatively ample sheaves

Definition (4.6.1). — Let $f : X \to Y$ be a quasi-compact morphism, and $\mathscr{L}$ an invertible $\mathscr{O}_X$-module. We say that $\mathscr{L}$ is *ample relative to f*, or *relative to Y*, or *f-ample*, or *Y-ample* (or even simply *ample* if no confusion may arise with the notion defined in (4.5.3)) if there exists an affine open cover (U_α) of Y such that, if we set $X_\alpha = f^{-1}(U_\alpha)$, then $\mathscr{L}|X_\alpha$ is an ample $\mathscr{O}_{X_\alpha}$-module for all α.

The existence of an f-ample $\mathscr{O}_X$-module implies that f is necessarily *separated* ((4.5.3) and (**I**, 5.5.5)).

Proposition (4.6.2). — *Let $f : X \to Y$ be a quasi-compact morphism, and $\mathscr{L}$ an invertible $\mathscr{O}_X$-module. If $\mathscr{L}$ is very ample relative to f, then it is ample relative to f.*

Proof. This follows from the local (on Y) character of the notion of a very ample sheaf (4.4.5), from the definition (4.6.1), and from criterion (4.5.10, (i)). □

Proposition (4.6.3). — *Let $f : X \to Y$ be a quasi-compact morphism, and $\mathscr{L}$ an invertible $\mathscr{O}_X$-module, and let $\mathscr{S}$ be the graded $\mathscr{O}_Y$-algebra $\bigoplus_{n \geqslant 0} f_*(\mathscr{L}^{\otimes n})$. Then the following conditions are equivalent:*

(a) *$\mathscr{L}$ is f-ample.*

(b) *$\mathscr{S}$ is quasi-coherent, and the canonical homomorphism $\sigma : f^*(\mathscr{S}) \to \bigoplus_{n \geqslant 0} \mathscr{L}^{\otimes n}$ (**0**, 4.4.3) is such that the Y-morphism $r_{\mathscr{L},\sigma} : G(\sigma) \to \mathrm{Proj}(\mathscr{S}) = P$ is everywhere defined and is a dominant open immersion.*

(b′) *The morphism f is separated, and the Y-morphism $r_{\mathscr{L},\sigma}$ is everywhere defined and is a homeomorphism from the underlying space of X to a subspace of* $\mathrm{Proj}(\mathscr{S})$.

Furthermore, if any of the above are satisfied, then, for all $n \in \mathbf{Z}$, the canonical homomorphism

$$r^*_{\mathscr{L},\sigma}(\mathscr{O}_P(n)) \longrightarrow \mathscr{L}^{\otimes n} \tag{4.6.3.1}$$

defined in (3.7.9.1) is an isomorphism.

Finally, for every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$, if we set $\mathscr{M} = \bigoplus_{n\geqslant 0} f_*(\mathscr{F} \otimes \mathscr{L}^{\otimes n})$, then the canonical homomorphism

$$r^*_{\mathscr{L},\sigma}(\widetilde{\mathscr{M}}) \longrightarrow \mathscr{F} \tag{4.6.3.2}$$

defined in (3.7.9.2) is an isomorphism.

Proof. We note that (a) implies that f is separated, and thus that $\mathscr{S}$ is quasi-coherent (**I**, 9.2.2, (a)). Since $r_{\mathscr{L},\sigma}$ being an everywhere defined immersion is of a local (on Y) character, to prove that (a) implies (b) we can suppose that Y is affine and $\mathscr{L}$ ample; the claim then follows from (4.5.2, (b)). It is clear that (b) implies (b'); finally, to prove that (b') implies (a), it suffices to consider an affine open cover (U_α) of Y and to apply the criterion (4.5.2, (b')) to each sheaf $\mathscr{L}|f^{-1}(U_\alpha)$. **II** | 90

For the final two claims, we use the fact that $\sigma^\flat$ is here the identity, and the clarification of the homomorphisms (3.7.9.1) and (3.7.9.2); from this, it immediately follows that (4.6.3.1) is an isomorphism. As for (4.6.3.2), we can restrict to the case where Y is affine, and thus $\mathscr{L}$ ample; it is clear that the homomorphism (4.6.3.2) is injective, and criterion (4.5.2, (c)) shows that it is surjective, whence the conclusion. □

Corollary (4.6.4). — *Let (U_α) be an open cover of Y. For $\mathscr{L}$ to be ample relative to Y, it is necessary and sufficient for $\mathscr{L}|f^{-1}(U_\alpha)$ to be ample relative to U_α for all α.*

Proof. Condition (b) is in fact local on Y. □

Corollary (4.6.5). — *Let $\mathscr{K}$ be an invertible $\mathscr{O}_Y$-module. For $\mathscr{L}$ to be Y-ample, it is necessary and sufficient for $\mathscr{L} \otimes f^*(\mathscr{K})$ to be Y-ample.*

Proof. This is an evident consequence of (4.6.4), by taking the U_α to be such that $\mathscr{K}|U_\alpha$ is isomorphic to $\mathscr{O}_Y|U_\alpha$ for all α. □

Corollary (4.6.6). — *Suppose that Y is affine; for $\mathscr{L}$ to be Y-ample, it is necessary and sufficient for $\mathscr{L}$ to be ample.*

Proof. This is an immediate consequence of the definition (4.6.1) and the criteria (4.6.3, (b)) and (4.5.2, (b)), since here $\operatorname{Proj}(\mathscr{S}) = \operatorname{Proj}(\Gamma(Y,\mathscr{S}))$ by definition. □

Corollary (4.6.7). — *Let $f : X \to Y$ be a quasi-compact morphism. Suppose that there exists a quasi-coherent $\mathscr{O}_Y$-module $\mathscr{E}$, and a Y-morphism $g : X \to P = \mathbf{P}(\mathscr{E})$ that is a homeomorphism from the underlying space of X to a subspace of P; then $\mathscr{L} = g^*(\mathscr{O}_P(1))$ is Y-ample.*

Proof. We can assume Y to be affine; the corollary then follows from the criterion (4.5.2, (a)), from equation (3.7.3.1), and from (4.2.3). □

Proposition (4.6.8). — *Let X be a quasi-compact scheme or a prescheme whose underlying space is Noetherian, and let $f : X \to Y$ be a quasi-compact separated morphism. For an invertible $\mathscr{O}_X$-module $\mathscr{L}$ to be f-ample, it is necessary and sufficient for one of the following equivalent conditions to be satisfied:*

- (c) *For every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$ of finite type, there exists an integer $n_0 > 0$ such that, for all $n \geqslant n_0$, the canonical homomorphism $\sigma : f^*(f_*(\mathscr{F} \otimes \mathscr{L}^{\otimes n})) \to \mathscr{F} \otimes \mathscr{L}^{\otimes n}$ is surjective.*
- (c') *For every quasi-coherent sheaf $\mathscr{J}$ of ideals of $\mathscr{O}_X$ of finite type, there exists an integer $n > 0$ such that the canonical homomorphism $\sigma : f^*(f_*(\mathscr{J} \otimes \mathscr{L}^{\otimes n})) \to \mathscr{J} \otimes \mathscr{L}^{\otimes n}$ is surjective.*

Proof. Since X is quasi-compact, so too is $f(X)$, and so there exists a finite cover (U_i) of $f(X)$ consisting of affine open subsets U_i of Y. To prove condition (c) when $\mathscr{L}$ is f-ample, we can replace Y by the U_i, and X by the $f^{-1}(U_i)$, since, if we obtain, for each i, an integer n_i such that (c) holds true (for U_i, $f^{-1}(U_i)$, and $\mathscr{L}|f^{-1}(U_i)$) for all $n \geqslant n_i$, then it suffices to take n_0 to be the largest of the n_i in order to obtain (c) for Y, X, and $\mathscr{L}$. But if Y is affine, condition (c) follows from (4.5.5, (d)), taking (4.6.6) into account. It is trivial that (c) implies (c'). Finally, to prove that (c') implies that $\mathscr{L}$ is f-ample, we can again restrict to the case where Y is affine: in fact, every quasi-coherent sheaf $\mathscr{J}_i$ of ideals of $\mathscr{O}_X|f^{-1}(U_i)$ of finite type is the restriction of a coherent sheaf of ideals of $\mathscr{O}_X$ of finite type (**I**, 9.4.7), and hypothesis (c′) implies that $\mathscr{J}_i \otimes (\mathscr{L}^{\otimes n}|f^{-1}(U_i))$ is generated by its sections (taking (**I**, 9.2.2) and (3.4.7) into account); it thus suffices to apply criterion (4.5.5, (d″)). □ **II** | 91

Proposition (4.6.9). — *Let $f : X \to Y$ be a quasi-compact morphism, and $\mathscr{L}$ an invertible $\mathscr{O}_X$-module.*

(i) *Let $n > 0$ be an integer. For $\mathscr{L}$ to be f-ample, it is necessary and sufficient for $\mathscr{L}^{\otimes n}$ to be f-ample.*

(ii) *Let $\mathscr{L}'$ be an invertible $\mathscr{O}_X$-module, and suppose that there exists an integer $n > 0$ such that the canonical homomorphism $\sigma : f^*(f_*(\mathscr{L}'^{\otimes n})) \to \mathscr{L}'^{\otimes n}$ is surjective. Then, if $\mathscr{L}$ is f-ample, so too is $\mathscr{L} \otimes \mathscr{L}'$.*

Proof. We can in fact immediately restrict to the case where Y is affine, and the proposition is then an immediate consequence of (4.5.6). □

Corollary (4.6.10). — *The tensor product of two f-ample $\mathscr{O}_X$-modules is f-ample.*

Proposition (4.6.11). — *Let Y be a quasi-compact prescheme, $f : X \to Y$ a morphism of finite type, and $\mathscr{L}$ an invertible $\mathscr{O}_X$-module. For $\mathscr{L}$ to be f-ample, it is necessary and sufficient for it to possess one of the following equivalent properties:*

(d) *There exists some $n_0 > 0$ such that, for every integer $n \geqslant n_0$, $\mathscr{L}^{\otimes n}$ is very ample relative to f.*

(d′) *There exists some $n > 0$ such that $\mathscr{L}^{\otimes n}$ is very ample relative to f.*

Proof. If $\mathscr{L}$ is ample relative to f, then there exists a *finite* cover (U_i) of Y by affine open subsets such that the $\mathscr{L}|f^{-1}(U_i)$ are ample. We thus conclude (4.5.10) that there exists an integer n_0 such that $\mathscr{L}^{\otimes n}|f^{-1}(U_i)$ is very ample relative to $f^{-1}(U_i) \to U_i$ for all $n \geqslant n_0$ and every i, and so $\mathscr{L}^{\otimes n}$ is very ample relative to f (4.4.5). Conversely, (d′) already implies that $\mathscr{L}^{\otimes n}$ is f-ample (4.6.2), and thus so too is $\mathscr{L}$ (4.6.9, (i)). □

Corollary (4.6.12). — *Let Y be a quasi-compact prescheme, $f : X \to Y$ a morphism of finite type, and $\mathscr{L}$ and $\mathscr{L}'$ invertible $\mathscr{O}_X$-modules. If $\mathscr{L}$ is f-ample, then there exists some n_0 such that $\mathscr{L}^{\otimes n} \otimes \mathscr{L}'$ is very ample relative to f for all $n \geqslant n_0$.*

Proof. We argue as in (4.6.11), by using a finite affine open cover of Y and (4.5.11). □

Proposition (4.6.13). — (i) *For every prescheme Y, every invertible $\mathscr{O}_Y$-module $\mathscr{L}$ is ample relative to the identity morphism 1_Y.*

(i *bis*) *Let $f : X \to Y$ be a quasi-compact morphism, and $j : X' \to X$ a quasi-compact morphism that is a homeomorphism from the underlying space of X' to a subspace of X. If $\mathscr{L}$ is an $\mathscr{O}_X$-module that is ample relative to f, then $j^*(\mathscr{L})$ is ample relative to $f \circ j$.*

(ii) *Let Z be a quasi-compact prescheme, $f : X \to Y$ and $g : Y \to Z$ quasi-compact morphisms, $\mathscr{L}$ an $\mathscr{O}_X$-module that is ample relative to f, and $\mathscr{K}$ an $\mathscr{O}_Y$-module that is ample relative to g. Then there exists an integer $n_0 > 0$ such that $\mathscr{L} \otimes f^*(\mathscr{K}^{\otimes n})$ is ample relative to $g \circ f$ for all $n \geqslant n_0$.*

(iii) *Let $f : X \to Y$ be a quasi-compact morphism, and $g : Y' \to Y$ a morphism, and let $X' = X_{(Y')}$. If $\mathscr{L}$ is an $\mathscr{O}_X$-module that is ample relative to f, then $\mathscr{L}' = \mathscr{L} \otimes_Y \mathscr{O}_{Y'}$ is an $\mathscr{O}_{X'}$-module that is ample relative to $f_{(Y')}$.*

(iv) *Let $f_i : X_i \to Y_i$ ($i = 1, 2$) be quasi-compact S-morphisms. If $\mathscr{L}_i$ is an $\mathscr{O}_{X_i}$-module that is ample relative to f_i ($i = 1, 2$), then $\mathscr{L}_1 \otimes_S \mathscr{L}_2$ is ample relative to $f_1 \times_S f_2$.*

(v) *Let $f : X \to Y$ and $g : Y \to Z$ be morphisms such that $g \circ f$ is quasi-compact. If an $\mathscr{O}_X$-module $\mathscr{L}$ is ample relative to $g \circ f$, and if g is separated or the underlying space of X is locally Noetherian, then $\mathscr{L}$ is ample relative to f.* **II** | 92

(vi) *Let $f : X \to Y$ be a quasi-compact morphism, and j the canonical injection $X_{\text{red}} \to X$. If $\mathscr{L}$ is an $\mathscr{O}_X$-module that is ample relative to f, then $j^*(\mathscr{L})$ is ample relative to f_{red}.*

Proof. Note first of all that (v) and (vi) follow from (i), (i *bis*), and (iv) by the same argument as in (4.4.10), by using (4.6.4) instead of (4.4.5); we leave the details of the argument to the reader. Claim (i) is trivially a consequence of (4.4.10, (i)) and (4.6.2). To prove (i *bis*), (iii), and (iv), we will use the following lemma:

Lemma (4.6.13.1). — (i) *Let $u : Z \to S$ be a morphism, $\mathscr{L}$ an invertible $\mathscr{O}_S$-module, and s a section of $\mathscr{L}$ over S, and let s' be the canonically corresponding section $u^*(\mathscr{L}) = \mathscr{L}'$ over Z. Then $Z_{s'} = u^{-1}(S_s)$.*

(ii) *Let Z and Z' be S-preschemes, p and p' the projections of $T = Z \times_S Z'$, $\mathscr{L}$ (resp. $\mathscr{L}'$) an invertible $\mathscr{O}_Z$-module (resp. invertible $\mathscr{O}_{Z'}$-module), and let t (resp. t') be a section of $\mathscr{L}$ (resp. $\mathscr{L}'$) over Z (resp. Z'), and s (resp. s') the corresponding section of $p^*(\mathscr{L})$ (resp. $p'^*(\mathscr{L}')$) over $Z \times_S Z'$. Then $T_{s\otimes s'} = Z_t \times_S Z'_{t'}$.*

Proof. It follows from the definitions that we can restrict to the case where all the preschemes in question are affine. Furthermore, in (i), we can suppose that $\mathscr{L} = \mathscr{O}_S$; claim (i) then follows immediately from (**I**, 1.2.2.2). Similarly, in (ii), we can restrict to the case where $\mathscr{L} = \mathscr{O}_Z$ and $\mathscr{L}' = \mathscr{O}_{Z'}$, and then the claim reduces to Lemma (4.3.2.4). □

We now prove (i *bis*). We can assume that Y is affine (4.6.4), and thus that $\mathscr{L}$ is ample (4.6.6); if s runs over the set of the union of the $\Gamma(X, \mathscr{L}^{\otimes n})$ $(n > 0)$, then the X_s form a base for the topology of X (4.5.2, (a)), and so, by hypothesis, the $j^{-1}(X_s)$ form a base for the topology of X'; we thus conclude, by Lemma (4.6.13.1, (i)) and (4.5.2, (a)), that $j^*(\mathscr{L})$ is ample.

Next we prove (iii). We can again suppose that Y and Y' are affine (4.6.4), whence it follows that the projection $h : X' \to X$ is affine (1.5.5). Since $\mathscr{L}$ is ample (4.6.6), if s runs over the set of sections of the $\mathscr{L}^{\otimes n}$ $(n > 0)$ over X such that X_s is affine, then the X_s cover X (4.5.2, (a')), and so the $h^{-1}(X_s)$ are affine (1.2.5) and cover X'; it thus follows again from Lemma (4.6.13.1, (i)) and from (4.5.2, (a')) that $\mathscr{L}'$ is ample, since the morphism $f_{(Y')}$ is quasi-compact (**I**, 6.6.4, (iii)).

To prove (iv), note first of all that $f_1 \times_S f_2$ is quasi-compact (**I**, 6.6.4, (iv)). We can further suppose that S, Y_1, and Y_2 are affine ((4.6.4) and (**I**, 3.2.7)), and thus that $\mathscr{L}_i$ is ample $(i = 1, 2)$ (4.6.6). The open subsets $(X_1)_{s_1} \times_S (X_2)_{s_2}$ form a cover of $X_1 \times_S X_2$, where s_i runs over the sections of $\mathscr{L}_i^{\otimes n_i}$ such that $(X_i)_{s_i}$ is affine (4.5.2, (a')). Then, replacing s_1 and s_2 with suitable powers, which does not change the $(X_i)_{s_i}$, we can assume that $n_1 = n_2$. We thus deduce, from (4.6.13.1, (ii)) and (4.5.2, (a')), that $\mathscr{L}_1 \otimes_S \mathscr{L}_2$ is ample, whence the claim, since $Y_1 \times_S Y_2$ is affine (4.6.6).

It remains only to prove (ii). By the same argument as in (4.4.10), but here using (4.6.4), we can restrict to the case where Z is affine. Since $\mathscr{K}$ is then ample, and Y quasi-compact, there exists a finite number of sections $s_i \in \Gamma(Y, \mathscr{K}^{\otimes k_i})$ such that the Y_{s_i} are *affine* and cover Y (4.5.2, (a')); **II** | 93
replacing the s_i with suitable powers, we can further suppose that all the k_i are equal to one single integer k. Let s'_i be the sections of $f^*(\mathscr{K}^{\otimes k})$ over X that canonically correspond to the s_i, so that the $X_{s'_i} = f^{-1}(Y_{s_i})$ (4.6.13.1, (i)) cover X. Since $\mathscr{L}|X_{s'_i}$ is ample ((4.6.4) and (4.6.6)), there exists, for each i, a finite number of sections $t_{ij} \in \Gamma(X, \mathscr{L}^{\otimes n_{ij}})$ such that the $X_{t_{ij}}$ are affine, contained in the $X_{s'_i}$, and cover $X_{s'_i}$ (4.5.2, (a')); we can also suppose that all the n_{ij} are equal to one single integer n. With this in mind, X is separated and quasi-compact, and so there exists an integer $m > 0$, and, for every (i, j), a section

$$u_{ij} \in \Gamma(X, \mathscr{L}^{\otimes n} \otimes_X f^*(\mathscr{K}^{\otimes mk}))$$

such that $t_{ij} \otimes s_i'^{\otimes m}$ is the restriction to $X_{s'_i}$ of u_{ij} (**I**, 9.3.1); furthermore, $X_{u_{ij}} = X_{t_{ij}}$, and so the $X_{u_{ij}}$ are affine and cover X. We can also suppose that m is of the form nr; if we set $n_0 = rk$, then we see (4.5.2, (a')) that $\mathscr{L} \otimes_{\mathscr{O}_X} f^*(\mathscr{K}^{\otimes n_0})$ is ample. Furthermore, there exists $h_0 > 0$ such that $\mathscr{K}^{\otimes h}$ is generated by its sections over Y for all $h \geqslant h_0$ (4.5.5); *a fortiori*, $f^*(\mathscr{K}^{\otimes h})$ is generated by its sections over X for all $h \geqslant h_0$, by definition of the inverse images ((**0**, 3.7.1) and (4.4.1)). We thus conclude that $\mathscr{L} \otimes f^*(\mathscr{K}^{\otimes n_0 + h})$ is ample for all $h \geqslant h_0$ (4.5.6), which finishes the proof. □

Remark (4.6.14). — Under the conditions of (ii), one should not conclude that $\mathscr{L} \otimes f^*(\mathscr{K})$ is ample for $g \circ f$; in fact, since $\mathscr{L} \otimes f^*(\mathscr{K}^{-1})$ is also ample for f (4.6.5), we would conclude that $\mathscr{L}$ is ample for $g \circ f$; taking, in particular, g to be the identity morphism, *every* invertible $\mathscr{O}_X$-module would be ample for f, which is not the case in general (see (5.1.6), (5.3.4, (i)), and (5.3.1)).

Proposition (4.6.15). — *Let $f : X \to Y$ be a quasi-compact morphism, $\mathscr{J}$ a quasi-coherent locally-nilpotent sheaf of ideals of $\mathscr{O}_X$, Z the closed subprescheme of X defined by $\mathscr{J}$, and $j : Z \to X$ the canonical injection. For an invertible $\mathscr{O}_X$-module $\mathscr{L}$ to be ample for f, it is necessary and sufficient for $j^*(\mathscr{L})$ to be ample for $f \circ j$.*

Proof. Since the question is local on Y (4.6.4), we can suppose Y to be affine; since X is then quasi-compact, we can suppose $\mathscr{J}$ to be nilpotent. Taking (4.6.6) into account, the proposition is then exactly the same as (4.5.13). □

Corollary (4.6.16). — *Let X be a locally Noetherian prescheme, and $f : X \to Y$ a quasi-compact morphism. For an invertible $\mathcal{O}_X$-module $\mathcal{L}$ to be ample for f, it is necessary and sufficient for its inverse image $\mathcal{L}'$ under the canonical injection $X_{\mathrm{red}} \to X$ to be ample for f_{red}.*

Proof. We have already seen that the condition is necessary (4.6.13, (vi)); conversely, if it is satisfied, then we can restrict, to prove that $\mathcal{L}$ is ample for f, to the case where Y is affine (4.6.4); then Y_{red} is also affine, and so $\mathcal{L}'$ is ample (4.6.6), and so too is $\mathcal{L}$ by (4.5.13), since X is then Noetherian and X_{red} a closed subprescheme of X defined by a quasi-coherent nilpotent sheaf of ideals (**I**, 6.1.6). □

Proposition (4.6.17). — *With the notation and hypotheses of (4.4.11), for $\mathcal{L}''$ to be ample relative to f'', it is necessary and sufficient for $\mathcal{L}$ to be ample relative to f and $\mathcal{L}'$ ample relative to f'.*

II | 94

Proof. The necessity of the condition follows from (4.6.13, (i *bis*)). To see that the condition is sufficient, we can restrict to the case where Y is affine, and then the fact that $\mathcal{L}''$ is ample follows from criterion (4.5.2, (a)) applied to $\mathcal{L}$, $\mathcal{L}'$, and $\mathcal{L}''$, noting that a section of $\mathcal{L}$ over X can be extended (by 0) to a section of $\mathcal{L}''$ over X''. □

Proposition (4.6.18). — *Let Y be a quasi-compact prescheme, $\mathcal{S}$ a quasi-coherent graded $\mathcal{O}_Y$-algebra of finite type, and $X = \operatorname{Proj}(\mathcal{S})$, and let $f : X \to Y$ be the structure morphism. Then f is of finite type, and there exists an integer $d > 0$ such that $\mathcal{O}_X(d)$ is invertible and f-ample.*

Proof. By (3.1.10), there exists an integer $d > 0$ such that $\mathcal{S}^{(d)}$ is generated by $\mathcal{S}_d$. We know that, under the canonical isomorphism between X and $X^{(d)} = \operatorname{Proj}(\mathcal{S}^{(d)})$, $\mathcal{O}_X(d)$ is identified with $\mathcal{O}_{X^{(d)}}(1)$ (3.2.9, (ii)). We thus see that we can restrict to the case where $\mathcal{S}$ is generated by $\mathcal{S}_1$; the proposition then follows from (4.4.3) and (4.6.2) (taking into account the fact that f is a morphism of finite type (3.4.1)). □

§5. Quasi-affine morphisms; quasi-projective morphisms; proper morphisms; projective morphisms

5.1. Quasi-affine morphisms

Definition (5.1.1). — We define a quasi-affine scheme to be a scheme isomorphic to some subscheme induced on some quasi-compact open subset of an affine scheme. We say that a morphism $f : X \to Y$ is quasi-affine, or that X (considered as a Y-prescheme via f) is a quasi-affine Y-scheme, if there exists a cover (U_α) of Y by affine open subsets such that the $f^{-1}(U_\alpha)$ are quasi-affine schemes.

It is clear that a quasi-affine morphism is *separated* ((**I**, 5.5.5) and (**I**, 5.5.8)) and *quasi-compact* (**I**, 6.6.1); every affine morphism is evidently quasi-affine.

Recall that, for any prescheme X, setting $A = \Gamma(X, \mathcal{O}_X)$, the identity homomorphism $A \to A = \Gamma(X, \mathcal{O}_X)$ defines a morphism $X \to \operatorname{Spec}(A)$, said to be *canonical* (**I**, 2.2.4); this is nothing but the canonical morphism defined in (4.5.1) for the specific case where $\mathcal{L} = \mathcal{O}_X$, if we remember that $\operatorname{Proj}(A[T])$ is canonically identified with $\operatorname{Spec}(A)$ (3.1.7).

Proposition (5.1.2). — *Let X be a quasi-compact scheme or a prescheme whose underlying space is Noetherian, and A the ring $\Gamma(X, \mathcal{O}_X)$. The following conditions are equivalent.*

- (a) *X is a quasi-affine scheme.*
- (b) *The canonical morphism $u : X \to \operatorname{Spec}(A)$ is an open immersion.*
- (b') *The canonical morphism $u : X \to \operatorname{Spec}(A)$ is a homeomorphism from X to some subspace of the underlying space of $\operatorname{Spec}(A)$.*
- (c) *The $\mathcal{O}_X$-module $\mathcal{O}_X$ is very ample relative to u (4.4.2).*
- (c') *The $\mathcal{O}_X$-module $\mathcal{O}_X$ is ample (4.5.1).*
- (d) *When f ranges over A, the X_f form a basis for the topology of X.*
- (d') *When f varies over A, the X_f that are affine form a cover of X.* **II** | 95
- (e) *Every quasi-coherent $\mathcal{O}_X$-module is generated by its sections over X.*
- (e') *Every quasi-coherent sheaf of ideals of $\mathcal{O}_X$ of finite type is generated by its sections over X.*

Proof. It is clear that (b) implies (a), and (a) implies (c) by (4.4.4, b) applied to the identity morphism (taking into account the remark preceding this proposition); Furthermore, (c) implies (c′) (4.5.10, i), and (c′), (b), and (b′) are all equivalent by (4.5.2, b) and (4.5.2, b′). Finally, (c′) is the same as each of (d), (d′), (e), and (e′) by (4.5.2, a), (4.5.2, a′), (4.5.2, c), and (4.5.5, d″). □

We further observe that, with the previous notation, the X_f that are affine form a *basis* for the topology of X, and that the canonical morphism u is *dominant* (4.5.2).

Corollary (5.1.3). — *Let X be a quasi-compact prescheme. If there exists a morphism $v : X \to Y$ from X to some affine scheme Y that is a homeomorphism from X to some open subspace of Y, then X is quasi-affine.*

Proof. There exists a family (g_α) of sections of $\mathscr{O}_Y$ over Y such that the $D(g_\alpha)$ form a basis for the topology of $v(X)$; if $v = (\psi, \theta)$ and we set $f_\alpha = \theta(g_\alpha)$, then we have $X_{f_\alpha} = \psi^{-1}(D(g_\alpha))$ (**I**, 2.2.4.1), so the X_{f_α} form a basis for the topology of X, and the criterion (5.1.2, d) is satisfied. □

Corollary (5.1.4). — *If X is a quasi-affine scheme, then* every *invertible $\mathscr{O}_X$-module is very ample (relative to the canonical morphism), and* a fortiori *ample.*

Proof. Such a module $\mathscr{L}$ is generated by its sections over X (5.1.2, e), so $\mathscr{L} \otimes \mathscr{O}_X = \mathscr{L}$ is very ample (4.4.8). □

Corollary (5.1.5). — *Let X be a quasi-compact prescheme. If there exists an invertible $\mathscr{O}_X$-module $\mathscr{L}$ such that $\mathscr{L}$ and $\mathscr{L}^{-1}$ are ample, then X is a quasi-affine scheme.*

Proof. Indeed, $\mathscr{O}_X = \mathscr{L} \otimes \mathscr{L}^{-1}$ is then ample (4.5.7). □

Proposition (5.1.6). — *Let $f : X \to Y$ be a quasi-compact morphism. Then the following conditions are equivalent.*

- (a) *The morphism f is quasi-affine.*
- (b) *The $\mathscr{O}_Y$-algebra $f_*(\mathscr{O}_X) = \mathscr{A}(X)$ is quasi-coherent, and the canonical morphism $X \to \operatorname{Spec}(\mathscr{A}(X))$ corresponding to the identity morphism $\mathscr{A}(X) \to \mathscr{A}(X)$ (1.2.7) is an open immersion.*
- (b′) *The $\mathscr{O}_Y$-algebra $\mathscr{A}(X)$ is quasi-coherent, and the canonical morphism $X \to \operatorname{Spec}(\mathscr{A}(X))$ is a homeomorphism from X to some subspace of* $\operatorname{Spec}(\mathscr{A}(X))$.
- (c) *The $\mathscr{O}_X$-module $\mathscr{O}_X$ is very ample for f.*
- (c′) *The $\mathscr{O}_X$-module $\mathscr{O}_X$ is ample for f.*
- (d) *The morphism f is separated, and, for every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$, the canonical homomorphism $\sigma : f^*(f_*(\mathscr{F})) \to \mathscr{F}$ (**0**, 4.4.3) is surjective.*

Furthermore, whenever f is quasi-affine, every invertible $\mathscr{O}_X$-module $\mathscr{L}$ is very ample relative to f.

Proof. The equivalence between (a) and (c′) follows from the local (on Y) character of the f-ampleness (4.6.4), Definition (5.1.1), and the criterion (5.1.2, c′). The other properties are local on Y and thus **II** | 96
follow immediately from (5.1.2) and (5.1.4), taking into account the fact that $f_*(\mathscr{F})$ is quasi-coherent whenever f is separated (**I**, 9.2.2, a). □

Corollary (5.1.7). — *Let $f : X \to Y$ be a quasi-affine morphism. For every open subset U of Y, the restriction $f^{-1}(U) \to U$ of f is quasi-affine.*

Corollary (5.1.8). — *Let Y be an affine scheme, and $f : X \to Y$ a quasi-compact morphism. For f to be quasi-affine, it is necessary and sufficient for X to be a quasi-affine scheme.*

Proof. This is an immediate consequence of (5.1.6) and (4.6.6). □

Corollary (5.1.9). — *Let Y be a quasi-compact scheme or a prescheme whose underlying space is Noetherian, and $f : X \to Y$ a morphism of* finite type. *If f is quasi-affine, then there exists a quasi-coherent $\mathscr{O}_Y$-subalgebra $\mathscr{B}$ of $\mathscr{A}(X) = f_*(\mathscr{O}_X)$ of* finite type (**I**, 9.6.2) *such that the morphism $X \to \operatorname{Spec}(\mathscr{B})$ corresponding to the canonical injection $\mathscr{B} \to \mathscr{A}(X)$ is an immersion. Further, every quasi-coherent $\mathscr{O}_Y$-subalgebra $\mathscr{B}'$ of finite type of $\mathscr{A}(X)$ containing $\mathscr{B}$ has the same property.*

Proof. Indeed, $\mathscr{A}(X)$ is the inductive limit of its quasi-coherent $\mathscr{O}_Y$-subalgebras of finite type (**I**, 9.6.5); the result is then a particular case of (3.8.4), taking into account the identification of $\operatorname{Spec}(\mathscr{A}(X))$ with $\operatorname{Proj}(\mathscr{A}(X)[T])$ (3.1.7). □

Proposition (5.1.10). —

(i) *A quasi-compact morphism $X \to Y$ that is a homeomorphism from the underlying space of X to some subspace of the underlying space of Y (so, in particular, any closed immersion) is quasi-affine.*

(ii) *The composition of any two quasi-affine morphisms is quasi-affine.*

(iii) *If $f : X \to Y$ is a quasi-affine S-morphism, then $f_{(S')} : X_{(S')} \to Y_{(S')}$ is a quasi-affine morphism for any extension $S' \to S$ of the base prescheme.*

(iv) *If $f : X \to Y$ and $g : X' \to Y'$ are quasi-affine S-morphisms, then $f \times_S g$ is quasi-affine.*

(v) *If $f : X \to Y$ and $g : Y \to Z$ are morphisms such that $g \circ f$ is quasi-affine, and if g is separated or the underlying space of X is locally Noetherian, then f is quasi-affine.*

(vi) *If f is a quasi-affine morphism, then so is f_{red}.*

Proof. Taking into account the criterion (5.1.6, c′), all of (i), (iii), (iv), (v), and (vi) follow immediately from (4.6.13, i *bis*), (4.6.13, iii), (4.6.13, iv), (4.6.13, v), and (4.6.13, vi) (respectively). To prove (ii), we can restrict to the case where Z is affine, and then the claim follows directly from applying (4.6.13, ii) to $\mathscr{L} = \mathscr{O}_X$ and $\mathscr{K} = \mathscr{O}_Y$. □

Remark (5.1.11). — Let $f : X \to Y$ and $g : Y \to Z$ be morphisms such that $X \times_Z Y$ is locally Noetherian. Then the graph immersion $\Gamma_f : X \to X \times_Z Y$ is quasi-affine, since it is quasi-compact (**I**, 6.3.5), and since (**I**, 5.5.12) shows that, in (v), the conclusion still holds true if we remove the hypothesis that g is separated.

Proposition (5.1.12). — *Let $f : X \to Y$ be a quasi-compact morphism, and $g : X' \to X$ a quasi-affine morphism. If $\mathscr{L}$ is an ample (for f) $\mathscr{O}_X$-module, then $g^*(\mathscr{L})$ is an ample (for $f \circ g$) $\mathscr{O}_{X'}$-module.*

Proof. Since $\mathscr{O}_{X'}$ is very ample for g, and the question is local on Y (4.6.4), it follows from (4.6.13, ii) that there exists (for Y affine) an integer n such that

$$g^*(\mathscr{L}^{\otimes n}) = (g^*(\mathscr{L}))^{\otimes n}$$

is ample for $f \circ g$, and so $g^*(\mathscr{L})$ is ample for $f \circ g$ (4.6.9). □

II | 97

5.2. Serre's criterion

Theorem (5.2.1). — (Serre's criterion). *Let X be a quasi-compact scheme or a prescheme whose underlying space is Noetherian. The following conditions are equivalent.*

(a) *X is an affine scheme.*

(b) *There exists a family of elements $f_\alpha \in A = \Gamma(X, \mathscr{O}_X)$ such that the X_{f_α} are affine, and such that the ideal generated by the f_α in A is equal to A itself.*

(c) *The functor $\Gamma(X, \mathscr{F})$ is exact in $\mathscr{F}$ on the category of quasi-coherent $\mathscr{O}_X$-modules, or, in other words, if*

$$0 \longrightarrow \mathscr{F}' \longrightarrow \mathscr{F} \longrightarrow \mathscr{F}'' \longrightarrow 0 \tag{*}$$

is an exact sequence of quasi-coherent $\mathscr{O}_X$-modules, then the sequence

$$0 \longrightarrow \Gamma(X, \mathscr{F}') \longrightarrow \Gamma(X, \mathscr{F}) \longrightarrow \Gamma(X, \mathscr{F}'') \longrightarrow 0$$

is also exact.

(c′) *Condition* (c) *holds for every exact sequence* $(*)$ *of quasi-coherent $\mathscr{O}_X$-modules such that $\mathscr{F}$ is isomorphic to an $\mathscr{O}_X$-submodule of $\mathscr{O}_X^n$ for some finite n.*

(d) $\mathrm{H}^1(X, \mathscr{F}) = 0$ *for every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$.*

(d′) $\mathrm{H}^1(X, \mathscr{J}) = 0$ *for every quasi-coherent sheaf of ideals $\mathscr{J}$ of $\mathscr{O}_X$.*

Proof. It is evident that (a) implies (b); furthermore, (b) implies that the X_{f_α} cover X, because, by hypothesis, the section 1 is a linear combination of the f_α, and the $D(f_\alpha)$ thus cover $\mathrm{Spec}(A)$. The final claim of (4.5.2) thus implies that $X \to \mathrm{Spec}(A)$ is an isomorphism.

We know that (a) implies (c) (**I**, 1.3.11), and (c) trivially implies (c′). We now prove that (c′) implies (b). First of all, (c′) implies that, for every *closed* point $x \in X$ and every open neighbourhood U of x, there exists some $f \in A$ such that $x \in X_f \subset U$. Let $\mathscr{J}$ (resp. $\mathscr{J}'$) be the quasi-coherent sheaf of ideals of $\mathscr{O}_X$ defining the closed reduced subprescheme of X that has $X - U$ (resp. $(X - U) \cup \{x\}$)

as its underlying space (**I**, 5.2.1); it is clear that we have $\mathscr{J}' \subset \mathscr{J}$, and that $\mathscr{J}'' = \mathscr{J}/\mathscr{J}'$ is a quasi-coherent $\mathscr{O}_X$ module that has support equal to $\{x\}$, and such that $\mathscr{J}''_x = k(x)$. Hypothesis (c′) applied to the exact sequence $0 \to \mathscr{J}' \to \mathscr{J} \to \mathscr{J}'' \to 0$ shows that $\Gamma(X, \mathscr{J}) \to \Gamma(X, \mathscr{J}'')$ is surjective. The section of $\mathscr{J}''$ whose germ at x is 1_x is thus the image of some section $f \in \Gamma(X, \mathscr{J}) \subset \Gamma(X, \mathscr{O}_X)$, and we have, by definition, that $f(x) = 1_x$ and $f(y) = 0$ in $X - U$, which establishes our claim. Now, if U is affine, then so is X_f (**I**, 1.3.6), so the union of the X_f that are affine ($f \in A$) is an open set Z that contains *all the closed points* of X; since X is a quasi-compact Kolmogoroff space, we necessarily have $Z = X$ (**0**, 2.1.3). Because X is quasi-compact, there are a *finite* number of elements $f_i \in A$ ($1 \leqslant i \leqslant n$) such that the X_{f_i} are affine and cover X. So consider the homomorphism $\mathscr{O}_X^n \to \mathscr{O}_X$ defined by the sections f_i (**0**, 5.1.1); since, for all $x \in X$, at least one of the $(f_i)_x$ is invertible, this homomorphism is *surjective*, and we thus have an exact sequence $0 \to \mathscr{R} \to \mathscr{O}_X^n \to \mathscr{O}_X \to 0$, where $\mathscr{R}$ is a quasi-coherent $\mathscr{O}_X$-submodule of $\mathscr{O}_X^n$. It then follows from (c′) that the corresponding **II** | 98
homomorphism $\Gamma(X, \mathscr{O}_X^n) \to \Gamma(X, \mathscr{O}_X)$ is surjective, which proves (b).

Finally, (a) implies (d) (**I**, 5.1.9.2), and (d) trivially implies (d′). It remains to show that (d′) implies (c′). But if $\mathscr{F}'$ is a quasi-coherent $\mathscr{O}_X$-submodule of $\mathscr{O}_X^n$, then the filtration $0 \subset \mathscr{O}_X \subset \mathscr{O}_X^2 \subset \ldots \subset \mathscr{O}_X^n$ defines a filtration of $\mathscr{F}'$ given by the $\mathscr{F}'_k = \mathscr{F}' \cap \mathscr{O}_X^k$ ($0 \leqslant k \leqslant n$), which are quasi-coherent $\mathscr{O}_X$-modules (**I**, 4.1.1), and $\mathscr{F}'_{k+1}/\mathscr{F}'_k$ is isomorphic to a quasi-coherent $\mathscr{O}_X$-submodule of $\mathscr{O}_X^{k+1}/\mathscr{O}_X^k = \mathscr{O}_X$, which is to say, a quasi-coherent sheaf of ideals of $\mathscr{O}_X$. Hypothesis (d′) thus implies that $\mathrm{H}^1(X, \mathscr{F}'_{k+1}/\mathscr{F}'_k) = 0$; the exact cohomology sequence $\mathrm{H}^1(X, \mathscr{F}'_k) \to \mathrm{H}^1(X, \mathscr{F}'_{k+1}) \to \mathrm{H}^1(X, \mathscr{F}'_{k+1}/\mathscr{F}'_k) = 0$ then lets us prove by induction on k that $H^1(X, \mathscr{F}'_k) = 0$ for all k. □

Remark (5.2.1.1). — When X is a *Noetherian* prescheme, we can replace "quasi-coherent" by "coherent" in the statements of (c′) and (d′). Indeed, in the proof of the fact that (c′) implies (b), $\mathscr{J}$ and $\mathscr{J}'$ are then *coherent* sheaves of ideals, and, furthermore, every quasi-coherent submodule of a coherent module is coherent (**I**, 6.1.1); whence the conclusion.

Corollary (5.2.2). — *Let $f : X \to Y$ be a separated quasi-compact morphism. The following conditions are equivalent.*

(a) *The morphism f is an affine morphism.*
(b) *The functor f_* is exact on the category of quasi-coherent $\mathscr{O}_X$-modules.*
(c) *For every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$, we have $\mathrm{R}^1 f_*(\mathscr{F}) = 0$.*
(c′) *for every quasi-coherent sheaf of ideals $\mathscr{J}$ of $\mathscr{O}_X$, we have $\mathrm{R}^1 f_*(\mathscr{J}) = 0$.*

Proof. All these conditions are local on Y, by definition of the functor $\mathrm{R}^1 f_*$ (T, 3.7.3), and so we can assume that Y is affine. If f is affine, then X is affine, and property (b) is nothing more than (**I**, 1.6.4). Conversely, we now show that (b) implies (a): for every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$, we have that $f_*(\mathscr{F})$ is a quasi-coherent $\mathscr{O}_Y$-module (**I**, 9.2.2, a). By hypothesis, the functor f_* is exact in $\mathscr{F}$, and the functor $\Gamma(Y, \mathscr{G})$ is exact in $\mathscr{G}$ (in the category of quasi-coherent $\mathscr{O}_Y$-modules) because Y is affine (**I**, 1.3.11); so $\Gamma(Y, f_*(\mathscr{F})) = \Gamma(X, \mathscr{F})$ is exact in $\mathscr{F}$, which proves our claim, by (5.2.1, c).

If f is affine, then $f^{-1}(U)$ is affine for every affine open subset U of Y (1.3.2), and so $\mathrm{H}^1(f^{-1}(U), \mathscr{F}) = 0$ (5.2.1, d), which, by definition, implies that $\mathrm{R}^1 f_*(\mathscr{F}) = 0$. Finally, suppose that condition (c′) is satisfied; the exact sequence of terms of low degree in the Leray spectral sequence (G, II, 4.17.1 and I, 4.5.1) gives, in particular, the exact sequence

$$0 \longrightarrow \mathrm{H}^1(Y, f_*(\mathscr{J})) \longrightarrow \mathrm{H}^1(X, \mathscr{J}) \longrightarrow \mathrm{H}^0(Y, \mathrm{R}^1 f_*(\mathscr{J})).$$

Since Y is affine, and $f_*(\mathscr{J})$ quasi-coherent (**I**, 9.2.2, a), we have that $\mathrm{H}^1(Y, f_*(\mathscr{J})) = 0$ (5.2.1); hypothesis (c′) thus implies that $\mathrm{H}^1(X, \mathscr{J}) = 0$, and we conclude, by (5.2.1), that X is an affine scheme. □

Corollary (5.2.3). — *If $f : X \to Y$ is an affine morphism, then, for every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$, the canonical homomorphism $\mathrm{H}^1(Y, f_*(\mathscr{F})) \to \mathrm{H}^1(X, \mathscr{F})$ is bijective.*

II | 99

Proof. We have the exact sequence

$$0 \longrightarrow \mathrm{H}^1(Y, f_*(\mathscr{F})) \longrightarrow \mathrm{H}^1(X, \mathscr{F}) \longrightarrow \mathrm{H}^0(Y, \mathrm{R}^1 f_*(\mathscr{F}))$$

of terms of low degree in the Leray spectral sequence, and the conclusion follows from (5.2.2). □

Remark (5.2.4). — In Chapter III, §1, we prove that, if X is affine, then we have $\mathrm{H}^i(X,\mathscr{F}) = 0$ for all $i > 0$ and all quasi-coherent $\mathscr{O}_X$-modules $\mathscr{F}$.

5.3. Quasi-projective morphisms

Definition (5.3.1). — We say that a morphism $f : X \to Y$ is *quasi-projective*, or that X (considered as a Y-prescheme via f) is *quasi-projective over* Y, or that X is a *quasi-projective* Y*-scheme*, if f is of finite type and there exists an invertible f-ample $\mathscr{O}_X$-module.

We note that this notion *is not local on* Y: the counterexamples of Nagata [Nag58b] and Hironaka show that, even if X and Y are non-singular algebraic schemes over an algebraically closed field, every point of Y can have an affine neighbourhood U such that $f^{-1}(U)$ is quasi-projective over U, without f being quasi-projective.

We note that a quasi-projective morphism is necessarily *separated* (4.6.1). When Y is quasi-compact, it is equivalent to say either that f is quasi-projective, or that f is of finite type and there exists a *very ample* (relative to f) $\mathscr{O}_X$-module ((4.6.2) and (4.6.11)). Further:

Proposition (5.3.2). — *Let Y be a quasi-compact scheme or a prescheme whose underlying space is Noetherian, and let X be a Y-prescheme. The following conditions are equivalent.*

(a) *X is a quasi-projective Y-scheme.*
(b) *X is of finite type over Y, and there exists some quasi-coherent $\mathscr{O}_Y$-module $\mathscr{E}$ of finite type such that X is Y-isomorphic to a subprescheme of $\mathbf{P}(\mathscr{E})$.*
(c) *X is of finite type over Y, and there exists some quasi-coherent graded $\mathscr{O}_Y$-algebra $\mathscr{S}$ such that $\mathscr{S}_1$ is of finite type and generates $\mathscr{S}$, and such that X is Y-isomorphic to a subprescheme induced on some everywhere-dense open subset of* $\operatorname{Proj}(\mathscr{S})$.

Proof. This follows immediately from the previous remark and from (4.4.3), (4.4.6), and (4.4.7). □

We note that, whenever Y is a *Noetherian* prescheme, we can, in conditions (b) and (c) of (5.3.2), remove the hypothesis that X is of finite type over Y, since this is then automatically satisfied (**I**, 6.3.5).

Corollary (5.3.3). — *Let Y be a quasi-compact scheme such that there exists an ample $\mathscr{O}_Y$-module $\mathscr{L}$* (4.5.3). *For a Y-scheme X to be quasi-projective, it is necessary and sufficient for it to be of finite type over Y and also isomorphic to a Y-subscheme of a projective bundle of the form $\mathbf{P}^r_Y$.*

Proof. If $\mathscr{E}$ is a quasi-coherent $\mathscr{O}_Y$-module of finite type, then $\mathscr{E}$ is isomorphic to a quotient of an $\mathscr{O}_Y$-module $\mathscr{L}^{\otimes(-n)} \otimes_{\mathscr{O}_Y} \mathscr{O}_Y^k$ (4.5.5), and so $\mathbf{P}(\mathscr{E})$ is isomorphic to a closed subscheme of $\mathbf{P}_Y^{k-1}$ ((4.1.2) and (4.1.4)). □

Proposition (5.3.4). —

(i) *A quasi-affine morphism of finite type (and, in particular, a quasi-compact immersion, or an affine morphism of finite type) is quasi-projective.*
(ii) *If $f : X \to Y$ and $g : Y \to Z$ are quasi-projective, and if Z is quasi-compact, then $g \circ f$ is quasi-projective.* II | 100
(iii) *If $f : X \to Y$ is a quasi-projective S-morphism, then $f_{(S')} : X_{(S')} \to Y_{(S')}$ is quasi-projective for every extension $S' \to S$ of the base prescheme.*
(iv) *If $f : X \to Y$ and $g : X' \to Y'$ are quasi-projective S-morphisms, then $f \times_S g$ is quasi-projective.*
(v) *If $f : X \to Y$ and $g : Y \to Z$ are morphisms such that $g \circ f$ is quasi-projective, and if g is separated or X locally Noetherian, then f is quasi-projective.*
(vi) *If f is a quasi-projective morphism, then so is f_{red}.*

Proof. (i) follows from (5.1.6) and (5.1.10, i). The other claims are immediate consequences of Definition (5.3.1), of the properties of morphisms of finite type (**I**, 6.3.4), and of (4.6.13). □

Remark (5.3.5). — We note that it can happen that f_{red} is quasi-projective without f being quasi-projective, even if we assume that Y is the spectrum of an algebra of finite rank over $\mathbf{C}$ and that f is proper.

Corollary (5.3.6). — *If X and X' are quasi-projective Y-schemes, then $X \sqcup X'$ is a quasi-projective Y-scheme.*

Proof. This follows from (4.6.18). □

5.4. Proper morphisms and universally closed morphisms

Definition (5.4.1). — We say that a morphism of preschemes $f : X \to Y$ is *proper* if it satisfies the following two conditions:

(a) f is separated and of finite type; and
(b) for every prescheme Y' and every morphism $Y' \to Y$, the projection $f_{(Y')} : X \times_Y Y' \to Y'$ is a closed morphism (**I**, 2.2.6).

When this is the case, we also say that X (considered as a Y-prescheme with structure morphism f) is proper over Y.

It is immediate that conditions (a) and (b) are *local* on Y. To show that the image of a closed subset Z of $X \times_Y Y'$ under the projection $q : X \times_Y Y' \to Y'$ is closed in Y', it suffices to see that $q(Z) \cap U'$ is closed in U' for every affine open subset U' of Y'; since $q(Z) \cap U' = q(Z \cap q^{-1}(U'))$, and since $q^{-1}(U')$ can be identified with $X \times_Y U'$ (**I**, 4.4.1), we see that to satisfy condition (b) of Definition (5.4.1), we can restrict to the case where Y' is an *affine* scheme. We will see below (5.6.3) that, if Y is locally Noetherian, then we can even restrict to proving (b) in the case where Y' is of finite type over Y.

It is clear that every proper morphism is *closed*.

Proposition (5.4.2). —

(i) *A closed immersion is a proper morphism.*
(ii) *The composition of two proper morphisms is proper.*
(iii) *If X and Y are S-preschemes, and $f : X \to Y$ a proper S-morphism, then $f_{(S')} : X_{(S')} \to Y_{(S')}$ is proper for every extension $S' \to S$ of the base prescheme.*
(iv) *If $f : X \to Y$ and $g : X' \to Y'$ are proper S-morphisms, then $f \times_S g : X \times_S X' \to Y \times_S Y'$ is a proper S-morphism.*

II | 101

Proof. It suffices to prove (i), (ii), and (iii) (**I**, 3.5.1). In each of the three cases, verifying condition (a) of (5.4.1) follows from previous results ((**I**, 5.5.1) and (**I**, 6.3.4)); it remains to verify condition (b). It is immediate in case (i), because if $X \to Y$ is a closed immersion, then so is $X \times_Y Y' \to Y \times_Y Y' = Y'$ ((**I**, 4.3.2) and (3.3.3)). To prove (ii), consider two proper morphisms $X \to Y$ and $Y \to Z$, and a morphism $Z' \to Z$. We can write $X \times_Z Z' = X \times_Y (Y \times_Z Z')$ (**I**, 3.3.9.1), and so the projection $X \times_Z Z' \to Z'$ factors as $X \times_Y (Y \times_Z Z') \to Y \times_Z Z' \to Z'$. Taking the initial remark into account, (ii) follows from the fact that the composition of two closed morphisms is closed. Finally, for every morphism $S' \to S$, we can identify $X_{(S')}$ with $X \times_Y Y_{(S')}$ (**I**, 3.3.11); for every morphism $Z \to Y_{(S')}$, we can write

$$X_{(S')} \times_{Y_{(S')}} Z = (X \times_Y Y_{(S')}) \times_{Y_{(S')}} Z = X \times_Y Z;$$

since by hypothesis $X \times_Y Z \to Z$ is closed, this proves (iii). □

Corollary (5.4.3). — *Let $f : X \to Y$ and $g : Y \to Z$ be morphisms such that $g \circ f$ is proper.*

(i) *If g is separated, then f is proper.*
(ii) *If g is separated and of finite type, and if f is surjective, then g is proper.*

Proof. (i) follows from (5.4.2) by the general procedure (**I**, 5.5.12). To prove (ii), we need only verify that condition (b) of Definition (5.4.1) is satisfied. For every morphism $Z' \to Z$, the diagram

$$\begin{tikzcd} X \times_Z Z' \arrow[r, "f \times 1_{Z'}"] \arrow[dr, "p"'] & Y \times_Z Z' \arrow[d, "p'"] \\ & Z' \end{tikzcd}$$

(where p and p' are the projections) commutes (**I**, 3.2.1); furthermore, $f \times 1_{Z'}$ is surjective because f is surjective (**I**, 3.5.2), and p is a closed morphism by hypothesis. Every closed subset F of $Y \times_Z Z'$ is thus the image under $f \times 1_{Z'}$ of some closed subset E of $X \times_Z Z'$, so $p'(F) = p(E)$ is closed in Z' by hypothesis, whence the corollary. □

Corollary (5.4.4). — *If X is a proper prescheme over Y, and $\mathscr{S}$ a quasi-coherent $\mathscr{O}_Y$-algebra, then every Y-morphism $f : X \to \operatorname{Proj}(\mathscr{S})$ is proper (and* a fortiori *closed).*

Proof. The structure morphism $p : \operatorname{Proj}(\mathscr{S}) \to Y$ is separated, and $p \circ f$ is proper by hypothesis. □

Corollary (5.4.5). — *Let $f : X \to Y$ be a separated morphism of finite type. Let $(X_i)_{1\leqslant i\leqslant n}$ (resp. $(Y_i)_{1\leqslant i\leqslant n}$) be a finite family of closed subpreschemes of X (resp. Y), and j_i (resp. h_i) the canonical injection $X_i \to X$ (resp. $Y_i \to Y$). Suppose that the underlying space of X is the union of the X_i, and that, for all i, there is a morphism $f_i : X_i \to Y_i$, such that the diagram*

$$\begin{tikzcd} X_i \arrow[r, "f_i"] \arrow[d, "j_i"'] & Y_i \arrow[d, "h_i"] \\ X \arrow[r, "f"'] & Y \end{tikzcd}$$

commutes. Then, for f to be proper, it is necessary and sufficient for all of the f_i to be proper.

II | 102

Proof. If f is proper, then so is $f \circ j_i$, because j_i is a closed immersion (5.4.2); since h_i is a closed immersion, and thus a separated morphism, f_i is proper, by (5.4.3). Conversely, suppose that all of the f_i are proper, and consider the prescheme Z given by the *sum* of the X_i; let u be the morphism $Z \to X$ which reduces to j_i on each X_i. The restriction of $f \circ u$ to each X_i is equal to $f \circ j_i = h_i \circ f_i$, and is thus proper, because both the h_i and the f_i are (5.4.2); it then follows immediately from Definition (5.4.1) that $f \circ u$ is proper. But since by hypothesis u is surjective, we conclude that f is proper by (5.4.3). □

Corollary (5.4.6). — *Let $f : X \to Y$ be a separated morphism of finite type; for f to be proper, it is necessary and sufficient for $f_{\text{red}} : X_{\text{red}} \to Y_{\text{red}}$ to be proper.*

Proof. This is a particular case of (5.4.5), with $n = 1$, $X_1 = X_{\text{red}}$, and $Y_1 = Y_{\text{red}}$ (**I**, 5.1.5). □

(5.4.7). If X and Y are Noetherian preschemes, and $f : X \to Y$ a separated morphism of finite type, then we can, to show that f is proper, restrict to the case of *dominant* morphisms and *integral* preschemes. Indeed, let X_i $(1 \leqslant i \leqslant n)$ be the (finitely many) irreducible components of X, and consider, for each i, the unique closed reduced subprescheme of X that has X_i as its underlying space, which we again denote by X_i (**I**, 5.2.1). Let Y_i be the unique closed reduced subprescheme of Y that has $\overline{f(X_i)}$ as its underlying space. If g_i (resp. h_i) is the injection morphism $X_i \to X$ (resp. $Y_i \to Y$), then we conclude that $f \circ g_i = h_i \circ f_i$, where f_i is a dominant morphism $X_i \to Y_i$ (**I**, 5.2.2); we are then under the right conditions to apply (5.4.5), and for f to be proper, it is necessary and sufficient for all the f_i to be proper.

Corollary (5.4.8). — *Let X and Y be separated S-preschemes of finite type over S, and $f : X \to Y$ an S-morphism. For f to be proper, it is necessary and sufficient that, for every S-prescheme S', the morphism $f \times_S 1_{S'} : X \times_S S' \to Y \times_S S'$ be closed.*

Proof. First note that, if $g : X \to S$ and $h : Y \to S$ are the structure morphisms, then we have, by definition, $g = h \circ f$, and so f is separated and of finite type ((**I**, 5.5.1) and (**I**, 6.3.4)). If f is proper, then so is $f \times_S 1_{S'}$ (5.4.2); *a fortiori*, $f \times_S 1_{S'}$ is closed. Conversely, suppose that the conditions of the statement are satisfied, and let Y' be a Y-prescheme; Y' can also be considered as an S-prescheme, and since $Y \to S$ is separated, $X \times_Y Y'$ can be identified with a closed subprescheme of $X \times_S Y'$ (**I**, 5.4.2). In the commutative diagram

$$\begin{tikzcd} X \times_Y Y' \arrow[r, "f\times 1_{Y'}"] \arrow[d] & Y \times_Y Y' = Y' \arrow[d] \\ X \times_S Y' \arrow[r, "f\times_S 1_{Y'}"'] & Y \times_S Y', \end{tikzcd}$$

the vertical arrows are closed immersions; it thus immediately follows that if $f \times 1_{Y'}$ over S is a closed morphism, then so is the base change $f \times 1_{Y'}$ over Y. □

Remark (5.4.9). — We say that a morphism $f : X \to Y$ is *universally closed* if it satisfies condition (b) of Definition (5.4.1). The reader will observe that, in (5.4.2) to (5.4.8), we can replace every occurrence of "proper" with "universally closed" without changing the validity of the results (and in the hypotheses of (5.4.3), (5.4.5), (5.4.6), and (5.4.8), we can omit the finiteness conditions). **II** | 103

(5.4.10). Let $f : X \to Y$ be a morphism of finite type. We say that a closed subset Z of X is *proper on* Y (or Y*-proper*, or *proper for* f) if the restriction of f to a closed subprescheme of X, with underlying space Z (**I**, 5.2.1), is *proper*. Since this restriction is then separated, it follows from (5.4.6) and (**I**, 5.5.1, vi) that the preceding property *does not depend* on the closed subprescheme of X that has Z as its underlying space. If $g : X' \to X$ is a *proper* morphism, then $g^{-1}(Z)$ is a *proper* subset of X': if T is a subprescheme of X that has Z as its underlying space, it suffices to note that the restriction of g to the closed subprescheme $g^{-1}(T)$ of X' is a proper morphism $g^{-1}(T) \to T$, by (5.4.2, iii), and to then apply (5.4.2, ii). Further, if X'' is a Y*-scheme* of finite type, and $u : X \to X''$ a Y-morphism, then $u(Z)$ is a *proper* subset of X''; indeed, let us take T to be the closed reduced subprescheme of X having Z as its underlying space; then the restriction of f to T is proper, and thus so is the restriction of u to T (5.4.3, i), thus $u(Z)$ is closed in X''; let T'' be a closed subprescheme of X'' having $u(Z)$ as its underlying space (**I**, 5.2.1), such that $u|T$ factors as $T \xrightarrow{v} T'' \xrightarrow{j} X''$, where j is the canonical injection (**I**, 5.2.2), and v is thus proper and surjective (5.4.5); if g is the restriction to T'' of the structure morphism $X'' \to Y$, then g is separated and of finite type, and we have that $f|T = g \circ v$; it thus follows from (5.4.3, ii) that g is proper, whence our assertion.

It follows, in particular, from these remarks that, if Z is a Y-proper subset of X, then

(1) for every closed subprescheme X' of X, $Z \cap X'$ is a Y-proper subset of X'; and
(2) if X is a subprescheme of a Y-scheme of finite type X'', then Z is also a Y-proper subset of X'' (and so, in particular, is *closed in* X'').

5.5. Projective morphisms

Proposition (5.5.1). — *Let X be a Y-prescheme. The following conditions are equivalent.*

(a) *X is Y-isomorphic to a* closed *subprescheme of a projective bundle $\mathbf{P}(\mathscr{E})$, where $\mathscr{E}$ is a quasi-coherent $\mathscr{O}_Y$-module of finite type.*
(b) *There exists a quasi-coherent graded $\mathscr{O}_Y$-algebra $\mathscr{S}$ such that $\mathscr{S}_1$ is of finite type and generates $\mathscr{S}$, and such that X is Y-isomorphic to* $\operatorname{Proj}(\mathscr{S})$.

Proof. Condition (a) implies (b), by (3.6.2, ii): if $\mathscr{J}$ is a quasi-coherent graded sheaf of ideals of $\mathbf{S}(\mathscr{E})$, then the quasi-coherent graded $\mathscr{O}_Y$-algebra $\mathscr{S} = \mathbf{S}(\mathscr{E})/\mathscr{J}$ is generated by $\mathscr{S}_1$, and $\mathscr{S}_1$, the canonical image of $\mathscr{E}$, is an $\mathscr{O}_Y$-module of finite type. Condition (b) implies (a) by (3.6.2) applied to the case where $\mathscr{M} \to \mathscr{S}_1$ is the identity map. □

II | 104

Definition (5.5.2). — We say that a Y-prescheme X is *projective* over Y, or is a projective Y-scheme, if it satisfies the equivalent conditions (a) and (b) of (5.5.1). We say that a morphism $f : X \to Y$ is projective if it makes X a projective Y-scheme.

It is clear that if $f : X \to Y$ is projective, then there exists a *very ample* (relative to f) $\mathscr{O}_X$-module (4.4.2).

Theorem (5.5.3). —

(i) *Every projective morphism is quasi-projective and proper.*
(ii) *Conversely, let Y be a quasi-compact scheme or a prescheme whose underlying space is Noetherian; then every morphism $f : X \to Y$ that is quasi-projective and proper is projective.*

Proof.

(i) It is clear that if $f : X \to Y$ is projective, then it is of finite type and quasi-projective (thus, in particular, separated); furthermore, it follows immediately from (5.5.1, b) and (3.5.3) that if f is projective, then so is $f \times_Y 1_{Y'} : X \times_Y Y' \to Y'$ for every morphism $Y' \to Y$. To show that f is universally closed, it is thus enough to show that a projective morphism f is *closed*.

Since the question is local on Y, we can suppose that $Y = \operatorname{Spec}(A)$, thus (5.5.1) $X = \operatorname{Proj}(S)$, where S is a graded A-algebra generated by a finite number of elements of S_1. For all $y \in Y$, the fibre $f^{-1}(y)$ can be identified with $\operatorname{Proj}(S) \times_Y \operatorname{Spec}(k(y))$ (**I**, 3.6.1), and so also with $\operatorname{Proj}(S \otimes_A k(y))$ (2.8.10); so $f^{-1}(y)$ is empty if and only if $S \otimes_A k(y)$ satisfies condition (TN) (2.7.4), or, in other words, if $S_n \otimes_A k(y) = 0$ for sufficiently large n. But since $(S_n)_y$ is an $\mathscr{O}_y$-module of finite type, the preceding condition implies that $(S_n)_y = 0$ for sufficiently large n, by Nakayama's lemma. If $\mathfrak{a}_n$ is the annihilator in A of the A-module S_n, then the preceding condition also implies that $\mathfrak{a}_n \not\subset \mathfrak{j}_y$ for sufficiently large n (**0**, 1.7.4). But since $S_n S_1 = S_{n+1}$, by hypothesis, we have that $\mathfrak{a}_n \subset \mathfrak{a}_{n+1}$, and if $\mathfrak{a}$ is the union of the $\mathfrak{a}_n$, then we see that $f(X) = V(\mathfrak{a})$, which proves that $f(X)$ is closed in Y. If now X' is an arbitrary closed subset of X, then there exists a closed subprescheme of X that has X' as its underlying space (**I**, 5.2.1), and it is clear (5.5.1, a) that the morphism $X' \to X \xrightarrow{f} Y$ is projective, and so $f(X')$ is closed in Y.

(ii) The hypothesis on Y and the fact that f is quasi-projective imply the existence of a quasi-coherent $\mathscr{O}_Y$-module $\mathscr{E}$ of finite type, as well as a Y-immersion $j : X \to \mathbf{P}(\mathscr{E})$ (5.3.2). But since f is proper, j is *closed*, by (5.4.4), and so f is projective.

□

Remark (5.5.4). —

(i) Let $f : X \to Y$ be a morphism such that f is proper, such that there exists a *very ample* (relative to f) $\mathscr{O}_X$-module $\mathscr{L}$, and such that the quasi-coherent $\mathscr{O}_Y$-module $\mathscr{E} = f_*(\mathscr{L})$ is *of finite type*. Then f is a *projective* morphism: indeed (4.4.4), there is then a Y-immersion $r : X \to \mathbf{P}(\mathscr{E})$, and, since f is proper, r is a *closed* immersion (5.4.4). We will see in Chapter III, §3, that when Y is *locally Noetherian*, the third condition above ($\mathscr{E}$ being of finite type) is a consequence of the first two, and so the first two conditions *characterise*, in this case, the projective morphisms, and if Y is quasi-compact, then we can replace the second condition (the existence of a very ample (relative to f) $\mathscr{O}_X$-module $\mathscr{L}$) by the hypothesis that there exists an *ample* (relative to f) $\mathscr{O}_X$-module (4.6.11).

(ii) Let Y be a quasi-compact scheme such that there exists an ample $\mathscr{O}_Y$-module. For a Y-scheme X to be *projective*, it is necessary and sufficient for it to be Y-isomorphic to a *closed* Y-subscheme of a projective bundle of the form $\mathbf{P}^r_Y$. The condition is clearly sufficient. Conversely, if X is projective over Y, then it is quasi-projective, and so there exists a Y- **II** | 105
immersion j of X into some $\mathbf{P}^r_Y$ (5.3.3) that is *closed*, by (5.4.4) and (5.5.3).

(iii) The argument of (5.5.3) shows that, for every prescheme Y and every integer $r \geqslant 0$, the structure morphism $\mathbf{P}^r_Y \to Y$ is *surjective*, because if we set $\mathscr{S} = \mathbf{S}_{\mathscr{O}_Y}(\mathscr{O}_Y^{r+1})$, then we evidently have $\mathscr{S}_y = \mathbf{S}_{k(y)}(k(y)^{r+1})$ (1.7.3), and so $(\mathscr{S}_n)_y \neq 0$ for every $y \in Y$ and every $n \geqslant 0$.

(iv) It follows from the examples of Nagata [Nag58b] that there exist proper morphisms that are not quasi-projective.

Proposition (5.5.5). —

(i) *A closed immersion is a projective morphism.*

(ii) *If $f : X \to Y$ and $g : Y \to Z$ are projective morphisms, and if Z is a quasi-compact scheme or a prescheme whose underlying space is Noetherian, then $g \circ f$ is projective.*

(iii) *If $f : X \to Y$ is a projective S-morphism, then $f_{(S')} : X_{(S')} \to Y_{(S')}$ is projective for every extension $S' \to S$ of the base prescheme.*

(iv) *If $f : X \to Y$ and $g : X' \to Y'$ are projective S-morphisms, then so is $f \times_S g$.*

(v) *If $g \circ f$ is a projective morphism, and if g is separated, then f is projective.*

(vi) *If f is projective, then so is f_{red}.*

Proof. (i) follows immediately from (3.1.7). We have to show (iii) and (iv) separately, because of the restriction introduced on Z in (ii) (cf. (**I**, 3.5.1)). To show (iii), we restrict to the case where $S = Y$ (**I**, 3.3.11), and the claim then immediately follows from (5.5.1, b) and (3.5.3). To show (iv), we are immediately led to the case where $X = \mathbf{P}(\mathscr{E})$ and $X' = \mathbf{P}(\mathscr{E}')$, where $\mathscr{E}$ (resp. $\mathscr{E}'$) is a quasi-coherent $\mathscr{O}_Y$-module (resp. quasi-coherent $\mathscr{O}_{Y'}$-module) of finite type. Let p and p' be the canonical projections of $T = Y \times_S Y'$ to Y and Y' (respectively); by (4.1.3.1), we have $\mathbf{P}(p^*(\mathscr{E})) = \mathbf{P}(\mathscr{E}) \times_Y T$ and $\mathbf{P}(p'^*(\mathscr{E}')) = \mathbf{P}(\mathscr{E}') \times_{Y'} T$; whence

$$\begin{aligned}\mathbf{P}(p^*(\mathscr{E})) \times_T \mathbf{P}(p'^*(\mathscr{E}')) &= (\mathbf{P}(\mathscr{E}) \times_Y T) \times_T (T \times_{Y'} \mathbf{P}(\mathscr{E}')) \\ &= \mathbf{P}(\mathscr{E}) \times_Y (T \times_{Y'} \mathbf{P}(\mathscr{E}')) = \mathbf{P}(\mathscr{E}) \times_S \mathbf{P}(\mathscr{E}')\end{aligned}$$

by replacing T with $Y \times_S Y'$, and using (**I**, 3.3.9.1). But $p^*(\mathscr{E})$ and $p'^*(\mathscr{E}')$ are of finite type over T (**0**, 5.2.4), and thus so is $p^*(\mathscr{E}) \otimes_{\mathscr{O}_T} p'^*(\mathscr{E}')$; since $\mathbf{P}(p^*(\mathscr{E})) \times_T \mathbf{P}(p'^*(\mathscr{E}'))$ can be identified with a closed subprescheme of $\mathbf{P}(p^*(\mathscr{E}) \otimes_{\mathscr{O}_T} p'^*(\mathscr{E}'))$ (4.3.3), this proves (iv). To show (v) and (vi), we can apply (**I**, 5.5.13), because every closed subprescheme of a projective Y-scheme is a projective Y-scheme, by (5.5.1, a).

It remains to prove (ii); by the hypothesis on Z, this follows from (5.5.3), (5.3.4, ii), and (5.4.2, ii). □

Proposition (5.5.6). — *If X and X' are projective Y-schemes, then $X \sqcup X'$ is a projective Y-scheme.*

Proof. This is an evident consequence of (5.5.2) and (4.3.6). □

Proposition (5.5.7). — *Let X be a projective Y-scheme, and $\mathscr{L}$ a Y-ample $\mathscr{O}_X$-module; then, for every section f of $\mathscr{L}$ over X, X_f is affine over Y.*

II | 106

Proof. Since the question is local on Y, we can assume that $Y = \operatorname{Spec}(A)$; furthermore, $X_{f^{\otimes n}} = X_f$, so by replacing $\mathscr{L}$ with some suitable $\mathscr{L}^{\otimes n}$, we can assume that $\mathscr{L}$ is very ample relative to the structure morphism $q : X \to Y$ (4.6.11). The canonical homomorphism $\sigma : q^*(q_*(\mathscr{L})) \to \mathscr{L}$ is thus surjective, and the corresponding morphism

$$r = r_{\mathscr{L},\sigma} : X \longrightarrow P = \mathbf{P}(q_*(\mathscr{L}))$$

is an immersion such that $\mathscr{L} = r^*(\mathscr{O}_P(1))$ (4.4.4); furthermore, since X is proper over Y, the immersion r is closed (5.4.4). But by definition, $f \in \Gamma(Y, q_*(\mathscr{L}))$, and $\sigma^\flat$ is the identity of $q_*(\mathscr{L})$; it then follows from Equation (3.7.3.1) that we have $X_f = r^{-1}(D_+(f))$; so X_f is a closed subprescheme of the affine scheme $D_+(f)$, and is thus also an affine scheme. □

In the particular case where $Y = X$, we obtain (taking (4.6.13, i) into account) the following corollary, whose direct proof is immediate anyway:

Corollary (5.5.8). — *Let X be a prescheme, and $\mathscr{L}$ an invertible $\mathscr{O}_X$-module. For every section f of $\mathscr{L}$ over X, X_f is affine over X (and thus also an affine scheme whenever X is an affine scheme).*

5.6. Chow's lemma

Theorem (5.6.1). — (Chow's lemma). *Let S be a prescheme, and X an S-scheme of finite type. Suppose that one of the following conditions is satisfied:*

(a) *S is Noetherian;*
(b) *S is a quasi-compact scheme, and X has a finite number of irreducible components.*

Under these hypotheses,

(i) *there exists a* quasi-projective *S-scheme X', and an S-morphism $f : X' \to X$ that is both* projective *and* surjective*;*
(ii) *we can take X' and f to be such that there exists an open subset $U \subset X$ for which $U' = f^{-1}(U)$ is dense in X', and for which the restriction of f to U' is an isomorphism $U' \simeq U$; and*
(iii) *if X is reduced (resp. irreducible, integral), then we can assume that X' is reduced (resp. irreducible, integral).*

Proof. The proof proceeds in multiple steps.

(A) We can first restrict to the case where X is *irreducible*. Indeed, in hypothesis (a), X is Noetherian, and so, under either hypothesis, the irreducible components X_i of X are finite in number. If the theorem is shown to be true for each of the closed reduced preschemes of X having the X_i as their underlying spaces, and if X'_i and $f_i : X'_i \to X_i$ are the prescheme and the morphism corresponding to X_i (respectively), then the prescheme X' given by the *sum* of the X'_i, and the morphism $f : X' \to X$ whose restriction to each X'_i is $j_i \circ f_i$ (where j_i is the canonical injection $X_i \to X$) satisfy the conclusion of the theorem. It is immediate that X' is reduced if all of the X'_i are; furthermore, we can satisfy (ii) by taking U to be the union of the sets $U_i \cap \complement\left(\bigcup_{j\neq i} X_j\right)$. Finally, since the X'_i are quasi-projective over S, so is X' (5.3.6); similarly, the morphisms $X'_i \to X$ are projective by (5.5.5, i) and (5.5.5, ii), and so f is projective (5.5.6), and is clearly surjective, by definition. **II** | 107

(B) Now suppose that X is *irreducible*. Since the structure morphism $r : X \to S$ is of finite type, there exists a finite cover (S_i) of S by affine open subsets, and for each i there is a finite cover (T_{ij}) of $r^{-1}(S_i)$ by affine open subsets, and the morphisms $T_{ij} \to S_i$ are of finite type, and so quasi-projective (5.3.4, i); since in both hypotheses (a) and (b) the immersion $S_i \to S$ is quasi-compact, it is also quasi-projective (5.3.4, i), and so the restriction of r to T_{ij} is a quasi-projective morphism (5.3.4, ii). Denote the T_{ij} by U_k $(1 \leqslant k \leqslant n)$. There exists, for each index k, an open immersion $\phi_k : U_k \to P_k$, where P_k is projective over S ((5.3.2) and (5.5.2)). Let $U = \bigcap_k U_k$; since X is irreducible, and the U_k nonempty, U is nonempty, and thus dense in X; the restrictions of the ϕ_k to U define a morphism

$$\phi : U \longrightarrow P = P_1 \times_S P_2 \times_S \cdots \times_S P_n$$

such that the diagrams

(5.6.1.1)
$$\begin{tikzcd} U \arrow[r, "\phi"] \arrow[d, "j_k"'] & P \arrow[d, "p_k"] \\ U_k \arrow[r, "\phi_k"'] & P_k \end{tikzcd}$$

commute, where j_k is the canonical injection $U \to U_k$, and p_k the canonical projection $P \to P_k$. If j is the canonical injection $U \to X$, then the morphism $\psi = (j, \phi)_S : U \to X \times_S P$ is an *immersion* (**I**, 5.3.14). In hypothesis (a), $X \times_S P$ is locally Noetherian ((3.4.1), (**I**, 6.3.7), and (**I**, 6.3.8)); in hypothesis (b), $X \times_S P$ is a quasi-compact scheme ((**I**, 5.5.1) and (**I**, 6.6.4)); in both cases, the *closure* X' in $X \times_S P$ of the subprescheme Z associated to ψ (and so with underlying space $\psi(U)$) exists, and ψ factors as

(5.6.1.2)
$$\psi : U \xrightarrow{\psi'} X' \xrightarrow{h} X \times_S P$$

where ψ' is an *open immersion* and h a *closed immersion* (**I**, 9.5.10). Let $q_1 : X \times_S P \to X$ and $q_2 : X \times_S P \to P$ be the canonical projections; we set

(5.6.1.3)
$$f : X' \xrightarrow{h} X \times_S P \xrightarrow{q_1} X,$$

(5.6.1.4)
$$g : X' \xrightarrow{h} X \times_S P \xrightarrow{q_2} P.$$

We will see that X' and f satisfy the conclusion of the theorem.

(C) First we show that f is *projective* and *surjective*, and that the restriction of f to $U' = f^{-1}(U)$ is an *isomorphism* from U' to U. Since the P_k are projective over S, so is P (5.5.5, iv), and so $X \times_S P$ is projective over X (5.5.5, iii), and thus so is X', which is a closed subprescheme of $X \times_S P$. Furthermore, we have $f \circ \psi' = q_1 \circ (h \circ \psi') = q_1 \circ \psi = j$, so $f(X')$ contains the open everywhere-dense subset U of X; but f is a *closed* morphism (5.5.3), so $f(X') = X$. Now note that $q_1^{-1}(U) = U \times_S P$ is induced on an open subset of $X \times_S P$, and, by definition, the prescheme $U' = h^{-1}(U \times_S P)$ is induced by X' on the open subset U'; it is thus the closure *relative to* $U \times_S P$ of the prescheme Z (**I**, 9.5.8). But the immersion ψ factors as **II** | 108
$U \xrightarrow{\Gamma_\phi} U \times_S P \xrightarrow{j\times 1} X \times_S P$, and since P is separated over S, the graph morphism Γ_ϕ is a

closed immersion (**I**, 5.4.3), and so Z is a *closed* subprescheme of $U \times_S P$, whence $U' = Z$. Since ψ is an immersion, the restriction of f to U' is an isomorphism onto U, and the inverse of ψ'; finally, by the definition of X', U' is dense in X'.

(D) We now show that g is an *immersion*, which will imply that X' is *quasi-projective* over S, because P is projective over S. Set

$$\begin{aligned} V_k &= \phi_k(U_k) \quad \text{(open subset of } P_k) \\ W_k &= p_k^{-1}(V_k) \quad \text{(open subset of } P) \\ U'_k &= f^{-1}(U_k) \quad \text{(open subset of } X') \\ U''_k &= g^{-1}(W_k) \quad \text{(open subset of } X'). \end{aligned}$$

It is clear that the U'_k form an open cover of X'; we will first see that the U''_k also form an open cover of X', by showing that $U'_k \subset U''_k$. For this, it will suffice to show that the diagram

(5.6.1.5)
$$\begin{tikzcd} U'_k \arrow[r, "g|U'_k"] \arrow[d, "f|U'_k"'] & P \arrow[d, "p_k"] \\ U_k \arrow[r, "\phi_k"'] & P_k \end{tikzcd}$$

commutes. But the prescheme $U'_k = h^{-1}(U_k \times_S P)$ is induced by X' on the open subset U'_k, and is thus the closure of $Z = U' \subset U'_k$ relative to U'_k (**I**, 9.5.8). To show the commutativity of (5.6.1.5), it thus suffices (since P_k is an S-scheme) to show that composing the diagram with the canonical injection $U' \to U'_k$ (or, equivalently, thanks to the isomorphism from U' to U, with ψ) gives us a commutative diagram (**I**, 9.5.6). But, by definition, the diagram thus obtains is exactly (5.6.1.1), whence our claim.

The W_k thus form an open cover of $g(X')$; to show that g is an immersion, it suffices to show that each of the restrictions $g|U''_k$ is an immersion into W_k (**I**, 4.2.4). For this, consider the morphism $u_k : W_k \xrightarrow{p_k} V_k \xrightarrow{\phi_k^{-1}} U_k \to X$; since X is separated over S, the graph morphism $\Gamma_{u_k} : W_k \to X \times_S W_k$ is a closed immersion (**I**, 5.4.3), and so the graph $T_k = \Gamma_{u_k}(W_k)$ is a closed subprescheme of $X \times_S W_k$; if we show that $U' \to X \times_S W_k$ factors through this subprescheme, then the map from the subprescheme induced by X' on the open subset U''_k of X' to $X \times_S W_k$ will also factor through this graph, by (**I**, 9.5.8). Since the restriction of q_2 to T_k is an isomorphism onto W_k, the restriction of g to U''_k will be an immersion into W_k, and our claim will be proven. Let v_k be the canonical injection $U' \to X \times_S W_k$; we have to show that there exists a morphism $w_k : U' \to W_k$ such that $v_k = \Gamma_{u_k} \circ w_k$. By the definition of the product, it suffices to prove that $q_1 \circ v_k = u_k \circ q_2 \circ v_k$ (**I**, 3.2.1), or, by composing on the right with the isomorphism $\psi' : U \to U'$, that $q_1 \circ \psi = u_k \circ q_2 \circ \psi$. But since $q_1 \circ \psi = j$ **II** | 109
and $q_2 \circ \psi = \phi$, our claim follows from the commutativity of (5.6.1.1), taking into account the definition of u_k.

(E) It is clear that since U, and thus U', is irreducible, so is the X' from the preceding construction, and the morphism f is thus *birational* (**I**, 2.2.9). If in addition X is reduced, then so is U', and hence X' is also reduced (**I**, 9.5.9). This finishes the proof.

□

Corollary (5.6.2). — *Suppose that one of the hypotheses,* (a) *and* (b), *of* (5.6.1) *is satisfied. For X to be proper over S, it is necessary and sufficient for there to exist a projective scheme X' over S, and a surjective S-morphism $f : X' \to X$ (which is thus projective, by* (5.5.5, v)*). Whenever this is the case, we can further choose f to be such that there exists a dense open subset U of X for which the restriction of f to $f^{-1}(U)$ is an isomorphism $f^{-1}(U) \simeq U$, and for which $f^{-1}(U)$ is dense in X'. If in addition X is irreducible (resp. reduced), then we can assume that X' is also irreducible (resp. reduced); when X and X' are irreducible, f is a birational morphism.*

Proof. The condition is sufficient, by (5.5.3) and (5.4.3, ii). It is necessary because, with the notation of (5.6.1), if X is proper over S, then X' is proper over S, because it is projective over X, and thus proper over X (5.5.3), and our claim follows from (5.4.2, ii); furthermore, since X' is quasi-projective over S, it is projective over S, by (5.5.3). □

Corollary (5.6.3). — *Let S be a locally Noetherian prescheme, and X an S-scheme of finite type over S, with structure morphism $f_0 : X \to S$. For X to be proper over S, it is necessary and sufficient that, for every morphism* of finite type *$S' \to S$, $(f_0)_{(S')} : X_{(S')} \to S'$ be a closed morphism. It even suffices for this condition to be verified only for every S-prescheme of the form $S' = S \otimes_{\mathbf{Z}} \mathbf{Z}[T_1, \ldots, T_n]$ (where the T_i are indeterminates).*

Proof. The condition being clearly necessary, we now show that it is sufficient. Since the question is local on S and S' (5.4.1), we can suppose that S and S' are affine and Noetherian. By Chow's lemma, there exists a projective S-scheme P, an immersion $j : X' \to P$, and a surjective projective morphism $f : X' \to X$, such that the diagram

$$\begin{tikzcd} X \arrow[d, "f_0"'] & X' \arrow[l, "f"'] \arrow[d, "j"] \\ S & P \arrow[l, "r"] \end{tikzcd}$$

commutes. Since P is of finite type over S, the first hypothesis implies that the projection $q_2 : X \times_S P \to P$ is a *closed* morphism. The morphism $(f, j) : X' \to X \times_S P$ factors as the graph immersion $\Gamma_j : X' \to X' \times_S P$, which is closed because P is separated over S, followed by the base change $f \times 1_P : X' \times_S P \to X \times_S P$. But f, being projective, is proper (5.5.3), and so $f \times 1_P$ is closed; hence (f, j) is closed. Since $j = q_2 \circ (f, j)$ and j is already an immersion, we conclude that j is a closed immersion, and thus proper (5.4.2, i). Furthermore, the structure morphism $r : P \to S$ is projective, and thus proper (5.5.3), so $f_0 \circ f = r \circ j$ is proper (5.4.2, ii); finally, since f is surjective, f_0 is proper, by (5.4.3).

To prove the proposition using only the second, weaker hypothesis (where S' is of the form $S \otimes_{\mathbf{Z}} \mathbf{Z}[T_1, \ldots, T_n]$), it suffices to show that it implies the first. But, if S' is affine and of finite type over $S = \operatorname{Spec}(A)$, then we have $S' = \operatorname{Spec}(A[c_1, \ldots, c_n])$ (**I**, 6.3.3), and S' is thus isomorphic **II** | 110
to a closed subprescheme of $S'' = \operatorname{Spec}(A[T_1, \ldots, T_n])$ (where the T_i are indeterminates). In the commutative diagram

$$\begin{tikzcd} X \times_S S' \arrow[r, "1_X \times j"] \arrow[d, "(f_0)_{(S')}"'] & X \times_S S'' \arrow[d, "(f_0)_{(S'')}"] \\ S' \arrow[r, "j"'] & S'' \end{tikzcd}$$

both j and $1_X \times j$ are closed immersions (**I**, 4.3.1), and $(f_0)_{(S'')}$ is closed by hypothesis; thus $(f_0)_{(S')}$ is also closed. □

§6. Integral morphisms and finite morphisms

6.1. Preschemes integral over another prescheme

Definition (6.1.1). — Let X be an S-prescheme, with structure morphism $f : X \to S$. We say that X is *integral over S*, or that f is an *integral morphism*, if there exists a cover (S_α) of S by affine opens such that, for all α, the induced prescheme $f^{-1}(S_\alpha)$ is an affine scheme whose ring B_α is an integral algebra over the ring A_α of S_α. We say that X is *finite over S*, or that f is a *finite morphism* if X is integral and of finite type over S.

If S is affine of ring A, then we also say "integral (resp. finite) over A" instead of "integral (resp. finite) over S".

(6.1.2). It is clear that, if X is integral over S, then it is *affine* over S. For an affine prescheme X over S to be integral (resp. finite) over S it is necessary and sufficient that the associated quasi-coherent $\mathscr{O}_S$-algebra $\mathscr{A}(X)$ be such that there exist a cover (S_α) of S by affine opens having the property that, for all α, $\Gamma(S_\alpha, \mathscr{A}(X))$ is an integral (resp. integral and of finite type) algebra over $\Gamma(S_\alpha, \mathscr{O}_S)$. A quasi-coherent $\mathscr{O}_S$-algebra with this property is said to be *integral* (resp. *finite*) over $\mathscr{O}_S$. Giving an integral (resp. finite) prescheme over S is thus (1.3.1) the same as giving a quasi-coherent $\mathscr{O}_S$-algebra that is integral (resp. finite) over $\mathscr{O}_S$. Note that a quasi-coherent $\mathscr{O}_S$-algebra $\mathscr{B}$ is finite if and only if it is an *$\mathscr{O}_S$-module of finite type* (**I**, 1.3.9); it is equivalent to say that $\mathscr{B}$ is an *integral* $\mathscr{O}_S$-algebra *of finite type*, since an algebra that is integral and of finite type over a ring A is an A-module of finite type.

Proposition (6.1.3). — *Let S be a locally Noetherian prescheme. For an affine prescheme X over S to be finite over S, it is necessary and sufficient that the $\mathscr{O}_S$-algebra $\mathscr{A}(X)$ be coherent.*

Proof. Taking the preceding remark into account, this reduces to noting that, if S is locally Noetherian, then the quasi-coherent $\mathscr{O}_S$-modules of finite type are exactly the coherent $\mathscr{O}_S$-modules (**I**, 1.5.1). □

Proposition (6.1.4). — *Let X be an integral (resp. finite) prescheme over S, with structure morphism $f : X \to S$. Then, for every affine open $U \subset S$ of ring A, $f^{-1}(U)$ is an affine scheme whose ring B is an integral (resp. finite) algebra over A.*

II | 111

Proof. We first prove the following lemma:

Lemma (6.1.4.1). — *Let A be a ring, M an A-module, and $(g_i)_{1\leqslant i\leqslant m}$ a finite system of elements of A such that the $D(g_i)$ (for $1 \leqslant i \leqslant m$) cover* $\operatorname{Spec}(A)$*. If, for all i, M_{g_i} is an A_{g_i}-module of finite type, then M is an A-module of finite type.*

Proof. We can assume that M_{g_i} admits a finite system of generators (m_{ij}/g_i^n) with $m_{ij} \in M$, with n the same for all indices i. We will show that the m_{ij} form a system of generators of M. Let M' be the sub-A-module of M generated by these elements, and let m be an element of M. By hypothesis, for each i, there exist $a_{ij} \in A$ and some integer p (independent of i) such that, in M_{g_i}, $m/1 = (\sum_j a_{ij}m_{ij})/g_i^p$; this implies that there exists an integer $r \geqslant p$ such that, for all i, we have $g_i^r m \in M'$. But, since the $D(g_i^r) = D(g_i)$ cover $\operatorname{Spec}(A)$, the ideal of A generated by the g_i^r is equal to A, or, in other words, there exist elements $a_i \in A$ such that $\sum_i a_i g_i^r = 1$; then $m = (\sum_i a_i g_i^r)m \in M'$, whence the lemma. □

Now we already know (1.3.2) that $f^{-1}(U)$ is affine. If ϕ is the homomorphism $A \to B$ corresponding to f, then there exists a finite cover of U by opens $D(g_i)$ (where $g_i \in A$) such that, if $h_i = \phi(g_i)$, B_{h_i} is an integral (resp. integral and finite) algebra over A_{g_i}. Indeed, there exists a cover of U by affine opens $V_\alpha \subset U$ such that, if $A_\alpha = A(V_\alpha)$, $B_\alpha = A(f^{-1}(V_\alpha))$ is an integral (resp. finite) algebra over A_α. Every $x \in U$ belongs to some V_α, so there exists $g \in A$ such that $x \in D(g) \subset V_\alpha$; if g_α is the image of g in A_α, then $A(D(g)) = A_g = (A_\alpha)_{g_\alpha}$; let $h = \phi(g)$, and let h_α be the image of g_α in B_α; we have

$$A(D(h)) = B_h = (B_\alpha)_{h_\alpha}$$

and, since B_α is integral (resp. finite) over A_α, $(B_\alpha)_{h_\alpha}$ is integral (resp. finite) over $(A_\alpha)_{g_\alpha}$. It now suffices to use the fact that U is quasi-compact to obtain the desired cover.

If we suppose first of all that the B_{h_i} are integral and finite over the A_{g_i}, then since B_{h_i} can also be written as B_{g_i} as an A_{g_i}-module, Lemma (6.1.4.1) shows that, in this case, B is an A-module of finite type.

Now suppose only that each B_{h_i} is integral over A_{g_i}; let $b \in B$, and let C be the sub-A-algebra of B generated by b. For all i, C_{h_i} is the algebra over A_{g_i} generated by $b/1$ in B_{h_i}; it follows from the hypothesis that each C_{h_i} is an A_{g_i}-module of finite type, and so (6.1.4.1) C is an A-module of finite type, which proves that B is integral over A. □

Proposition (6.1.5). —

(i) *A closed immersion is finite (and* a fortiori *integral).*
(ii) *The composition of two finite (resp. integral) morphisms is finite (resp. integral).*
(iii) *If $f : X \to Y$ is a finite (resp. integral) S-morphism, then $f_{(S')} : X_{(S')} \to Y_{(S')}$ is finite (resp. integral) for any base extension $S' \to S$.*
(iv) *If $f : X \to Y$ and $g : X' \to Y'$ are finite (resp. integral) S-morphisms, then $f \times_S g : X \times_S X' \to Y \times_S Y'$ is finite (resp. integral).*

(v) *If $f : X \to Y$ and $g : Y \to Z$ are morphisms such that $g \circ f$ is finite (resp. integral), if g is separated, then f is finite (resp. integral).*
(vi) *If $f : X \to Y$ is a finite (resp. integral) morphism, then f_{red} is finite (resp. integral).*

II | 112

Proof. By (**I**, 5.5.12), it suffices to prove (i), (ii), and (iii). To prove that a closed immersion $X \to S$ is finite, we can restrict to the case where $S = \operatorname{Spec}(A)$, and everything then follows from noting that a quotient ring $A/\mathfrak{J}$ is a monogeneous A-module. To prove that the composition of two finite (resp. integral) morphisms $X \to Y$, $Y \to Z$ is finite (resp. integral), we can again assume that Z (and thus X and Y (1.3.4)) is affine, and then the claim is equivalent to saying that, if B is a finite (resp. integral) A-algebra and C a finite (resp. integral) B-algebra, then C is a finite (resp. integral) A-algebra, which is immediate. Finally, to prove (iii), we can restrict to the case where $S = Y$, since $X_{(S')}$ can be identified with $X \times_Y Y_{(S')}$ (**I**, 3.3.11); we can further suppose that $S = \operatorname{Spec}(A)$ and $S' = \operatorname{Spec}(A')$; then X is affine of ring B (1.3.4), and $X_{(S')}$ affine of ring $A' \otimes_A B$, and it suffices to note that, if B is a finite (resp. integral) A-algebra, then $A' \otimes_A B$ is a finite (resp. integral) A'-algebra. □

We also note that, if X and Y are S-preschemes that are finite (resp. integral) over S, then their *sum* $X \sqcup Y$ is a finite (resp. integral) prescheme over S, since this reduces to showing that, if B and C are finite (resp. integral) A-algebras over A, then so too is $B \times C$.

Corollary (6.1.6). — *If X is an integral (resp. finite) prescheme over S, then, for every open $U \subset S$, $f^{-1}(U)$ is integral (resp. finite) over U.*

Proof. This is a particular case of (6.1.5, (iii)). □

Corollary (6.1.7). — *Let $f : X \to Y$ be a finite morphism. Then, for all $y \in Y$, the fibre $f^{-1}(y)$ is a finite algebraic scheme over $k(y)$, and* a fortiori *its underlying space is discrete and finite.*

Proof. Indeed, as a $k(y)$-prescheme, $f^{-1}(y)$ can be identified with $X \times_Y \operatorname{Spec}(k(y))$ (**I**, 3.6.1), which is finite over $\operatorname{Spec}(k(y))$ (6.1.5, (iii)); it is thus an affine scheme whose ring is an algebra of finite rank over $k(y)$ (6.1.4). The corollary then follows from (**I**, 6.4.4). □

Corollary (6.1.8). — *Let X and S be integral preschemes, and $f : X \to S$ a* dominant *morphism. If f is integral (resp. finite) then the field $R(X)$ of rational functions on X is algebraic (resp. algebraic of finite degree) over the field $R(S)$ of rational functions on S.*

Proof. Let s be the generic point of S; the $k(s)$-prescheme $f^{-1}(s)$ is integral (resp. finite) over $\operatorname{Spec}(k(s))$ (6.1.5, (iii)) and contains, by hypothesis, the generic point x of X; the local ring of x in $f^{-1}(s)$ is equal to $k(x)$ (**I**, 3.6.5), and is thus a local ring of an integral (resp. finite) algebra over $k(s)$ (6.1.4), whence the corollary. □

Remark (6.1.9). — The hypothesis that g be *separated* is essential for the validity of (6.1.5, (v)): if Y is not separated over Z, then the identity 1_Y is the composite morphism $Y \xrightarrow{\Delta_Y} Y \times_Z Y \xrightarrow{p_1} Y$, but Δ_Y is not an integral morphism, as follows from (6.1.10):

Proposition (6.1.10). — *Every integral morphism is universally closed.*

Proof. Let $f : X \to Y$ be an integral morphism; by (6.1.5, (iii)), it suffices to show that f is *closed*. Let Z be a closed subset of X; then there exists a subprescheme of X whose underlying space is Z **II** | 113 (**I**, 5.2.1), and it thus follows from (6.1.5, (i) and (ii)) that it suffices to prove that $f(X)$ is *closed* in Y. By (6.1.5, (vi)), we can suppose that X and Y are *reduced*; further, if T is the closed reduced subprescheme of Y whose underlying space is $\overline{f(X)}$ (**I**, 5.2.1), then we know that f factors as $X \xrightarrow{g} T \xrightarrow{j} Y$, where j is the injection morphism (**I**, 5.2.2), and since j is separated (**I**, 5.5.1, (i)), it follows from (6.1.5, (v)) that g is an integral morphism. We can thus suppose that $f(X)$ is *dense* in Y. Finally, since the question is local on Y, we can restrict to the case where $Y = \operatorname{Spec}(A)$. Then $X = \operatorname{Spec}(B)$, where B is an A-algebra that is integral over A (6.1.4); furthermore, A is reduced (**I**, 5.1.4), and the hypothesis that $f(X)$ be dense in Y implies that the homomorphism $\phi : A \to B$ corresponding to f is *injective* (**I**, 1.2.7). Under these conditions, to say that $f(X) = Y$ is to say that every prime ideal of A is the intersection with A of a prime ideal of B, which is exactly the first theorem of Cohen–Seidenberg ([SZ60, t. I, p. 257, th. 3]). □

Corollary (6.1.11). — *Every finite morphism $f : X \to Y$ is projective.*

Proof. Since f is affine, $\mathscr{O}_X$ is a *very ample* $\mathscr{O}_X$-module with respect to f (5.1.2); furthermore, $f_*(\mathscr{O}_X)$ is a quasi-coherent $\mathscr{O}_Y$-module *of finite type* (6.1.2); finally, f is separated, of finite type, and universally closed (6.1.10), and thus satisfies the conditions of criterion (5.5.4, (i)). □

Proposition (6.1.12). — *Let $f : X' \to X$ be a finite morphism, and let $\mathscr{B} = f_*(\mathscr{O}_{X'})$ (which is a quasi-coherent $\mathscr{O}_X$-algebra, and a $\mathscr{O}_X$-module of finite type). Let $\mathscr{F}'$ be a quasi-coherent $\mathscr{O}_{X'}$-module; for $\mathscr{F}'$ to be locally free of rank r, it is necessary and sufficient that $f_*(\mathscr{F}')$ be a locally free $\mathscr{B}$-module of rank r.*

Proof. It is clear that, if $f_*(\mathscr{F}')|U$ is isomorphic to $\mathscr{B}^r|U$ (where $U \subset X$ is open), then $\mathscr{F}'|f^{-1}(U)$ is isomorphic to $\mathscr{O}^r_{X'}|f^{-1}(U)$ (1.4.2). Conversely, suppose that $\mathscr{F}'$ is locally free of rank r; we will show that $f_*(\mathscr{F}')$ is locally isomorphic to $\mathscr{B}^r$ as a $\mathscr{B}$-module. Let x be a point of X; as U runs over a fundamental system of affine neighbourhoods of x, $f^{-1}(U)$ runs over a fundamental system of affine neighbourhoods (1.2.5) of the finite set $f^{-1}(x)$, since f is closed (6.1.10). The proposition then follows from the following lemma: □

Lemma (6.1.12.1). — *Let Y be a prescheme, $\mathscr{E}$ a locally free $\mathscr{O}_Y$-module of rank r, and Z a finite subset of Y contained inside some affine open V. Then there exists a neighbourhood $U \subset V$ of Z such that $\mathscr{E}|U$ is isomorphic to $\mathscr{O}^r_Y|U$.*

Proof. We can evidently assume that Y is affine; for all $z_i \in Z$, there exists in the closure $\overline{\{z_i\}}$ at least one closed point z'_i (**0**, 2.1.3); if Z' is the set of the z'_i then every neighbourhood of Z' is a neighbourhood of Z, and we can thus assume that Z is discrete and closed in Y. Consider the closed reduced subprescheme of Y that has Z as its underlying space (**I**, 5.2.1) and let $j : Z \to Y$ be the canonical injection; $j^*(\mathscr{E}) = \mathscr{E} \otimes_Y \mathscr{O}_Z$ is locally free of rank r on the discrete scheme Z, and is thus isomorphic to $\mathscr{O}^r_Z$; in other words, there exist r sections s_i (for $1 \leqslant i \leqslant r$) of $\mathscr{E} \otimes_Y \mathscr{O}_Z$ over Z such that the homomorphism $\mathscr{O}^r_Z \to \mathscr{E} \otimes_Y \mathscr{O}_Z$ defined by these sections is bijective. But $Y = \operatorname{Spec}(A)$ is affine, Z is defined by an ideal $\mathfrak{J}$ of A, and we have $\mathscr{E} = \widetilde{M}$, where M is an A-module; the s_i are elements of $M \otimes_A (A/\mathfrak{J})$ and are thus images of r elements $t_i \in M = \Gamma(Y, \mathscr{E})$. For all $z_j \in Z$ there is thus a neighbourhood V_j of z_j such that the restrictions of the t_i to V_j define an isomorphism $\mathscr{O}^r_Y|V_j \to \mathscr{E}|V_j$ (**0**, 5.5.4); the neighbourhood U given by the union of the V_j is the desired neighbourhood. □ **II** | 114

Proposition (6.1.13). — *Let $g : X' \to X$ be an integral morphism of preschemes, Y a normal locally integral prescheme, and f a rational map from Y to X' such that $g \circ f$ is an everywhere defined rational map* (**I**, 7.2.1). *Then f is everywhere defined.*

Proof. If f_1 and f_2 are morphisms (from dense open subsets of Y to X') in the class f, then it is clear that $g \circ f_1$ and $g \circ f_2$ are equivalent morphisms, which justifies the notation $g \circ f$ for their equivalence class. We recall also that, if we further suppose Y to be *locally Noetherian*, then the hypothesis that Y is normal already implies that Y is locally integral (**I**, 6.1.13).

To prove the proposition, note first of all that the question is local on Y, and so we can suppose that there exists in the class $g \circ f$ a *morphism* $h : Y \to X$. Consider the inverse image $Y' = X'_{(h)} = X'_{(Y)}$, and note that the morphism $g' = g_{(Y)} : Y' \to Y$ is *integral* (6.1.5, (iii)). Given the correspondence between rational maps from Y to X' and rational Y-sections of Y' (**I**, 7.1.2), we see that it suffices to prove the specific case of (6.1.13) where $X = Y$; in other words, the following: □

Corollary (6.1.14). — *Let X be a normal locally integral prescheme, $g : X' \to X$ an* integral *morphism, and f a rational X-section of X'. Then f is everywhere defined.*

Proof. Since the question is local on X, we can assume that X is integral, and then f is identified with a morphism from an open U of X to X' (**I**, 7.2.2) that is a U-section of $g^{-1}(U)$. Since g is separated, f is a closed immersion from U into $g^{-1}(U)$ (**I**, 5.4.6); let Z be the closed subprescheme of $g^{-1}(U)$ associated to f (**I**, 4.2.1), which is isomorphic to U, and thus integral; let X_1 be the reduced subprescheme of X' whose underlying space is the closure $\overline{Z}$ of Z in X' (**I**, 5.2.1); then Z is an induced subprescheme on an open of X_1 (**I**, 5.2.3), and, since it is irreducible, so too is X_1, which is thus integral. The morphism f can then be considered as a rational X-section of X_1; since the restriction of g to X_1 is an integral morphism (6.1.5, (i) and (ii)), we can finally reduce to proving (6.1.14) in the specific case where $X' = X_1$; in other words, the following: □

Corollary (6.1.15). — *Let X be a normal integral prescheme, X' an integral prescheme, and $g : X' \to X$ an* integral *morphism. If there exists a rational X-section f of X', then g is an isomorphism.*

Proof. Since the question is local on X, we can assume that X is affine of integral ring A, and then X' is affine of ring A' with A' integral over A (6.1.4) and integral; furthermore, the argument of (6.1.14) shows that there exists a dense open of X that is isomorphic to a dense open of X', and so A and A' have the same field of fractions. Also, by (**I**, 8.2.1.1), and the hypothesis that the $\mathscr{O}_x$ are integrally closed, the ring A is integrally closed, and so $A' = A$, which finishes the proof of (6.1.13). □

6.2. Quasi-finite morphisms

Proposition (6.2.1). — *Let $f : X \to Y$ be a morphism locally of finite type, and x a point of X. Then the following conditions are equivalent:* **II** | 115

a) *The point x is isolated in its fibre $f^{-1}(f(x))$.*
b) *The ring $\mathscr{O}_x$ is a quasi-finite $\mathscr{O}_{f(x)}$-module* (**0**, 7.4.1).

Proof. Since the question is clearly local on X and on Y, we can assume that $X = \operatorname{Spec}(A)$ and $Y = \operatorname{Spec}(B)$ are affine, with A a B-algebra of finite type (**I**, 6.3.3). Furthermore, we can replace X by $X \times_Y \operatorname{Spec}(\mathscr{O}_{f(x)})$ without changing either the fibre $f^{-1}(f(x))$ or the local ring $\mathscr{O}_x$ (**I**, 3.6.5); we can thus assume that B is a local ring (equal to $\mathscr{O}_{f(x)}$); if $\mathfrak{n}$ is the maximal ideal of B, then $f^{-1}(f(x))$ is an affine scheme of ring $A/\mathfrak{n}A$, of finite type over $k(f(x)) = B/\mathfrak{n}$ (**I**, 6.4.11). With this, if (a) is satisfied then we can further suppose that $f^{-1}(f(x))$ consists of the single point x; thus $A/\mathfrak{n}A$ is of finite rank over $B/\mathfrak{n}$ (**I**, 6.4.4), or, in other words, A is a quasi-finite B-module. Conversely, if A is a quasi-finite B-module, then $f^{-1}(f(x))$ is an Artinian affine scheme, and thus discrete (**I**, 6.4.4); so x is isolated in its fibre, and this shows that (b) implies (a). □

Corollary (6.2.2). — *Let $f : X \to Y$ be a morphism of finite type. Then the following conditions are equivalent:*

a) *Every point $x \in X$ is isolated in its fibre $f^{-1}(f(x))$ (or, in other words, the subspace $f^{-1}(f(x))$ is* discrete*).*
b) *For all $x \in X$, the prescheme $f^{-1}(f(x))$ is a finite $k(f(x))$-prescheme.*
c) *For all $x \in X$, the ring $\mathscr{O}_x$ is a quasi-finite $\mathscr{O}_{f(x)}$-module.*

Proof. The equivalence of (a) and (c) follows from (6.2.1). Since $f^{-1}(f(x))$ is an algebraic $k(f(x))$-prescheme (**I**, 6.4.11), the equivalence of (a) and (b) follows from (**I**, 6.4.4). □

Definition (6.2.3). — If $f : X \to Y$ is a morphism of finite type satisfying the equivalent conditions of (6.2.2), we say that f is *quasi-finite*, or that X is *quasi-finite over Y*.

It is clear that every *finite* morphism is quasi-finite (6.1.7).

Proposition (6.2.4). —

(i) *An immersion $X \to Y$ that is closed, or such that X is Noetherian, is a quasi-finite morphism.*
(ii) *If $f : X \to Y$ and $g : Y \to Z$ are quasi-finite morphisms, then $g \circ f$ is quasi-finite.*
(iii) *If X and Y are S-preschemes, and $f : X \to Y$ a quasi-finite S-morphism, then $f_{(S')} : X_{(S')} \to Y_{(S')}$ is quasi-finite for any base extension $g : S' \to S$.*
(iv) *If $f : X \to Y$ and $g : X' \to Y'$ are quasi-finite S-morphisms, then*
$$f \times_S g : X \times_S X' \longrightarrow Y \times_S Y'$$
is quasi-finite.
(v) *Let $f : X \to Y$ and $g : Y \to Z$ be morphisms such that $g \circ f$ is quasi-finite; if, further, g is separated, or X is Noetherian, or $X \times_Z Y$ is locally Noetherian, then f is quasi-finite.*
(vi) *If f is quasi-finite, then f_{red} is quasi-finite.*

Proof. If $f : X \to Y$ is an immersion, then every fibre has at most one point, and claim (i) then follows from (**I**, 6.3.4, (i)) and (**I**, 6.3.5). To prove (ii), note first of all that $h = g \circ f$ is of finite type (**I**, 6.3.4, (ii)); furthermore, if $z = h(x)$ and $y = f(x)$, then y is isolated in $g^{-1}(z)$, and so there exists an open neighbourhood V of y in Y that does not meet any point of $g^{-1}(z)$ apart from y; thus $f^{-1}(V)$

is an open neighbourhood of x that does not meet any of the $f^{-1}(y')$, where $y' \neq y$ is in $g^{-1}(z)$; since x is isolated in $f^{-1}(y)$, it is isolated in $h^{-1}(z) = f^{-1}(g^{-1}(z))$. To prove (iii), we can reduce to the case where $Y = S$ (**I**, 3.3.11); we again note first of all that $f' = f_{(S')}$ is of finite type (**I**, 6.3.4, (iii)); also, if $x' \in X' = X_{(S')}$, and if we set $y' = f'(x')$ and $y = g(y')$, then $f'^{-1}(y')$ can be identified with $f^{-1}(y) \otimes_{k(y)} k(y')$ (**I**, 3.6.5); since $f^{-1}(y)$ is of finite rank over $k(y)$ by hypothesis, $f'^{-1}(y')$ is of finite rank over $k(y')$, and thus discrete. Claims (iv), (v), and (vi) follow from (i), (ii), and (iii) by the general method (**I**, 5.5.12), except when the hypothesis in (v) is not "g is separated"; in these cases, we remark first of all that, if x is isolated in $f^{-1}(g^{-1}(g(f(x))))$, then it is *a fortiori* isolated in $f^{-1}(f(x))$; the fact that f is of finite type then follows from (**I**, 6.3.6). □ II | 116

Proposition (6.2.5). — *Let A be a* complete *local Noetherian ring, X an A-scheme locally of finite type, and x a point of X over the closed point y of $Y = \operatorname{Spec}(A)$. Suppose that x is isolated in its fibre $f^{-1}(y)$ (where f is the structure morphism $X \to Y$). Then $\mathscr{O}_x$ is an A-module of finite type, and X is Y-isomorphic to the sum* (**I**, 3.1) *of $X' = \operatorname{Spec}(\mathscr{O}_x)$ (which is a finite Y-scheme) and an A-scheme X''.*

Proof. It follows from (6.2.1) that $\mathscr{O}_x$ is a quasi-finite A-module. Since $\mathscr{O}_x$ is Noetherian (**I**, 6.3.7), and the homomorphism $A \to \mathscr{O}_x$ is local, the hypothesis that A is *complete* implies that $\mathscr{O}_x$ is an A-module *of finite type* (**0**, 7.4.3). Let $X' = \operatorname{Spec}(\mathscr{O}_x)$ be the local scheme of X at the point x (**I**, 2.4.1), and let $g : X' \to X$ be the canonical morphism. Since the composite $X' \xrightarrow{g} X \xrightarrow{f} Y$ is finite (6.1.1), and since f is separated, g is finite (6.1.5, (v)), and so $g(X')$ is *closed* in X (6.1.10); also, since g is of finite type, g is a local isomorphism at the closed point x' of X' by the definition of g and (**I**, 6.5.4); but since X' is the only open neighbourhood of x', this implies that g is an open immersion, and so $g(X')$ is also *open* in X, which finishes the proof. □

Corollary (6.2.6). — *Let A be a* complete *local Noetherian ring, $Y = \operatorname{Spec}(A)$, and $f : X \to Y$ a separated quasi-finite morphism. Then X is Y-isomorphic to a sum $X' \sqcup X''$, where X' is a finite Y-scheme, and X'' is a quasi-finite Y-scheme such that, if y is the closed point of Y, then $X'' \cap f^{-1}(y) = \varnothing$.*

Proof. Indeed, the fibre $f^{-1}(y)$ is finite and discrete by hypothesis, and the corollary then follows, by induction on the number of points in this fibre, from (6.2.5). □

Remark (6.2.7). — In Chapter V, we will see that, if Y is *locally Noetherian*, then a separated quasi-finite morphism $X \to Y$ is necessarily *quasi-affine*.

6.3. Integral closure of a prescheme

Proposition (6.3.1). — *Let $(X, \mathscr{A})$ be a ringed space, $\mathscr{B}$ a (commutative) $\mathscr{A}$-algebra, and f a section of $\mathscr{B}$ over X. Then the following properties are equivalent:*

a) The sub-$\mathscr{A}$-module of $\mathscr{B}$ generated by the f^n for $n \geqslant 0$ (**0**, 5.1.1) *is of finite type.*
b) There exists a sub-$\mathscr{A}$-algebra $\mathscr{C}$ of $\mathscr{B}$ that is an $\mathscr{A}$-module of finite type and such that $f \in \Gamma(X, \mathscr{C})$.
c) For all $x \in X$, f_x is integral over the stalk $\mathscr{A}_x$.

II | 117

Proof. Since the sub-$\mathscr{A}$-module of $\mathscr{B}$ generated by the f^n is an $\mathscr{A}$-algebra, it is clear that (a) implies (b). On the other hand, (b) implies that, for all $x \in X$, the $\mathscr{A}_x$-module $\mathscr{C}_x$ is of finite type, which implies that every element of the algebra $\mathscr{C}_x$, and, in particular, f_x, is integral over $\mathscr{A}_x$. Finally, if we have, for some $x \in X$, a relation of the form

$$f_x^n + (a_1)_x f_x^{n-1} + \ldots + (a_n)_x = 0$$

where the a_i (for $1 \leqslant i \leqslant n$) are sections of $\mathscr{A}$ over an open neighbourhood U of x, then the section $f^n|U + a_1 \cdot f^{n-1}|U + \ldots + a_n$ is zero over a neighbourhood $V \subset U$ of x, from which it immediately follows that the $f^k|V$ (for $k \geqslant 0$) are linear combinations of the $f^j|V$ (for $0 \leqslant j \leqslant n-1$) with coefficients in $\Gamma(V, \mathscr{A})$; we thus conclude that (c) implies (a). □

If the equivalent conditions of (6.3.1) are satisfied then we say that the section f is *integral over* $\mathscr{A}$.

Corollary (6.3.2). — *Under the hypotheses of (6.3.1), there exists a (unique) sub-$\mathscr{A}$-module $\mathscr{A}'$ of $\mathscr{B}$ such that, for all $x \in X$, $\mathscr{A}'_x$ is the set of germs $f_x \in \mathscr{B}_x$ that are integral over $\mathscr{A}_x$. For every open $U \subset X$, the sections of $\mathscr{A}'$ over U are the sections $f \in \Gamma(U, \mathscr{B})$ that are integral over $\mathscr{A}|U$.*

Proof. The existence of $\mathscr{A}'$ is immediate, by taking $\Gamma(U, \mathscr{A}')$ to be the set of $f \in \Gamma(U, \mathscr{B})$ such that f_x is integral over $\mathscr{A}_x$ for all $x \in U$. The second claim follows immediately from (6.3.1). □

It is clear that $\mathscr{A}'$ is a sub-$\mathscr{A}$-algebra of $\mathscr{B}$; we say that it is the *integral closure of* $\mathscr{A}$ *in* $\mathscr{B}$.

(6.3.3). Let $(X, \mathscr{A})$ and $(Y, \mathscr{B})$ be ringed spaces, and let

$$g = (\psi, \theta) : X \longrightarrow Y$$

be a morphism. Let $\mathscr{C}$ (resp. $\mathscr{D}$) be an $\mathscr{A}$-algebra (resp. $\mathscr{B}$-algebra), and let

$$u : \mathscr{D} \longrightarrow \mathscr{C}$$

be a g-morphism (**0**, 4.4.1). Then, if $\mathscr{A}'$ (resp. $\mathscr{B}'$) is the integral closure of $\mathscr{A}$ (resp. $\mathscr{B}$) in $\mathscr{C}$ (resp. $\mathscr{D}$), the *restriction* of u to $\mathscr{B}'$ is a g-morphism

$$u' : \mathscr{B}' \longrightarrow \mathscr{A}'.$$

Indeed, if j is the canonical injection $\mathscr{B}' \to \mathscr{D}$, then it suffices to show that

$$v = u^\sharp \circ g^*(j) : g^*(\mathscr{B}') \longrightarrow \mathscr{C}$$

sends $g^*(\mathscr{B}')$ to $\mathscr{A}'$. But an element of $g^*(\mathscr{B}')_x = \mathscr{B}'_{\psi(x)} \otimes_{\mathscr{B}_{\psi(x)}} \mathscr{A}_x$ is integral over $\mathscr{A}_x$ by the definition of $\mathscr{B}'$, and thus so too is its image under v_x, which proves the claim.

Proposition (6.3.4). — *Let X be a prescheme, and $\mathscr{A}$ a quasi-coherent $\mathscr{O}_X$-algebra. Then the integral closure $\mathscr{O}'_X$ of $\mathscr{O}_X$ in $\mathscr{A}$ is a quasi-coherent $\mathscr{O}_X$-algebra, and, for every affine open U of X, $\Gamma(U, \mathscr{O}'_X)$ is the integral closure of $\Gamma(U, \mathscr{O}_X)$ in $\Gamma(U, \mathscr{A})$.*

Proof. We can restrict to the case where $X = \operatorname{Spec}(B)$ is affine, and $\mathscr{A} = \widetilde{A}$, where A is a B-algebra; let B' be the integral closure of B in A. Everything then reduces to proving that, for all $x \in X$, an **II** | 118
element of A_x which is integral over B_x necessarily belongs to B'_x, which follows from the fact that, for a commutative ring C, the operations of taking the integral closure in a C-algebra and passing to a ring of fractions (with respect to a multiplicative subset of C) commute [SZ60, t. I, pp. 261 and 257]. □

The X-scheme $X' = \operatorname{Spec}(\mathscr{O}'_X)$ is then called the *integral closure of X with respect to* $\mathscr{A}$ (or *with respect to* $\operatorname{Spec}(\mathscr{A})$); it is clear that X' is *integral* over X (6.1.2).

We immediately deduce from (6.3.4) that, if $f : X' \to X$ is the structure morphism, then, for every open U of X, $f^{-1}(U)$ is the *integral closure of the prescheme induced by X on U, with respect to* $\mathscr{A}|U$.

(6.3.5). Let X and Y be preschemes, $f : X \to Y$ a morphism, $\mathscr{A}$ (resp. $\mathscr{B}$) a quasi-coherent $\mathscr{O}_X$-algebra (resp. quasi-coherent $\mathscr{O}_Y$-algebra), and let $u : \mathscr{B} \to \mathscr{A}$ be an f-morphism. We have seen (6.3.3) that we obtain an f-morphism $u' : \mathscr{O}'_Y \to \mathscr{O}'_X$, where $\mathscr{O}'_X$ (resp. $\mathscr{O}'_Y$) is the integral closure of $\mathscr{O}_X$ (resp. $\mathscr{O}_Y$) in $\mathscr{A}$ (resp. $\mathscr{B}$). Then, if X' (resp. Y') is the integral closure of X (resp. Y) with respect to $\mathscr{A}$ (resp. $\mathscr{B}$), we canonically obtain from u a morphism $f' = \operatorname{Spec}(u') : X' \to Y'$ (1.5.6) such that the diagram

(6.3.5.1)
$$\begin{tikzcd} X' \arrow[r, "f'"] \arrow[d] & Y' \arrow[d] \\ X \arrow[r, "f"'] & Y \end{tikzcd}$$

commutes.

(6.3.6). Suppose that X has only a *finite* number of irreducible components X_i (for $1 \leqslant i \leqslant r$), with generic points ξ_i, and consider, in particular, the integral closure of X with respect to some quasi-coherent $\mathscr{R}(X)$-*algebra* $\mathscr{A}$ (quasi-coherent as either an $\mathscr{O}_X$-algebra or as an $\mathscr{R}(X)$-algebra, since the two are equivalent). We know (**I**, 7.3.5) that $\mathscr{A}$ is a direct sum of r quasi-coherent $\mathscr{O}_X$-algebras $\mathscr{A}_i$, where the support of $\mathscr{A}_i$ is contained inside X_i, and the sheaf induced by $\mathscr{A}_i$ on X_i is a simple sheaf whose fibre A_i is an algebra over $\mathscr{O}_{\xi_i}$. It is then clear (6.3.4) that the integral closure $\mathscr{O}'_X$ of $\mathscr{O}_X$ in $\mathscr{A}$ is the *direct sum* of the integral closures $\mathscr{O}^{(i)}_X$ of $\mathscr{O}_X$ in each of the $\mathscr{A}_i$, and thus the integral closure

$X' = \operatorname{Spec}(\mathscr{O}'_X)$ of X with respect to $\mathscr{A}$ is the X-scheme given by the *sum* of the $\operatorname{Spec}(\mathscr{O}_X^{(i)}) = X'_i$ (for $1 \leqslant i \leqslant r$).

Suppose further that the $\mathscr{O}_X$-algebra $\mathscr{A}$ is *reduced*, or, equivalently, that each of the algebras A_i is reduced, and can thus be considered as an algebra over the *field* $k(\xi_i)$ (equal to the field of rational functions of the reduced subprescheme of X that has X_i as its underlying space); then (1.3.8) each of the X'_i is a *reduced* X-scheme, and X' is also the integral closure of X_{red}. Suppose further that each of the algebras A_i is a *direct sum of a finite number of fields* K_{ij} (for $1 \leqslant j \leqslant s_i$); if $\mathscr{K}_{ij}$ is the sub-algebra of $\mathscr{A}_i$ corresponding to K_{ij}, then it is clear that $\mathscr{O}_X^{(i)}$ is the *direct sum* of the integral closures $\mathscr{O}_X^{(ij)}$ of $\mathscr{O}_X$ in each of the $\mathscr{K}_{ij}$. Then X'_i is the *sum* of the X-schemes $X'_{ij} = \operatorname{Spec}(\mathscr{O}_X^{(ij)})$ (for $1 \leqslant j \leqslant s_i$). Furthermore, under these hypotheses, and with this notation, we have:

II | 119

Proposition (6.3.7). — *Each of the X'_{ij} is an integral normal X-prescheme, and its field of rational functions $R(X'_{ij})$ is canonically identified with the algebraic closure K'_{ij} of $k(\xi_i)$ in K_{ij}.*

Proof. By the above, we can suppose that X is integral, and so $r = 1$ and $s_1 = 1$, so that the unique algebra A_1 is a field K; let ξ be the generic point of X, and let $f : X' \to X$ be the structure morphism. For every non-empty affine open U of X, $f^{-1}(U)$ can be identified with the spectrum of the integral closure B'_U in the field K of the integral ring $B_U = \Gamma(U, \mathscr{O}_X)$ (6.3.4); since the ring B'_U is integral and integrally closed, so too are the local rings of the points of its spectrum, and thus $f^{-1}(U)$ is by definition an *integral* and *normal* scheme ((**0**, 4.1.4) and (**I**, 5.1.4)). Furthermore, since (0) is the only prime ideal of B'_U over the prime ideal (0) of B_U [SZ60, t. I, p. 259], $f^{-1}(\xi)$ consists of a single point ξ', and $k(\xi')$ is the field of fractions K' of B'_U, which is exactly the algebraic closure of $k(\xi)$ in K. Finally, X' is irreducible, since, if U runs over the set of non-empty affine opens of X, then the $f^{-1}(U)$ give an open cover of X' by irreducible opens; furthermore, the intersection $f^{-1}(U \cap V)$ of any two of these opens contains ξ', and is thus non-empty, and we conclude by (**0**, 2.1.4). □

Corollary (6.3.8). — *Let X be a reduced prescheme that has only a finite number of irreducible components X_i (where $1 \leqslant i \leqslant r$), and let ξ_i be the generic point of X_i. Then the integral closure X' of X with respect to $\mathscr{R}(X)$ is the sum of the r X-schemes X'_i, which are integral and normal. If $f : X' \to X$ is the structure morphism, then $f^{-1}(\xi_i)$ consists only of the generic point ξ'_i of X'_i, and we have $k(\xi'_i) = k(\xi_i)$, or, in other words, that f is birational.*

In this case, we say that X' is the *normalisation* of the reduced prescheme X; we note that f, since it is birational and integral, is *surjective* (6.1.10). Then in order to have $X' = X$, it is necessary and sufficient that X be *normal*. If X is an integral prescheme, then it follows from (6.3.8) that its normalisation X' is integral.

(6.3.9). Let X and Y be integral preschemes, $f : X \to Y$ a dominant morphism, and $L = R(X)$ (resp. $K = R(Y)$) the field of rational functions of X (resp. Y); there is a canonical injection $K \to L$ corresponding to f, and if we identify K (resp. L) with the simple sheaf $\mathscr{R}(Y)$ (resp. $\mathscr{R}(X)$), this injection is an f-morphism. Let K_1 (resp. L_1) be an extension of K (resp. L), and suppose we have a morphism $K_1 \to L_1$ such that the diagram

$$\begin{tikzcd} K_1 \arrow[r] & L_1 \\ K \arrow[u] \arrow[r] & L \arrow[u] \end{tikzcd}$$

commutes; if K_1 (resp. L_1) is considered as a simple sheaf on Y (resp. X), and thus as an $\mathscr{R}(Y)$-algebra (resp. $\mathscr{R}(X)$-algebra), this implies that $K_1 \to L_1$ is an f-morphism. With this, if X' (resp. Y') is the integral closure of X (resp. Y) with respect to L_1 (resp. K_1), then X' (resp. Y') is a normal integral prescheme (6.3.6) whose field of rational functions is canonically identified with the algebraic closure L' (resp. K') of L (resp. K) in L_1 (resp. K_1), and there exists a (necessarily dominant) canonical morphism $f' : X' \to Y'$ that makes the diagram (6.3.5.1) commute. **II | 120**

The most important case is when we take $L_1 = L$, with K_1 then being an extension of K contained in L, and when we suppose X to be integral and *normal*, so that $X' = X$. The above then shows that, since X is normal, if Y' is the integral closure of Y with respect to a field $K_1 \subset L = R(X)$, then every dominant morphism $f : X \to Y$ factors as

$$f : X \xrightarrow{f'} Y' \longrightarrow Y$$

where f' is dominant; also, since the monomorphism $K_1 \to L$ is given, f' is necessarily unique, as we see by reducing to the case where X and Y are affine. We thus see that, given Y, L, and a K-monomorphism $K_1 \to L$, the integral closure Y' of Y with respect to K_1 is the solution of a *universal problem*.

Remark (6.3.10). — Consider the hypotheses of (6.3.6), and suppose further that each of the algebras A_i is *of finite rank* over $k(\xi_i)$ (which implies that A_i is a direct sum of a finite number of fields); we can then show, in certain cases, that the structure morphism $X' \to X$ is not just integral, but even *finite*. Restrict to the case where X is *reduced*; since the question is local on X, we can further suppose that X is affine of ring C, and that C has only a finite number of minimal prime ideals $\mathfrak{p}_i$ (for $1 \leqslant i \leqslant r$) such that the $C_i = C/\mathfrak{p}_i$ are integral; then X' is finite over X if the integral closure of each C_i in every finite-degree extension of its field of fractions is a *C-module of finite type* (6.3.4). We know that this condition is always satisfied if C is an *algebra of finite type over a field* [SZ60, t. I, p. 267, th. 9], or *over* $\mathbf{Z}$ [Nag58a, I,p. 93, th. 3], or *over a complete Noetherian local ring* [Nag55, p. 298]. We thus conclude that $X' \to X$ will be a finite morphism whenever X is a scheme *of finite type* over a field, or over $\mathbf{Z}$, or over a complete Noetherian local ring.

6.4. Determinant of an endomorphism of $\mathscr{O}_X$-modules

(6.4.1). Let A be a (commutative) ring, E a free A-module of rank n, and u an endomorphism of E; recall that, to define the *characteristic polynomial* of u, we consider the endomorphism $u \otimes 1$ of the free $A[T]$-module of rank n, $E \otimes_A A[T]$ (where T is an indeterminate), and we set

(6.4.1.1) $$P(u, T) = \det(T \cdot I - (u \otimes 1))$$

(where I is the identity automorphism of $E \otimes_A A[T]$). We have

(6.4.1.2) $$P(u, T) = T^n - \sigma_1(u)T^{n-1} + \ldots + (-1)^n\sigma_n(u)$$

where $\sigma_i(u)$ is an element of A, equal to a homogeneous polynomial of degree i (with integer coefficients) with respect to the entries of the matrix of u in some arbitrary basis of E; we say that the $\sigma_i(u)$ are the *elementary symmetric functions* of u; in particular, we have that $\sigma_1(u) = \operatorname{Tr} u$ and $\sigma_n(u) = \det u$. Recall that, by the Hamilton–Cayley theorem, we have

(6.4.1.3) $$P(u, u) = u^n - \sigma_1(u)u^{n-1} + \ldots + (-1)^n\sigma_n(u) = 0$$

which can also be written as **II** | 121

(6.4.1.4) $$(\det u) \cdot I_E = uQ(u)$$

(where I_E is the identity automorphism of E), where

(6.4.1.5) $$Q(u) = (-1)^{n+1}(u^{n-1} - \sigma_1(u)u^{n-2} + \ldots + (-1)^{n-1}\sigma_{n-1}(u)).$$

Let $\phi : A \to B$ be a ring homomorphism, which makes B into an A-algebra; consider the B-module $E_{(B)} = E \otimes_A B$, which is free of rank n, and the extension $u \otimes 1$ of u to an endomorphism of $E_{(B)}$; it is immediate that we have $\sigma_i(u \otimes 1) = \phi(\sigma_i(u))$ for all indices i.

(6.4.2). Now suppose that A is an *integral* ring, with field of fractions K, and let E be an A-module *of finite type* (but not necessarily free). Let n be the *rank* of E, i.e. the rank of the free K-module $E \otimes_A K$; to every endomorphism u of E there canonically corresponds the endomorphism $u \otimes 1$ of $E \otimes_A K$; by an abuse of language, we also define the *characteristic polynomial* of u, denoted by $P(u, T)$, to be the polynomial $P(u \otimes 1, T)$, whose coefficients $\sigma_i(u \otimes 1)$ (which belong to K) are also denoted by $\sigma_i(u)$ and called the *elementary symmetric functions of u*; in particular, $\det u = \det(u \otimes 1)$ by definition. With this notation, Equations (6.4.1.3) to (6.4.1.5) make sense and still hold true, if we interpret u^j as the composite

$$E \xrightarrow{x \mapsto x \otimes 1} E \otimes_A K \xrightarrow{(u \otimes 1)^j} E \otimes_A K.$$

If F is the torsion submodule of E, and if $E_0 = E/F$, then $u(F) \subset F$, and so, by passing to quotients, u gives an endomorphism u_0 of E_0; furthermore, $E \otimes_A K$ can be identified with $E_0 \otimes_A K$, and $u \otimes 1$ with $u_0 \otimes 1$, and so $\sigma_i(u) = \sigma_i(u_0)$ for $1 \leqslant i \leqslant n$.

If E is *torsion free*, then E is canonically identified with a sub-A-module of $E \otimes_A K$, and the relation $u \otimes 1 = 0$ is equivalent to $u = 0$. If E is a free A-module, then the two definitions of $\sigma_i(u)$ given in (6.4.1) and (6.4.2) coincide, by the above, which justifies the notation used.

We also note that, if E is a *torsion module*, or, in other words, if $E_0 = \{0\}$, then the exterior algebra of E_0 consists of K, and the determinant of the unique endomorphism u_0 of E_0 is *equal to* 1.

Proposition (6.4.3). — *Let A be an integral ring, E an A-module of finite type, and u an endomorphism of E; then the elementary symmetric functions $\sigma_i(u)$ of u (and, in particular,* $\det u$*) are elements of K that are integral over A.*

Proof. Let A' be the integral closure of A; since $A'[T]$ is an integrally closed ring [Jaf60, p. 99], it is the integral closure of $A[T]$ in its field of fractions $K(T)$. Replacing u by $T \cdot I - u \otimes 1$, and A by $A[T]$, we see that we can reduce to proving that $\det u$ is integral over A. If n is the rank of E, then $\det(u) = \det(\wedge^n u)$ and $(\wedge^n u) \otimes 1 = \wedge^n(u \otimes 1)$, so we can suppose that $n = 1$. But then the map $u \mapsto \det u$ is a homomorphism from the A-module $\operatorname{Hom}_A(E, E)$ to K; since E is of finite type, $\operatorname{Hom}_A(E, E)$ is isomorphic to a sub-A-module of the A-module of finite type E^m if E admits a system of m generators, and so the elements $\det u$ belong to a sub-A-module of K of finite type, and are thus integral over A. □

II | 122

Corollary (6.4.4). — *Under the hypotheses of (6.4.3), if we further suppose A to be normal, then the $\sigma_i(u)$ (and, in particular,* $\operatorname{Tr} u$ *and* $\det u$*) belong to A.*

Proposition (6.4.5). — *Let A be an integral ring, E an A-module of finite type of rank n, and u an endomorphism of E such that the $\sigma_i(u)$ belong to A. For u to be an automorphism of E, it is necessary that* $\det u$ *be invertible in A; this condition is sufficient if E is torsion free.*

Proof. The condition is *sufficient* when E is torsion free, since the hypothesis and equations (6.4.1.4) and (6.4.1.5) (which hold in E, and not just in $E \otimes_A K$, since E is torsion free) prove that $(\det u)^{-1} Q(u)$ is the inverse of u.

The condition is *necessary*, since, if u is invertible, then it follows from (6.4.3) that $\det(u^{-1})$ belongs to the integral closure A' of A in its field of fractions K, and is evidently the inverse of $\det u$ *in* A'. Our claim then follows from: □

Lemma (6.4.5.1). — *Let A be a subring of a ring A' such that A' is* integral *over A. If an element $x \in A$ is invertible in A', then it is also invertible in A.*

Proof. In the contrary case, x would belong to a maximal ideal $\mathfrak{m}$ of A, and it follows from the first theorem of Cohen–Seidenberg [SZ60, t. I, p. 257, th. 3] that there would be a maximal ideal $\mathfrak{m}'$ of A' such that $\mathfrak{m} = \mathfrak{m}' \cap A$; we would then have that $x \in \mathfrak{m}'$, which is a contradiction. □

Corollary (6.4.6). — *Let A be an integral and integrally closed ring, E a torsion-free A-module of finite type, and u an endomorphism of E. For u to be an automorphism of E, it is necessary and sufficient that* $\det u$ *be invertible in A.*

Proof. This follows from (6.4.4) and (6.4.5). □

Remark (6.4.7). — We will later need a generalisation of the above results. Consider a *reduced* Noetherian ring A; let $\mathfrak{p}_\alpha$ (for $1 \leqslant \alpha \leqslant r$) be its minimal prime ideals, K_α the field of fractions of the integral ring $A/\mathfrak{p}_\alpha$, and K the total ring of fractions of A, which is the *direct sum* of the fields K_α. Let E be an A-module of finite type, and *suppose* that $E \otimes_A K$ is a *free* K-module of rank n (which here is no longer a consequence of the other hypotheses); equivalently, we can ask that all the K_α-vector spaces $E \otimes_A K_\alpha = E_\alpha$ have *the same dimension* n; if then u is an endomorphism of E, we again set $P(u, T) = P(u \otimes 1, T)$ and $\sigma_j(u) = \sigma_j(u \otimes 1)$, and, in particular, $\det u = \det(u \otimes 1)$; the $\sigma_j(u)$ are thus elements of K. It is immediate that $E \otimes_A K$ is the direct sum of the E_α, and that the latter are stable under $u \otimes 1$; the restriction of $u \otimes 1$ to E_α is exactly the extension u_α of u to this K_α-vector space; we thus conclude that $\sigma_j(u)$ is the element of K whose components in the K_α are the $\sigma_j(u_\alpha)$. Since the integral closure of A in K is the *direct sum* of the integral closures of A in the K_α, the $\sigma_j(u)$ are *integral* over A.

Lemma (6.4.7.1). — *The sub-A-algebra of K generated by all the elements $\sigma_j(u)$ (for $1 \leqslant j \leqslant n$), where u runs over $\operatorname{Hom}_A(E, E)$, is an A-module of finite type.*

Proof. It suffices to prove that the sub-$A[T]$-algebra of $K[T]$ generated by the $P(u, T)$ is an $A[T]$-module of finite type, since if the $F_i(T)$ (for $1 \leqslant i \leqslant m$) form a system of generators for this $A[T]$-module, then the coefficients of the $F_i(T)$ are integral over A, and thus generate an A-algebra that is an A-module of finite type [SZ60, t. I, p. 255, th. 1]. We can thus replace A by $A[T]$ (which II | 123
is Noetherian), and E by $E \otimes_A A[T] = E'$, which is such that $E' \otimes_{A[T]} K[T] = E \otimes_A K[T]$ is a free $K[T]$-module of rank n. Using the initial notation, we thus see that it suffices to prove that the A-module generated by the elements $\det u$, where u runs over $\operatorname{Hom}_A(E, E)$, is of finite type; *a fortiori* (since every submodule of an A-module of finite type is of finite type) it suffices to prove that, as v runs over the set of endomorphisms of $\wedge^n E$, the A-module generated by the $\det v$ is of finite type; in other words, we can again reduce to the case where $n = 1$. But then the proposition follows from the fact that $\operatorname{Hom}_A(E, E)$ is an A-module of finite type, and that $v \mapsto \det v$ is a homomorphism from this A-module into K. □

Let F be the kernel of the canonical homomorphism $E \to E \otimes_A K$, and let $E_0 = E/F$; we see, as above, that $E \otimes_A K$ can be identified with $E_0 \otimes_A K$, that $u(F) \subset F$, and that, if u_0 is the endomorphism of E_0 induced from u by passing to the quotient, then $u \otimes 1$ can be identified with $u_0 \otimes 1$, and $\sigma_j(u) = \sigma_j(u_0)$ for all j. *If we have* $F = 0$, then equations (6.4.1.3) and (6.4.1.5) still make sense and hold true whenever E is identified with a submodule of $E \otimes_A K$, and the u^j with homomorphisms $E \to E \otimes_A K$; then Proposition (6.4.5) extends also to this case, with the same proof.

(6.4.8). Let $(X, \mathscr{A})$ be a ringed space, $\mathscr{E}$ a *locally free* $\mathscr{A}$-module (of finite rank), and u an endomorphism of $\mathscr{E}$. By hypothesis, there exists a base $\mathfrak{B}$ for the topology of X such that, for all $V \in \mathfrak{B}$, $\mathscr{E}|V$ is isomorphic to some $\mathscr{A}^n|V$ (where n may vary with V). for all $V \in \mathfrak{B}$, u_V is thus an endomorphism of the $\Gamma(V, \mathscr{A})$-module $\Gamma(V, \mathscr{E})$, which is free by hypothesis; the determinant $\det u_V$ is thus defined and belongs to $\Gamma(V, \mathscr{A})$. Furthermore, if $e_1, \ldots, e_n$ form a basis of $\Gamma(V, \mathscr{E})$, then their restrictions to every open $W \subset V$ form a basis of $\Gamma(W, \mathscr{E})$ over $\Gamma(W, \mathscr{A})$, and so $\det u_W$ is the restriction of $\det u_V$ to W. There thus exists exactly one section of $\mathscr{A}$ over X, which we denote by $\det u$, and call the *determinant* of u, such that the restriction of $\det u$ to each $V \in \mathfrak{B}$ is $\det u_V$. It is clear that, for all $x \in X$, we have $(\det u)_x = \det u_x$; for endomorphisms u and v of $\mathscr{E}$, we have

(6.4.8.1) $$\det(u \circ v) = (\det u)(\det v)$$

as well as

(6.4.8.2) $$\det(1_{\mathscr{E}}) = 1_{\mathscr{A}}$$

and, if the rank of $\mathscr{E}$ is constant (which will be the case (**0**, 5.4.1) if X is connected) and equal to n,

(6.4.8.3) $$\det(s \cdot u) = s^n \det u$$

for all $s \in \Gamma(X, \mathscr{A})$ (note that $\det(0) = 0_{\mathscr{A}}$ if $n \geqslant 1$, but $\det(0) = 1_{\mathscr{A}}$ for $n = 0$). Furthermore, for u to be an *automorphism* of $\mathscr{E}$, it is necessary and sufficient that $\det u$ be *invertible* in $\Gamma(X, \mathscr{A})$.

If the rank of $\mathscr{E}$ is constant, then we can similarly define the elementary symmetric functions $\sigma_i(u)$, which are elements of $\Gamma(X, \mathscr{A})$; we again have the relations in (6.4.1.3) and (6.4.1.5).

We have thus defined a homomorphism $\det : \operatorname{Hom}_{\mathscr{A}}(\mathscr{E}, \mathscr{E}) \to \Gamma(X, \mathscr{A})$ of multiplicative monoids; II | 124
if we note that $\operatorname{Hom}_{\mathscr{A}}(\mathscr{E}, \mathscr{E}) = \Gamma(X, \mathscr{H}om_{\mathscr{A}}(\mathscr{E}, \mathscr{E}))$ by definition, then we see that we can replace X in this definition by an arbitrary open U of X, which immediately defines a homomorphism $\det : \mathscr{H}om_{\mathscr{A}}(\mathscr{E}, \mathscr{E}) \to \mathscr{A}$ of sheaves of multiplicative monoids. If $\mathscr{E}$ has constant rank, then we similarly define homomorphisms $\sigma_i : \mathscr{H}om_{\mathscr{A}}(\mathscr{E}, \mathscr{E}) \to \mathscr{A}$ of sheaves of sets; for $i = 1$, the homomorphism $\sigma_1 = \operatorname{Tr}$ is a homomorphism of $\mathscr{A}$-modules.

Let $(Y, \mathscr{B})$ be another ringed space, and let $f : (X, \mathscr{A}) \to (Y, \mathscr{B})$ be a morphism of ringed spaces; if $\mathscr{F}$ is a locally free $\mathscr{B}$-module, then $f^*(\mathscr{F})$ is a locally free $\mathscr{A}$-module (which is of the same rank as $\mathscr{F}$ if the latter is of constant rank) (**0**, 5.4.5). For every endomorphism v of $\mathscr{F}$, $f^*(v)$ is an endomorphism of $f^*(\mathscr{F})$, and it follows immediately from the definitions that $\det f^*(v)$ is the section of $\mathscr{A} = f^*(\mathscr{B})$ over X that canonically corresponds to $\det v \in \Gamma(Y, \mathscr{B})$. We can further say that the homomorphism $f^*(\det) : f^*(\mathscr{H}om_{\mathscr{B}}(\mathscr{F}, \mathscr{F})) \to f^*(\mathscr{B}) = \mathscr{A}$ is the composition

$$f^*(\mathscr{H}om_{\mathscr{B}}(\mathscr{F}, \mathscr{F})) \xrightarrow{\gamma^\sharp} \mathscr{H}om_{\mathscr{A}}(f^*(\mathscr{F}), f^*(\mathscr{F})) \xrightarrow{\det} \mathscr{A}$$

(**0**, 4.4.6). We have analogous results for the σ_i.

(6.4.9). Now suppose that X is a *locally integral prescheme*, so that the sheaf $\mathscr{R}(X)$ of rational functions on X is a locally simple sheaf of fields (**I**, 7.3.4), and quasi-coherent as an $\mathscr{O}_X$-module. If $\mathscr{E}$ is a quasi-coherent $\mathscr{O}_X$-module *of finite type*, then $\mathscr{E}' = \mathscr{E} \otimes_{\mathscr{O}_X} \mathscr{R}(X)$ is a locally free $\mathscr{R}(X)$-module (**I**, 7.3.6); for every endomorphism u of $\mathscr{E}$, $u \otimes 1_{\mathscr{R}(X)}$ is then an endomorphism of $\mathscr{E}'$, and $\det(u \otimes 1)$ is a section of $\mathscr{R}(X)$ over X, which we also call the *determinant* of u, and also denote by $\det u$. It follows from (6.4.3) that $\det u$ is a section of the *integral closure* of $\mathscr{O}_X$ in $\mathscr{R}(X)$ (6.3.2); if, further, X is *normal*, then $\det u$ is a *section of* $\mathscr{O}_X$ over X, and if we further suppose that $\mathscr{E}$ is *torsion free*, then for u to be an automorphism of $\mathscr{E}$ it is necessary and sufficient that $\det u$ be *invertible*, by (6.4.6). Equations (6.4.8.1) to (6.4.8.3) still hold true; from the homomorphism $u \mapsto \det u$, applied to the modules of sections of $\mathscr{H}om_{\mathscr{O}_X}(\mathscr{E}, \mathscr{E})$, we obtain a homomorphism of sheaves $\det : \mathscr{H}om_{\mathscr{O}_X}(\mathscr{E}, \mathscr{E}) \to \mathscr{R}(X)$, which takes values in $\mathscr{O}_X$ if X is normal. We have analogous definitions and results for the other elementary symmetric functions $\sigma_j(u)$, if $\mathscr{E}'$ is of *constant rank*; if, further, X is *normal*, then the $\sigma_j(u)$ are *sections of* $\mathscr{O}_X$ over X.

Finally, let X and Y be integral preschemes, and $f : X \to Y$ a *dominant* morphism. We know that there exists a canonical homomorphism $f^*(\mathscr{R}(Y)) \to \mathscr{R}(X)$ (**I**, 7.3.8)[1], whence we obtain, for every quasi-coherent $\mathscr{O}_Y$-module $\mathscr{F}$ of finite type, a canonical homomorphism $\theta : f^*(\mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{R}(Y)) \to f^*(\mathscr{F}) \otimes_{\mathscr{O}_X} \mathscr{R}(X)$. If v is an endomorphism of $\mathscr{F}$, then $f^*(v \otimes 1_{\mathscr{R}(Y)})$ is an endomorphism of $f^*(\mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{R}(Y))$, and we have a commutative diagram **II** | 125

$$\begin{tikzcd} f^*(\mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{R}(Y)) \arrow[r, "f^*(v\otimes 1)"] \arrow[d, "\theta"'] & f^*(\mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{R}(Y)) \arrow[d, "\theta"] \\ f^*(\mathscr{F}) \otimes_{\mathscr{O}_X} \mathscr{R}(X) \arrow[r, "f^*(v)\otimes 1"'] & f^*(\mathscr{F}) \otimes_{\mathscr{O}_X} \mathscr{R}(X) \end{tikzcd}$$

We thus easily conclude that $\det f^*(v)$ is the canonical image, under the homomorphism $f^*(\mathscr{R}(Y)) \to \mathscr{R}(X)$, of the section $\det v$ of $\mathscr{R}(Y)$; indeed, we can immediately reduce to the case where $X = \operatorname{Spec}(A)$ and $Y = \operatorname{Spec}(B)$ are affine, with A and B integral rings having respective fields of fractions K and L, and with the homomorphism $B \to A$ injective and therefore extending to a monomorphism $L \to K$; if $\mathscr{F} = \widetilde{M}$, where M is a B-module of finite type, then the rank of $M \otimes_B L$ over L is *equal* to that of $(M \otimes_B A) \otimes_A K$ over K, and $\det((u \otimes 1) \otimes 1)$ is the image in K of $\det(u \otimes 1)$ for any endomorphism u of M, whence the conclusion.

(6.4.10). Finally, suppose that X is a *locally Noetherian reduced prescheme*, so that the sheaf $\mathscr{R}(X)$ of rational functions on X is again a quasi-coherent $\mathscr{O}_X$-module (**I**, 7.3.4); let $\mathscr{E}$ be a *coherent* $\mathscr{O}_X$-module such that $\mathscr{E}' = \mathscr{E} \otimes_{\mathscr{O}_X} \mathscr{R}(X)$ is *locally free* (of finite rank). By (6.4.7), if $\mathscr{E}'$ is of constant rank, then we can, for any endomorphism u of $\mathscr{E}$, define the $\sigma_j(u)$, which are sections of $\mathscr{R}(X)$ over X. If we do not suppose $\mathscr{E}'$ to be of constant rank, we can still define the homomorphism $\det : \mathscr{H}om_{\mathscr{O}_X}(\mathscr{E}, \mathscr{E}) \to \mathscr{R}(X)$.

[1] See *Errata and Addenda*, List 1.

6.5. Norm of an invertible sheaf

(6.5.1). Let $(X, \mathscr{A})$ be a ringed space and $\mathscr{B}$ a (commutative) $\mathscr{A}$-algebra. The $\mathscr{A}$-module $\mathscr{B}$ is canonically identified with a sub-$\mathscr{A}$-module of $\mathscr{H}om_{\mathscr{A}}(\mathscr{B}, \mathscr{B})$, and a section f of $\mathscr{B}$ over an open U of X is identified with multiplication by this section. If $(X, \mathscr{A})$ and $\mathscr{B}$ satisfy one of the conditions given in (6.4.8), (6.4.9), or (6.4.10), then we can define $\det(f)$ (and, in certain cases, the $\sigma_j(f)$) as sections of $\mathscr{A}$ or $\mathscr{R}(X)$ over U; we call these the *norm* of f (resp. the *elementary symmetric functions* of f), and denote the former by $N_{\mathscr{B}/\mathscr{A}}(f)$. We will suppose that *one* of the following conditions is satisfied:

(I) *$\mathscr{B}$ is a locally free $\mathscr{A}$-module (of finite rank).*

(II) *$(X, \mathscr{A})$ is a locally Noetherian reduced prescheme, $\mathscr{B}$ is a coherent $\mathscr{A}$-module such that $\mathscr{B} \otimes_{\mathscr{A}} \mathscr{R}(X)$ is a locally free $\mathscr{R}(X)$-module, and, for every section $f \in \Gamma(U, \mathscr{B})$ over an open U of X, the norm $N_{\mathscr{B}/\mathscr{A}}(f)$ is a section of $\mathscr{A}$ over U.*

Note that the latter condition is automatically satisfied whenever the locally Noetherian prescheme X is *normal* (6.4.9). **II** | 126

The hypothesis that $\mathscr{B} \otimes_{\mathscr{A}} \mathscr{R}(X)$ is locally free can also be expressed in the following way: denote by X_α the closed reduced subpreschemes of X whose underlying spaces are the irreducible components of X (**I**, 5.2.1), which are thus locally Noetherian integral preschemes. Every $x \in X$ belongs to a finite number of the subspaces X_α; on the other hand, $\mathscr{B} \otimes_{\mathscr{A}} \mathscr{R}(X_\alpha)$ is a locally free $\mathscr{R}(X_\alpha)$-module of constant rank k_α (**I**, 7.3.6); to say that $\mathscr{B} \otimes_{\mathscr{A}} \mathscr{R}(X)$ is a locally free $\mathscr{R}(X)$-module means that, for all $x \in X$, *the ranks k_α that correspond to the indices such that $x \in X_\alpha$ are equal*. This is a local statement, and we can reduce to the case $X = \operatorname{Spec}(C)$, where C is a reduced Noetherian ring, and $\mathscr{B} = \widetilde{D}$, where D is a C-algebra that is a C-module of finite type; if $\mathfrak{p}_i$ (for $1 \leqslant i \leqslant m$) are the minimal prime ideals of C, then the total ring of fractions L of C is the direct sum of the fields of fractions K_i of the integral rings $C/\mathfrak{p}_i$, and $D \otimes_C L$ is the direct sum of the $D \otimes_C K_i$, whence the conclusion.

It is clear that, under hypothesis (I) or (II), we have thus defined a *homomorphism of sheaves of multiplicative monoids* $N_{\mathscr{B}/\mathscr{A}} : \mathscr{B} \to \mathscr{A}$, also denoted by N if no confusion may arise, and we call this homomorphism the *norm*. For sections f and g of $\mathscr{B}$ over the same open U, we thus have

$$N_{\mathscr{B}/\mathscr{A}}(fg) = N_{\mathscr{B}/\mathscr{A}}(f) N_{\mathscr{B}/\mathscr{A}}(g) \tag{6.5.1.1}$$

for the corresponding sections of $\mathscr{A}$ over U;

$$N_{\mathscr{B}/\mathscr{A}}(1_{\mathscr{B}}) = 1_{\mathscr{A}}; \tag{6.5.1.2}$$

finally, for any section s of $\mathscr{A}$ over U,

$$N_{\mathscr{B}/\mathscr{A}}(s \cdot 1_{\mathscr{B}}) = s^n \tag{6.5.1.3}$$

if the rank of $\mathscr{B}$ is constant and equal to n (for $s = 0_{\mathscr{A}}$, this formula gives $N(0_{\mathscr{B}}) = 0_{\mathscr{A}}$ if $n \geqslant 1$, and $N(0_{\mathscr{B}}) = N(1_{\mathscr{B}}) = 1_{\mathscr{A}}$ if $n = 0$).

In hypothesis (I), for $f \in \Gamma(U, \mathscr{B})$ to be invertible it is necessary and sufficient that $N(f) \in \Gamma(U, \mathscr{A})$ be invertible. In hypothesis (II), this condition is necessary; it is sufficient (by (6.4.7)) if we suppose that $\mathscr{B} \to \mathscr{B} \otimes_{\mathscr{A}} \mathscr{R}(X)$ is *injective* and that the following more restrictive hypothesis is satisfied:

(II *bis*) *$(X, \mathscr{A})$ is a locally Noetherian reduced prescheme, $\mathscr{B}$ is a coherent $\mathscr{A}$-module such that $\mathscr{B} \otimes_{\mathscr{A}} \mathscr{R}(X)$ is a locally free $\mathscr{R}(X)$-module, and, for any section $f \in \Gamma(U, \mathscr{B})$ over an open U such that $\mathscr{B} \otimes_{\mathscr{A}} \mathscr{R}(X)|U$ is of constant rank n on $\mathscr{R}(X)|U$, the $\sigma_j(f)$ (for $1 \leqslant j \leqslant n$) are sections of $\mathscr{A}$ over U.*

(We again note that this condition is satisfied if X is *normal*.)

(6.5.2). Suppose that one of the hypotheses (I) or (II) of (6.5.1) is satisfied, and let $\mathscr{L}'$ be an *invertible* $\mathscr{B}$-module. We will canonically associate to it (up to unique isomorphism) an *invertible* $\mathscr{A}$-module $\mathscr{L}$ in the following way. Denote by $\mathscr{A}^*$ (resp. $\mathscr{B}^*$) the subsheaf of $\mathscr{A}$ (resp. of $\mathscr{B}$) such that $\Gamma(U, \mathscr{A}^*)$ (resp. $\Gamma(U, \mathscr{B}^*)$) is the set of invertible elements of $\Gamma(U, \mathscr{A})$ (resp. of $\Gamma(U, \mathscr{B})$) for every open $U \subset X$; these are sheaves of multiplicative groups, and $N_{\mathscr{B}/\mathscr{A}}$ restricted to $\mathscr{B}^*$ is a *homomorphism* $\mathscr{B}^* \to \mathscr{A}^*$ of sheaves of groups (6.5.1). Let $\mathfrak{L}$ be the set of pairs (U_λ, v_λ) that have the following property: U_λ is **II** | 127 an open of X, and ν_λ is an isomorphism $\mathscr{L}'|U_\lambda \xrightarrow{\sim} \mathscr{B}|U_\lambda$ of $(\mathscr{B}|U_\lambda)$-modules. By hypothesis, the U_λ form a cover of X; for arbitrary indices λ and μ, set $\omega_{\lambda\mu} = (\nu_\lambda|U_\lambda \cap U_\mu) \circ (\nu_\mu|U_\lambda \cap U_\mu)^{-1}$, which is an automorphism of $\mathscr{B}|U_\lambda \cap U_\mu$ canonically identified with a section of $\mathscr{B}^*$ over $U_\lambda \cap U_\mu$, and $(\omega_{\lambda\mu})$ is a 1-cocycle for the cover $\mathfrak{U} = (U_\lambda)$ with values in $\mathscr{B}^*$ (**0**, 5.4.7). The fact that $N_{\mathscr{B}/\mathscr{A}} : \mathscr{B}^* \to \mathscr{A}^*$ is a homomorphism implies that $(N_{\mathscr{B}/\mathscr{A}}\omega_{\lambda\mu})$ is a 1-cocycle of $\mathfrak{U}$ with values in $\mathscr{A}^*$, and thus corresponds (up to unique isomorphism) to an invertible $\mathscr{A}$-module $\mathscr{L}$ (**0**, 5.4.7) which we denote by $N_{\mathscr{B}/\mathscr{A}}(\mathscr{L}')$, and call the *norm* of the invertible $\mathscr{B}$-module $\mathscr{L}'$.

Let $\mathfrak{M}$ be a subset of $\mathfrak{L}$ such that the corresponding U_λ still form a cover of X, and let $\mathfrak{B}$ be the resulting cover; the restriction of the cocycle $(\omega_{\lambda\mu})$ to $\mathfrak{B}$ defines a 1-cocycle $(N_{\mathscr{B}/\mathscr{A}}\omega_{\lambda\mu})$ of $\mathfrak{B}$ with values in $\mathscr{A}^*$, the restriction of the 1-cocycle $(N_{\mathscr{B}/\mathscr{A}}\omega_{\lambda\mu})$ of $\mathfrak{U}$; it is clear that there is a canonical isomorphism from the invertible $\mathscr{A}$-module defined by this 1-cocycle of $\mathfrak{B}$ to $N_{\mathscr{B}/\mathscr{A}}(\mathscr{L}')$, which allows us to define the invertible $\mathscr{A}$-module by an arbitrary sub-cover of $\mathfrak{U}$. This possibility immediately shows that, if $\mathscr{L}'_1$ and $\mathscr{L}'_2$ are invertible $\mathscr{B}$-modules, then, by (6.5.1.1) and (6.5.1.2),

(6.5.2.1) $$N(\mathscr{L}'_1 \otimes_{\mathscr{B}} \mathscr{L}'_2) = N(\mathscr{L}'_1) \otimes_{\mathscr{A}} N(\mathscr{L}'_2)$$

and

(6.5.2.2) $$N_{\mathscr{B}/\mathscr{A}}(\mathscr{B}) = \mathscr{A}$$

as well as

(6.5.2.3) $$N(\mathscr{L}'^{-1}) = (N(\mathscr{L}'))^{-1}$$

up to canonical isomorphisms. Furthermore, it follows from (6.5.1.3) that, if $\mathscr{L}$ is an invertible $\mathscr{A}$-module and if $\mathscr{B}$ is of constant rank n on $\mathscr{A}$ in case (I) (resp. $\mathscr{B} \otimes_{\mathscr{A}} \mathscr{R}(X)$ is of constant rank n on $\mathscr{R}(X)$ in case (II)), we have, up to canonical isomorphism,

(6.5.2.4) $$N_{\mathscr{B}/\mathscr{A}}(\mathscr{L} \otimes_{\mathscr{A}} \mathscr{B}) = \mathscr{L}^{\otimes n}.$$

(6.5.3). We now show that $N_{\mathscr{B}/\mathscr{A}}$ is a covariant *functor* in the category of invertible $\mathscr{B}$-modules. Let $h' : \mathscr{L}'_1 \to \mathscr{L}'_2$ be a homomorphism of invertible $\mathscr{B}$-modules, and let $\mathfrak{B} = (U_\lambda)$ be an open cover of X such that, for all λ, we have $(\mathscr{B}|U_\lambda)$-isomorphisms $\eta_\lambda^{(1)} : \mathscr{L}'_1|U_\lambda \xrightarrow{\sim} \mathscr{B}|U_\lambda$ and $\eta_\lambda^{(2)} : \mathscr{L}'_2|U_\lambda \xrightarrow{\sim} \mathscr{B}|U_\lambda$; there is thus, for each λ, an endomorphism h'_λ of $\mathscr{B}|U_\lambda$ such that $h'_\lambda \circ \eta_\lambda^{(1)} = \eta_\lambda^{(2)} \circ (h'|U_\lambda)$, and we can evidently identify h'_λ with a section of $\mathscr{B}$ over U_λ (**0**, 5.1.1). So, for every pair (λ, μ) of indices, the restrictions to $U_\lambda \cap U_\mu$ of $(\eta_\lambda^{(2)})^{-1} \circ h'_\lambda \circ \eta_\lambda^{(1)}$ and $(\eta_\mu^{(2)})^{-1} \circ h'_\mu \circ \eta_\mu^{(1)}$ agree. We thus obtain, for 1-cocycles $(\omega_{\lambda\mu}^{(1)})$ and $(\omega_{\lambda\mu}^{(2)})$ with values in $\mathscr{B}^*$ corresponding to $\mathscr{L}'_1$ and $\mathscr{L}'_2$, the relation

$$\omega_{\lambda\mu}^{(2)} h'_\mu = h'_\lambda \omega_{\lambda\mu}^{(1)}.$$

If we set $h_\lambda = N(h'_\lambda)$, we thus have the analogous relations **II** | 128

$$N(\omega_{\lambda\mu}^{(2)}) h_\mu = h_\lambda N(\omega_{\lambda\mu}^{(1)})$$

and so the h_λ define a homomorphism $N(\mathscr{L}'_1) \to N(\mathscr{L}'_2)$ which we denote by $N_{\mathscr{B}/\mathscr{A}}(h')$, or $N(h')$. In hypothesis (I), for h' to be an *isomorphism*, it is necessary and sufficient (since it is a local question) for $N_{\mathscr{B}/\mathscr{A}}(h')$ to be an isomorphism. In hypothesis (II), this condition is again necessary; it is sufficient if hypothesis (II *bis*) is satisfied and $\mathscr{B} \to \mathscr{B} \otimes_{\mathscr{A}} \mathscr{R}(X)$ is injective.

Take, in particular, $\mathscr{L}'_1 = \mathscr{B}$; the homomorphisms $\mathscr{B} \to \mathscr{L}'$ can then be identified (**0**, 5.1.1) with the sections of $\mathscr{L}'$ over X, whence a canonical map

$$N_{\mathscr{B}/\mathscr{A}} : \Gamma(X, \mathscr{L}') \longrightarrow \Gamma(X, N_{\mathscr{B}/\mathscr{A}}(\mathscr{L}')).$$

It again follows from (6.5.1.1) that, if $f'_1 \in \Gamma(X, \mathscr{L}'_1)$ and $f'_2 \in \Gamma(X, \mathscr{L}'_2)$, then

(6.5.3.1) $$N(f'_1 \otimes f'_2) = N(f'_1) \otimes N(f'_2).$$

For every invertible $\mathscr{A}$-module $\mathscr{L}$ and every section $f \in \Gamma(X, \mathscr{L})$, we have, taking (6.5.2.4) into account, that

(6.5.3.2) $$N_{\mathscr{B}/\mathscr{A}}(f \otimes 1_{\mathscr{B}}) = f^{\otimes n}$$

whenever $\mathscr{B}$ is of constant rank n in hypothesis (I) (resp. whenever $\mathscr{B}\otimes_{\mathscr{A}}\mathscr{R}(X)$ is of constant rank n in hypothesis (II)). Finally, for the homomorphism $\mathscr{B}\to\mathscr{L}'$ corresponding to a section f' of $\mathscr{L}'$ over X to be an isomorphism, it is necessary and sufficient for f'_x to be a basis for $\mathscr{L}'_x$ for all $x\in X$; in hypothesis (I), this condition is thus equivalent to saying that $(N(f'))_x$ is a basis for $(N(\mathscr{L}'))_x$ for all x; in hypothesis (II), this condition is again necessary, and it is sufficient whenever $\mathscr{B}$ satisfies hypothesis (II *bis*) and $\mathscr{B}\to\mathscr{B}\otimes_{\mathscr{A}}\mathscr{R}(X)$ is injective.

(6.5.4). Let $(X,\mathscr{A})$ and $(X',\mathscr{A}')$ be ringed spaces, $f:X'\to X$ a morphism, $\mathscr{B}$ an $\mathscr{A}$-algebra, and $\mathscr{B}'=f^*(\mathscr{B})$ the inverse image $\mathscr{A}'$-algebra. Suppose that one of the following hypotheses is satisfied:

(1) $\mathscr{B}$ satisfies hypothesis (I) of (6.5.1).
(2) $(X,\mathscr{A})$ and $\mathscr{B}$ satisfy hypothesis (II) of (6.5.1), $(X',\mathscr{A}')$ is a locally Noetherian reduced prescheme, and, if we denote by X_α and X'_β the closed reduced subpreschemes of X and X' (respectively) that have the irreducible components of these spaces as their underlying spaces, then the restriction of f to each X'_β is a *dominant* morphism from X'_β to X_α.

Under these conditions, $\mathscr{B}'$ satisfies hypothesis (I) or hypothesis (II) (respectively) of (6.5.1). The first claim is immediate; to establish the second, it suffices to show that, for all $x'\in X'$, the ranks of the $\mathscr{B}'\otimes_{\mathscr{O}_{X'}}\mathscr{R}(X'_\beta)$ are *the same* for the β such that $x'\in X'_\beta$. But if the restriction of f to X'_β is a dominant morphism to X_α, then the rank of $\mathscr{B}'\otimes_{\mathscr{O}_{X'}}\mathscr{R}(X'_\beta)$ is equal to that of $\mathscr{B}\otimes_{\mathscr{O}_X}\mathscr{R}(X_\alpha)$ (as we immediately see by reducing to the affine case, as in (6.4.9)), whence our claim, by hypothesis (II) and (6.5.1).

With this in mind, it follows from (6.4.8), (6.4.9), and (6.4.10) that, if s is a section of $\mathscr{B}$ over an open $U\subset X$, and s' the corresponding section of $\mathscr{B}'$ over $f^{-1}(U)$, then $N_{\mathscr{B}'/\mathscr{A}'}(s')$ is the section of $\mathscr{A}'$ over $f^{-1}(U)$ that corresponds to the section $N_{\mathscr{B}/\mathscr{A}}(s)$ of $\mathscr{A}$ over U. **II** | 129

If $\mathscr{M}$ is an invertible $\mathscr{B}$-module, then we deduce from the above that, if $\mathscr{M}'=f^*(\mathscr{M})$ (which is an invertible $\mathscr{B}'$-module), we have $N_{\mathscr{B}'/\mathscr{A}'}(\mathscr{M}')=f^*(N_{\mathscr{B}/\mathscr{A}}(\mathscr{M}))$ up to canonical isomorphism.

(6.5.5). Suppose from now on that $(X,\mathscr{A})$ is a *prescheme*. The data of a quasi-coherent $\mathscr{A}$-algebra $\mathscr{B}$, which is an *$\mathscr{A}$-module of finite type*, is then equivalent, as we know, to that of a *finite* morphism $g:X'\to X$ such that $g_*(\mathscr{O}_{X'})=\mathscr{B}$, defined up to X-isomorphism ((6.1.2) and (1.3.1)). Furthermore, the data of a quasi-coherent $\mathscr{O}_{X'}$-module $\mathscr{F}'$ is equivalent to that of a quasi-coherent $\mathscr{B}$-module $\mathscr{F}$ such that $g_*(\mathscr{F}')=\mathscr{F}$ (1.4.3), and for $\mathscr{F}'$ to be invertible it is necessary and sufficient that $\mathscr{F}$ be invertible (6.1.12). To translate the above results in terms of finite morphisms g, it will be necessary to suppose either that $g_*(\mathscr{O}_{X'})$ is a *locally free* $\mathscr{O}_X$-module (of finite type) or that $(X,\mathscr{O}_X)$ and $g_*(\mathscr{O}_{X'})$ satisfy hypothesis (II). For every invertible $\mathscr{O}_{X'}$-module $\mathscr{L}'$, we thus set

$$N_{X'/X}(\mathscr{L}')=N_{g_*(\mathscr{O}_{X'})/\mathscr{O}_X}(g_*(\mathscr{L}')) \tag{6.5.5.1}$$

and we call this the *norm* (with respect to g) of $\mathscr{L}'$. Similarly, if $h':\mathscr{L}'_1\to\mathscr{L}'_2$ is a homomorphism of invertible $\mathscr{O}_{X'}$-modules, then we set

$$N_{X'/X}(h')=N_{g_*(\mathscr{O}_{X'})/\mathscr{O}_X}(g_*(h')):N_{X'/X}(\mathscr{L}'_1)\longrightarrow N_{X'/X}(\mathscr{L}'_2). \tag{6.5.5.2}$$

In particular, for $\mathscr{L}'_1=\mathscr{O}_{X'}$, we thus obtain a canonical map

$$N_{X'/X}:\Gamma(X',\mathscr{L}')\longrightarrow\Gamma(X,N_{X'/X}(\mathscr{L}')). \tag{6.5.5.3}$$

We leave to the reader the majority of these translations, and we restrict ourselves to spelling out the details of the following:

Proposition (6.5.6). — *Let $g:X'\to X$ be a finite morphism, and suppose that either $g_*(\mathscr{O}_{X'})$ is a locally free $\mathscr{O}_X$-module or that $(X,\mathscr{O}_X)$ and $g_*(\mathscr{O}_{X'})$ satisfy (II* bis*) (which will be the case, in particular, if X is locally Noetherian and normal). For a homomorphism $h':\mathscr{L}'_1\to\mathscr{L}'_2$ of invertible $\mathscr{O}_{X'}$-modules to be an isomorphism, it is necessary and sufficient, in the first hypothesis, that $N_{X'/X}(h')$ be an isomorphism; in the second hypothesis, this condition is again necessary, and is sufficient if the homomorphism $g_*(\mathscr{O}_{X'})\to g_*(\mathscr{O}_{X'})\otimes_{\mathscr{O}_X}\mathscr{R}(X)$ is injective.*

Proof. Note that we use here the fact that, for $g_*(h')$ to be an isomorphism, it is necessary and sufficient for h' to be an isomorphism (1.4.2). ☐

Corollary (6.5.7). — *Let $g : X' \to X$ be a finite morphism, and suppose that either $g_*(\mathscr{O}_{X'})$ is a locally free $\mathscr{O}_X$-module or that $(X, \mathscr{O}_X)$ and $g_*(\mathscr{O}_{X'})$ satisfy (II* bis*) and $g_*(\mathscr{O}_{X'}) \to g_*(\mathscr{O}_{X'}) \otimes_{\mathscr{O}_X} \mathscr{R}(X)$ is injective. Let $\mathscr{L}'$ be an invertible $\mathscr{O}_{X'}$-module, f' a section of $\mathscr{L}'$ over X', and $f = N_{X'/X}(f')$ the corresponding section of $\mathscr{L} = N_{X'/X}(\mathscr{L}')$ over X (6.5.5.3). Then $g(X' \setminus X'_{f'}) = X \setminus X_f$, and X_f is the largest open subset* **II** | 130 *U of X such that $g^{-1}(U) \subset X'_{f'}$.*

Proof. Indeed, $g(X' \setminus X'_{f'})$ is closed in X (6.1.10); it thus suffices to prove the last claim. But the relation $U \subset X_f$ is equivalent to the fact that the homomorphism $\mathscr{O}_X|U \to \mathscr{L}|U$ defined by $f|U$ is an isomorphism. By (6.5.6), this is equivalent to saying that the homomorphism $\mathscr{O}_{X'}|g^{-1}(U) \to \mathscr{L}'|g^{-1}(U)$ defined by $f'|g^{-1}(U)$ is an isomorphism, which is equivalent to the relation $g^{-1}(U) \subset X'_{f'}$. □

Proposition (6.5.8). — *Let $g : X' \to X$ be a finite morphism, and $f : Y \to X$ a morphism; let $Y' = X'_{(Y)}$, $g' = g_{(Y)}$, and $f' = f_{(X')}$, so that the diagram*

$$\begin{tikzcd} X' \arrow[d, "g"'] & Y' \arrow[l, "f'"'] \arrow[d, "g'"] \\ X & Y \arrow[l, "f"] \end{tikzcd}$$

commutes.

Suppose that either $g_*(\mathscr{O}_{X'})$ is a locally free $\mathscr{O}_X$-module or that $(X, \mathscr{O}_X)$ and $g_*(\mathscr{O}_{X'})$ satisfy (II). Suppose further that Y is a locally Noetherian reduced prescheme, and that the restriction of f to any irreducible component of Y is a dominant morphism to an irreducible component of X. Then, for every invertible $\mathscr{O}_{X'}$-module $\mathscr{L}'$, we have

$$N_{Y'/Y}(f'^*(\mathscr{L}')) = f^*(N_{X'/X}(\mathscr{L}'))$$

up to canonical isomorphism.

Proof. Note that we have $f^*(g_*(\mathscr{L}')) = g'_*(f'^*(\mathscr{L}'))$, by (1.5.2), and, in particular, $g'_*(\mathscr{O}_{Y'}) = f^*(g_*(\mathscr{O}_{X'}))$; if $g_*(\mathscr{O}_{X'})$ is locally free, then so too is $g'_*(\mathscr{O}_{Y'})$. The conclusion then follows from the definitions and (6.5.4). □

Remark (6.5.9). — We later generalise the notion of norm developed above, by placing it in relation to the notion of direct image of a divisor.

6.6. Application: criteria for ampleness

Proposition (6.6.1). — *Let Y be a prescheme, $f : X \to Y$ a quasi-compact morphism, and $g : X' \to X$ a finite and surjective morphism. Suppose that either $g_*(\mathscr{O}_{X'})$ is a locally free $\mathscr{O}_X$-module or that $(X, \mathscr{O}_X)$ and $g_*(\mathscr{O}_{X'})$ satisfy (II* bis*). Then, for every invertible $\mathscr{O}_{X'}$-module $\mathscr{L}'$ that is ample for $f \circ g$, $\mathscr{L} = N_{X'/X}(\mathscr{L}')$ is ample for f.*

Proof. We can suppose Y to be affine (4.6.4), and then, by (4.6.6), the statement is equivalent to: □

Corollary (6.6.2). — *Let X be a quasi-compact prescheme, $g : X' \to X$ a finite surjective morphism, such that either $g_*(\mathscr{O}_{X'})$ is a locally free $\mathscr{O}_X$-module or $(X, \mathscr{O}_X)$ and $g_*(\mathscr{O}_{X'})$ satisfy (II* bis*). Then, for every ample $\mathscr{O}_{X'}$-module $\mathscr{L}'$, $\mathscr{L} = N_{X'/X}(\mathscr{L}')$ is ample.*

Proof. In the second hypothesis, we can further suppose that the canonical homomorphism $g_*(\mathscr{O}_{X'}) \to g_*(\mathscr{O}_{X'}) \otimes_{\mathscr{O}_X} \mathscr{R}(X)$ is *injective*. Indeed, if not, let $\mathscr{T}$ be the kernel of this homomorphism, **II** | 131 which is a coherent ideal of $\mathscr{B} = g_*(\mathscr{O}_{X'})$ (**I**, 6.1.1), and set $X'' = \operatorname{Spec}(\mathscr{B}/\mathscr{T})$; we thus have a commutative diagram

$$\begin{tikzcd} X'' \arrow[rr, "h"] \arrow[dr, "g'"'] & & X' \arrow[dl, "g"] \\ & X & \end{tikzcd}$$

where h is a closed immersion (1.4.10). Furthermore, we know that the support of $\mathscr{T}$ is a closed set (**0**, 5.2.2) that is nowhere dense in X (**I**, 7.4.6), whence we conclude that, for the generic point x

of an irreducible component of X, there is an affine open neighbourhood U of x such that $\mathscr{B}|U = (\mathscr{B}/\mathscr{T})|U$. Since g is, by hypothesis, surjective, we thus conclude that $x \in g'(X'')$; g' is thus dominant, and, since it is a finite morphism, it is *surjective* (6.1.10); by definition,

$$g'_*(\mathscr{O}_{X''}) \otimes_{\mathscr{O}_X} \mathscr{R}(X) = (\mathscr{B}/\mathscr{T}) \otimes_{\mathscr{O}_X} \mathscr{R}(X) = g_*(\mathscr{O}_{X'}) \otimes_{\mathscr{O}_X} \mathscr{R}(X)$$

thus $(X, \mathscr{O}_X)$ and $g'_*(\mathscr{O}_{X''})$ satisfy (II *bis*), and furthermore $g'_*(\mathscr{O}_{X''}) \to g'_*(\mathscr{O}_{X''}) \otimes_{\mathscr{O}_X} \mathscr{R}(X)$ is injective. Finally, $h^*(\mathscr{L}') = \mathscr{L}''$ is an ample $\mathscr{O}_{X''}$-module (4.6.13, (i *bis*)), and we have that $N_{X''/X}(\mathscr{L}'') = N_{X'/X}(\mathscr{L}')$. Indeed, to define these two invertible $\mathscr{O}_X$-modules, we can use the same affine open cover (U_λ) of X such that the restrictions of $g_*(\mathscr{L}')$ and $g'_*(\mathscr{L}'')$ to U_λ are isomorphic to $\mathscr{B}|U_\lambda$ and $(\mathscr{B}/\mathscr{T})|U_\lambda$ (respectively). We immediately see that, for every isomorphism $\eta_\lambda : g_*(\mathscr{L}')|U_\lambda \to \mathscr{B}|U_\lambda$, there is a canonically corresponding isomorphism

$$\eta'_\lambda : g'_*(\mathscr{L}'')|U_\lambda \longrightarrow (\mathscr{B}/\mathscr{T})|U_\lambda$$

so that, if $(\omega_{\lambda\mu})$ and $(\omega'_{\lambda\mu})$ are the 1-cocycles corresponding to the systems of isomorphisms (η_λ) and (η'_λ) (6.5.2), $\omega'_{\lambda\mu}$ is the canonical image in $\Gamma(U_\lambda \cap U_\mu, \mathscr{B}/\mathscr{T})$ of $\omega_{\lambda\mu} \in \Gamma(U_\lambda \cap U_\mu, \mathscr{B})$. By the definition of $\mathscr{T}$, we thus conclude that

$$N_{\mathscr{B}/\mathscr{A}}(\omega_{\lambda\mu}) = N_{(\mathscr{B}/\mathscr{T})/\mathscr{A}}(\omega'_{\lambda\mu})$$

(where $\mathscr{A} = \mathscr{O}_X$), whence the claimed equality.

So suppose that the homomorphism $g_*(\mathscr{O}_{X'}) \to g_*(\mathscr{O}_{X'}) \otimes_{\mathscr{O}_X} \mathscr{R}(X)$ is injective when we are in hypothesis (II *bis*). It suffices to prove that, as f runs over the sections of $\mathscr{L}^{\otimes n}$ (for $n > 0$) over X, the X_f form a base for the topology of X (4.5.2). But let $x \in X$, and let U be an arbitrary neighbourhood of x; since $g^{-1}(x)$ is finite (6.1.7) and $\mathscr{L}'$ is ample, there exists an integer $n > 0$ and a section f' of $\mathscr{L}'^{\otimes n}$ over X' such that $X'_{f'}$ is a neighbourhood of $g^{-1}(x)$ contained inside $g^{-1}(U)$ (4.5.4). Since

$$\mathscr{L}^{\otimes n} = N_{X'/X}(\mathscr{L}'^{\otimes n})$$

it suffices to take $f = N_{X'/X}(f')$; indeed, then $X \setminus X_f = g(X' \setminus X'_{f'})$ (6.5.7), and so $x \in X_f \subset U$. □

Corollary (6.6.3). — *Under the hypotheses of (6.6.1), for an invertible $\mathscr{O}_X$-module $\mathscr{L}$ to be ample for f, it is necessary and sufficient that $\mathscr{L}' = g^*(\mathscr{L})$ be ample for $f \circ g$.*

Proof. The condition is necessary, since g is affine (5.1.12). To prove that the condition is sufficient, we can suppose that Y is affine (4.6.4), and so X and X' are quasi-compact and $\mathscr{L}'$ is ample (4.6.6), and we need to show that $\mathscr{L}$ is ample. But the set of points $x \in X$ that admit a neighbourhood where $g_*(\mathscr{O}_{X'})$ (resp. $g_*(\mathscr{O}_{X'}) \otimes_{\mathscr{O}_X} \mathscr{R}(X)$) has a given rank n in the first (resp. second) hypothesis is simultaneously open and closed in X, and so X is the prescheme given by the sum of a finite number of these opens, and we can thus suppose that it is equal to one of them (4.6.17). But then $N_{X'/X}(\mathscr{L}') = \mathscr{L}^{\otimes n}$, and so $\mathscr{L}^{\otimes n}$ is ample by (6.6.2), and thus so too is $\mathscr{L}$ (4.5.6). □ **II | 132**

Corollary (6.6.4). — *Suppose that the hypotheses of (6.6.1) are satisfied, and suppose further that $f : X \to Y$ is of finite type. Then, for f to be quasi-projective, it is necessary and sufficient that $f \circ g$ be quasi-projective. If we further suppose that Y is a quasi-compact scheme, or a prescheme whose underlying space is Noetherian, then for f to be projective, it is necessary and sufficient that $f \circ g$ be projective.*

Proof. The hypothesis implies that $f \circ g$ is of finite type. Taking into account the definition of quasi-projective morphisms (5.3.1), the first claim follows from (6.6.1) and (6.6.3). Taking into account this result, along with (5.5.3, (ii)), it remains to show that, if f is quasi-projective, then for f to be proper, it is necessary and sufficient that $f \circ g$ be proper. But f is then separated (5.3.1) and of finite type; since g is surjective, our claim follows from (5.4.2, (ii)) and (5.4.3, (ii)). □

In particular:

Corollary (6.6.5). — *Let X be a prescheme of finite type over a field K, and K' a finite-degree extension of K. For X to be projective (resp. quasi-projective) over K, it is necessary and sufficient that $X' = X \otimes_K K'$ be projective (resp. quasi-projective) over K'.*

Proof. The condition is necessary ((5.3.4, (iii)) and (5.5.5, (iii))). Conversely, suppose that it is satisfied, and let $g : X' \to X$ be the canonical projection. It is clear that g is a finite morphism (6.1.5, (iii)) and surjective (**I**, 3.5.2, (ii)). Furthermore, $g_*(\mathscr{O}_{X'})$ is a locally free $\mathscr{O}_X$-module, since it is isomorphic to $\mathscr{O}_X \otimes_K K'$ (1.5.2). It then follows from the hypothesis and from (6.1.11) and (5.5.5, (ii)) that X' is projective (resp. quasi-projective) *over* K; we then deduce from (6.6.4) that X is projective (resp. quasi-projective) over K. ☐

In Chapter V, we will show that the statement of (6.6.5) remains true when K' is an *arbitrary* extension of K.

The rest of this section is dedicated to the proof of the criterion in (6.6.11), which is a rather technical refinement of (6.6.1); it can be omitted on a first reading.

Lemma (6.6.6). — *Let X be a reduced Noetherian prescheme, and $\mathscr{E}$ a coherent $\mathscr{O}_X$-module such that $\mathscr{E} \otimes_{\mathscr{O}_X} \mathscr{R}(X)$ is a locally free $\mathscr{R}(X)$-module of constant rank n. Then there exists a reduced Noetherian prescheme Z and a birational finite morphism $h : Z \to X$ that has the following property: the morphisms of sheaves of sets $\sigma_i : \mathscr{H}om_{\mathscr{O}_X}(\mathscr{E}, \mathscr{E}) \to \mathscr{R}(X)$ (for $1 \leqslant i \leqslant n$) (cf. (6.4.10)) send $\mathscr{H}om_{\mathscr{O}_X}(\mathscr{E}, \mathscr{E})$ to the coherent $\mathscr{O}_X$-algebra $h_*(\mathscr{O}_Z)$.*

Proof. Consider an affine open U of X, of ring $A(U) = A$; let $E = \Gamma(U, \mathscr{E})$, and let C_U be the subalgebra of $R(U)$ generated by the $\sigma_i(u)$ where u runs over $\operatorname{Hom}_A(E, E)$; we have seen (6.4.7.1) that this A-algebra is an *A-module of finite type*. Furthermore, it is clear that forming the algebras C_U commutes with the restriction operations of an affine open U to an affine open $U' \subset U$. We have thus defined a *finite* sub-$\mathscr{O}_X$-algebra $\mathscr{C}$ of $\mathscr{R}(X)$ such that $\Gamma(U, \mathscr{C}) = C_U$ for every affine open U of X. We take $Z = \operatorname{Spec}(\mathscr{C})$, and take h to be the structure morphism, which is thus finite (6.1.2); since **II | 133**
$\mathscr{C}$ is reduced, Z is a reduced Noetherian prescheme (1.3.8). Finally, the total ring of fractions of C_U is $R(U)$, by definition, and since C_U is contained inside the integral closure of $A(U)$ in $R(U)$, there is a bijective correspondence between minimal prime ideals of $A(U)$ and minimal prime ideals of C_U [SZ60, t. I, p. 259], which proves that h is birational and finishes the proof. ☐

Corollary (6.6.7). — *Under the hypotheses of (6.6.6), let W be an open of X such that, for all $x \in W$, either X is normal at the point x, or $\mathscr{E}_x$ is a free $\mathscr{O}_x$-module. Then we can suppose h to be defined such that the restriction of h to $h^{-1}(W)$ is an isomorphism from $h^{-1}(W)$ to W.*

Proof. Either hypothesis implies that, if $U \subset W$ is an affine open, then, with the notation of (6.6.6), $(\sigma_i(u))_x \in A_x$ for all $x \in U$ (6.4.3), and so $\sigma_i(u) \in A$, and the conclusion follows from the definition of h given in (6.6.6). ☐

(6.6.8). Let X be a reduced Noetherian prescheme, and $g : X' \to X$ a finite surjective morphism, so that $\mathscr{B} = g_*(\mathscr{O}_{X'})$ is a *coherent* $\mathscr{O}_X$-algebra; suppose further that $\mathscr{B} \otimes_{\mathscr{O}_X} \mathscr{R}(X)$ is a *locally free* $\mathscr{R}(X)$-module *of constant rank n*. We can then apply Lemma (6.6.6), taking $\mathscr{E} = \mathscr{B}$, whence, with the notation of (6.6.6), we obtain a homomorphism of sheaves of multiplicative monoids $\sigma_n : \mathscr{H}om_{\mathscr{O}_X}(\mathscr{B}, \mathscr{B}) \to h_*(\mathscr{O}_Z)$, and by composing this homomorphism with the canonical homomorphism $\mathscr{B} \to \mathscr{H}om_{\mathscr{O}_X}(\mathscr{B}, \mathscr{B})$ (6.5.1), we thus obtain a homomorphism of sheaves of multiplicative monoids:

$$N' : \mathscr{B} = g_*(\mathscr{O}_{X'}) \longrightarrow h_*(\mathscr{O}_Z) = \mathscr{C}. \tag{6.6.8.1}$$

With this in mind, for every invertible $\mathscr{O}_{X'}$-module $\mathscr{L}'$, $g_*(\mathscr{L}')$ is an invertible $\mathscr{B}$-module (6.1.12), and the method of (6.5.2) allows us to functorially associate to $\mathscr{L}'$ an invertible $\mathscr{C}$-module, which we denote by $N'(g_*(\mathscr{L}'))$.

Lemma (6.6.9). — *Let X be a reduced Noetherian prescheme, and $g : X' \to X$ a finite surjective morphism such that $g_*(\mathscr{O}_{X'}) \otimes_{\mathscr{O}_X} \mathscr{R}(X)$ is a locally free $\mathscr{R}(X)$-module of constant rank. Then there exists a reduced Noetherian prescheme Z and a finite birational morphism $h : Z \to X$ that has the following property: for every ample $\mathscr{O}_{X'}$-module $\mathscr{L}'$, the invertible $\mathscr{O}_Z$-module $\mathscr{M}$ such that $h_*(\mathscr{M}) = N'(g_*(\mathscr{L}'))$ (using the notation of (6.6.8)) is ample.*

Proof. Suppose first of all that the homomorphism $\mathscr{B} \to \mathscr{B} \otimes_{\mathscr{O}_X} \mathscr{R}(X)$ is *injective*. Define Z and h as in (6.6.6) (with $\mathscr{E} = g_*(\mathscr{O}_{X'})$). Let $z \in Z$; we have to show that there exists an integer $m > 0$ and a section t of $\mathscr{M}^{\otimes m}$ over Z such that Z_t is an affine open that contains z (4.5.2). Let $x = h(z)$, and let

U be an affine open of X that contains x; then $h^{-1}(U)$ is an affine open neighbourhood of z, and it suffices to find t such that $z \in Z_t \subset h^{-1}(U)$, since Z_t will then necessarily be affine (5.5.8). There exists, by hypothesis, an integer $n > 0$ and a section s' of $\mathscr{L}'^{\otimes n}$ over X' such that

$$g^{-1}(x) \subset X'_{s'} \subset g^{-1}(U) \tag{6.6.9.1}$$

by (4.5.4). By definition, s' is also a section of $g_*(\mathscr{L}'^{\otimes n})$ over X, and it corresponds, as in (6.5.2), to a section

$$s = N'(s') \quad \text{of} \quad N'\big(g_*(\mathscr{L}'^{\otimes n})\big) = N'(g_*(\mathscr{L}'))^{\otimes n}$$

over X. We will show that, if t is the section s considered as a section of $\mathscr{M}^{\otimes n}$ over Z, then t is the desired section. Set **II** | 134

$$V = X \setminus g(X' \setminus X'_{s'}) \tag{6.6.9.2}$$

which is an open of X that contains x and is contained in U, by (6.6.9.1) and (6.1.10). We will show that

$$h^{-1}(V) \subset Z_t \subset h^{-1}(U) \tag{6.6.9.3}$$

which will finish the proof. It is equivalent to say that the set T of $y \in X$ such that s_y is invertible contains V and is contained in U. For this, consider first of all an affine open W contained in V; then $g^{-1}(W)$ is an affine open in X', and by (6.6.9.2) $s'_{y'}$ is invertible for all $y' \in g^{-1}(W)$; by the hypotheses on X and $\mathscr{B}$, we can apply the results of (6.4.7), and we see that, if $y = g(y')$, then s_y is invertible; in other words, $V \subset T$. On the other hand, it also follows from (6.4.7) that, conversely, if s_y is invertible, then so too is $s'_{y'}$, which implies that $y' \in g^{-1}(U)$ by (6.6.9.1), and so $y \in U$, whence $T \subset U$ in this case.

We pass from this to the general case by the same argument as in (6.6.2), replacing X' by X'' such that $g'_*(\mathscr{O}_{X''}) \to g'_*(\mathscr{O}_{X''}) \otimes_{\mathscr{O}_X} \mathscr{R}(X)$ is injective, and $\mathscr{L}'$ by an ample $\mathscr{O}_{X''}$-module $\mathscr{L}''$ such that $N'(g_*(\mathscr{L}')) = N'(g'_*(\mathscr{L}''))$. Lemma (6.6.9) is then proven in all cases (with a suitable choice of h). □

Corollary (6.6.10). — *Suppose that the hypotheses of (6.6.9) are satisfied; for every invertible $\mathscr{O}_X$-module $\mathscr{L}$ such that $g^*(\mathscr{L})$ is ample, $h^*(\mathscr{L})$ is ample.*

Proof. If we set $\mathscr{L}' = g^*(\mathscr{L})$, then $g_*(\mathscr{L}') = \mathscr{L} \otimes_{\mathscr{O}_X} \mathscr{B}$ (**0**, 5.4.10), so

$$N'(g_*(\mathscr{L}')) = (\mathscr{L} \otimes_{\mathscr{O}_X} \mathscr{C})^{\otimes n}$$

(by the same argument as for (6.5.2.4)). We thus conclude that $\mathscr{M} = (h^*(\mathscr{L}))^{\otimes n}$, and since $\mathscr{M}$ is ample, so too is $h^*(\mathscr{L})$ (4.5.6). □

Proposition (6.6.11). — *Let Y be an affine scheme, X a reduced Noetherian prescheme, $f : X \to Y$ a quasi-compact morphism, and $g : X' \to X$ a finite surjective morphism. Let W be an open subset of X such that, for all $x \in W$, either X is normal at the point x or there exists an open neighbourhood $T \subset W$ of x such that $(g_*(\mathscr{O}_{X'}))|T$ is a locally free $(\mathscr{O}_X|T)$-module. Then there exists a reduced Y-prescheme Z and a* finite birational *Y-morphism $h : Z \to X$ such that the restriction of h to $h^{-1}(W)$ is an isomorphism from $h^{-1}(W)$ to W and has the following property: for every invertible $\mathscr{O}_X$-module $\mathscr{L}$ such that $g^*(\mathscr{L})$ is ample for $f \circ g$, $h^*(\mathscr{L})$ is ample for $f \circ h$.*

Proof. Since Y is affine, $g^*(\mathscr{L})$ is ample, and the problem thus reduces to proving that, for a suitable choice of h, $h^*(\mathscr{L})$ is ample (4.6.6). We will show that we can replace g by a finite surjective morphism $g' : X'' \to X$ such that $g'^*(\mathscr{L})$ is ample and $g'_*(\mathscr{O}_{X''}) \otimes_{\mathscr{O}_X} \mathscr{R}(X)$ is a *locally free* $\mathscr{R}(X)$-module *of constant rank*; we will then have reduced to the conditions of (6.6.10), and the proposition will thus be proven.

For this, let $\mathscr{B} = g_*(\mathscr{O}_{X'})$; denote by X_i (for $1 \leqslant i \leqslant n$) the closed reduced subpreschemes of X that have the irreducible components of X as their underlying space (**I**, 5.2.1); they are integral by hypothesis. Let X'_i be the closed subprescheme $g^{-1}(X_i)$ of X', and $g_i : X'_i \to X_i$ the morphism g restricted to X'_i, which is finite (6.1.5, (iii)) and surjective; let k_i be the *rank* of the $\mathscr{O}_{X_i}$-algebra $\mathscr{B}_i = (g_i)_*(\mathscr{O}_{X'_i})$. Since $\mathscr{B}_i \otimes_{\mathscr{O}_{X_i}} \mathscr{R}(X_i)$ is a constant presheaf (**I**, 7.3.5), the rank k_i is also the rank of the $(\mathscr{O}_X|U)$-algebra $\mathscr{B}|U$ for every open U of X that meets *only* the irreducible component X_i. **II** | 135

If T is an open subset of X such that $\mathscr{B}|T$ is isomorphic to $\mathscr{O}_X^m|T$, then it follows from the above remark that the numbers k_i are equal to m for all the indices i such that $T \cap X_i \neq \varnothing$. So let U be the open subset of X given by the points that admit a neighbourhood on which $\mathscr{B}$ is a locally free $\mathscr{O}_X$-module, and let U_j (for $1 \leqslant j \leqslant s$) be its connected components, which are open in X and finitely many (since U is Noetherian); denote by V_j the closed subprescheme of X' given by the *closure* of the subprescheme induced on the open $g^{-1}(U_j)$ (**I**, 9.5.11). By the above, for all indices i such that $X_i \cap U_j \neq \varnothing$, the ranks k_i are all equal to a single integer m_j; note also that a single X_i cannot meet two U_j with different indices j. Let i_λ be the indices i such that $X_i \cap U = \varnothing$. Consider the product k of all the k_i, set $n_i = k/k_i$, and let X'' be the prescheme defined as follows. For each j (for $1 \leqslant j \leqslant s$), consider k/m_j preschemes isomorphic to V_j, and for each λ, k/k_{i_λ} preschemes isomorphic to X'_{i_λ}; then X'' is the *sum* of all these preschemes. We define a morphism $g'' : X'' \to X'$ that reduces to the canonical injection on each of the summands of X''; it is clear that g'' is a finite dominant morphism, and thus surjective (since a finite morphism is closed (6.1.10)); set $g' = g \circ g''$, which is a finite surjective morphism $X'' \to X$; we have $g'^*(\mathscr{L}) = g''^*(g^*(\mathscr{L}))$, and so $g'^*(\mathscr{L})$ is an ample $\mathscr{O}_{X''}$-module (5.1.12). It is then clear that, for this new prescheme X'', the ranks defined as the k_i for X' are all *equal to* k; taking (**I**, 7.3.3) into account, we immediately conclude that, for every affine open T of X, $(g'_*(\mathscr{O}_{X''}) \otimes_{\mathscr{O}_X} \mathscr{R}(X))|T$ is an $(\mathscr{R}(X)|T)$-module isomorphic to $(\mathscr{R}(X)|T)^k$. □

Corollary (6.6.12). — *If, in the statement of (6.6.11), we have $W = X$, then for an invertible $\mathscr{O}_X$-module $\mathscr{L}$ to be ample for f, it is necessary and sufficient that $g^*(\mathscr{L})$ be ample for $f \circ g$.*

Remark (6.6.13). — In Chapter III, we will see that, if Y is Noetherian, if f is of finite type, and if the restriction of f to the closed reduced subprescheme of X that has $X \setminus W$ as its underlying space is *proper*, then the conclusion of (6.6.12) still holds true. But we will give, in Chapter V, examples of algebraic schemes X over a field K (with the structure morphism $X \to \operatorname{Spec}(K)$ not proper) whose normalisation X' is quasi-affine, but which are not quasi-affine (in that $\mathscr{O}_X$ is not ample, even though $\mathscr{O}_{X'}$ is (5.1.12) and the morphism $X' \to X$ is finite and surjective (6.3.10)). We will see in the next section that this circumstance cannot happen when we replace "quasi-affine" by "affine".

6.7. Chevalley's theorem We are going to prove (with the help of Serre's criterion (5.2.1)) the following theorem, which was proven by C. Chevalley by other methods, in the case of *algebraic* schemes.

II | 136

Theorem (6.7.1). — *Let X be an affine scheme, Y a Noetherian prescheme, and $f : X \to Y$ a finite surjective morphism. Then Y is an affine scheme.*

Proof. It is clear that $f_{\mathrm{red}} : X_{\mathrm{red}} \to Y_{\mathrm{red}}$ is finite (6.1.5, (vi)); since X_{red} is an affine scheme, and since saying that Y is affine is equivalent to saying that Y_{red} is affine (since Y is Noetherian (**I**, 6.1.7)), we see that we can suppose Y to be *reduced*. For every closed subset Y' of Y, there exists exactly one reduced subprescheme of Y that has Y' as its underlying space (**I**, 5.1.2); its inverse image $f^{-1}(Y')$, which is canonically isomorphic to $X \times_Y Y'$ (**I**, 4.4.1), is affine as a closed subprescheme of X, and the restriction of f to $f^{-1}(Y')$, which can be identified with $f \times_Y 1_{Y'}$, is a finite surjective morphism (6.1.5, (iii)). By the principle of Noetherian induction (**0**, 2.2.2), we can thus (taking (**I**, 6.1.7) into account) reduce to proving the theorem under the hypothesis that for *every* closed subset $Y' \neq Y$, every closed subprescheme of Y that has Y' as its underlying space is affine. We thus conclude that, *for every coherent $\mathscr{O}_Y$-module $\mathscr{F}$ whose (closed) support Z is distinct from Y, we have* $\mathrm{H}^1(Y, \mathscr{F}) = 0$. Indeed, there exists a closed subprescheme Y' of Y that has Z as its underlying space and is such that, if $j : Y' \to Y$ is the canonical injection, then $\mathscr{F} = j_*(j^*(\mathscr{F}))$ (**I**, 9.3.5); then (5.2.3) $\mathrm{H}^1(Y, \mathscr{F}) = \mathrm{H}^1(Y', j^*(\mathscr{F})) = 0$, by (**I**, 5.1.9.2).

Suppose first of all that Y is not irreducible, and let Y' be an irreducible component of Y, and $Y'' = Y \setminus Y'$; we again denote by Y' the closed reduced subprescheme of Y that has Y' as its underlying space, and by j the canonical injection $Y' \to Y$. Let $\mathscr{F}$ be a coherent $\mathscr{O}_Y$-module, and consider the canonical homomorphism

$$\rho : \mathscr{F} \longrightarrow \mathscr{F}' = j_*(j^*(\mathscr{F}))$$

(**0**, 4.4.3); $\mathscr{F}'$ is a coherent $\mathscr{O}_Y$-module by (**0**, 5.3.10) and (**0**, 5.3.12), since $j_*(\mathscr{O}_{Y'}) = \mathscr{O}_Y/\mathscr{J}$, where we denote by $\mathscr{J}$ the sheaf of ideals of $\mathscr{O}_Y$ that defines the subprescheme Y'. Then $\mathscr{G} = \operatorname{Ker}\rho$ and $\mathscr{K} = \operatorname{Im}\rho$ are also coherent $\mathscr{O}_Y$-modules (**0**, 5.3.4); but, by definition, the fibre $\mathscr{F}'_y$ of $\mathscr{F}'$ at the generic point y of Y' is equal to $\mathscr{F}_y$, since y is interior to Y' and thus $\mathscr{J}_y = 0$, since Y is reduced. We thus conclude that y is not contained in the (closed) support of $\mathscr{G}$; also, the support of $\mathscr{F}'$ (and *a fortiori* that of $\mathscr{K}$) is contained in Y'; in other words, the supports of $\mathscr{G}$ and $\mathscr{K}$ are *distinct from* Y. We thus deduce that $\mathrm{H}^1(Y,\mathscr{G}) = \mathrm{H}^1(Y,\mathscr{K}) = 0$, and the exact sequence of cohomology applied to the exact sequence $0 \to \mathscr{G} \to \mathscr{F} \to \mathscr{K} \to 0$ implies that $\mathrm{H}^1(Y,\mathscr{F}) = 0$. We thus conclude by Serre's criterion (5.2.1).

So suppose that Y is irreducible, and thus *integral*. We can also suppose that X is *integral*: if we denote by X_i the closed reduced subpreschemes of X that have the irreducible components of X as their underlying space (**I**, 5.2.1), and by f_i the restriction of f to X_i, then at least one of the f_i is dominant, and since it is a finite morphism (6.1.5), it is surjective (6.1.10); since X_i is also an affine scheme, we see that we can replace X by X_i in the statement.

Lemma (6.7.1.1). — *Let X and Y be integral Noetherian preschemes, x (resp. y) the generic point of X (resp. Y), and $f : X \to Y$ a finite surjective morphism. Let $\mathscr{L}$ be an invertible $\mathscr{O}_X$-module such that there exists an affine open neighbourhood U of y and a section $g \in \Gamma(X,\mathscr{L})$ such that $x \in X_g \subset f^{-1}(U)$. Then there exist* **II | 137**
integers $m,n > 0$, a homomorphism $u : \mathscr{O}_Y^m \to f_*(\mathscr{L}^{\otimes n})$, and an open neighbourhood V of y such that the restriction $u|V$ is an isomorphism from $\mathscr{O}_Y^m|V$ to $f_*(\mathscr{L}^{\otimes n})|V$.

Proof. Let C be the (integral) ring of U, and $k = \mathscr{O}_y$ its field of fractions: since f is finite, $U' = f^{-1}(U)$ is affine (1.3.2); let D be its (integral) ring with field of fractions $K = \mathscr{O}_x$; by hypothesis, D is a C-module of finite type (6.1.4), and so K is an extension of finite rank of k. The fibre $f^{-1}(y) = X \times_Y \operatorname{Spec}(k(y)) = X \times_Y \operatorname{Spec}(\mathscr{O}_y)$ can be identified with $\operatorname{Spec}(K)$ (**I**, 3.6.6); let s_i (for $1 \leqslant i \leqslant m$) be elements of D that form a basis of K over k. There exists $n > 0$ such that the sections $(s_i|X_g)g^{\otimes n}$ of $\mathscr{L}^{\otimes n}$ over X_g extend to sections b_i (for $1 \leqslant i \leqslant m$) of $\mathscr{L}^{\otimes n}$ over X (**I**, 9.3.1). The b_i are also, by definition, sections of $f_*(\mathscr{L}^{\otimes n})$ over Y, and thus define a homomorphism $u : \mathscr{O}_Y^m \to f_*(\mathscr{L}^{\otimes n})$ (**0**, 5.1.1); we will show that u is the desired homomorphism. We have that $\mathscr{L}^{\otimes n}|U' = \widetilde{M}$, where M is a D-module of finite type, so if ϕ is the injection $C \to D$ corresponding to the morphism $f^{-1}(U) \to U$ given by the restriction of f, then $M_{[\phi]}$ is a C-module of finite type; then

$$f_*(\mathscr{L}^{\otimes n})|U = (M_{[\phi]})^{\sim}$$

(**I**, 1.6.3) is coherent, and since U is an arbitrary affine open of Y, $f_*(\mathscr{L}^{\otimes n})$ is coherent; furthermore, $u|U = \widetilde{\theta}$, where θ is a C-homomorphism $C^m \to M_{[\phi]}$, and $u_y = \theta_y$ is the homomorphism $\theta \otimes 1 : k^m = C^m \otimes_C k \to M_{[\phi]} \otimes_C k$; but the latter is, by definition, an *isomorphism*, since the $(b_i)_x$ form a basis of $M_{[\phi]} \otimes K$ over k, with g_x being, by hypothesis, a generator of $(\mathscr{L}^{\otimes n})_x$. We thus conclude that the supports of the $\mathscr{O}_Y$-modules $\operatorname{Ker} u$ and $\operatorname{Coker} u$ do not contain y; since these $\mathscr{O}_Y$-modules are coherent (**0**, 5.3.3), their supports are closed (**0**, 5.2.2), whence the lemma. □

With this, the hypotheses of Lemma (6.7.1.1) are satisfied in the case that we are considering, by taking $\mathscr{L} = \mathscr{O}_X$, since X is affine (**I**, 1.1.10); set $\mathscr{A} = \mathscr{O}_Y$ and $\mathscr{B} = f_*(\mathscr{O}_X)$. By Serre's criterion (5.2.1.1), it suffices to prove that, for every coherent $\mathscr{O}_Y$-module $\mathscr{F}$, we have that $\mathrm{H}^1(Y,\mathscr{F}) = 0$; it even suffices to prove this in the case where $\mathscr{F} \subset \mathscr{O}_Y$, which implies that $\mathscr{F}$ is torsion free, since Y is integral; in fact, we will show that $\mathrm{H}^1(Y,\mathscr{F}) = 0$ for *every* coherent *torsion-free* $\mathscr{O}_Y$-module $\mathscr{F}$. But the homomorphism $u : \mathscr{A}^m \to \mathscr{B}$ defines a homomorphism

$$v : \mathscr{G} = \mathscr{H}om_{\mathscr{A}}(\mathscr{B},\mathscr{F}) \longrightarrow \mathscr{H}om_{\mathscr{A}}(\mathscr{A}^m,\mathscr{F}) = \mathscr{F}^m.$$

We will first show that v is *injective*: by hypothesis, $\mathscr{T} = \operatorname{Coker} u$ has a support that does not meet V, and is thus a *torsion* $\mathscr{O}_Y$-module (**I**, 7.4.6); the exact sequence

$$\mathscr{A}^m \longrightarrow \mathscr{B} \longrightarrow \mathscr{T} \longrightarrow 0$$

gives, by left exactness of the functor $\mathscr{H}om_{\mathscr{A}}$, the exact sequence

$$0 \longrightarrow \mathscr{H}om_{\mathscr{A}}(\mathscr{T},\mathscr{F}) \longrightarrow \mathscr{G} \xrightarrow{v} \mathscr{F}^m.$$

But since $\mathscr{F}$ is torsion free, we have that $\mathscr{H}om_{\mathscr{A}}(\mathscr{T},\mathscr{F}) = 0$ (**0**, 5.2.6), whence our claim. We thus have the exact sequence

$$0 \longrightarrow \mathscr{G} \longrightarrow \mathscr{F}^m \longrightarrow \operatorname{Coker} v \longrightarrow 0$$

where $\mathscr{G}$ and $\operatorname{Coker} v$ are coherent $\mathscr{O}_Y$-modules ((**0**, 5.3.4) and (**0**, 5.3.5)); by the exact sequence of cohomology, it would suffice to show that $\mathrm{H}^1(Y,\mathscr{G}) = \mathrm{H}^1(Y,\operatorname{Coker} v) = 0$ in order to deduce that $\mathrm{H}^1(Y,\mathscr{F}^m) = (\mathrm{H}^1(Y,\mathscr{F}))^m = 0$, and thus that $\mathrm{H}^1(Y,\mathscr{F}) = 0$. But the restriction $v|V$ is an isomorphism, and so the support of $\operatorname{Coker} v$ is distinct from Y, whence $\mathrm{H}^1(Y,\operatorname{Coker} v) = 0$ by the hypothesis at the start. Now, $\mathscr{G}$ is a coherent $\mathscr{B}$*-module* (**I**, 9.6.4); since X is affine over Y, there exists a quasi-coherent $\mathscr{O}_X$-module $\mathscr{K}$ such that $\mathscr{G}$ is isomorphic to $f_*(\mathscr{K})$ (1.4.3); since X is affine, we have that $\mathrm{H}^1(X,\mathscr{K}) = 0$ (**I**, 5.1.9.2), and so $\mathrm{H}^1(Y,\mathscr{G}) = 0$ by (5.2.3), which finishes the proof of Theorem (6.7.1). □ **II** | 138

Corollary (6.7.2). — *Let X be a Noetherian prescheme, $(X_i)_{1\leqslant i\leqslant n}$ a finite cover of the space X consisting of closed subsets. For X to be affine, it is necessary and sufficient that, for each i, there exist a closed subprescheme of X that has X_i as its underlying space and is affine.*

Proof. Indeed, if this is the case, then let X' be the scheme given by the *sum* of the X_i; it is clear that X' is affine, and we define a surjective morphism $f : X' \to X$ by taking the restriction of f to X_i to be the canonical injection. Everything reduces to showing that f is *finite*, by (6.7.1), and this we have already seen in (6.1.5). □

Corollary (6.7.3). — *For a Noetherian prescheme X to be affine, it is necessary and sufficient that the closed reduced subpreschemes whose underlying spaces are the irreducible components of X be affine.*

§7. Valuative criteria

In this section, we give valuative criteria for separation and properness for a given morphism, that is, criteria which introduce a variable auxiliary scheme of the form $\operatorname{Spec}(A)$, where A is a valuation ring. Under certain suitable "Noetherian" hypotheses, we can refine our criteria and restrict to the case where A is a *discrete* valuation ring. This will be the only case that we need to concern ourselves with in all that follows, and we introduce arbitrary valuation rings, in the general case, only to discuss the links with the classical study of such objects.

7.1. Reminder on valuation rings

(7.1.1). Amongst the many diverse equivalent properties that characterise valuation rings, we will use the following: a ring A is said to be a *valuation ring* if it is an integral ring which is not a field, and A is *maximal* in the set of local rings strictly contained in the field of fractions K of A under the domination relation (**I**, 8.1.1). Recall that a valuation ring is *integrally closed*. If A is a valuation ring, then so too is $A_{\mathfrak{p}}$ for any prime ideal $\mathfrak{p} \neq 0$ of A.

(7.1.2). Let K be a field, and A a local subring of K that is not a field; then there exists a valuation ring that both dominates A and has K as its field of fractions ([CC, p. 1-07, lemma 2]). **II** | 139

Now let B be a valuation ring, k its residue field, K its field of fractions, and L an extension of k. Then there exists a *complete* valuation ring C that dominates B and whose residue field is L. Indeed, L is an algebraic extension of a pure transcendental extension $L' = k(T_\mu)_{\mu\in M}$; we know that we can extend the valuation of B corresponding to B to a valuation of $K' = K(T_\mu)_{\mu\in M}$ in such a way that L' is the residue field of this valuation ([Jaf60, p. 98]); replacing B by the completion of the ring of this extended valuation, we see that we can restrict to the case where B is complete and L is an algebraic closure of k. If $\overline{K}$ is an algebraic closure of K, we can then extend the valuation that defines B to $\overline{K}$, and the corresponding residue field is an algebraic closure of k, as we can see by lifting to $\overline{K}$ the coefficients of a monic polynomial of $k[T]$. We are thus finally led to the case where $L = k$, and it then suffices to take C to be the completion of B in order to satisfy our claim.

(7.1.3). Let K be a field, and A a subring of K; the integral closure A' of A in K is the intersection of the valuation rings that contain A and have K as their field of fractions ([Sam53b, p. 51, th. 2]). Proposition (7.1.2) can then be expressed geometrically in an equivalent form:

Proposition (7.1.4). — *Let Y be a prescheme, $p : X \to Y$ a morphism, x a point of X, $y = p(x)$, and $y' \neq y$ a specialisation (**0**, 2.1.2) of y. Then there exists a local scheme Y' which is the spectrum of some valuation ring, and a separated morphism $f : Y' \to Y$ such that, denoting the unique closed point of Y' by a and the generic point of Y' by b, we have $f(a) = y'$ and $f(b) = y$. We can furthermore suppose that one of the following two additional properties is satisfied:*

(i) *Y' is the spectrum of a complete valuation ring whose residue field is algebraically closed, and there exists a $k(y)$-homomorphism $k(x) \to k(b)$.*
(ii) *There exists a $k(y)$-isomorphism $k(x) \xrightarrow{\sim} k(b)$.*

Proof. Let Y_1 be the closed reduced subprescheme of Y that has $\overline{\{y\}}$ as its underlying space (**I**, 5.2.1), and let X_1 be the closed subprescheme given by the inverse image $p^{-1}(Y_1)$; since $y' \in \overline{\{y\}}$ by hypothesis, and since $k(x)$ is the same in X and in X_1, we can assume that Y is *integral*, with generic point y; $\mathcal{O}_{y'}$ is then an integral local ring that is not a field, and whose field of fractions is $\mathcal{O}_y = k(y)$, and $k(x)$ is then an extension of $k(y)$. To satisfy the conditions $f(a) = y'$ and $f(b) = y$ as well as the additional condition (i) (resp. (ii)), we take $Y' = \operatorname{Spec}(A')$, where A' is a complete valuation ring that dominates $\mathcal{O}_{y'}$ and whose algebraically closed residue field extends $k(x)$ (resp. a valuation ring that dominates $\mathcal{O}_{y'}$ and whose field of fractions is $k(x)$); the existence of such an A' is guaranteed by (7.1.2). □

(7.1.5). Recall that a local ring A is said to be *of dimension 1* if there exists a prime ideal distinct from the maximal ideal $\mathfrak{m}$, and if every prime ideal of A distinct from $\mathfrak{m}$ is a *minimal* prime ideal; when A is *integral*, it is equivalent to ask that $\mathfrak{m}$ and (0) be the only prime ideals, with $\mathfrak{m} \neq (0)$; in other words, $Y = \operatorname{Spec}(A)$ consists of two points a and b: a is the unique *closed* point, we have $\mathfrak{j}_a = \mathfrak{m}$, and **II** | 140
$k(a) = k$ is the *residue field* $k = A/\mathfrak{m}$; b is the *generic point* of Y, $\mathfrak{j}_b = (0)$, with the set $\{b\}$ being the unique open subset of Y distinct from both $\varnothing$ and Y (an open subset which is thus *everywhere dense*), and $k(b) = K$ is the *field of fractions* of A.

(7.1.6). For a Noetherian local ring A of dimension 1, we know ([CC, pp. 2-08 and 17-01]) that the following conditions are equivalent:

(a) A is normal;
(b) A is regular;
(c) A is a valuation ring;

furthermore, A is then a *discrete valuation ring*. Propositions (7.1.2) and (7.1.3) then have the following analogues for discrete valuation rings:

Proposition (7.1.7). — *Let A be an integral local Noetherian ring that is not a field, K its field of fractions, and L an extension of finite type of K; then there exists a discrete valuation ring that dominates A and has L as its field of fractions.*

Proof. Suppose first of all that $L = K$. Let $\mathfrak{m}$ be the maximal ideal of A, $(x_1, \ldots, x_n)$ a system of non-null generators of $\mathfrak{m}$, and B the subring $A[x_2/x_1, \ldots, x_n/x_1]$ of K, which is Noetherian. It is immediate that the ideal $\mathfrak{m}B$ of B is identical to the principal ideal x_1B; if $\mathfrak{p}$ is a minimal prime ideal over x_1B, then $\mathfrak{p}$ has height 1 ([SZ60, t. I, p. 277]); in other words, $B_\mathfrak{p}$ is a local Noetherian ring *of dimension 1*; it is clear that $\mathfrak{p}B_\mathfrak{p} \cap A$ is an ideal of A that contains $\mathfrak{m}$ and that does not contain 1, and is thus equal to $\mathfrak{m}$, and so $B_\mathfrak{p}$ *dominates* A (**I**, 8.1.1). It follows from the Krull-Akizuki Theorem ([Nag55, p. 293]) that the integral closure C of $B_\mathfrak{p}$ is a Noetherian ring (even though C is not necessarily a $B_\mathfrak{p}$-module of finite type); if $\mathfrak{n}$ is a maximal ideal of C, then $C_\mathfrak{n}$ is a normal local Noetherian ring of dimension 1 ([Nag55, p. 295]), and thus a discrete valuation ring that dominates $B_\mathfrak{p}$ and *a fortiori* A.

Now, if L is an extension of finite type of K, we can, by the above, restrict to the case where A is already a discrete valuation ring. Let w be a valuation of K associated to A; there exists a discrete valuation w' of L that *extends* w: we can restrict, by induction on the number of generators of L, to the case where $L = K(\alpha)$, and then the proposition is classical ([Jaf60, p. 106]). □

Corollary (7.1.8). — *Let A be a Noetherian integral ring, K its field of fractions, and L an extension of finite type of K. Then the integral closure of A in L is the intersection of the discrete valuation rings that have L as their field of fractions and that contain A.*

Proof. Indeed, such a discrete valuation ring, being normal, contains *a fortiori* every element of L that is integral over A. It thus suffices to prove that, if $x \in L$ is not integral over A, then there exists a discrete valuation ring C that has L as its field of fractions, contains A, and does not contain x. The hypothesis on x implies that $x \notin B = A[1/x]$, or, in other words, that $1/x$ is not invertible in the Noetherian ring B. There is thus a prime ideal $\mathfrak{p}$ of B that contains $1/x$. The integral local ring $B_{\mathfrak{p}}$ is Noetherian and contained in L, which is an extension of finite type of the field of fractions of $B_{\mathfrak{p}}$ (with the latter containing K). By (7.1.7), there thus exists a discrete valuation ring C that dominates $B_{\mathfrak{p}}$ and has L as its field of fractions; since $1/x \in \mathfrak{p}B_{\mathfrak{p}}$ belongs to the maximal ideal of C, we have that $x \notin C$, which concludes the proof. □

The geometric form of (7.1.7) is the following: **II** | 141

Proposition (7.1.9). — *Let Y be a locally Noetherian prescheme, $p : X \to Y$ a morphism locally of finite type, x a point of X, $y = p(x)$, and $y' \neq y$ a specialisation of y. Then there exists a local scheme Y', spectrum of a discrete valuation ring, a separated morphism $f : Y' \to Y$, and a rational Y-map g from Y' to X, such that, denoting the closed point of Y' by a, and the generic point of Y' by b, we have $f(a) = y'$, $f(b) = y$, $g(b) = x$, and such that, in the commutative diagram*

(7.1.9.1)
$$\begin{tikzcd} & k(x) \arrow[dl, "\gamma"'] \\ k(b) & k(y) \arrow[l, "\phi"] \arrow[u, "\pi"'] \end{tikzcd}$$

(where π, ϕ, and γ are the homomorphisms corresponding to p, f, and g, respectively) the homomorphism γ is bijective.

Proof. As in (7.1.4), we can restrict to the case where Y is integral with generic point y (taking (**I**, 6.3.4, iv) into account), and, since the question is local on X and Y, we can assume that p is of finite type; we are then in the situation of (7.1.4), with the additional property that $k(x)$ is an extension *of finite type* of $k(y)$ (**I**, 6.4.11) and that $\mathcal{O}_{y'}$ is Noetherian; this lets us apply (7.1.7) and take $Y' = \operatorname{Spec}(A')$, where A' is a discrete valuation ring that dominates $\mathcal{O}_{y'}$ and whose field of fractions is $k(x)$. We have thus defined a commutative diagram (7.1.9.1) where γ is a bijection, with π and ϕ corresponding to the morphisms p and f. Furthermore, since X and Y are locally Noetherian (**I**, 6.6.2) and since Y' is integral, there exists exactly one rational Y-map g from Y' to X to which corresponds the isomorphism γ (**I**, 7.1.15), which finishes the proof. □

7.2. Valuative criterion for separatedness

Proposition (7.2.1). — *Let X and Y be preschemes, and $f : X \to Y$ a quasi-compact morphism. The following two conditions are equivalent:*

(a) *The morphism f is closed.*
(b) *For all $x \in X$, and every specialisation $y' \neq y$ of $y = f(x)$, there exists a specialisation x' of x such that $f(x') = y'$.*

Proof. Condition (b) says that $f(\overline{\{x\}}) = \overline{\{y\}}$, and is thus a consequence of (a). To show that (b) implies (a), consider a closed subset X' of the underlying space X; let $Y' = \overline{f(X')}$, and show that $Y' = f(X')$ as follows. Consider the closed reduced subpreschemes of X and Y whose underlying spaces are X' and Y' (respectively) (**I**, 5.2.1); there then exists a morphism $f' : X' \to Y'$ such that the diagram

$$\begin{tikzcd} X' \arrow[r, "f'"] \arrow[d] & Y' \arrow[d] \\ X \arrow[r, "f"'] & Y \end{tikzcd}$$

commutes (**I**, 5.2.2), and, since f is quasi-compact, so too is f'. We are thus led to proving that, if f is a quasi-compact and *dominant* morphism, then condition (b) implies that $f(X) = Y$. But let y' be a **II** | 142 point of Y, and let y be the generic point of an irreducible component of Y that contains y'; by (b), it suffices to show that $f^{-1}(y)$ is not empty. But we know that this property is a consequence of the fact that f is quasi-compact and dominant (**I**, 6.6.5). □

Corollary (7.2.2). — *Let $f : X \to Y$ be a quasi-compact immersion. For the underlying space X to be closed in Y, it is necessary and sufficient for it to contain every specialisation (in Y) of all of its points.*

Proposition (7.2.3). — *Let Y be a prescheme (resp. a locally Noetherian prescheme), and $f : X \to Y$ a morphism (resp. a morphism locally of finite type). The following conditions are equivalent:*

(a) *f is separated.*
(b) *The diagonal morphism $X \to X \times_Y X$ is quasi-compact, and, for every Y-prescheme of the form $Y' = \operatorname{Spec}(A)$, with A some valuation ring (resp. some discrete valuation ring), any two Y-morphisms from Y' to X that agree on the generic point of Y' are equal.*
(c) *The diagonal morphism $X \to X \times_Y X$ is quasi-compact, and, for every Y-prescheme of the form $Y' = \operatorname{Spec}(A)$, with A some valuation ring (resp. some discrete valuation ring), any two Y'-sections of $X' = X_{(Y')}$ that agree on the generic point of Y' are equal.*

Proof. The equivalence of (b) and (c) follows from the bijective correspondence between Y-morphisms from Y' to X and Y'-sections of X' (**I**, 3.3.14). If X is separated over Y, condition (b) is satisfied, by (**I**, 7.2.2.1), since Y' is integral. It remains to show that (b) implies that the diagonal morphism $\Delta : X \to X \times_Y X$ is closed, and it is equivalent to show that it satisfies the criterion of (7.2.2). But let z be a point of the diagonal $\Delta(X)$, and $z' \neq z$ a specialisation of z in $X \times_Y X$. There then exists (7.1.4) a valuation ring A and a morphism f from $Y' = \operatorname{Spec}(A)$ to $X \times_Y X$ such that f sends the closed point a of Y' to z', and the generic point b of Y' to z; this morphism makes Y' an $(X \times_Y X)$-prescheme, and *a fortiori* a Y-prescheme. If we compose the two projections of $X \times_Y X$ with f, then we obtain two Y-morphisms, g_1 and g_2, from Y' to X, which, by hypothesis, agree on the point b; they are thus equal to one single morphism g, which implies (**I**, 5.3.1) that f factors as $f = \Delta \circ g$, and thus $z' \in \Delta(X)$. If we suppose that Y is locally Noetherian and f is locally of finite type, then $X \times_Y X$ is locally Noetherian (**I**, 6.6.7); we can thus follow the same argument as before by supposing that A is a discrete valuation ring, by (7.1.9). □

Remark (7.2.4). — (i) The hypothesis that the morphism Δ is quasi-compact is always satisfied whenever Y is locally Noetherian and f is locally of finite type, because $X \times_Y X$ is then locally Noetherian (**I**, 6.6.4, i). In the general case, this also means that, for every cover (U_α) of X by affine opens, the sets $U_\alpha \cap U_\beta$ are *quasi-compact*.

(ii) For f to be separated, it is *sufficient* to require condition (b) or (c) only for *complete* valuation rings A whose residue fields are *algebraically closed*; this follows from the proof of (7.2.3) and from (7.1.4).

II | 143

7.3. Valuative criterion for properness

Proposition (7.3.1). — *Let A be a valuation ring, $Y = \operatorname{Spec}(A)$, b the generic point of Y, X an integral* scheme, *and $f : X \to Y$ a* closed *morphism such that $f^{-1}(b)$ consists of a single point x and such that the corresponding homomorphism $k(b) \to k(x)$ is bijective. Then f is an isomorphism.*

Proof. Since f is closed and dominant, we have that $f(X) = Y$; it suffices (**I**, 4.2.2) to prove that, for all $y' \neq b$ in Y, there exists *exactly one* point x' such that $f(x') = y'$, and that the corresponding homomorphism $\mathscr{O}_{y'} \to \mathscr{O}_{x'}$ is bijective, since then f will be a homeomorphism. But if $f(x') = y'$ then $\mathscr{O}_{x'}$ is a local ring contained in $K = k(x) = k(b)$ and dominating $\mathscr{O}_{y'}$; the latter is the local ring $A_{y'}$, and is thus a valuation ring (7.1.1) that has K as its field of fractions. Also, $\mathscr{O}_{x'} \neq K$, since x' is not the generic point of X (**0**, 2.1.3); we thus conclude that $\mathscr{O}_{x'} = \mathscr{O}_{y'}$. Since X is an integral scheme, the fact that $\mathscr{O}_{x'} = \mathscr{O}_{x''}$ implies that $x' = x''$ (**I**, 8.2.2), which finishes the proof. □

(7.3.2). Let A be a valuation ring, K its field of fractions, $Y = \operatorname{Spec}(A)$, and b the generic point of Y, such that $\mathscr{O}_b = k(b)$ is equal to K; let $f : X \to Y$ be a morphism. We know (**I**, 7.1.4) that the *rational Y-sections* of X are in bijective correspondence with the *germs* of Y-sections (defined in a neighbourhood of b) at the point b, whence we have a canonical map

$$\Gamma_{\mathrm{rat}}(X/Y) \longrightarrow \Gamma(f^{-1}(b)/\operatorname{Spec}(K)) \tag{7.3.2.1}$$

with the elements of $\Gamma(f^{-1}(b)/\operatorname{Spec}(K))$ being identified, by definition (**I**, 3.4.5), with the *points of* $f^{-1}(b) = X \otimes_A K$ *that are rational over* K. When f is *separated*, it follows from (**I**, 5.4.7) that the map (7.3.2.1) is *injective*, since Y is an integral scheme.

Composing (7.3.2.1) with the canonical map $\Gamma(X/Y) \to \Gamma_{\mathrm{rat}}(X/Y)$ (**I**, 7.1.2), we obtain a canonical map

$$\Gamma(X/Y) \longrightarrow \Gamma(f^{-1}(b)/\operatorname{Spec}(K)). \tag{7.3.2.2}$$

When f is *separated*, this map is again *injective* (**I**, 5.4.7).

Proposition (7.3.3). — *Let A be a valuation ring with field of fractions K, $Y = \operatorname{Spec}(A)$, b the generic point of Y, and $f : X \to Y$ a* separated *and* closed *morphism. Then the canonical map (7.3.2.2) is bijective (which is equivalent to saying that it is* surjective*, and implies that the rational Y-sections of X are* everywhere defined*).*

Proof. So let x be a point of $f^{-1}(b)$ that is *rational* over K. Since f is separated, so too is the morphism $f^{-1}(b) \to \operatorname{Spec}(K)$ corresponding to f (**I**, 5.5.1, iv), and, since every section of $f^{-1}(b)$ is a closed immersion (**I**, 5.4.6), $\{x\}$ is closed *in* $f^{-1}(b)$. Consider the closed reduced subprescheme X' of X that has the closure $\overline{\{x\}}$ of $\{x\}$ *in* X as its underlying space. It is clear that the restriction of f to X' satisfies the hypotheses of (7.3.1), and is thus an *isomorphism* from X' to Y, whose inverse isomorphism is the desired Y-section of X. □

(7.3.4). To state the two following results, we use a terminology that will be justified and discussed in chapter IV: if F is a subset of a prescheme Y, we define the *codimension* of F in Y, denoted $\operatorname{codim}_Y F$, to be the lower bound of the integers $\dim(\mathscr{O}_z)$ over all z in F. **II** | 144

Corollary (7.3.5). — *Let Y be a locally Noetherian reduced prescheme, and N the set of points $y \in Y$ where Y is not regular* (**0**, 4.1.4)*; suppose that* $\operatorname{codim}_Y N \geqslant 2$*. Let $f : X \to Y$ be a morphism of finite type, both* separated *and* closed*, and let g be a rational Y-section of X; if Y' is the set of points of Y where g is not defined (a set which is* closed (**I**, 7.2.1)*), then* $\operatorname{codim}_Y Y' \geqslant 2$.

Proof. It suffices to prove that g is defined at every point $z \in Y$ such that $\dim \mathscr{O}_z \leqslant 1$. If $\dim \mathscr{O}_z = 0$, then z is the generic point of an irreducible component of Y (**I**, 1.1.14), and so belongs to every everywhere-dense open subset of Y, and, in particular, to the domain of definition of g. So suppose that $\dim \mathscr{O}_z = 1$; by hypothesis, $\mathscr{O}_z$ is then a regular Noetherian local ring, and thus, by (7.1.6), a *discrete valuation ring*. Let $Z = \operatorname{Spec}(\mathscr{O}_z)$; since $U = Y - Y'$ is everywhere dense, $U \cap Z$ is nonempty (**I**, 2.4.2); let g' be the rational map from Z to X induced by g (**I**, 7.2.8); it suffices to show that g' is a *morphism* (**I**, 7.2.9). But g' can be considered as a rational Z-section of the Z-prescheme $f^{-1}(Z) = X \times_Y Z$; it is clear that the morphism $f^{-1}(Z) \to Z$ corresponding to f is closed, and it follows from (**I**, 5.5.1, i) that it is separated; we thus conclude from (7.3.3) that g' is everywhere defined; since Z is reduced, and X is separated over Y, g' is a morphism (**I**, 7.2.2). □

Corollary (7.3.6). — *Let S be a locally Noetherian prescheme, and X and Y both S-preschemes; suppose that Y is reduced, and further that the set N of points $y \in Y$ where Y is not regular is such that* $\operatorname{codim}_Y N \geqslant 2$*; suppose finally that the structure morphism $X \to S$ is proper. Let f be a rational S-map from Y to X, and let Y' be the points of Y where f is not defined; then* $\operatorname{codim}_Y Y' \geqslant 2$.

Proof. We know (**I**, 7.1.2) that we can identify the rational S-maps from Y to X with the rational Y-sections of $X \times_S Y$; since the structure morphism $X \times_S Y \to Y$ is closed (5.4.1), we can apply (7.3.5), whence the corollary. □

Remark (7.3.7). — The hypotheses on Y in (7.3.5) and (7.3.6) will be satisfied in particular when Y is *normal* (**0**, 4.1.4), by (7.1.6).

We can characterise the universally closed morphisms (resp. proper morphisms) by a converse of (7.3.3):

Theorem (7.3.8). — *Let Y be a prescheme (resp. a locally Noetherian prescheme), and $f : X \to Y$ a quasi-compact separated morphism (resp. a morphism of finite type). The following conditions are equivalent:*

(a) *f is universally closed (resp. proper).*

(b) *For every Y-scheme of the form $Y' = \operatorname{Spec}(A)$, where A is a valuation ring (resp. a discrete valuation ring) with field of fractions K, the canonical map*

$$\operatorname{Hom}_Y(Y', X) \longrightarrow \operatorname{Hom}_Y(\operatorname{Spec}(K), X)$$

corresponding to the canonical injection $A \to K$ is surjective (resp. bijective). **II** | 145

(c) *For every Y-scheme of the form $Y' = \operatorname{Spec}(A)$, where A is a valuation ring (resp. a discrete valuation ring), the canonical map (7.3.2.2) with respect to the Y'-prescheme $X_{(Y')}$ is surjective (resp. bijective).*

Proof. The equivalence of (b) and (c) follows immediately from (**I**, 3.3.14); (a) implies (c), since (a) implies, in either case, that $f_{(Y')}$ is separated (**I**, 5.5.1, iv) and closed, and it suffices to apply (7.3.3). It remains to prove that (b) implies (a). We first consider the case where Y is arbitrary, and f is separated and quasi-compact. If condition (b) is satisfied by f, then it is also satisfied by $f_{(Y'')} : X_{(Y'')} \to Y''$, where Y'' is an arbitrary Y-prescheme, thanks to the equivalence between (b) and (c), and the fact that $X_{(Y'')} \times_{Y''} Y' = X \times_Y Y'$ for every morphism $Y' \to Y''$ (**I**, 3.3.9.1); since, further, $f_{(Y'')}$ is separated and quasi-compact whenever f is ((**I**, 5.5.1, iv) and (**I**, 6.6.4, iii)), we are led to proving that (b) implies that f is *closed*. For this, it suffices to verify condition (b) of (7.2.1). So let $x \in X$, and y' be a specialisation of $y = f(x)$, distinct from y; by (7.1.4), there exists a scheme Y', the spectrum of some valuation ring, and a separated morphism $g : Y' \to Y$ such that, letting a denote the closed point and b the generic point of Y', we have that $g(a) = y'$, $g(b) = y$, and that there exists a $k(y)$-homomorphism $k(x) \to k(b)$. The latter corresponds canonically to a Y-morphism $\operatorname{Spec}(k(b)) \to X$ (**I**, 2.4.6), and it thus follows from (b) that there exists a Y-morphism $h : Y' \to X$ to which the previous morphism corresponds. We then have that $h(b) = x$; if we set $h(a) = x'$, then x' is a specialisation of x, and we have that $f(x') = f(h(a)) = g(a) = y'$.

If now Y is locally Noetherian and f of finite type, then hypothesis (b) implies, first of all, that f is *separated*, by (7.2.3), with the diagonal morphism $X \to X \times_Y X$ being quasi-compact (7.2.4). Further, to show that f is proper, it suffices to show that $f_{(Y'')} : X_{(Y'')} \to Y''$ is *closed* for every Y-prescheme Y'' *of finite type*, taking (5.6.3) into account. Since Y'' is then locally Noetherian, we can follow the same reasoning as in the first case by taking Y' to be the spectrum of a discrete valuation ring, and applying (7.1.9) instead of (7.1.4). ☐

Remarks (7.3.9). — (i) Whenever Y is an arbitrary prescheme and f a separated morphism, for f to be universally closed, it *suffices* that condition (b) or (c) be satisfied for the *complete* valuation rings A whose residue field is *algebraically closed*; this follows from the above proof and from (7.1.4).

(ii) From criterion (c) of (7.3.8) we obtain a new proof of the fact that a projective morphism $X \to Y$ is closed (5.5.3), and it is closer to the classical approach. We can indeed assume that Y is affine, and thus that X can be identified with a closed subprescheme of a projective bundle $\mathbf{P}^n_Y$ (5.3.3); to prove that $X \to Y$ is closed, it suffices to verify that the structure morphism $\mathbf{P}^n_Y \to Y$ is closed, and criterion (c) of (7.3.8), combined with (4.1.3.1), tells us that we can reduce to proving the following fact: *if Y is the spectrum of a valuation ring A, with field of fractions K, then every point of $\mathbf{P}^n_Y$ with values in K comes from (by restriction to the generic point of Y) a point of $\mathbf{P}^n_Y$ with values in A.* But every invertible $\mathscr{O}_Y$-module is trivial (**I**, 2.4.8); so it follows from (4.2.6) that a point of $\mathbf{P}^n_Y$ with values in K can be identified with a class of tuples $(\zeta c_0, \zeta c_1, \ldots, \zeta c_n)$, where $\zeta \in K^\times$ and the $c_i \in K$ are not all zero. However, by multiplying the c_i by an element of A of suitable valuation, we can suppose that the c_i all belong to A, **II** | 146
and that at least one of them is invertible. But then, by (4.2.6), the system $(c_0, \ldots, c_n)$ also defines a point of $\mathbf{P}^n_Y$ with values in A, which proves our claim.

(iii) Criteria (7.2.3) and (7.3.8) are particularly simple when we consider the data of a Y-prescheme X as being equivalent to the data of the functor

$$X(Y') = \operatorname{Hom}_Y(Y', X)$$

for Y-preschemes Y'; these criteria allow us, for example, to prove that, under certain conditions, the "Picard schemes" are proper.

Corollary (7.3.10). — *Let Y be an integral scheme (resp. a locally Noetherian integral scheme), X an integral scheme, and $f : X \to Y$ a dominant morphism.*

(i) *If f is quasi-compact and universally closed, then every valuation ring whose field of fractions is the field $R(X)$ of rational functions on X, and which dominates a local ring of Y, also dominates a local ring of X.*

(ii) *Conversely, suppose that f is of finite type, and that the property described in (i) is verified by every valuation ring (resp. every discrete valuation ring) that has $R(X)$ as its field of fractions. Then f is proper.*

Proof. Note first of all that the hypotheses imply, in any case, that f is separated (**I**, 5.5.9).

(i) Let $K = R(Y)$, $L = R(X)$, y a point of Y, and A a valuation ring that dominates $\mathscr{O}_y$ and has L as its field of fractions; the injection $\mathscr{O}_y \to A$ then defines a morphism h from $Y' = \operatorname{Spec}(A)$ to Y (**I**, 2.4.4) such that $h(a) = y$, where we write a to denote the closed point of Y'; furthermore, if η is the generic point of Y, which is also the generic point of $\operatorname{Spec}(\mathscr{O}_y)$, then we have $h(b) = \eta$, writing b to denote the generic point of Y' (since $K \subset L$ by hypothesis). If ξ is the generic point of X, then $k(\xi) = k(b) = L$ by hypothesis, whence we have a Y-morphism $g : \operatorname{Spec}(L) \to X$ such that $g(b) = \xi$; by (7.3.8), g comes from a Y-morphism $g' : Y' \to X$. If $x = g'(a)$, it is clear that A dominates $\mathscr{O}_x$.

(ii) Since the question is local on Y, we can always suppose that Y is affine (resp. affine and Noetherian). Since f is of finite type, we can apply, in either case, Chow's lemma (5.6.1). There is thus a projective morphism $p : P \to Y$, an immersion $j : X' \to P$, and a projective morphism $g : X' \to X$ that is both surjective and birational, with X' integral, such that the diagram

$$\begin{tikzcd} P \arrow[d, "p"'] & X' \arrow[l, "j"'] \arrow[d, "g"] \\ Y & X \arrow[l, "f"] \end{tikzcd}$$

commutes. It suffices to prove that j is a *closed* immersion, since then $f \circ g = p \circ j$ will be a projective morphism, and thus proper, and, since g is surjective, f will also be proper (5.4.3). Let Z be the closed reduced subprescheme of P that has $\overline{j(X')}$ as its underlying space (**I**, 5.2.1); since X' is integral, j factors as $i \circ h$, where $i : Z \to P$ is the canonical injection, $h : X' \to Z$ a dominant open immersion (**I**, 5.2.3), and Z is integral; furthermore, Z is projective over Y, **II** | 147
and we see that we can restrict to the case where P is *integral* and j is *dominant* and *birational*, and everything then reduces to showing that j is *surjective*. But let $z \in P$; then $\mathscr{O}_z$ is an integral (resp. integral and Noetherian) local ring whose field of fractions is

$$L = R(P) = R(X') = R(X).$$

We can restrict to the case where z is not the generic point of P. There then exists ((7.1.2) and (7.1.7)) a valuation ring (resp. a discrete valuation ring) A which dominates $\mathscr{O}_z$ and has L as its field of fractions. *A fortiori*, A dominates $\mathscr{O}_y$, where $y = p(z)$, and, by hypothesis, there thus exists some $x \in X$ such that A dominates $\mathscr{O}_x$. Since g is proper, the first part of the proof shows that A also dominates $\mathscr{O}_{x'}$ for some $x' \in X'$; it then follows that $\mathscr{O}_z$ and $\mathscr{O}_{j(x')} = \mathscr{O}_{x'}$ are allied (**I**, 8.1.4), and, since P is a scheme, this implies that $z = j(x')$ (**I**, 8.2.2) and finishes the proof. □

Corollary (7.3.11). — *Let X and Y be integral schemes, and $f : X \to Y$ a dominant, quasi-compact, and universally closed morphism. Suppose further that Y is affine of (integral) ring B. Then $\Gamma(X, \mathscr{O}_X)$ is canonically isomorphic to a subring of the integral closure of B in $R(X)$.*

Proof. Indeed (**I**, 8.2.1.1), $\Gamma(X, \mathscr{O}_X)$ can be identified with the intersection of the $\mathscr{O}_x$ over $x \in X$; by (7.3.10), (7.1.2), and (7.1.3), $\Gamma(X, \mathscr{O}_X)$ is then contained in the intersection of the valuation rings that contain B and that have $R(X)$ as their field of fractions; the conclusion then follows from (7.1.3). □

Remarks (7.3.12). — Under the hypotheses of (7.3.11), and when we suppose that $R(X)$ is an extension of finite type of $R(Y)$, we can, in many cases, conclude that $\Gamma(X, \mathscr{O}_X)$ is a *module of finite type* over the ring $B = \Gamma(Y, \mathscr{O}_Y)$. For example, this will be the case whenever B is an *algebra of finite type over a field*, since we then know that the integral closure of B in an extension of finite type of its field of fractions is a B-module of finite type ([SZ60, t. I, p. 267, th. 9]); the conclusion then follows from (7.3.11) and the fact that B is Noetherian.

In particular, *a proper affine scheme X over a field K is finite*. Indeed, by (1.6.4), (5.4.6), and (**I**, 6.4.4, (c)), we can restrict to the case where X is *reduced*. Furthermore, it suffices to prove that each of the closed subpreschemes of X that have an irreducible component of X as their underlying space (of which there are finitely many) is finite over K, which means (taking (5.4.5) into account) that we are finally reduced to the case where X is *integral*. But then the result follows from the above remarks.

In chapter III, we will again prove the preceding proposition by other methods, and as a consequence of more general results, by showing that, if $f : X \to Y$ is proper and Y is locally Noetherian, $f_*(\mathscr{F})$ is coherent for any coherent $\mathscr{O}_X$-module $\mathscr{F}$ (**III**, 4.4.2).

Finally, note that criterion (7.3.10) is taken as the *definition* of proper morphisms in classical algebraic geometry. We only mention this here as a remark, since criterion (7.3.8) seems more manageable in all the applications with which we are familiar.

II | 148

7.4. Algebraic curves and function fields of dimension 1

The aim of this section is to show how to formulate the classical notion of algebraic curves (as presented, for example, in the book of C. Chevalley [Che51]) in the language of schemes. Throughout this section, *we write k to mean a field, all the schemes in question are k-schemes of finite type, and all the morphisms are k-morphisms*.

Proposition (7.4.1). — *Let X be a prescheme of finite type over k (and thus Noetherian); let x_i $(1 \leqslant i \leqslant n)$ be the generic points of the irreducible components X_i of X, and let $K_i = k(x_i)$ $(1 \leqslant i \leqslant n)$. Then the following conditions are equivalent:*

(a) *Each of the K_i is an extension of k with transcendence degree equal to* 1.
(b) *For every closed point x of X, the local ring $\mathscr{O}_x$ is of dimension* 1 (7.1.5).
(c) *The closed irreducible subsets of X that are distinct from the X_i are exactly the closed points of X.*

Proof. Since X is quasi-compact, every closed irreducible subset F of X contains a closed point (**0**, 2.1.3). By (**I**, 2.4.2), there is a bijective correspondence between the prime ideals of $\mathscr{O}_x$ and the closed irreducible subsets of X that contain x (**I**, 1.1.14); the equivalence between (b) and (c) follows immediately from this. Now, if $\mathfrak{p}_\alpha$ $(1 \leqslant \alpha \leqslant r)$ are the minimal prime ideals of the local Noetherian ring $\mathscr{O}_x$, then the local rings $\mathscr{O}_x/\mathfrak{p}_\alpha$ are integral, and have the K_i such that $x \in X_i$ as their fields of fractions. Furthermore, we know ([CC, p. 4-06, th. 2]) that the dimension of a local integral k-algebra of finite type is equal to the transcendence degree over k of its field of fractions. Finally, the dimension of $\mathscr{O}_x$ is the supremum of the dimensions of the $\mathscr{O}_x/\mathfrak{p}_\alpha$; but condition (a) implies that these dimensions are equal to 1, and so (a) implies (b); conversely, if $\mathscr{O}_x$ is of dimension 1, then none of the $\mathfrak{p}_\alpha$ can be equal to the maximal ideal of $\mathscr{O}_x$, otherwise $\mathscr{O}_x$ would be of dimension 0; thus each of the $\mathscr{O}_x/\mathfrak{p}_\alpha$ is of dimension 1, which shows that (b) implies (a). □

We note that, under the conditions of (7.4.1), the set X is either *empty* or *infinite*, as an immediate result of (**I**, 6.4.4).

Definition (7.4.2). — We define an *algebraic curve over k* to be a non-empty algebraic *scheme* over k that satisfies the conditions of (7.4.1).

In the language of dimensions, which will be introduced in Chapter IV, this can be expressed by saying that an algebraic curve over k is a non-empty algebraic k-scheme *whose irreducible components are all of dimension* 1.

We note that, if X is an algebraic curve over k, then the closed reduced subpreschemes X_i $(1 \leqslant i \leqslant n)$ of X whose underlying spaces are the irreducible components of X are also algebraic curves over k.

Corollary (7.4.3). — *Let X be an irreducible algebraic curve. The only non-closed point of X is its generic point. The closed subsets of X that are distinct from X are the finite sets of closed points; these are also the only subsets of X that are not everywhere dense.*

Proof. If a point $x \in X$ is not closed, then its closure in X is an irreducible closed subset of X, and thus necessarily the whole of X, by (7.4.1), and thus x is the generic point of X. A closed subset F of X that is distinct from X cannot contain the generic point of X, and so all its points are closed (in X, and *a fortiori* in F); by considering the closed reduced subpreschemes of X that have F as their underlying space (**I**, 5.2.1), it thus follows from (**I**, 6.2.2) that F is finite and discrete. The closure in X of any infinite subset of X is thus necessarily equal to X itself. □ **II** | 149

If X is an arbitrary algebraic curve, by applying (7.4.3) to the irreducible components of X, we see that the only non-closed points of X are the generic points of these components.

Corollary (7.4.4). — *Let X and Y be irreducible algebraic curves over k, and $f : X \to Y$ a k-morphism. For f to be dominant, it is necessary and sufficient for $f^{-1}(y)$ to be finite for all $y \in Y$.*

Proof. Indeed, if f is not dominant, then $f(X)$ is necessarily a *finite* subset of Y, by (7.4.3), and so it is not possible for $f^{-1}(y)$ to be finite for every point of Y, since otherwise X would be finite, which is a contradiction (7.4.1). Conversely, if f is dominant, then for any $y \in Y$ distinct from the generic point η of Y, we have that $f^{-1}(y)$ is closed in X, since $\{y\}$ is closed in Y (7.4.3); also, by hypothesis, $f^{-1}(y)$ does not contain the generic point ξ of X, and is thus finite, by (7.4.3). Finally, to see that, when f is dominant, $f^{-1}(\eta)$ is finite, we note that the fibre $f^{-1}(\eta)$ is an irreducible scheme of finite type over $k(\eta)$, and with generic point ξ ((**I**, 6.3.9) and (**I**, 6.4.11)). Since $k(\xi)$ and $k(\eta)$ are extensions of finite type of k, both of transcendence degree 1, we have that $k(\xi)$ is necessarily an extension of finite degree of $k(\eta)$, and so ξ is closed in $f^{-1}(\eta)$ (**I**, 6.4.2), and $f^{-1}(\eta)$ thus consists of a single point ξ. □

We will see, in Chapter III, that, if $f : X \to Y$ is a *proper* morphism of Noetherian preschemes such that $f^{-1}(y)$ is finite for all $y \in Y$, then f is necessarily *finite*; it will thus follow from (7.4.4) that a proper dominant morphism from an irreducible algebraic curve to an algebraic curve is *finite*.

Corollary (7.4.5). — *Let X be an algebraic curve over k. For X to be regular, it is necessary and sufficient for X to be normal, or for the local rings of its closed points to be discrete valuation rings.*

Proof. This follows immediately from (7.4.1, (b)) and (7.1.6). □

Corollary (7.4.6). — *Let X be a reduced algebraic curve, and $\mathscr{A}$ a reduced coherent $\mathscr{R}(X)$-algebra; then the integral closure X' of X with respect to $\mathscr{A}$ (6.3.4) is a normal algebraic curve, and the canonical morphism $X' \to X$ is finite.*

Proof. The fact that $X' \to X$ is finite follows from (6.3.10); X' is thus an algebraic k-scheme; furthermore, if x_i $(1 \leqslant i \leqslant n)$ are the generic points of the irreducible components of X, and x'_j $(1 \leqslant j \leqslant m)$ the generic points of the irreducible components of X', then each of the $k(x'_j)$ is a finite algebraic extension of one of the $k(x_i)$ (6.3.6), and thus of transcendence degree 1 over k. So X' is indeed an algebraic curve over k, and, furthermore, we know that X' is a finite sum of normal integral schemes ((6.3.6) and (6.3.7)). □

(7.4.7). We say that an algebraic curve X over k is *complete* if it is *proper* over k.

Corollary (7.4.8). — *For a reduced algebraic curve X over k to be complete, it is necessary and sufficient for its normalisation X' to be complete.*

II | 150

Proof. The canonical morphism $f : X' \to X$ is finite (7.4.6), and thus proper (6.1.11) and surjective (6.3.8); if $g : X \to \operatorname{Spec}(k)$ is the structure morphism, then g is proper if and only if $g \circ f$ is proper, by (5.4.2, (ii)) and (5.4.3, (ii)), since g is separated by hypothesis. □

Proposition (7.4.9). — *Let X be a* normal *algebraic curve over k, and Y a* proper *algebraic k-scheme. Then every rational k-map from X to Y is everywhere defined, or, in other words, is a morphism.*

Proof. It follows from (7.3.7) that, at the points $x \in X$ where such a map is not defined, the dimension of $\mathscr{O}_x$ must be $\geqslant 2$, and so the set of such points is empty; the final claim follows from (**I**, 7.2.3). □

Corollary (7.4.10). — *A normal algebraic curve over k is quasi-projective over k.*

Proof. Since X is a finite sum of normal integral algebraic curves (6.3.8), we can restrict to the case where X is integral (5.3.6). Since X is quasi-compact, it is covered by a finite number of affine open subsets U_i ($1 \leqslant i \leqslant n$), and, since each of these U_i is of finite type over k, for each i there exists some integer n_i along with a k-immersion $f_i : U_i \to \mathbf{P}_k^{n_i}$ ((5.3.3) and (5.3.4, (i))). Since U_i is dense in X, it follows from (7.4.9) that f_i can be extended to a k-morphism $g_i : X \to \mathbf{P}_k^{n_i}$, whence we obtain a k-morphism $g = (g_1, \ldots, g_n)_k$ from X to the product P of the $\mathbf{P}_k^{n_i}$ over k. Furthermore, for each i, since the restriction of g_i to U_i is an immersion, so too is the restriction of g to U_i (**I**, 5.3.14). Since the U_i cover X, and since g is separated (**I**, 5.5.1, (v)), g is an immersion from X into P (**I**, 8.2.8). Since the Segre morphism (4.3.3) gives an immersion of P into $\mathbf{P}_k^N$, this proves that X is quasi-projective. □

Corollary (7.4.11). — *Any normal algebraic curve X is isomorphic to an everywhere-dense open subscheme of a complete normal algebraic curve $\widehat{X}$, and this $\widehat{X}$ is unique up to unique isomorphism.*

Proof. If X_1 and X_2 are complete normal curves, then it follows from (7.4.9) that every isomorphism from any dense open U_1 in X_1 to any dense open U_2 in X_2 can be uniquely extended to an isomorphism from X_1 to X_2; whence the uniqueness claim. To prove the existence of $\widehat{X}$, it suffices to note that we can consider X as a subscheme of a projective bundle $\mathbf{P}_k^n$ (7.4.10). Let $\overline{X}$ be the closure of X in $\mathbf{P}_k^n$ (**I**, 9.5.11); since X is induced by $\overline{X}$ on a dense open subset of $\overline{X}$ (**I**, 9.5.10), the generic points x_i of the irreducible components of X are also the generic points of the irreducible components of $\overline{X}$, and the $k(x_i)$ are the same for both of these schemes, and so (7.4.1) $\overline{X}$ is an algebraic curve over k that is reduced (**I**, 9.5.9) and projective over k (5.5.1), whence complete (5.5.3). So we take for $\widehat{X}$ the *normalisation* of $\overline{X}$, which is again complete (7.4.8); furthermore, if $h : \widehat{X} \to \overline{X}$ is the canonical morphism, then the restriction of h to $h^{-1}(X)$ is an isomorphism to X, since X is normal (6.3.4), and since $h^{-1}(X)$ contains the generic points of the irreducible components of $\widehat{X}$ (6.3.8), it is dense in $\widehat{X}$, which finishes the proof. □

II | 151

Remark (7.4.12). — We will show, in Chapter V, that the conclusion of (7.4.10) still holds true without the assumption that the curve is normal (or even reduced); we will also show that, for an algebraic curve (reduced or not) to be affine, it is necessary and sufficient for its (reduced) irreducible components to *not* be complete.

Corollary (7.4.13). — *Let X be a* normal *irreducible curve over k, with function field $K = R(X)$, and let Y be a* complete *integral curve over k, with function field $L = R(Y)$. Then there is a canonical bijective correspondence between* dominant *k-morphisms $X \to Y$ and k-monomorphisms $L \to K$.*

Proof. By (7.4.9), rational k-maps from X to Y can be identified with k-morphisms $u : X \to Y$. Since the dominant morphisms $u : X \to Y$ are characterised by being those such that $u(x) = y$ (writing x and y to denote the generic points of X and Y, respectively), the corollary follows from these remarks and from (**I**, 7.1.13). □

(7.4.14). We can refine the result of (7.4.13) in the case where Y is the *projective line* $\mathbf{P}_k^1 = \operatorname{Proj}(k[T_0, T])$, where T_0 and T are indeterminates. Then Y is an integral scheme (2.4.4), and the scheme induced on the open subset $D_+(T_0)$ of Y is isomorphic to $\operatorname{Spec}(k[T])$ (2.3.6), and so the generic point of Y is the ideal (0) of $k[T]$, and the field of rational functions of Y is $k(T)$, which proves that Y is a complete algebraic curve over k. Furthermore, the only graded prime ideal of $S = k[T_0, T]$ that contains T_0 and is distinct from S_+ is the principal ideal (T_0), and so the complement of $D_+(T_0)$ in $Y = \mathbf{P}_k^1$ consists of *one closed point*, called the "point at infinity", which we denote by ∞ (for a general study of the links between vector bundles and projective bundles, see (8.4)). With these notations:

Corollary (7.4.15). — *Let X be a* normal *irreducible curve over k, with function field $K = R(X)$. Then there exists a canonical bijective correspondence between the set K and the set of morphisms u from X to $\mathbf{P}_k^1$ that are distinct from the constant morphism with value ∞. For such a morphism to be dominant, it is necessary and sufficient for the corresponding element of K to be transcendental over k.*

Proof. This claim follows immediately from (7.4.9) and the following:

Lemma (7.4.15.1). — *Let X be an integral prescheme over k, and let $K = R(X)$ be its field of rational functions. Then there exists a canonical bijective correspondence between the set K and the set of rational maps u from X to $\mathbf{P}^1_k$ that are distinct from the constant morphism with value ∞. For such a rational map to be dominant, it is necessary and sufficient for the corresponding element of K to be transcendental over k.*

First of all, rational maps from X to $\mathbf{P}^1_k$ correspond bijectively to points of $\mathbf{P}^1_k$ with values in the extension K of k (**I**, 7.1.12). If such a point is located (**I**, 3.4.5) at the generic point of $\mathbf{P}^1_k$, then the corresponding rational map is clearly dominant. In the converse case, since every point of $\mathbf{P}^1_k$ that is distinct from the generic point is closed (7.4.3), the image of the domain of definition U of u by the unique morphism $U \to \mathbf{P}^1_k$ of the class u (**I**, 7.2.2) consists of one closed point y of $\mathbf{P}^1_k$, and this morphism (which is not necessarily everywhere defined on X) is thus not dominant; as an abuse of language, we thus say that the rational map u is "constant, of value y". It remains to place in bijective correspondence the points of $\mathbf{P}^1_k$ with value in K that are located (**I**, 3.4.5) *not* at ∞, and the elements of K, and then to verify that the location of such a point is the generic point of $\mathbf{P}^1_k$ if and only if it corresponds to an element that is transcendental over k. But this is immediate (4.2.6, example 1). □ **II** | 152

Corollary (7.4.16). — *Let X and Y be algebraic curves over k that are* normal, complete, *and irreducible; let $K = R(X)$ and $L = R(Y)$ be their fields. Then there exists a canonical bijective correspondence between the set of k-isomorphisms $X \xrightarrow{\sim} Y$ and the set of k-isomorphisms $L \xrightarrow{\sim} K$.*

Proof. This is an evident consequence of (7.4.13). □

(7.4.17). This corollary (7.4.16) shows that an algebraic curve over k that is normal, complete, and irreducible, is *determined by its field of rational functions K up to unique isomorphism*; by definition, K is an extension of finite type of k, of transcendence degree 1 (we classically call this a *field of algebraic functions of one variable*). Furthermore:

Proposition (7.4.18). — *For every extension K of k of finite type and of transcendence degree* 1*, there exists an algebraic curve X (determined up to unique isomorphism) that is normal, complete, and irreducible, and such that $R(X) = K$. The set of local rings of X can be identified* (**I**, 8.2.1) *with the set consisting of the field K and the valuation rings that contain k and have K as their field of fractions.*

Proof. Indeed, K is an extension of finite degree of a pure transcendental extension $k(T)$ of k, which can be identified, as we have seen, with the field of rational functions of the projective line $Y = \mathbf{P}^1_k$. Let X be the *integral closure* of Y with respect to K (6.3.4); then X is a normal algebraic curve over k, with function field K (6.3.7), and it is complete, since the morphism $X \to Y$ is finite (7.4.6). The local rings $\mathscr{O}_x$ of X are either the field K, when x is the generic point, or discrete valuation rings that contain k and have K as their field of fractions, when x is distinct from the generic point (7.4.5). Conversely, let A be such a ring; since the morphism $X \to \operatorname{Spec}(k)$ is proper, the fact that A dominates k implies that A also dominates a local ring $\mathscr{O}_x$ of X (7.3.10); since the latter is a valuation ring that has K as a field of fractions, it is necessarily equal to A. □

Remarks (7.4.19). — It follows from (7.4.16) and (7.4.18) that *the data of an algebraic curve over k that is normal, complete, and irreducible, is essentially equivalent to the data of an extension K of k that is of finite type and of transcendence degree* 1. We note that, if k' is an extension of the base field k, then $X \otimes_k k'$ will again be a complete algebraic curve over k' (5.4.2, (iii)), but, in general, it will be neither reduced nor irreducible. It will, however, be both reduced and irreducible if K is a separable extension of k, and k is algebraically closed in K (this can be expressed, in classical terminology, which we will not use, by saying that K is a "regular extension" of k). But even in this case, it is possible for $X \otimes_k k'$ to not be normal. The reader will find details on these questions in Chapter IV.

§8. Blowup schemes; projecting cones; projective closure

8.1. Blowup preschemes

(8.1.1). Let Y be a prescheme, and, for every integer $n \geqslant 0$, let $\mathscr{I}_n$ be a quasi-coherent sheaf of ideals of $\mathscr{O}_Y$; suppose that the following conditions are satisfied:

(8.1.1.1) $$\mathscr{I}_0 = \mathscr{O}_Y,\ \mathscr{I}_n \subset \mathscr{I}_m \text{ for } m \leqslant n,$$

(8.1.1.2) $$\mathscr{I}_m \mathscr{I}_n \subset \mathscr{I}_{m+n} \text{ for any } m, n.$$

We note that these hypotheses imply **II** | 153

(8.1.1.3) $$\mathscr{I}_1^n \subset \mathscr{I}_n.$$

Set

(8.1.1.4) $$\mathscr{S} = \bigoplus_{n \geqslant 0} \mathscr{I}_n.$$

It follows from (8.1.1.1) and (8.1.1.2) that $\mathscr{S}$ is a quasi-coherent graded $\mathscr{O}_Y$-algebra, and thus defines a Y-scheme $X = \operatorname{Proj}(\mathscr{S})$. If $\mathscr{J}$ is an *invertible* sheaf of ideals of $\mathscr{O}_Y$, then $\mathscr{I}_n \otimes_{\mathscr{O}_Y} \mathscr{J}^{\otimes n}$ is canonically identified with $\mathscr{I}_n \mathscr{J}^n$. If we then replace the $\mathscr{I}_n$ by the $\mathscr{I}_n \mathscr{J}^n$, and, in doing so, replace $\mathscr{S}$ by a quasi-coherent $\mathscr{O}_Y$-algebra $\mathscr{S}_{(\mathscr{J})}$, then $X_{(\mathscr{J})} = \operatorname{Proj}(\mathscr{S}_{(\mathscr{J})})$ is canonically isomorphic to X (3.1.8).

(8.1.2). Suppose that Y is *locally integral*, so that the sheaf $\mathscr{R}(Y)$ of rational functions is a quasi-coherent $\mathscr{O}_Y$-algebra (**I**, 7.3.7). We say that an $\mathscr{O}_Y$-submodule $\mathscr{I}$ of $\mathscr{R}(Y)$ is a *fractional ideal* of $\mathscr{R}(Y)$ if it is of *finite type* (**0**, 5.2.1). Suppose we have, for all $n \geqslant 0$, a quasi-coherent fractional ideal $\mathscr{I}_n$ of $\mathscr{R}(Y)$, such that $\mathscr{I}_0 = \mathscr{O}_Y$, and such that condition (8.1.1.2) (but not necessarily the second condition (8.1.1.1)) is satisfied; we can then again define a quasi-coherent graded $\mathscr{O}_Y$-algebra by Equation (8.1.1.4), and the corresponding Y-scheme $X = \operatorname{Proj}(\mathscr{S})$; we will again have a canonical isomorphism from X to $X_{(\mathscr{J})}$ for every *invertible* fractional ideal $\mathscr{J}$ of $\mathscr{R}(Y)$.

Definition (8.1.3). — Let Y be a prescheme (resp. a locally integral prescheme), and $\mathscr{I}$ a quasi-coherent ideal of $\mathscr{O}_Y$ (resp. a quasi-coherent fractional ideal of $\mathscr{R}(Y)$). We say that the Y-scheme $X = \operatorname{Proj}(\bigoplus_{n \geqslant 0} \mathscr{I}^n)$ is obtained by blowing up the ideal $\mathscr{I}$, or is the blow-up prescheme of Y relative to $\mathscr{I}$. When $\mathscr{I}$ is a quasi-coherent ideal of $\mathscr{O}_Y$, and Y' is the closed subprescheme of Y defined by $\mathscr{I}$, we also say that X is the Y-scheme obtained by blowing up Y'.

By definition, $\mathscr{S} = \bigoplus_{n \geqslant 0} \mathscr{I}^n$ is then generated by $\mathscr{S}_1 = \mathscr{I}$; if $\mathscr{I}$ is an $\mathscr{O}_Y$-module of *finite type*, then X is *projective* over Y (5.5.2). Without any hypotheses on $\mathscr{I}$, the $\mathscr{O}_X$-module $\mathscr{O}_X(1)$ is *invertible* (3.2.5) and *very ample*, by (4.4.3) applied to the structure morphism $X \to Y$.

We note that, if $f : X \to Y$ is the structure morphism, then the restriction of f to $f^{-1}(Y - Y')$ is an *isomorphism* onto $Y - Y'$ whenever $\mathscr{I}$ is an *ideal of* $\mathscr{O}_Y$ and Y' is the closed subprescheme that it defines: indeed, since the question is local on Y, it suffices to assume that $\mathscr{I} = \mathscr{O}_Y$, and our claim then follows from (3.1.7).

If we replace $\mathscr{I}$ by $\mathscr{I}^d$ ($d > 0$), then the blow-up Y-scheme X is replaced by a canonically isomorphic Y-scheme X' (8.1.1); similarly, for every *invertible* ideal (resp. *invertible* fractional ideal) $\mathscr{J}$, the blow-up prescheme $X_{(\mathscr{J})}$ relative to the ideal $\mathscr{I}\mathscr{J}$ is canonically isomorphic to X (8.1.1).

In particular, whenever $\mathscr{I}$ is an *invertible* ideal (resp. *invertible* fractional ideal), the Y-scheme obtained by blowing up $\mathscr{I}$ is *isomorphic to* Y (3.1.7).

Proposition (8.1.4). — *Let Y be an integral prescheme.*

(i) *For every sequence $(\mathscr{I}_n)$ of quasi-coherent fractional ideals of $\mathscr{R}(Y)$ that satisfies* (8.1.1.2) *and such that $\mathscr{I}_0 = \mathscr{O}_Y$, the Y-scheme $X = \operatorname{Proj}(\bigoplus_{n \geqslant 0} \mathscr{I}_n)$ is integral, and the structure morphism $f : X \to Y$ is dominant.* **II** | 154

(ii) *Let $\mathscr{I}$ be a quasi-coherent fractional ideal of $\mathscr{R}(Y)$, and let X be the Y-scheme given by the blow up of Y relative to $\mathscr{I}$. If $\mathscr{I} \neq 0$, then the structure morphism $f : X \to Y$ is then birational and surjective.*

Proof.

(i) This follows from the fact that $\mathscr{S} = \bigoplus_{n \geqslant 0} \mathscr{I}_n$ is an *integral* $\mathscr{O}_Y$-algebra ((3.1.12) and (3.1.14)), since, for all $y \in Y$, $\mathscr{O}_y$ is an integral ring (**I**, 5.1.4).

(ii) By (i), X is integral; if, furthermore, x and y are the generic points of X and Y (respectively), then we have $f(x) = y$, and it remains to show that $k(x)$ has dimension one over $k(y)$. But x is also the generic point of the fibre $f^{-1}(y)$; if ψ is the canonical morphism $Z \to Y$, where $Z = \operatorname{Spec}(k(y))$, then the prescheme $f^{-1}(y)$ can be identified with $\operatorname{Proj}(\mathscr{S}')$, where $\mathscr{S}' = \psi^*(\mathscr{S})$ (3.5.3). But it is clear that $\mathscr{S}' = \bigoplus_{n \geqslant 0} (\mathscr{I}_y)^n$, and, since $\mathscr{I}$ is a quasi-coherent fractional ideal of $\mathscr{R}(Y)$ that is not zero, $\mathscr{I}_y \neq 0$ (**I**, 7.3.6), whence $\mathscr{I}_y = k(y)$; then $\operatorname{Proj}(\mathscr{S}')$ can be identified with $\operatorname{Spec}(k(y))$ (3.1.7), whence the conclusion.

□

We show a *converse* of (8.1.4) in (**III**, 2.3.8).

(8.1.5). We return to the setting and notation of (8.1.1). By definition, the injection homomorphisms $\mathscr{I}_{n+1} \to \mathscr{I}_n$ (8.1.1.1) define, for every $k \in \mathbf{Z}$, an injective homomorphism of degree zero of graded $\mathscr{S}$-modules

(8.1.5.1)
$$u_k : \mathscr{S}_+(k+1) \longrightarrow \mathscr{S}(k);$$

since $\mathscr{S}_+(k+1)$ and $\mathscr{S}(k+1)$ are canonically **(TN)**-isomorphic, they give a canonical correspondence between u_k and an injective homomorphism of $\mathscr{O}_X$-modules (3.4.2):

(8.1.5.2)
$$\widetilde{u}_k : \mathscr{O}_X(k+1) \longrightarrow \mathscr{O}_X(k).$$

Recall as well (3.2.6) that we have defined canonical homomorphisms

(8.1.5.3)
$$\lambda : \mathscr{O}_X(h) \otimes_{\mathscr{O}_X} \mathscr{O}_X(k) \longrightarrow \mathscr{O}_X(h+k)$$

and, since the diagram

$$\begin{tikzcd} \mathscr{S}(h) \otimes_{\mathscr{S}} \mathscr{S}(k) \otimes_{\mathscr{S}} \mathscr{S}(l) \arrow[r] \arrow[d] & \mathscr{S}(h+k) \otimes_{\mathscr{S}} \mathscr{S}(l) \arrow[d] \\ \mathscr{S}(h) \otimes_{\mathscr{S}} \mathscr{S}(k+l) \arrow[r] & \mathscr{S}(h+k+l) \end{tikzcd}$$

commutes, it follows from the functoriality of the λ (3.2.6) that the homomorphisms (8.1.5.3) define the structure of a *quasi-coherent graded $\mathscr{O}_X$-algebra* on

(8.1.5.4)
$$\mathscr{S}_X = \bigoplus_{n \in \mathbf{Z}} \mathscr{O}_X(n).$$

Furthermore, the diagram **II** | 155

$$\begin{tikzcd} \mathscr{S}(h) \otimes_{\mathscr{S}} \mathscr{S}_+(k+1) \arrow[r] \arrow[d, "1\otimes u_k"'] & \mathscr{S}_+(h+k+1) \arrow[d, "u_{k+h}"] \\ \mathscr{S}(h) \otimes_{\mathscr{S}} \mathscr{S}(k) \arrow[r] & \mathscr{S}(h+k) \end{tikzcd}$$

commutes; the functoriality of the λ then implies that we have a commutative diagram

(8.1.5.5)
$$\begin{tikzcd} \mathscr{O}_X(h) \otimes_{\mathscr{O}_X} \mathscr{O}_X(k+1) \arrow[r, "\lambda"] \arrow[d, "1\otimes\widetilde{u}_k"'] & \mathscr{O}_X(h+k+1) \arrow[d, "\widetilde{u}_{k+h}"] \\ \mathscr{O}_X(h) \otimes_{\mathscr{O}_X} \mathscr{O}_X(k) \arrow[r, "\lambda"] & \mathscr{O}_X(h+k) \end{tikzcd}$$

where the horizontal arrows are the canonical homomorphisms. We can thus say that the $\widetilde{u}_k$ define an *injective homomorphism* (of degree zero) *of graded $\mathscr{S}_X$-modules*

(8.1.5.6)
$$\widetilde{u} : \mathscr{S}_X(1) \longrightarrow \mathscr{S}_X.$$

(8.1.6). Keeping the notation from (8.1.5), we now note that, for $n \geqslant 0$, the composite homomorphism $\widetilde{v}_n = \widetilde{u}_{n-1} \circ \widetilde{u}_{n-2} \circ \ldots \circ \widetilde{u}_0$ is an *injective* homomorphism $\mathscr{O}_X(n) \to \mathscr{O}_X$; we denote by $\mathscr{I}_{n,X}$ its image, which is thus a quasi-coherent ideal of $\mathscr{O}_X$, *isomorphic* to $\mathscr{O}_X(n)$. Furthermore, the diagram

$$\begin{tikzcd} \mathscr{O}_X(m) \otimes_{\mathscr{O}_X} \mathscr{O}_X(n) \arrow[r, "\lambda"] \arrow[d, "\widetilde{v}_m\otimes\widetilde{v}_n"'] & \mathscr{O}_X(m+n) \arrow[d, "\widetilde{v}_{m+n}"] \\ \mathscr{O}_X \arrow[r, "\mathrm{id}"'] & \mathscr{O}_X \end{tikzcd}$$

commutes for $m \geqslant 0$, $n \geqslant 0$. We thus deduce the following inclusions:

(8.1.6.1) $$\mathscr{I}_{0,X} = \mathscr{O}_X, \quad \mathscr{I}_{n,X} \subset \mathscr{I}_{m,X} \qquad \text{for } 0 \leqslant m \leqslant n;$$

(8.1.6.2) $$\mathscr{I}_{m,X}\mathscr{I}_{n,X} \subset \mathscr{I}_{m+n,X} \qquad \text{for } m \geqslant 0, n \geqslant 0.$$

II | 156

Proposition (8.1.7). — *Let Y be a prescheme, $\mathscr{I}$ a quasi-coherent ideal of $\mathscr{O}_Y$, and $X = \operatorname{Proj}(\bigoplus_{n\geqslant 0}\mathscr{I}^n)$ the Y-scheme given by blowing up $\mathscr{I}$. We then have, for all $n > 0$, a canonical isomorphism*

(8.1.7.1) $$\mathscr{O}_X(n) \xrightarrow{\sim} \mathscr{I}^n\mathscr{O}_X = \mathscr{I}_{n,X}$$

(cf. (0, 4.3.5)), and thus that $\mathscr{I}^n\mathscr{O}_X$ is a very-ample invertible $\mathscr{O}_X$-module if $n > 0$.

Proof. The last claim is immediate, since $\mathscr{O}_X(1)$ is invertible (3.2.5) and very ample for Y by definition ((4.4.3) and (4.4.9)). Also by definition, the image of v_n is exactly $\mathscr{I}^n\mathscr{S}$, and (8.1.7.1) then follows from the exactness of the functor $\widetilde{\mathscr{M}}$ (3.2.4) and from Equation (3.2.4.1). □

Corollary (8.1.8). — *Under the hypotheses of (8.1.7), if $f : X \to Y$ is the structure morphism, and Y' the closed subprescheme of Y defined by $\mathscr{I}$, then the closed subprescheme $X' = f^{-1}(Y')$ of X is defined by $\mathscr{I}\mathscr{O}_X$ (which is canonically isomorphic to $\mathscr{O}_X(1)$), from which we obtain a canonical short exact sequence*

(8.1.8.1) $$0 \longrightarrow \mathscr{O}_X(1) \longrightarrow \mathscr{O}_X \longrightarrow \mathscr{O}_{X'} \longrightarrow 0.$$

Proof. This follows from (8.1.7.1) and from (I, 4.4.5). □

(8.1.9). Under the hypotheses of (8.1.7), we can be more precise about the structure of the $\mathscr{I}_{n,X}$. Note that the homomorphism

$$\widetilde{u}_{-1} : \mathscr{O}_X \longrightarrow \mathscr{O}_X(-1)$$

canonically corresponds to a section s of $\mathscr{O}_X(-1)$ over X, which we call the *canonical section* (relative to $\mathscr{I}$) (0, 5.1.1). In the diagram in (8.1.5.5), the horizontal arrows are isomorphisms (3.2.7); by replacing h with k, and k with -1 in this diagram, we obtain that $\widetilde{u}_k = 1_k \otimes \widetilde{u}_{-1}$ (where 1_k denotes the identity on $\mathscr{O}_X(k)$), or, equivalently, that the homomorphism $\widetilde{u}_k$ is given exactly by *tensoring with the canonical section* s (for all $k \in \mathbf{Z}$). The homomorphism $\widetilde{u}$ (8.1.5.6) can then be understood in the same way.

Thus, for all $n \geqslant 0$, the homomorphism $\widetilde{v}_n : \mathscr{O}_X(n) \to \mathscr{O}_X$ is given exactly by tensoring with $s^{\otimes n}$; we thus deduce:

Corollary (8.1.10). — *With the notation of (8.1.8), the underlying space of X' is the set of $x \in X$ such that $s(x) = 0$, where s denotes the canonical section of $\mathscr{O}_X(-1)$.*

Proof. Indeed, if c_x is a generator of the fibre $(\mathscr{O}_X(1))_x$ at a point x, then $s_x \otimes c_x$ is canonically identified with a generator of the fibre of $\mathscr{I}_{1,X}$ at the point x, and is thus invertible if and only if $s_x \notin \mathfrak{m}_x(\mathscr{O}_x(-1))_x$, or, equivalently, if and only if $s(x) \neq 0$. □

Proposition (8.1.11). — *Let Y be an integral prescheme, $\mathscr{I}$ a quasi-coherent fractional ideal of $\mathscr{R}(Y)$, and X the Y-scheme given by blowing up $\mathscr{I}$. Then $\mathscr{I}\mathscr{O}_X$ is an invertible $\mathscr{O}_X$-module that is very ample for Y.*

Proof. Since the question is local on Y (4.4.5), we can reduce to the case where $Y = \operatorname{Spec}(A)$, with A an integral domain with field of fractions K, and $\mathscr{I} = \widetilde{\mathfrak{I}}$, with $\mathfrak{I}$ some fractional ideal of K; there then exists an element $a \neq 0$ of A such that $a\mathfrak{I} \subset A$. Let $S = \bigoplus_{n\geqslant 0}\mathfrak{I}^n$; the map $x \mapsto ax$ is an A-isomorphism from $\mathfrak{I}^{n+1} = (S(1))_n$ to $a\mathfrak{I}^{n+1} = a\mathfrak{I}S_n \subset \mathfrak{I}^n = S_n$, and thus defines a (TN)-isomorphism of degree zero of graded S-modules $S_+(1) \to a\mathfrak{I}S$. On the other hand, $x \mapsto a^{-1}x$ is an isomorphism of degree zero of graded S-modules $a\mathfrak{I}S \xrightarrow{\sim} \mathfrak{I}S$. We thus obtain, by composition (3.2.4), an isomorphism of $\mathscr{O}_X$-modules $\mathscr{O}_X(1) \xrightarrow{\sim} \mathscr{I}\mathscr{O}_X$, and, since S is generated by $S_1 = \mathfrak{I}$, $\mathscr{O}_X(1)$ is invertible (3.2.5) and very ample ((4.4.3) and (4.4.9)), whence our claim. □ II | 157

8.2. Preliminary results on the localisation of graded rings

(8.2.1). Let S be a graded ring, which for the moment we do not assume to be concentrated in nonnegative degrees. We define

(8.2.1.1) $$S^{\geqslant} = \bigoplus_{n\geqslant 0} S_n, \qquad S^{\leqslant} = \bigoplus_{n\leqslant 0} S_n$$

which are both graded subrings of S, in only positive and negative degrees (respectively). If f is a homogeneous element of degree d (positive or negative) in S, then the localization $S_f = S'$ is again endowed with the structure of a graded ring, by taking S'_n ($n \in \mathbf{Z}$) to be the set of the x/f^k for $x \in S_{n+kd}$ ($k \geqslant 0$); we define $S_{(f)} = S'_0$, and will write $S_f^{\geqslant}$ and $S_f^{\leqslant}$ for $S'^{\geqslant}$ and $S'^{\leqslant}$ (respectively). If $d > 0$, then

(8.2.1.2) $$(S^{\geqslant})_f = S_f$$

since, if $x \in S_{n+kd}$ with $n + kd < 0$, then we can write $x/f^k = xf^h/f^{h+k}$, and we also have that $n + (h+k)d > 0$ for h sufficiently large and > 0. We thus conclude, by definition, that

(8.2.1.3) $$(S^{\geqslant})_{(f)} = (S_f^{\geqslant})_0 = S_{(f)}.$$

If M is a graded S-module, then we similarly define

(8.2.1.4) $$M^{\geqslant} = \bigoplus_{n\geqslant 0} M_n, \qquad M^{\leqslant} = \bigoplus_{n\leqslant 0} M_n$$

which are (respectively) a graded $S^{\geqslant}$-module and a graded $S^{\leqslant}$-module, and their intersection is the S_0 module M_0. If $f \in S_d$, then we define M_f to be the graded S_f-module whose elements of degree n are the z/f^k for $z \in M_{n+kd}$ ($k \geqslant 0$); we denote by $M_{(f)}$ the set of elements of degree zero of M_f, and this is an $S_{(f)}$-module, and we will write $M_f^{\geqslant}$ and $M_f^{\leqslant}$ to mean $(M_f)^{\geqslant}$ and $(M_f)^{\leqslant}$ (respectively). If $d > 0$, then we see, as above, that

(8.2.1.5) $$(M^{\geqslant})_f = M_f$$

and

(8.2.1.6) $$(M^{\geqslant})_{(f)} = (M_f^{\geqslant})_0 = M_{(f)}.$$

(8.2.2). Let $\mathbf{z}$ be an indeterminate, which we will call the *homogenisation variable*. If S is a graded ring (with arbitrary integer degrees), then the polynomial algebra[2]

(8.2.2.1) $$\widehat{S} = S[\mathbf{z}]$$

is a graded S-algebra, where we define the degree of $f\mathbf{z}^n$ ($n \geqslant 0$), with f homogeneous, as **II** | 158

(8.2.2.2) $$\deg(f\mathbf{z}^n) = n + \deg f.$$

Lemma (8.2.3). — (i) *There are canonical isomorphisms of (non-graded) rings*

(8.2.3.1) $$\widehat{S}_{(\mathbf{z})} \xrightarrow{\sim} \widehat{S}/(\mathbf{z}-1)\widehat{S} \xrightarrow{\sim} S.$$

(ii) *There is a canonical isomorphism of (non-graded) rings*

(8.2.3.2) $$\widehat{S}_{(f)} \xrightarrow{\sim} S_f^{\leqslant}$$

for all $f \in S_d$ with $d > 0$.

Proof. The first of the isomorphisms in (8.2.3.1) was defined in (2.2.5), and the second is trivial; the isomorphism $\widehat{S}_{(\mathbf{z})} \xrightarrow{\sim} S$ thus defined thus gives a correspondence between $x\mathbf{z}^n/\mathbf{z}^{n+k}$ (where $\deg(x) = k$ for $k \geqslant -n$) and the element x. The homomorphism (8.2.3.2) gives a correspondence between $x\mathbf{z}^n/f^k$ (where $\deg(x) = kd - n$) and the element x/f^k of degree $-n$ in $S_f^{\leqslant}$, and it is again clear that this does indeed give an isomorphism. □

[2]This should not be confused with the use of the notation $\widehat{S}$ for the separated completion of a ring.

(8.2.4). Let M be a graded S-module. It is clear that the S-module

(8.2.4.1) $$\widehat{M} = M \otimes_S \widehat{S} = M \otimes_S S[\mathbf{z}]$$

is the direct sum of the S-modules $M \otimes_S S\mathbf{z}^n$, and thus of the abelian groups $M_k \otimes_S S\mathbf{z}^n$ ($k \in \mathbf{Z}$, $n \geqslant 0$); we define on $\widehat{M}$ the structure of a graded $\widehat{S}$-module by setting

(8.2.4.2) $$\deg(x \otimes \mathbf{z}^n) = n + \deg x$$

for all homogeneous x in M. We leave it to the reader to prove the analogue of (8.2.3):

Lemma (8.2.5). — (i) *There is a canonical di-isomorphism of (non-graded) modules*

(8.2.5.1) $$\widehat{M}_{(\mathbf{z})} \xrightarrow{\sim} M.$$

(ii) *For all $f \in S_d$ ($d > 0$), there is a di-isomorphism of (non-graded) modules*

(8.2.5.2) $$\widehat{M}_{(f)} \xrightarrow{\sim} M_f^{\leqslant}.$$

(8.2.6). Let S be a *positively*-graded ring, and consider the decreasing sequence of graded ideals of S

(8.2.6.1) $$S_{[n]} = \bigoplus_{m \geqslant n} S_m \qquad (n \geqslant 0)$$

(so, in particular, we have $S_{[0]} = S$ and $S_{[1]} = S_+$). Since it is evident that $S_{[m]}S_{[n]} \subset S_{[m+n]}$, we can define a *graded ring* $S^\natural$ by setting

(8.2.6.2) $$S^\natural = \bigoplus_{n \geqslant 0} S_n^\natural \quad \text{with} \quad S_n^\natural = S_{[n]}.$$

$S_0^\natural$ is then the ring S considered as a *non-graded* ring, and $S^\natural$ is thus an $S_0^\natural$-algebra. For every homogeneous element $f \in S_d$ ($d > 0$), we denote by $f^\natural$ the element f considered as belonging to $S_{[d]} = S_d^\natural$. With this notation:

II | 159

Lemma (8.2.7). — *Let S be a positively-graded ring, and f a homogeneous element of S_d ($d > 0$). There are canonical ring isomorphisms*

(8.2.7.1) $$S_f \xrightarrow{\sim} \bigoplus_{n \in \mathbf{Z}} S(n)_{(f)}$$

(8.2.7.2) $$(S_f^{\geqslant})_{f/1} \xrightarrow{\sim} S_f$$

(8.2.7.3) $$S^\natural_{(f^\natural)} \xrightarrow{\sim} S_f^{\geqslant}$$

where the first two are isomorphisms of graded rings.

Proof. It is immediate, by definition, that we have $(S_f)_n = (S(n)_f)_0$, whence the isomorphism in (8.2.7.1), which is exactly the identity. Next, since $f/1$ is invertible in S_f, there is a canonical isomorphism $S_f \xrightarrow{\sim} (S_f^{\geqslant})_{f/1} = (S_f)_{f/1}$, by (8.2.1.2) applied to S_f; the inverse isomorphism is, by definition, the isomorphism in (8.2.7.2). Finally, if $x = \sum_{m \geqslant n} y_m$ is an element of $S_{[n]}$ with $n = kd$, then the element $x/(f^\natural)^k$ corresponds to the element $\sum_m y_m/f^k$ of $S_f^{\geqslant}$, and we can quickly verify that this defines an isomorphism (8.2.7.3). □

(8.2.8). If M is a graded S-module, then we similarly define, for all $n \in \mathbf{Z}$,

(8.2.8.1) $$M_{[n]} = \bigoplus_{m \geqslant n} M_m$$

and, since $S_{[m]}M_{[n]} \subset M_{[m+n]}$ ($m \geqslant 0$), we can define a graded $S^\natural$-module $M^\natural$ by setting

(8.2.8.2) $$M^\natural = \bigoplus_{n \in \mathbf{Z}} M_n^\natural \quad \text{with} \quad M_n^\natural = M_{[n]}.$$

We leave to the reader the proof of:

Lemma (8.2.9). — *With the notation of (8.2.7) and (8.2.8), there are canonical di-isomorphisms of modules*

(8.2.9.1) $$M_f \xrightarrow{\sim} \bigoplus_{n\in\mathbf{Z}} M(n)_{(f)}$$

(8.2.9.2) $$(M_f^{\geqslant})_{f/1} \xrightarrow{\sim} M_f$$

(8.2.9.3) $$M^\natural_{(f^\natural)} \xrightarrow{\sim} M_f^{\geqslant}$$

where the first two are di-isomorphisms of graded modules.

Lemma (8.2.10). — *Let S be a positively-graded ring.*

(i) *For $S^\natural$ to be an $S_0^\natural$-algebra of finite type (resp. a Noetherian ring), it is necessary and sufficient for S to be an S_0-algebra of finite type (resp. a Noetherian ring).*
(ii) *For $S^\natural_{n+1} = S^\natural_1 S^\natural_n$ $(n \geqslant n_0)$, it is necessary and sufficient for $S_{n+1} = S_1 S_n$ $(n \geqslant n_0)$.*
(iii) *For $S^\natural_n = (S^\natural_1)^n$ $(n \geqslant n_0)$, it is necessary and sufficient for $S_n = S_1^n$ $(n \geqslant n_0)$.*
(iv) *If (f_α) is a set of homogeneous elements of S_+ such that S_+ is the radical in S of the ideal of S generated by the f_α, then $S^\natural_+$ is the radical in $S^\natural$ of the ideal of $S^\natural$ generated by the $f^\natural_\alpha$.*

Proof.

(i) If $S^\natural$ is an $S^\natural_0$-algebra of finite type, then $S_+ = S^\natural_1$ is a module of finite type over $S = S^\natural_0$, by (2.1.6, i), and so S is an S_0-algebra of finite type (2.1.4); if $S^\natural$ is a Noetherian ring, then so too is $S^\natural_0 = S$ (2.1.5). Conversely, if S is an S_0-algebra of finite type, then we know (2.1.6, ii) that there exist $h > 0$ and $m_0 > 0$ such that $S_{n+h} = S_h S_n$ for $n \geqslant m_0$; we can clearly assume that $m_0 \geqslant h$. Furthermore, the S_m are S_0-modules of finite type (2.1.6, i). So, if $n \geqslant m_0 + h$, then $S^\natural_n = S_h S^\natural_{n-h} = S^\natural_h S^\natural_{n-h}$; and if $m < m_0 + h$ then, letting $E = S_{m_0} + \ldots + S_{m_0+h-1}$, we have that **II | 160**

$$S^\natural_m = S_m + \ldots + S_{m_0+h-1} + S_h E + S_h^2 E + \ldots.$$

For $1 \leqslant m \leqslant m_0$, let G_m be the union of the finite systems of generators of the S_0-modules S_i for $m \leqslant i \leqslant m_0 + h - 1$, considered as a subset of $S_{[m]}$. For $m_0 + 1 \leqslant m \leqslant m_0 + h - 1$, let G_m be the union of the finite system of generators of the S_0-modules S_i for $m \leqslant i \leqslant m_0 + h - 1$ and of $S_h E$, considered as a subset of $S_{[m]}$. It is clear that $S^\natural_m = S^\natural_0 G_m$ for $1 \leqslant m \leqslant m_0 + h - 1$, and thus the union G of the G_m for $1 \leqslant m \leqslant m_0 + h - 1$ is a system of generators of the $S^\natural_0$-algebra $S^\natural$. We thus conclude that, if $S = S^\natural_0$ is a Noetherian ring, then so too is $S^\natural$.

(ii) It is clear that, if $S_{n+1} = S_1 S_n$ for $n \geqslant n_0$, then $S^\natural_{n+1} = S_1 S^\natural_n$, and *a fortiori* $S^\natural_{n+1} = S^\natural_1 S^\natural_n$ for $n \geqslant n_0$. Conversely, this last equality can be written as

$$S_{n+1} + S_{n+2} + \ldots = (S_1 + S_2 + \ldots)(S_n + S_{n+1} + \ldots)$$

and comparing terms of degree $n+1$ (in S) on both sides gives that $S_{n+1} = S_1 S_n$.

(iii) If $S_n = S_1^n$ for $n \geqslant n_0$, then $S^\natural_n = S_1^n + S_1^{n+1} + \ldots$; since $S^\natural_1$ contains $S_1 + S_1^2 + \ldots$, we have that $S^\natural_n \subset S_1^{\natural n}$, and thus $S^\natural_n = S_1^{\natural n}$ for $n \geqslant n_0$. Conversely, the only terms of $S_1^{\natural n} = (S_1 + S_2 + \ldots)^n$ that are of degree n in S are those of S_1^n; the equality $S^\natural_n = S_1^{\natural n}$ thus implies that $S_n = S_1^n$.

(iv) It suffices to show that, if an element $g \in S_{k+h}$ is considered as an element of $S^\natural_k$ $(k > 0$, $h \geqslant 0)$, then there exists an integer $n > 0$ such that g^n is a linear combination (in $S^\natural_{kn}$) of the $f^\natural_\alpha$ with coefficients in $S^\natural$. By hypothesis, there exists an integer m_0 such that, for $m \geqslant m_0$, we have, *in S*, that $g^m = \sum_\alpha c_{\alpha m} f_\alpha$, where the indices α here are *independent of m*; furthermore, we can clearly assume that the $c_{\alpha m}$ are homogeneous, with

$$\deg(c_{\alpha m}) = m(k+h) - \deg f_\alpha$$

in S. So take m_0 sufficiently large to ensure that $km_0 > \deg f_\alpha$ for all the f_α that appear in g^{m_0}; for all α, let $c'_{\alpha m}$ be the element $c_{\alpha m}$ considered as having degree $km - \deg f_\alpha$ *in $S^\natural$*; we then have, in $S^\natural$, that $g^m = \sum_\alpha c'_{\alpha m} f^\natural_\alpha$, which finishes the proof.

□

(8.2.11). Consider the graded S_0-algebra

(8.2.11.1) $$S^\natural \otimes_S S_0 = S^\natural / S_+ S^\natural = \bigoplus_{n \geqslant 0} S_{[n]} / S_+ S_{[n]}.$$

Since S_n is a quotient S_0-module of $S_{[n]}/S_+S_{[n]}$, there is a canonical homomorphism of graded S_0-algebras

(8.2.11.2) $$S^\natural \otimes_S S_0 \longrightarrow S$$

which is clearly *surjective*, and thus corresponds (2.9.2) to a canonical *closed immersion*

(8.2.11.3) $$\operatorname{Proj}(S) \longrightarrow \operatorname{Proj}(S^\natural \otimes_S S_0).$$

II | 161

Proposition (8.2.12). — *The canonical morphism (8.2.11.3) is bijective. For the homomorphism (8.2.11.2) to be (TN)-bijective, it is necessary and sufficient for there to exist some n_0 such that $S_{n+1} = S_1 S_n$ for $n \geqslant n_0$. If this latter condition is satisfied, then (8.2.11.3) is an isomorphism; the converse is true whenever S is Noetherian.*

Proof. To prove the first claim, it suffices (2.8.3) to show that the kernel $\mathfrak{I}$ of the homomorphism (8.2.11.2) consists of *nilpotent* elements. But if $f \in S_{[n]}$ is an element whose class modulo $S_+S_{[n]}$ belongs to this kernel, then this implies that $f \in S_{[n+1]}$; then f^{n+1}, considered as an element of $S_{[n(n+1)]}$, is also an element of $S_+S_{[n(n+1)]}$, since it can be written as $f \cdot f^n$; so the class of f^{n+1} modulo $S_+S_{[n(n+1)]}$ is zero, which proves our claim. Since the hypothesis that $S_{n+1} = S_1 S_n$ for $n \geqslant n_0$ is equivalent to $S^\natural_{n+1} = S^\natural_1 S^\natural_n$ for $n \geqslant n_0$ (8.2.10, ii), this hypothesis is equivalent, by definition, to the fact that (8.2.11.2) is (TN)-injective, and thus (TN)-bijective, and so (8.2.11.3) is an isomorphism, by (2.9.1). Conversely, if (8.2.11.3) is an isomorphism, then the sheaf $\widetilde{\mathfrak{I}}$ on $\operatorname{Proj}(S^\natural \otimes_S S_0)$ is zero (2.9.2, i); since $S^\natural \otimes_S S_0$ is Noetherian, as a quotient of $S^\natural$ (8.2.10, i), we conclude from (2.7.3) that $\mathfrak{I}$ satisfies condition (TN), and so $S^\natural_{n+1} = S^\natural_1 S^\natural_n$ for $n \geqslant n_0$, and this finishes the proof, by (8.2.10, ii). □

(8.2.13). Consider now the canonical injections $(S_+)^n \to S_{[n]}$, which define an injective homomorphism of degree zero of graded rings

(8.2.13.1) $$\bigoplus_{n \geqslant 0} (S_+)^n \longrightarrow S^\natural.$$

Proposition (8.2.14). — *For the homomorphism (8.2.13.1) to be a (TN)-isomorphism, it is necessary and sufficient for there to exist some n_0 such that $S_n = S_1^n$ for all $n \geqslant n_0$. Whenever this is the case, the morphism corresponding to (8.2.13.1) is everywhere defined and is an isomorphism*

$$\operatorname{Proj}(S^\natural) \xrightarrow{\sim} \operatorname{Proj}(\bigoplus_{n \geqslant 0} (S_+)^n);$$

the converse is true whenever S is Noetherian.

Proof. The first two claims are evident, given (8.2.10, iii) and (2.9.1). The third will follow from (8.2.10, i and iii) and the following lemma:

Lemma (8.2.14.1). — *Let T be a positively-graded ring that is also a T_0-algebra of finite type. If the morphism corresponding to the injective homomorphism $\bigoplus_{n \geqslant 0} T_1^n \to T$ is everywhere defined and also an isomorphism $\operatorname{Proj}(T) \to \operatorname{Proj}(\bigoplus_{n \geqslant 0} T_1^n)$, then there exists some n_0 such that $T_n = T_1^n$ for $n \geqslant n_0$.*

Let g_i ($1 \leqslant i \leqslant r$) be generators of the T_0-module T_1. The hypothesis implies first of all that the $D_+(g_i)$ cover $\operatorname{Proj}(T)$ (2.8.1). Let $(h_j)_{1 \leqslant j \leqslant s}$ be a system of homogeneous elements of T_+, with $\deg(h_j) = n_j$, that form, with the g_i, a system of generators of the ideal T_+, or, equivalently (2.1.3), a system of generators of T as a T_0-algebra; if we set $T' = \bigoplus_{n \geqslant 0} T_1^n$, then the element $h_j / g_i^{n_j}$ of the ring $T_{(g_i)}$ must, by hypothesis, belong to the subring $T'_{(g_i)}$, and so there exists some integer k such that $T_1^k h_j \subset T_1^{k+n_j}$ for all j. We thus conclude, by induction on the exponent r, that $T_1^k h_j^r \subset T'$ for all $r \geqslant 1$, and, by definition of the h_j, we thus have that $T_1^k T \subset T'$. Also, there exists, for all j, an integer m_j such that $h_j^{m_j}$ belongs to the ideal of T generated by the g_i (2.3.14), so $h_j^{m_j} \in T_1 T$, and

$h_j^{m_j k} \in T_1^k T \subset T'$. There is thus an integer $m_0 \geqslant k$ such that $h_j^m \in T_1^{mn_j}$ for $m \geqslant m_0$. So, if q is the largest of the integers n_j, then $n_0 = qsm_0 + k$ is the required number. Indeed, an element of T_n, for $n \geqslant n_0$, is the sum of monomials belonging to $T_1^\alpha u$, where u is a product of powers of the h_j; if $\alpha \geqslant k$, then it follows from the above that $T_1^\alpha u \subset T_1^n$; in the other case, one of the exponents of the h_j is $\geqslant m_0$, so $u \in T_1^\beta v$, where $\beta \geqslant k$ and v is again a product of powers of the h_j; we can then reduce to the previous case, and so we conclude that $T_1^\alpha u \subset T_1^n$ in all cases. □ **II | 162**

Remark (8.2.15). — The condition $S_n = S_1^n$ for $n \geqslant n_0$ clearly implies that $S_{n+1} = S_1 S_n$ for $n \geqslant n_0$, but the converse is not necessarily true, even if we assume that S is Noetherian. For example, let K be a field, $A = K[\mathbf{x}]$, and $B = K[\mathbf{y}]/\mathbf{y}^2 K[\mathbf{y}]$, where $\mathbf{x}$ and $\mathbf{y}$ are indeterminates, with $\mathbf{x}$ taken to have degree 1 and $\mathbf{y}$ to have degree 2, and let $S = A \otimes_K B$, so that S is a graded algebra over K that has a basis given by the elements 1, $\mathbf{x}^n$ ($n \geqslant 1$), and $\mathbf{x}^n\mathbf{y}$ ($n \geqslant 0$). It is immediate that $S_{n+1} = S_1 S_n$ for $n \geqslant 2$, but $S_1^n = K\mathbf{x}^n$ while $S_n = K\mathbf{x}^n + K\mathbf{x}^{n-2}\mathbf{y}$ for $n \geqslant 2$.

8.3. Projecting cones

(8.3.1). Let Y be a prescheme; in all of this section, we will consider only *Y-preschemes* and *Y-morphisms*. Let $\mathscr{S}$ be a quasi-coherent *positively*-graded $\mathscr{O}_Y$-algebra; *we further assume that* $\mathscr{S}_0 = \mathscr{O}_Y$. Following the notation introduced in (8.2.2), we let

$$\widehat{\mathscr{S}} = \mathscr{S}[\mathbf{z}] = \mathscr{S} \otimes_{\mathscr{O}_Y} \mathscr{O}_Y[\mathbf{z}] \tag{8.3.1.1}$$

which we consider as a positively-graded $\mathscr{O}_Y$-algebra by defining the degrees as in (8.2.2.2), so that, for every affine open subset U of Y, we have

$$\Gamma(U, \widehat{\mathscr{S}}) = (\Gamma(U, \mathscr{S}))[\mathbf{z}].$$

In what follows, we write

$$X = \operatorname{Proj}(\mathscr{S}), \quad C = \operatorname{Spec}(\mathscr{S}), \quad \widehat{C} = \operatorname{Proj}(\widehat{\mathscr{S}}) \tag{8.3.1.2}$$

(where, in the definition of C, we consider $\mathscr{S}$ as a non-graded $\mathscr{O}_Y$-algebra), and we say that C (resp. $\widehat{C}$) is the *affine cone* (resp. *projective cone*) defined by $\mathscr{S}$; we will sometimes say "cone" instead of "affine cone". By an abuse of language, we also say that C (resp. $\widehat{C}$) is the *affine projecting cone of X* (resp. the *projective projecting cone of X*), with the implicit understanding that the prescheme X is given in the form $\operatorname{Proj}(\mathscr{S})$; finally, we say that $\widehat{C}$ is the *projective closure* of C (with the data of $\mathscr{S}$ being implicit in the structure of C).

Proposition (8.3.2). — *There exist canonical Y-morphisms*

$$Y \xrightarrow{\varepsilon} C \xrightarrow{i} \widehat{C} \tag{8.3.2.1}$$

$$X \xrightarrow{j} \widehat{C} \tag{8.3.2.2}$$

such that ε and j are closed immersions, and i is an affine morphism, which is a dominant open immersion, for which **II | 163**

$$i(C) = \widehat{C} - j(X); \tag{8.3.2.3}$$

furthermore, $\widehat{C}$ is the smallest closed subprescheme of $\widehat{C}$ containing $i(C)$.

Proof. To define i, consider the open subset of $\widehat{C}$ given by

$$\widehat{C}_{\mathbf{z}} = \operatorname{Spec}(\widehat{\mathscr{S}}/(\mathbf{z}-1)\widehat{\mathscr{S}}) \tag{8.3.2.4}$$

(3.1.4), where $\mathbf{z}$ is canonically identified with a section of $\widehat{\mathscr{S}}$ over Y. The isomorphism $i : C \xrightarrow{\sim} \widehat{C}_{\mathbf{z}}$ then corresponds to the canonical isomorphism (8.2.3.1)

$$\widehat{\mathscr{S}}/(\mathbf{z}-1)\widehat{\mathscr{S}} \xrightarrow{\sim} \mathscr{S}.$$

The morphism ε corresponds to the augmentation homomorphism $\mathscr{S} \to \mathscr{S}_0 = \mathscr{O}_Y$, which has kernel $\mathscr{S}_+$ (1.2.7), and, since the latter is surjective, ε is a closed immersion (1.4.10). Finally, j corresponds (3.5.1) to the surjective homomorphism of degree zero $\widehat{\mathscr{S}} \to \mathscr{S}$, which restricts to the identity on $\mathscr{S}$ and is zero on $\mathbf{z}\widehat{\mathscr{S}}$, which is its kernel; j is everywhere defined, and is a closed immersion, by (3.6.2).

To prove the other claims of (8.3.2), we can clearly restrict to the case where $Y = \operatorname{Spec}(A)$ is affine, and $\mathscr{S} = \widetilde{S}$, with S a graded A-algebra, whence $\widehat{\mathscr{S}} = (\widehat{S})^{\sim}$; the homogeneous elements f of S_+ can then be identified with sections of $\widehat{\mathscr{S}}$ over Y, and the open subset of $\widehat{C}$, denoted $D_+(f)$ in (2.3.3), can then be written as $\widehat{C}_f$ (3.1.4); similarly, the open subset of C denoted $D(f)$ in (**I**, 1.1.1) can be written as C_f (**0**, 5.5.2). With this in mind, it follows from (2.3.14) and from the definition of $\widehat{S}$ that, in this case, the open subsets $\widehat{C}_{\mathbf{z}} = i(C)$ and $\widehat{C}_f$ (with f homogeneous in S_+) form a *cover* of $\widehat{C}$. Furthermore, with this notation,

$$i^{-1}(\widehat{C}_f) = C_f; \tag{8.3.2.5}$$

indeed, $\widehat{C}_f \cap i(C) = \widehat{C}_f \cap \widehat{C}_{\mathbf{z}} = \widehat{C}_{f\mathbf{z}} = \operatorname{Spec}(\widehat{S}_{(f\mathbf{z})})$. But, if $d = \deg(f)$, then $\widehat{S}_{(f\mathbf{z})}$ is canonically isomorphic to $(\widehat{S}_{(\mathbf{z})})_{f/\mathbf{z}^d}$ (2.2.2), and it follows from the definition of the isomorphism in (8.2.3.1) that the image of $(\widehat{S}_{(\mathbf{z})})_{f/\mathbf{z}^d}$ under the corresponding isomorphism of rings of fractions is exactly S_f. Since $C_f = \operatorname{Spec}(S_f)$, this proves (8.3.2.5) and shows, at the same time, that the morphism i is affine; furthermore, the restriction of i to C_f, considered as a morphism to $\widehat{C}_f$, corresponds (**I**, 1.7.3) to the canonical homomorphism $\widehat{S}_{(f)} \to \widehat{S}_{(f\mathbf{z})}$, and, by the above and (8.2.3.2), we can claim the following result:

(8.3.2.6). If $Y = \operatorname{Spec}(A)$ is affine, and $\mathscr{S} = \widetilde{S}$, then, for every homogeneous f in S_+, $\widehat{C}_f$ is canonically identified with $\operatorname{Spec}(S_f^{\leqslant})$, and the morphism $C_f \to \widehat{C}_f$ given by restricting i then corresponds to the canonical injection $S_f^{\leqslant} \to S_f$.

Now note that (for Y affine) the complement of $\widehat{C}_{\mathbf{z}}$ in $\widehat{C} = \operatorname{Proj}(\widehat{S})$ is, by definition, the set of graded prime ideals of $\widehat{S}$ containing $\mathbf{z}$, which is exactly $j(X)$, by definition of j, which proves (8.3.2.3). II | 164

Finally, to prove the last claim of (8.3.2), we can assume that Y is affine. With the above notation, note that, in the ring $\widehat{S}$, $\mathbf{z}$ is not a zero divisor; since the closure of $i(C)$ is $\widehat{C}$, it suffices to prove the following lemma:

Lemma (8.3.2.7). — *Let T be a positively-graded ring, $Z = \operatorname{Proj}(T)$, and g a homogeneous element of T of degree $d > 0$. If g is not a zero divisor in T, then Z is the smallest closed subprescheme of Z that contains $Z_g = D_+(g)$.*

By (**I**, 4.1.9), the question is local on Z; for every homogeneous element $h \in T_e$ ($e > 0$), it thus suffices to prove that Z_h is the smallest closed subprescheme of Z_h that contains Z_{gh}; it follows from the definitions and from (**I**, 4.3.2) that this condition is equivalent to asking for the canonical homomorphism $T_{(h)} \to T_{(gh)}$ to be *injective*. But this homomorphism can be identified with the canonical homomorphism $T_{(h)} \to (T_{(h)})_{g^e/h^d}$ (2.2.3). But since g^e is not a zero divisor in T, g^e/h^d is not a zero divisor in T_h (nor *a fortiori* in $T_{(h)}$), since the fact that $(g^e/h^d)(t/h^m) = 0$ (for $t \in T$ and $m > 0$) implies the existence of some $n > 0$ such that $h^n g^e t = 0$, whence $h^n t = 0$, and thus $t/h^m = 0$ in T_h. This thus finishes the proof (**0**, 1.2.2). □

(8.3.3). We will often identify the affine cone C with the subprescheme induced by the projective cone $\widehat{C}$ on the open subset $i(C)$ by means of the open immersion i. The closed subprescheme of C associated to the closed immersion ε is called the *vertex prescheme* of C; we also say that ε, which is a Y-section of C, is the *vertex section*, or the *zero section*, of C; we can identify Y with the vertex prescheme of C by means of ε. Also, $i \circ \varepsilon$ is a Y-section of $\widehat{C}$, and thus also a closed immersion (**I**, 5.4.6), corresponding to the canonical surjective homomorphism of degree zero $\widehat{\mathscr{S}} = \mathscr{S}[\mathbf{z}] \to \mathscr{O}_Y[\mathbf{z}]$ (3.1.7), whose kernel is $\mathscr{S}_+[\mathbf{z}] = \mathscr{S}_+\widehat{\mathscr{S}}$; the subprescheme of $\widehat{C}$ associated to this closed immersion is also called the *vertex prescheme* of $\widehat{C}$, and $i \circ \varepsilon$ the *vertex section* of $\widehat{C}$; it can be identified with Y by means of $i \circ \varepsilon$. Finally, the closed subprescheme of $\widehat{C}$ associated to j is called the *part at infinity* of $\widehat{C}$, and can be identified with X by means of j.

(8.3.4). The subpreschemes of C (resp. $\widehat{C}$) induced on the *open* subsets

$$E = C - \varepsilon(Y), \qquad \widehat{E} = \widehat{C} - i(\varepsilon(Y)) \tag{8.3.4.1}$$

are called (by an abuse of language) the *punctured affine cone* and the *punctured projective cone* (respectively) defined by $\mathscr{S}$; we note that, despite this nomenclature, E *is not necessarily affine* over Y, nor $\widehat{E}$ projective over Y (8.4.3). When we identify C with $i(C)$, we thus have the underlying spaces

$$C \cup \widehat{E} = \widehat{C}, \qquad C \cap \widehat{E} = E \tag{8.3.4.2}$$

so that $\widehat{C}$ can be considered as being obtained by *gluing* the open subpreschemes C and $\widehat{E}$; furthermore, by (8.3.2.3),

$$E = \widehat{E} - j(X). \tag{8.3.4.3}$$

If $Y = \operatorname{Spec}(A)$ is affine, then, with the notation of (8.3.2), **II** | 165

$$E = \bigcup C_f, \qquad \widehat{E} = \bigcup \widehat{C}_f, \qquad C_f = C \cap \widehat{C}_f \tag{8.3.4.4}$$

where f runs over the set of homogeneous elements of S_+ (or only a subset M of this set, with M generating an ideal of S_+ whose radical in S_+ is S_+ itself, or, equivalently, such that the X_f for $f \in M$ cover X (2.3.14)). The gluing of C and $\widehat{C}_f$ along C_f is thus determined by the injection morphisms $C_f \to C$ and $C_f \to \widehat{C}_f$, which, as we have seen (8.3.2.6), correspond (respectively) to the canonical homomorphisms $S \to S_f$ and $S_f^{\leqslant} \to S_f$.

Proposition (8.3.5). — *With the notation of* (8.3.1) *and* (8.3.4), *the morphism associated* (3.5.1) *to the canonical injection $\phi : \mathscr{S} \to \widehat{\mathscr{S}} = \mathscr{S}[\mathbf{z}]$ is a surjective affine morphism (called the canonical retraction)*

$$p : \widehat{E} \longrightarrow X \tag{8.3.5.1}$$

such that

$$p \circ j = 1_X. \tag{8.3.5.2}$$

Proof. To prove the proposition, we can restrict to the case where Y is affine. Taking into account the expression in (8.3.4.4) for $\widehat{E}$, the fact that the domain of definition $G(\phi)$ of p is equal to $\widehat{E}$ will follow from the first of the following claims:

(8.3.5.3). If $Y = \operatorname{Spec}(A)$ is affine, and $\mathscr{S} = \widetilde{S}$, then, for all homogeneous $f \in S_+$,

$$p^{-1}(X_f) = \widehat{C}_f \tag{8.3.5.4}$$

and the restriction of p to $\widehat{C}_f = \operatorname{Spec}(S_f^{\leqslant})$, considered as a morphism from $\widehat{C}_f$ to X_f, corresponds to the canonical injection $S_{(f)} \to S_f^{\leqslant}$. If, further, $f \in S_1$, then $\widehat{C}_f$ is isomorphic to $X_f \otimes_{\mathbf{Z}} \mathbf{Z}[T]$ (where T is an indeterminate).

Indeed, Equation (8.3.5.4) is exactly a particular case of (2.8.1.1), and the second claim is exactly the definition of $\operatorname{Proj}(\phi)$ whenever Y is affine (2.8.1). Equation (8.3.5.2) and the surjectivity of p then follow from the fact that the composition $\mathscr{S} \to \widehat{\mathscr{S}} \to \mathscr{S}$ of the canonical homomorphisms is the identity on $\mathscr{S}$. Finally, the last claim of (8.3.5.3) follows from the fact that $S_f^{\leqslant}$ is isomorphic to $S_{(f)}[T]$ whenever $f \in S_1$ (2.2.1). □

Corollary (8.3.6). — *The restriction*

$$\pi : E \longrightarrow X \tag{8.3.6.1}$$

of p to E is a surjective affine morphism. If Y is affine and f homogeneous in S_+, then

$$\pi^{-1}(X_f) = C_f \tag{8.3.6.2}$$

and the restriction of π to C_f corresponds to the canonical injection $S_{(f)} \to S_f$. If, further, $f \in S_1$, then C_f is isomorphic to $X_f \otimes_{\mathbf{Z}} \mathbf{Z}[T, T^{-1}]$ (where T is an indeterminate).

Proof. Equation (8.3.6.2) follows immediately from (8.3.5.3) and (8.3.2.5), and shows the surjectivity of π; we have already seen that the immersion i, restricted to C_f, corresponds to the injection $S_f^{\leqslant} \to S_f$ (8.3.2). Finally, the last claim is a consequence of the fact that, for $f \in S_1$, S_f is isomorphic to $S_{(f)}[T,T^{-1}]$ (2.2.1). □ **II | 166**

Remark (8.3.7). — Whenever Y is affine, the elements of the underlying space of E are the (not-necessarily-graded) prime ideals $\mathfrak{p}$ of S not containing S_+, by definition of the immersion ε (8.3.2). For such an ideal $\mathfrak{p}$, the $\mathfrak{p} \cap S_n$ clearly satisfy the conditions of (2.1.9), and so there exists exactly one *graded* prime ideal $\mathfrak{q}$ of S such that $\mathfrak{q} \cap S_n = \mathfrak{p} \cap S_n$ for all n; the map $\pi : E \to X$ of underlying spaces can then be understood via the equation

$$\pi(\mathfrak{p}) = \mathfrak{q}. \tag{8.3.7.1}$$

Indeed, to prove this equation, it suffices to consider some homogeneous f in S_+ such that $\mathfrak{p} \in D(f)$, and to note that $\mathfrak{q}_{(f)}$ is the inverse image of $\mathfrak{p}_f$ under the injection $S_{(f)} \to S_f$.

Corollary (8.3.8). — *If $\mathscr{S}$ is generated by $\mathscr{S}_1$, then the morphisms p and π are of finite type; for all $x \in X$, the fibre $p^{-1}(x)$ is isomorphic to* $\operatorname{Spec}(k(x)[T])$*, and the fibre $\pi^{-1}(x)$ is isomorphic to* $\operatorname{Spec}(k(x)[T,T^{-1}])$.

Proof. This follows immediately from (8.3.5) and (8.3.6) by noting that, whenever Y is affine and S is generated by S_1, the X_f, for $f \in S_1$, form a cover of X (2.3.14). □

Remark (8.3.9). — The punctured affine cone corresponding to the graded $\mathscr{O}_Y$-algebra $\mathscr{O}_Y[T]$ (where T is an indeterminate) can be identified with $G_m = \operatorname{Spec}(\mathscr{O}_Y[T,T^{-1}])$, since it is exactly C_T, as we have seen in (8.3.2) (see (8.4.4) for a more general result). This prescheme is canonically endowed with the structure of a "*Y-scheme in commutative groups*". This idea will be explained in detail later on, but, for now, can be quickly summarised as follows. A Y-scheme in groups is a Y-scheme G endowed with two Y-morphisms, $p : G \times_Y G \to G$ and $s : G \to G$, that satisfy conditions formally analogous to the axioms of the composition law and the symmetry law of a group: the diagram

$$\begin{tikzcd} G \times G \times G \arrow[r, "p\times 1"] \arrow[d, "1\times p"'] & G \times G \arrow[d, "p"] \\ G \times G \arrow[r, "p"'] & G \end{tikzcd}$$

should commute ("associativity"), and there should be a condition which corresponds to the fact that, for groups, the maps

$$(x,y) \longmapsto (x,x^{-1},y) \longmapsto (x,x^{-1}y) \longmapsto x(x^{-1}y)$$

and

$$(x,y) \longmapsto (x,x^{-1},y) \longmapsto (x,yx^{-1}) \longmapsto (yx^{-1})x$$

should both reduce to $(x,y) \mapsto y$; the sequence of morphisms corresponding, for example, to the first composite map is

$$G \times G \xrightarrow{(1,s)\times 1} G \times G \times G \xrightarrow{1\times p} G \times G \xrightarrow{p} G$$

and the reader should write down the second sequence.

It is immediate (**I**, 3.4.3) that the data of a structure of a Y-scheme in groups on a Y-scheme G is equivalent to the data, for *every* Y-prescheme Z, of a *group* structure on the set $\operatorname{Hom}_Y(Z,G)$, where these structures should be such that, for every Y-morphism $Z \to Z'$, the corresponding map $\operatorname{Hom}_Y(Z',G) \to \operatorname{Hom}_Y(Z,G)$ is a group homomorphism. In the particular case of G_m that we consider here, $\operatorname{Hom}_Y(Z,G_m)$ can be identified with the set of Z-sections of $Z \times_Y G_m$ (**I**, 3.3.14), and thus with the set of Z-sections of $\operatorname{Spec}(\mathscr{O}_Z[T,T^{-1}])$; finally, the same reasoning as in (**I**, 3.3.15) shows that this set is canonically identified with the set of *invertible* elements of the ring $\Gamma(Z,\mathscr{O}_Z)$, and the group structure on this set is the structure coming from the multiplication in the ring $\Gamma(Z,\mathscr{O}_Z)$. The **II | 167** reader can verify that the morphisms p and s from above are obtained in the following way: they correspond, by (1.2.7) and (1.4.6), to the homomorphisms of $\mathscr{O}_Y$-algebras

$$\pi : \mathscr{O}_Y[T, T^{-1}] \longrightarrow \mathscr{O}_Y[T, T^{-1}, T', T'^{-1}]$$
$$\sigma : \mathscr{O}_Y[T, T^{-1}] \longrightarrow \mathscr{O}_Y[T, T^{-1}]$$

and are entirely defined by the data of $\pi(T) = TT'$ and $\sigma(T) = T^{-1}$.

With this in mind, G_m can be considered as a "*universal domain of operators*" for every *affine cone* $C = \operatorname{Spec}(\mathscr{S})$, where $\mathscr{S}$ is a quasi-coherent positively-graded $\mathscr{O}_Y$-algebra. This means that we can canonically define a Y-morphism $G_m \times_Y C \to C$ which has the formal properties of an external law of a set endowed with a group of operators; or, again, as above for schemes in groups, we can give, for every Y-prescheme Z, an external law on $\operatorname{Hom}_Y(Z, C)$, having the group $\operatorname{Hom}_Y(Z, G_m)$ as its set of operators, with the usual axioms of sets endowed with a group of operators, and a compatibility condition with respect to the Y-morphisms $Z \to Z'$. In the current case, the morphism $G_m \times_Y C \to C$ is defined by the data of a homomorphism of $\mathscr{O}_Y$-algebras $\mathscr{S} \to \mathscr{S} \otimes_{\mathscr{O}_Y} \mathscr{O}_Y[T, T^{-1}] = \mathscr{S}[T, T^{-1}]$, which associates, to each section $s_n \in \Gamma(U, \mathscr{S}_n)$ (where U is an open subset of Y), the section $s_n T^n \in \Gamma(U, \mathscr{S} \otimes_{\mathscr{O}_Y} \mathscr{O}_Y[T, T^{-1}])$.

Conversely, suppose that we are given a quasi-coherent, *a priori non-graded*, $\mathscr{O}_Y$-algebra $\mathscr{S}$, and, on $C = \operatorname{Spec}(\mathscr{S})$, a structure of a "*$Y$-scheme in sets endowed with a group of operators*" that has the Y-scheme in groups G_m as its domain of operators; then we canonically obtain a *grading* of $\mathscr{O}_Y$-algebras on $\mathscr{S}$. Indeed, the data of a Y-morphism $G_m \times_Y C \to C$ is equivalent to that of a homomorphism of $\mathscr{O}_Y$-algebras $\psi : \mathscr{S} \to \mathscr{S}[T, T^{-1}]$, which can be written as $\psi = \sum_{n \in \mathbf{Z}} \psi_n T^n$, where the $\psi_n : \mathscr{S} \to \mathscr{S}$ are homomorphisms of $\mathscr{O}_Y$-modules (with $\psi_n(s) = 0$ except for finitely many n for every section $s \in \Gamma(U, \mathscr{S})$, for any open subset U of Y). We can then prove that the axioms of sets endowed with a group of operators imply that the $\psi_n(\mathscr{S}) = \mathscr{S}_n$ define a grading (with arbitrary integer degrees) of $\mathscr{O}_Y$-algebras on $\mathscr{S}$, with the ψ_n being the corresponding projectors. We thus obtain the notion of a structure of an "*affine cone*" on every affine Y-scheme, defined in a "geometric" way without any reference to any prior grading. We will not further develop this point of view here, and we leave the **II** | 168
work of precisely formulating the definitions and results corresponding to the information given above to the reader.

8.4. Projective closure of a vector bundle

(8.4.1). Let Y be a prescheme, and $\mathscr{E}$ a quasi-coherent $\mathscr{O}_Y$-module. If we take $\mathscr{S}$ to be the graded $\mathscr{O}_Y$-algebra $\mathbf{S}_{\mathscr{O}_Y}(\mathscr{E})$, then Definition (8.3.1.1) shows that $\widehat{\mathscr{S}}$ can be identified with $\mathbf{S}_{\mathscr{O}_Y}(\mathscr{E} \oplus \mathscr{O}_Y)$. With the affine cone $\operatorname{Spec}(\mathscr{S})$ defined by $\mathscr{S}$ being, by definition, $\mathbf{V}(\mathscr{E})$, and $\operatorname{Proj}(\mathscr{S})$ being, by definition, $\mathbf{P}(\mathscr{E})$, we see that:

Proposition (8.4.2). — *The projective closure of a vector bundle $\mathbf{V}(\mathscr{E})$ on Y is canonically isomorphic to $\mathbf{P}(\mathscr{E} \oplus \mathscr{O}_Y)$, and the part at infinity of the latter is canonically isomorphic to $\mathbf{P}(\mathscr{E})$.*

Remark (8.4.3). — Take, for example, $\mathscr{E} = \mathscr{O}_Y^r$ with $r \geqslant 2$; then the punctured cones E and $\widehat{E}$ defined by $\mathscr{S}$ are neither affine nor projective over Y if $Y \neq \varnothing$. The second claim is immediate, because $\widehat{C} = \mathbf{P}(\mathscr{O}_Y^{r+1})$ is projective over Y, and the underlying spaces of E and $\widehat{E}$ are non-closed open subsets of $\widehat{C}$, and so the canonical immersions $E \to \widehat{E}$ and $\widehat{E} \to \widehat{C}$ are not projective (5.5.3); we then conclude by (5.5.5, v). Now, supposing, for example, that $Y = \operatorname{Spec}(A)$ is affine, and $r = 2$, then $C = \operatorname{Spec}(A[T_1, T_2])$, and E is then the prescheme induced by C on the open subset $D(T_1) \cup D(T_2)$; but we have already seen that the latter is not affine (**I**, 5.5.11); *a fortiori* $\widehat{E}$ cannot be affine, since E is the open subset where the section $\mathbf{z}$ over $\widehat{E}$ does not vanish (8.3.2).

However:

Proposition (8.4.4). — *If $\mathscr{L}$ is an invertible $\mathscr{O}_Y$-module, then there are canonical isomorphisms for both the punctured cones E and $\widehat{E}$ corresponding to $C = \mathbf{V}(\mathscr{L})$:*

$$\operatorname{Spec}\left(\bigoplus_{n \in \mathbf{Z}} \mathscr{L}^{\otimes n}\right) \xrightarrow{\sim} E \tag{8.4.4.1}$$

$$\mathbf{V}(\mathscr{L}^{-1}) \xrightarrow{\sim} \widehat{E}. \tag{8.4.4.2}$$

Furthermore, there exists a canonical isomorphism from the projective closure of $\mathbf{V}(\mathscr{L})$ *to the projective closure of* $\mathbf{V}(\mathscr{L}^{-1})$ *that sends the zero section (resp. the part at infinity) of the former to the part at infinity (resp. the zero section) of the latter.*

Proof. We have here that $\mathscr{S} = \bigoplus_{n\geqslant 0}\mathscr{L}^{\otimes n}$; the canonical injection

$$\mathscr{S} \longrightarrow \bigoplus_{n\in\mathbf{Z}}\mathscr{L}^{\otimes n}$$

defines a canonical dominant morphism

$$\text{(8.4.4.3)} \qquad \operatorname{Spec}\left(\bigoplus_{n\in\mathbf{Z}}\mathscr{L}^{\otimes n}\right) \longrightarrow \mathbf{V}(\mathscr{L}) = \operatorname{Spec}\left(\bigoplus_{n\geqslant 0}\mathscr{L}^{\otimes n}\right)$$

and it suffices to prove that this morphism is an isomorphism from the scheme $\operatorname{Spec}(\bigoplus_{n\in\mathbf{Z}}\mathscr{L}^{\otimes n})$ to E. Since the question is local on Y, we can assume that $Y = \operatorname{Spec}(A)$ is affine and that $\mathscr{L} = \mathscr{O}_Y$, and **II | 169** so $\mathscr{S} = (A[T])^\sim$ and $\bigoplus_{n\in\mathbf{Z}}\mathscr{L}^{\otimes n} = (A[T,T^{-1}])^\sim$. But $A[T,T^{-1}]$ is the localization $A[T]_T$ of $A[T]$, and thus (8.4.4.3) identifies $\operatorname{Spec}(\bigoplus_{n\in\mathbf{Z}}\mathscr{L}^{\otimes n})$ with the prescheme induced by $C = \mathbf{V}(\mathscr{L})$ on the open subset $D(T)$; the complement $V(T)$ of this open subset in C is the underlying space of the closed subprescheme of C defined by the ideal $TA[T]$, which is exactly the zero section of C, and so $E = D(T)$.

The isomorphism in (8.4.4.2) will be a consequence of the last claim, since $\mathbf{V}(\mathscr{L}^{-1})$ is the complement of the part at infinity of its projective closure, and $\widehat{E}$ is the complement of the zero section of the projective closure of $C = \mathbf{V}(\mathscr{L})$. But these projective closures are $\mathbf{P}(\mathscr{L}^{-1}\oplus\mathscr{O}_Y)$ and $\mathbf{P}(\mathscr{L}\oplus\mathscr{O}_Y)$ (respectively); but we can write $\mathscr{L}\oplus\mathscr{O}_Y = \mathscr{L}\otimes(\mathscr{L}^{-1}\oplus\mathscr{O}_Y)$. The existence of the desired canonical isomorphism then follows from (4.1.4), and everything reduces to showing that this isomorphism swaps the zero sections and the parts at infinity. For this, we can reduce to the case where $Y = \operatorname{Spec}(A)$ is affine, $L = Ac$, and $L^{-1} = Ac'$, with the canonical isomorphism $L\otimes L^{-1}\to A$ sending $c\otimes c'$ to the element 1 of A. Then $\mathbf{S}(L\oplus A)$ is the tensor product of $A[\mathbf{z}]$ with $\bigoplus_{n\geqslant 0}Ac^{\otimes n}$, and $\mathbf{S}(L^{-1}\oplus A)$ is the tensor product of $A[\mathbf{z}]$ with $\bigoplus_{n\geqslant 0}Ac'^{\otimes n}$, and the isomorphism defined in (4.1.4) sends $\mathbf{z}^h\otimes c'^{\otimes(n-h)}$ to the element $\mathbf{z}^{n-h}\otimes c^{\otimes h}$. But, in $\mathbf{P}(\mathscr{L}^{-1}\oplus\mathscr{O}_Y)$, the part at infinity is the set of points where the section $\mathbf{z}$ vanishes, and the zero section is the set of points where the section c' vanishes; since we have analogous definitions for $\mathbf{P}(\mathscr{L}\oplus\mathscr{O}_Y)$, the conclusion follows immediately from the above explanation. ☐

8.5. Functorial behaviour

(8.5.1). Let Y and Y' be preschemes, $q : Y'\to Y$ a morphism, and $\mathscr{S}$ (resp. $\mathscr{S}'$) a quasi-coherent *positively*-graded $\mathscr{O}_Y$-algebra (resp. quasi-coherent *positively*-graded $\mathscr{O}_{Y'}$-algebra). Consider a q-morphism of graded algebras

$$\text{(8.5.1.1)} \qquad \phi : \mathscr{S} \longrightarrow \mathscr{S}'.$$

We know (1.5.6) that this corresponds, canonically, to a morphism

$$\Phi = \operatorname{Spec}(\phi) : \operatorname{Spec}(\mathscr{S}') \longrightarrow \operatorname{Spec}(\mathscr{S})$$

such that the diagram

$$\text{(8.5.1.2)} \qquad \begin{array}{ccc} C' & \xrightarrow{\Phi} & C \\ \downarrow & & \downarrow \\ Y' & \xrightarrow[q]{} & Y \end{array}$$

commutes, where we write $C = \operatorname{Spec}(\mathscr{S})$ and $C' = \operatorname{Spec}(\mathscr{S}')$. *Suppose, further, that* $\mathscr{S}_0 = \mathscr{O}_Y$ *and* $\mathscr{S}'_0 = \mathscr{O}_{Y'}$; let $\varepsilon : Y\to C$ and $\varepsilon' : Y'\to C'$ be the canonical immersions (8.3.2); we then have a commutative diagram

(8.5.1.3)
$$\begin{tikzcd} Y' \arrow[r, "q"] \arrow[d, "\varepsilon'"'] & Y \arrow[d, "\varepsilon"] \\ C' \arrow[r, "\Phi"'] & C \end{tikzcd}$$

which corresponds to the diagram II | 170

$$\begin{tikzcd} \mathscr{S} \arrow[r, "\phi"] \arrow[d] & \mathscr{S}' \arrow[d] \\ \mathscr{O}_Y \arrow[r] & \mathscr{O}_{Y'} \end{tikzcd}$$

where the vertical arrows are the augmentation homomorphisms, and so the commutativity follows from the hypothesis that ϕ is assumed to be a homomorphism of *graded* algebras.

Proposition (8.5.2). — *If E (resp. E') is the punctured affine cone defined by $\mathscr{S}$ (resp. $\mathscr{S}'$), then $\Phi^{-1}(E) \subset E'$; if, further, $\operatorname{Proj}(\phi) : G(\phi) \to \operatorname{Proj}(\mathscr{S})$ is everywhere defined (or, equivalently, if $G(\phi) = \operatorname{Proj}(\mathscr{S}')$), then $\Phi^{-1}(E) = E'$, and conversely.*

Proof. The first claim follows from the commutativity of (8.5.1.3). To prove the second, we can restrict to the case where $Y = \operatorname{Spec}(A)$ and $Y' = \operatorname{Spec}(A')$ are affine, and $\mathscr{S} = \widetilde{S}$ and $\mathscr{S}' = \widetilde{S}'$. For every homogeneous f in S_+, writing $f' = \phi(f)$, we have that $\Phi^{-1}(C_f) = C'_{f'}$ (I, 2.2.4.1); saying that $G(\phi) = \operatorname{Proj}(S')$ implies that the radical (in S'_+) of the ideal generated by the $f' = \phi(f)$ is S'_+ itself ((2.8.1) and (2.3.14)), and this is equivalent to saying that the $C'_{f'}$ cover E' (8.3.4.4). □

(8.5.3). The q-morphism ϕ canonically extends to a q-morphism of graded algebras

(8.5.3.1)
$$\widehat{\phi} : \widehat{\mathscr{S}} \longrightarrow \widehat{\mathscr{S}'}$$

by letting $\widehat{\phi}(\mathbf{z}) = \mathbf{z}$. This induces a morphism

$$\widehat{\Phi} = \operatorname{Proj}(\widehat{\phi}) : G(\widehat{\phi}) \longrightarrow \widehat{C} = \operatorname{Proj}(\widehat{\mathscr{S}})$$

such that the diagram

$$\begin{tikzcd} G(\widehat{\phi}) \arrow[r, "\widehat{\Phi}"] \arrow[d] & \widehat{C} \arrow[d] \\ Y' \arrow[r, "q"'] & Y \end{tikzcd}$$

commutes (3.5.6). It follows immediately from the definitions that, if we write $i : C \to \widehat{C}$ and $i' : C' \to \widehat{C}'$ to mean the canonical open immersions (8.3.2), then $i'(C') \subset G(\widehat{\phi})$, and the diagram

(8.5.3.2)
$$\begin{tikzcd} C' \arrow[r, "\Phi"] \arrow[d, "i'"'] & C \arrow[d, "i"] \\ G(\widehat{\phi}) \arrow[r, "\widehat{\Phi}"'] & \widehat{C} \end{tikzcd}$$

commutes. Finally, if we let $X = \operatorname{Proj}(\mathscr{S})$ and $X' = \operatorname{Proj}(\mathscr{S}')$, and if $j : X \to \widehat{C}$ and $j' : X' \to \widehat{C}'$ are the canonical closed immersions (8.3.2), then it follows from the definition of these immersions that $j'(G(\phi)) \subset G(\widehat{\phi})$, and that the diagram II | 171

(8.5.3.3)
$$\begin{tikzcd} G(\phi) \arrow[r, "\operatorname{Proj}(\phi)"] \arrow[d, "j'"'] & X \arrow[d, "j"] \\ G(\widehat{\phi}) \arrow[r, "\widehat{\Phi}"'] & \widehat{C} \end{tikzcd}$$

commutes.

Proposition (8.5.4). — *If $\widehat{E}$ (resp. $\widehat{E}'$) is the punctured projective cone defined by $\mathscr{S}$ (resp. by $\mathscr{S}'$), then $\widehat{\Phi}^{-1}(\widehat{E}) \subset \widehat{E}'$; furthermore, if $p : \widehat{E} \to X$ and $p' : \widehat{E}' \to X'$ are the canonical retractions, then $p'(\widehat{\Phi}^{-1}(\widehat{E})) \subset G(\phi)$, and the diagram*

(8.5.4.1)
$$\begin{tikzcd} \widehat{\Phi}^{-1}(\widehat{E}) \arrow[r, "\widehat{\Phi}"] \arrow[d, "p'"'] & \widehat{E} \arrow[d, "p"] \\ G(\phi) \arrow[r, "\mathrm{Proj}(\phi)"'] & X \end{tikzcd}$$

commutes. If $\mathrm{Proj}(\phi)$ *is everywhere defined, then so too is $\widehat{\Phi}$, and we have that $\widehat{\Phi}^{-1}(\widehat{E}) = \widehat{E}'$.*

Proof. The first claim follows from the commutativity of Diagrams (8.5.1.3) and (8.5.3.2), and the two following claims from the definition of the canonical retractions (8.3.5) and the definition of $\widehat{\phi}$. To see that $\widehat{\Phi}$ is everywhere defined whenever $\mathrm{Proj}(\phi)$ is, we can restrict to the case where $Y = \mathrm{Spec}(A)$ and $Y' = \mathrm{Spec}(A')$ are affine, and where $\mathscr{S} = \widetilde{S}$ and $\mathscr{S}' = \widetilde{S}'$; the hypothesis is that, when f runs over the set of homogeneous elements of S_+, the radical in S'_+ of the ideal generated in S'_+ by the $\phi(f)$ is S'_+ itself; we thus immediately conclude that the radical in $(S'[\mathbf{z}])_+$ of the ideal generated by $\mathbf{z}$ and the $\phi(f)$ is $(S'[\mathbf{z}])_+$ itself, whence our claim; this also shows that $\widehat{E}'$ is the union of the $\widehat{C}'_{\phi(f)}$, and hence equal to $\widehat{\Phi}^{-1}(\widehat{E})$. □

Corollary (8.5.5). — *Whenever* $\mathrm{Proj}(\phi)$ *is everywhere defined, the inverse image under $\widehat{\Phi}$ of the underlying space of the part at infinity (resp. of the vertex prescheme) of $\widehat{C}$ is the underlying space of the part at infinity (resp. of the vertex prescheme) of $\widehat{C}'$.*

Proof. This follows immediately from (8.5.4) and (8.5.2), taking into account the equalities (8.3.4.1) and (8.3.4.2). □

8.6. A canonical isomorphism for punctured cones

(8.6.1). Let Y be a prescheme, $\mathscr{S}$ a quasi-coherent positively-graded $\mathscr{O}_Y$-algebra *such that* $\mathscr{S}_0 = \mathscr{O}_Y$, and let X be the Y-scheme $\mathrm{Proj}(\mathscr{S})$. We are going to apply the results of (8.5) to the case where $Y' = X$, and $q : X \to Y$ is the structure morphism; let

(8.6.1.1)
$$\mathscr{S}_X = \bigoplus_{n\in\mathbf{Z}} \mathscr{O}_X(n)$$

which is a quasi-coherent graded $\mathscr{O}_X$-algebra, with multiplication defined by means of the canonical homomorphisms (3.2.6.1) **II** | 172

$$\mathscr{O}_X(m) \otimes_{\mathscr{O}_X} \mathscr{O}_X(n) \longrightarrow \mathscr{O}_X(m+n)$$

whose associativity is ensured by the commutative diagram in (2.5.11.4). Let $\mathscr{S}'$ be the quasi-coherent positively-graded $\mathscr{O}_X$-subalgebra $\mathscr{S}_X^{\geqslant} = \bigoplus_{n\geqslant 0} \mathscr{O}_X(n)$ of $\mathscr{S}_X$.

Finally, consider the canonical q-morphism

(8.6.1.2)
$$\alpha : \mathscr{S} \longrightarrow \mathscr{S}_X^{\geqslant}$$

defined in (3.3.2.3) as a homomorphism $\mathscr{S} \to q_*(\mathscr{S}_X)$, but which clearly sends $\mathscr{S}$ to $q_*(\mathscr{S}_X^{\geqslant})$. Write

(8.6.1.3)
$$C_X = \mathrm{Spec}(\mathscr{S}_X^{\geqslant}), \quad \widehat{C}_X = \mathrm{Proj}(\mathscr{S}_X^{\geqslant}[\mathbf{z}]), \quad X' = \mathrm{Proj}(\mathscr{S}_X^{\geqslant})$$

and denote by E_X and $\widehat{E}_X$ the corresponding punctured affine and punctured projective cones (respectively); denote the canonical morphisms defined in (8.3) by $\varepsilon_X : X \to C_X$, $i_X : C_X \to \widehat{C}_X$, $j_X : X' \to \widehat{C}_X$, $p_X : \widehat{E}_X \to X'$, and $\pi_X : E_X \to X'$.

Proposition (8.6.2). — *The structure morphism $u : X' \to X$ is an* isomorphism, *and the morphism* $\mathrm{Proj}(\alpha)$ *is everywhere defined and identical to u. The morphism* $\mathrm{Proj}(\widehat{\alpha}) : \widehat{C}_X \to \widehat{C}$ *is everywhere defined, and its restrictions to $\widehat{E}_X$ and E_X are* isomorphisms *to $\widehat{E}$ and E (respectively). Finally, if we identify X' with X via u, then the morphisms p_X and π_X are identified with the structure morphisms of the X-preschemes $\widehat{E}_X$ and E_X.*

Proof. We can clearly restrict to the case where $Y = \operatorname{Spec}(A)$ is affine, and $\mathscr{S} = \widetilde{S}$; then X is the union of affine open subsets X_f, where f runs over the set of homogeneous elements of S_+, with the ring of each X_f being $S_{(f)}$. It follows from (8.2.7.1) that

$$\Gamma(X_f, \mathscr{S}_X^{\geqslant}) = S_f^{\geqslant}. \tag{8.6.2.1}$$

So $u^{-1}(X_f) = \operatorname{Proj}(S_f^{\geqslant})$. But if $f \in S_d$ ($d > 0$), then $\operatorname{Proj}(S_f^{\geqslant})$ is canonically isomorphic to $\operatorname{Proj}((S_f^{\geqslant})^{(d)})$ (2.4.7), and we also know that $(S_f^{\geqslant})^{(d)} = (S^{(d)})_f^{\geqslant}$ can be identified with $S_{(f)}[T]$ (2.2.1) by the map $T \mapsto f/1$; we thus conclude (3.1.7) that the structure morphism $u^{-1}(X_f) \to X_f$ is an isomorphism, whence the first claim. To prove the second, note that the restriction $u^{-1}(X_f) \cap G(\alpha) \to X = \operatorname{Proj}(S)$ of $\operatorname{Proj}(\alpha)$ corresponds to the canonical map $x \mapsto x/1$ from S to $S_f^{\geqslant}$ (2.6.2); we thus deduce, first of all, that $G(\alpha) = X'$, and then, taking into account the fact that $u^{-1}(X_f) = (u^{-1}(X_f))_{f/1}$, that it follows from (2.8.1.1) that the image of $u^{-1}(X_f)$ under $\operatorname{Proj}(\alpha)$ is contained in X_f, and the restriction of $\operatorname{Proj}(\alpha)$ to $u^{-1}(X_f)$, considered as a morphism to $X_f = \operatorname{Spec}(S_{(f)})$, is indeed identical to that of u. Finally, applying (8.3.5.4) to p_X instead of p, we see that $p_X^{-1}(u^{-1}(X_f)) = \operatorname{Spec}((S_f^{\geqslant})_{f/1}^{\leqslant})$, and this open subset is, by (8.5.4.1), the inverse image under $\operatorname{Proj}(\widehat{\alpha})$ of $p^{-1}(X_f) = \operatorname{Spec}(S_f^{\leqslant})$ (8.3.5.3). Taking (8.2.3.2) into account, the restriction of $\operatorname{Proj}(\widehat{\alpha})$ to $p_X^{-1}(u^{-1}(X_f))$ corresponds to the isomorphism inverse to (8.2.7.2), restricted to $S_f^{\leqslant}$, whence the third claim; the last claim is evident by definition.

We note also that it follows from the commutative diagram in (8.5.3.2) that *the restriction to C_X of $\operatorname{Proj}(\widehat{\alpha})$ is exactly the morphism* $\operatorname{Spec}(\alpha)$. □ **II** | 173

Corollary (8.6.3). — *Considered as X-schemes, $\widehat{E}_X$ is canonically isomorphic to* $\operatorname{Spec}(\mathscr{S}_X^{\leqslant})$*, and E_X to* $\operatorname{Spec}(\mathscr{S}_X)$.

Proof. Since we know that the morphisms p_X and π_X are affine ((8.3.5) and (8.3.6)), it suffices (given (1.3.1)) to prove the corollary in the case where $Y = \operatorname{Spec}(A)$ is affine and $\mathscr{S} = \widetilde{S}$. The first claim follows from the existence of the canonical isomorphisms (8.2.7.2) $(S_f^{\geqslant})_{f/1}^{\leqslant} \xrightarrow{\sim} S_f^{\leqslant}$ and from the fact that these isomorphisms are compatible with the map sending f to fg (where f and g are homogeneous in S_+). Similarly, applying (8.3.6.2) to π_X instead of π, we see that $\pi_X^{-1}(u^{-1}(X_f)) = \operatorname{Spec}((S_f^{\geqslant})_{f/1})$ for f homogeneous in S_+, and the second claim then follows from the existence of the canonical isomorphisms (8.2.7.2) $(S_f^{\geqslant})_{f/1} \xrightarrow{\sim} S_f$.

We can then say that $\widehat{C}_X$, considered as an X-scheme, is given by *gluing* the affine X-schemes $C_X = \operatorname{Spec}(\mathscr{S}_X^{\geqslant})$ and $\widehat{E}_X = \operatorname{Spec}(\mathscr{S}_X^{\leqslant})$ over X, where the intersection of the two affine X-schemes is the open subset $E_X = \operatorname{Spec}(\mathscr{S}_X)$. □

Corollary (8.6.4). — *Assume that $\mathscr{O}_X(1)$ is an invertible $\mathscr{O}_X$-module, and that $\mathscr{S}_X$ is isomorphic to $\bigoplus_{n\in\mathbf{Z}}(\mathscr{O}_X(1))^{\otimes n}$ (which will be the case, in particular, whenever $\mathscr{S}$ is generated by $\mathscr{S}_1$ ((3.2.5) and (3.2.7))). Then the punctured projective cone $\widehat{E}$ can be identified with the rank-1 vector bundle $\mathbf{V}(\mathscr{O}_X(-1))$ on X, and the punctured affine cone E with the subprescheme of this vector bundle induced on the complement of the zero section. With this identification, the canonical retraction $\widehat{E} \to X$ is identified with the structure morphism of the X-scheme $\mathbf{V}(\mathscr{O}_X(-1))$. Finally, there exists a canonical Y-morphism $\mathbf{V}(\mathscr{O}_X(1)) \to C$, whose restriction to the complement of the zero section of $\mathbf{V}(\mathscr{O}_X(1))$ is an isomorphism from this complement to the punctured affine cone E.*

Proof. If we write $\mathscr{L} = \mathscr{O}_X(1)$, then $\mathscr{S}_X^{\geqslant}$ is identical to $\mathbf{S}_{\mathscr{O}_X}(\mathscr{L})$, and so $\widehat{E}_X$ is canonically identified with $\mathbf{V}(\mathscr{L}^{-1})$, by (8.6.3), and C_X with $\mathbf{V}(\mathscr{L})$. The morphism $\mathbf{V}(\mathscr{L}) \to C$ is the restriction of $\operatorname{Proj}(\widehat{\alpha})$, and the claims of the corollary are then particular cases of (8.6.2). □

We note that the inverse image under the morphism $\mathbf{V}(\mathscr{O}_X(1)) \to C$ of the underlying space of the vertex prescheme of C is the underlying space of the zero section of $\mathbf{V}(\mathscr{O}_X(1))$ (8.5.5); but, in general, the corresponding subpreschemes of C and of $\mathbf{V}(\mathscr{O}_X(1))$ are not isomorphic. This problem will be studied below.

8.7. Blowing up projecting cones

(8.7.1). Under the conditions of (8.6.1), we have, writing $r = \mathrm{Proj}(\widehat{\alpha})$, a commutative diagram

(8.7.1.1)
$$\begin{tikzcd} X \arrow[r, "i_X \circ \varepsilon_X"] \arrow[d, "q"'] & \widehat{C}_X \arrow[d, "r"] \\ Y \arrow[r, "i \circ \varepsilon"'] & \widehat{C} \end{tikzcd}$$

by (8.5.1.3) and (8.5.3.2); furthermore, the restriction of r to the complement $\widehat{C}_X - i_X(\varepsilon_X(X))$ of the zero section is an *isomorphism* to the complement $\widehat{C} - i(\varepsilon(Y))$ of the zero section, by (8.6.2). If we suppose, to simplify things, that Y is affine and that $\mathscr{S}$ is of finite type and generated by $\mathscr{S}_1$, then X is projective over Y and $\widehat{C}_X$ is projective over X (5.5.1); hence $\widehat{C}_X$ is projective over Y (5.5.5, ii), and *a fortiori* over $\widehat{C}$ (5.5.5, v). We then have a projective Y-morphism $r : \widehat{C}_X \to \widehat{C}$ (whose restriction to C_X is a projective Y-morphism $C_X \to C$) that *contracts X to Y* and induces an *isomorphism* when restricted to the *complements of X and Y*. We thus have a connection between C_X and C, analogous to that which exists between a blow-up prescheme and the original prescheme (8.1.3). We will effectively show that C_X can be identified with the homogeneous spectrum of a graded $\mathscr{O}_C$-algebra. II | 174

(8.7.2). Keeping the notation of (8.6.1), consider, for all $n \geqslant 0$, the quasi-coherent ideal

(8.7.2.1)
$$\mathscr{S}_{[n]} = \bigoplus_{m \geqslant n} \mathscr{S}_m$$

of the graded $\mathscr{O}_Y$-algebra $\mathscr{S}$. It is clear that

(8.7.2.2)
$$\mathscr{S}_{[0]} = \mathscr{S}, \qquad \mathscr{S}_{[n]} \subset \mathscr{S}_{[m]} \qquad \text{for } m \leqslant n$$

(8.7.2.3)
$$\mathscr{S}_{[m]}\mathscr{S}_{[n]} \subset \mathscr{S}_{[m+n]}.$$

Consider the $\mathscr{O}_C$-module associated to $\mathscr{S}_{[n]}$, which is a quasi-coherent ideal of $\mathscr{O}_C = \widetilde{\mathscr{S}}$ (1.4.4)

(8.7.2.4)
$$\mathscr{I}_n = (\mathscr{S}_{[n]})^{\sim}.$$

We thus deduce, from (8.7.2.2) and (8.7.2.3), using (1.4.4) and (1.4.8.1), the analogous formulas

(8.7.2.5)
$$\mathscr{I}_0 = \mathscr{O}_C, \qquad \mathscr{I}_n \subset \mathscr{I}_m \qquad \text{for } m \leqslant n$$

(8.7.2.6)
$$\mathscr{I}_m \mathscr{I}_n \subset \mathscr{I}_{m+n}.$$

We are thus in the setting of (8.1.1), which leads us to introduce the quasi-coherent graded $\mathscr{O}_C$-algebra

(8.7.2.7)
$$\mathscr{S}^\natural = \bigoplus_{n \geqslant 0} \mathscr{I}_n = \left(\bigoplus_{n \geqslant 0} \mathscr{S}_{[n]} \right)^{\sim}.$$

Proposition (8.7.3). — *There is a canonical C-isomorphism*

(8.7.3.1)
$$h : C_X \xrightarrow{\sim} \mathrm{Proj}(\mathscr{S}^\natural).$$

Proof. Suppose first of all that $Y = \mathrm{Spec}(A)$ is affine, so that $\mathscr{S} = \widetilde{S}$, with S a positively-graded A-algebra, and $C = \mathrm{Spec}(S)$. Definition (8.2.7.4) then shows, with the notation of (8.2.6), that $\mathscr{S}^\natural = (S^\natural)^{\sim}$. To define (8.7.3.1), consider a homogeneous element $f \in S_d$ ($d > 0$) and the corresponding element $f^\natural \in S^\natural$ (8.2.6); the S-isomorphism in (8.2.7.3) then defines a C-isomorphism

(8.7.3.2)
$$\mathrm{Spec}(S_f^{\geqslant}) \xrightarrow{\sim} \mathrm{Spec}(S^\natural_{(f^\natural)}).$$

But with the notation of (8.6.2), if $v : C_X \to X$ is the structure morphism, then it follows from (8.6.2.1) that $v^{-1}(X_f) = \mathrm{Spec}(S_f^{\geqslant})$. We also have that $\mathrm{Spec}(S^\natural_{(f^\natural)}) = D_+(f^\natural)$, which means that II | 175

(8.7.3.2) defines an isomorphism $v^{-1}(X_f) \to D_+(f^\natural)$. Furthermore, if $g \in S_e$ ($e > 0$), then the diagram

$$\begin{tikzcd} v^{-1}(X_{fg}) \arrow[r, "\sim"] \arrow[d] & D_+(f^\natural g^\natural) \arrow[d] \\ v^{-1}(X_f) \arrow[r, "\sim"] & D_+(f^\natural) \end{tikzcd}$$

commutes, by definition of the isomorphism in (8.2.7.3). Finally, by definition, S_+ is generated by the homogeneous f, and so it follows from (8.2.10, iv) and from (2.3.14) that the $D_+(f^\natural)$ form a cover of $\operatorname{Proj}(S^\natural)$, and that the $v^{-1}(X_f)$ form a cover of C_X, since the X_f form a cover of X; in this case, we have thus defined the isomorphism (8.7.3.1).

To prove (8.7.3) in the general case, it suffices to show that, if U and U' are affine open subsets of Y, given by rings A and A' (respectively), and such that $U' \subset U$, then, setting $\mathscr{S}|U = \widetilde{S}$ and $\mathscr{S}|U' = \widetilde{S}'$, the diagram

(8.7.3.3)
$$\begin{tikzcd} C_{U'} \arrow[r] \arrow[d] & \operatorname{Proj}(S'^\natural) \arrow[d] \\ C_U \arrow[r] & \operatorname{Proj}(S^\natural) \end{tikzcd}$$

commutes. But S' is canonically identified with $S \otimes_A A'$, and so $S'^\natural$ is canonically identified with

$$S^\natural \otimes_S S' = S^\natural \otimes_A A';$$

thus $\operatorname{Proj}(S'^\natural) = \operatorname{Proj}(S^\natural) \times_U U'$ (2.8.10); similarly, if $X = \operatorname{Proj}(S)$ and $X' = \operatorname{Proj}(S')$, then $X' = X \times_U U'$ and $\mathscr{S}_{X'} = \mathscr{S}_X \otimes_{\mathscr{O}_U} \mathscr{O}_{U'}$ (3.5.4), or, equivalently, $\mathscr{S}_{X'} = j^*(\mathscr{S}_X)$, where j is the projection $X' \to X$. We then have, by (1.5.2), that $C_{U'} = C_U \times_X X' = C_U \times_U U'$, and the commutativity of (8.7.3.3) is immediate. □

Remark (8.7.4). — (i) The end of the proof of (8.7.3) can be immediately generalised in the following way. Let $g : Y' \to Y$ be a morphism, $\mathscr{S}' = g^*(\mathscr{S})$, and $X' = \operatorname{Proj}(\mathscr{S}')$; then we have a commutative diagram

(8.7.4.1)
$$\begin{tikzcd} C_{X'} \arrow[r] \arrow[d] & \operatorname{Proj}(\mathscr{S}'^\natural) \arrow[d] \\ C_X \arrow[r] & \operatorname{Proj}(\mathscr{S}^\natural) \end{tikzcd}$$

Now let $\phi : \mathscr{S}'' \to \mathscr{S}$ be a homomorphism of graded $\mathscr{O}_Y$-algebras such that, if we write $X'' = \operatorname{Proj}(\mathscr{S}'')$, then $u = \operatorname{Proj}(\phi) : X \to X''$ is everywhere defined; we also have a Y-morphism $v : C \to C''$ (with $C'' = \operatorname{Spec}(\mathscr{S}'')$) such that $\mathscr{A}(v) = \phi$, and, since ϕ is a homomorphism of graded algebras, ϕ induces a v-morphism of graded algebras $\psi : \mathscr{S}''^\natural \to \mathscr{S}^\natural$ (1.4.1). Furthermore, it follows from (8.2.10, iv) and from the hypothesis on ϕ that $\operatorname{Proj}(\psi)$ is everywhere defined. Finally, taking (3.5.6.1) into account, there is a canonical u-morphism $\mathscr{S}_{X''} \to \mathscr{S}_X$, whence (1.5.6) a morphism $w : C_{X''} \to C_X$. With this in mind, the diagram **II | 176**

(8.7.4.2)
$$\begin{tikzcd} C_{X''} \arrow[r, "\sim"] \arrow[d, "w"'] & \operatorname{Proj}(\mathscr{S}''^\natural) \arrow[d, "\operatorname{Proj}(\psi)"] \\ C_X \arrow[r, "\sim"] & \operatorname{Proj}(\mathscr{S}^\natural) \end{tikzcd}$$

is commutative, as we can immediately verify by restricting to the case where Y is affine.

(ii) Note that, by (8.7.2.5) and (8.7.2.6), we have $\mathscr{I}_1^m \subset \mathscr{I}_m \subset \mathscr{I}_1$ for all $m > 0$. But, by definition, $\mathscr{I}_1 = (\mathscr{S}_+)^\sim$, and so $\mathscr{I}_1$ defines the closed subprescheme $\varepsilon(Y)$ in C ((1.4.10) and (8.3.2)); we thus conclude that, for all $m > 0$, *the support of $\mathscr{O}_C/\mathscr{I}_m$ is contained in the underlying space of the vertex prescheme $\varepsilon(Y)$*; on the inverse image of the punctured affine cone E, the structure morphism $\operatorname{Proj}(\mathscr{S}^\natural) \to C$ thus restricts to an *isomorphism* (by (8.7.3) and (8.7.1)).

Furthermore, by canonically identifying C with an open subset of $\widehat{C}$ (8.3.3), we can clearly extend the ideals $\mathscr{I}_m$ of $\mathscr{O}_C$ to ideals $\mathscr{J}_m$ of $\mathscr{O}_{\widehat{C}}$, by asking them to agree with $\mathscr{O}_{\widehat{C}}$ on the open subset $\widehat{E}$ of $\widehat{C}$. If we define $\mathscr{T} = \bigoplus_{n\geqslant 0} \mathscr{J}_n$, which is a quasi-coherent graded $\mathscr{O}_{\widehat{C}}$-algebra, we can extend the isomorphism (8.7.3.1) to a $\widehat{C}$-isomorphism

$$\widehat{C}_X \xrightarrow{\sim} \mathrm{Proj}(\mathscr{T}). \tag{8.7.4.3}$$

Indeed, over $\widehat{E}$, it follows from the above that $\mathrm{Proj}(\mathscr{T})$ is canonically identified with $\widehat{E}$, and we thus define the isomorphism (8.7.4.3) over $\widehat{E}$ by asking for it to agree with the canonical isomorphism $\widehat{E}_X \to \widehat{E}$ (8.6.2); it is clear that this isomorphism and (8.7.3.1) then agree over E.

Corollary (8.7.5). — *Suppose that there exists some $n_0 > 0$ such that*

$$\mathscr{S}_{n+1} = \mathscr{S}_1\mathscr{S}_n \qquad \text{for } n \geqslant n_0. \tag{8.7.5.1}$$

Then the vertex subprescheme of C_X (isomorphic to X) is the inverse image under the canonical morphism $r : C_X \to C$ of the vertex subprescheme of C (isomorphic to Y). Conversely, if this property is true, and if we further assume that Y is Noetherian and that $\mathscr{S}$ is of finite type, then there exists some $n_0 > 0$ such that (8.7.5.1) holds true.

Proof. Since the first claim is local on Y, we can assume that $Y = \mathrm{Spec}(A)$ is affine, so that $\mathscr{S} = \widetilde{S}$, with S a positively-graded A-algebra. The claim then follows from (8.2.12), since $\mathrm{Proj}(S^\natural \otimes_S S_0) = C_X \times_C \varepsilon(Y)$ (by the identification in (8.7.3.1)), or, in other words, since this prescheme is the inverse image of $\varepsilon(Y)$ in C_X (**I**, 4.4.1). The converse also follows from (8.2.12) whenever Y is Noetherian affine and S is of finite type. If Y is Noetherian (but not necessarily affine) and $\mathscr{S}$ is of finite type, **II** | 177
then there exists a finite cover of Y by Noetherian affine open subsets U_i, and we then deduce from the above that, for all i, there exists an integer n_i such that $\mathscr{S}_{n+1}|U_i = (\mathscr{S}_1|U_i)(\mathscr{S}_n|U_i)$ for $n \geqslant n_i$; the largest of the n_i then ensures that (8.7.5.1) holds true. ☐

(8.7.6). Now consider the C-prescheme Z given by *blowing up* the *vertex subprescheme* $\varepsilon(Y)$ in the affine cone C; by Definition (8.1.3), it is exactly the prescheme $\mathrm{Proj}(\bigoplus_{n\geqslant 0} \mathscr{S}_+^n)$; the canonical injection

$$\iota : \bigoplus_{n\geqslant 0} \mathscr{S}_+^n \longrightarrow \mathscr{S}^\natural \tag{8.7.6.1}$$

defines (by the identification in (8.7.3)) a canonical dominant C-morphism

$$G(\iota) \longrightarrow Z \tag{8.7.6.2}$$

where $G(\iota)$ is an open subset of C_X (3.5.1); note that it could be the case that $G(\iota) \neq C_X$, as shown by the example where $Y = \mathrm{Spec}(K)$, with K a field, and $\mathscr{S} = \widetilde{S}$, with $S = K[\mathbf{y}]$, where $\mathbf{y}$ is an indeterminate *of degree* 2; if R_n denotes the set $(S_+)^n$, considered as a subset of $S_{[n]} = S_n^\natural$, then $S_+^\natural$ is not the radical in $S^\natural$ of the ideal generated by the union of the R_n (cf. (2.3.14)).

Corollary (8.7.7). — *Assume that there exists some $n_0 > 0$ such that*

$$\mathscr{S}_n = \mathscr{S}_1^n \quad \text{for } n \geqslant n_0. \tag{8.7.7.1}$$

Then the canonical morphism (8.7.6.2) is everywhere defined, and is an isomorphism $C_X \xrightarrow{\sim} Z$. Conversely, if this property is true, and if we further assume that Y is Noetherian and that $\mathscr{S}$ is of finite type, then there exists some n_0 such that (8.7.7.1) holds true.

Proof. The first claim is local on Y, and thus follows from (8.2.14); the converse follows similarly, arguing as in (8.7.5). ☐

Remark (8.7.8). — Since condition (8.7.7.1) implies (8.7.5.1), we see that, whenever it holds true, not only can C_X be identified with the prescheme given by blowing up the vertex (identified with Y) of the affine cone C, but also the vertex (identified with X) of C_X can be identified with the closed subprescheme given by the inverse image of the vertex Y of C. Furthermore, hypothesis (8.7.7.1) implies that, on $X = \mathrm{Proj}(\mathscr{S})$, the $\mathscr{O}_X$-modules $\mathscr{O}_X(n)$ are invertible ((3.2.5) and (3.2.9)), and that $\mathscr{O}_X(n) = \mathscr{L}^{\otimes n}$ with $\mathscr{L} = \mathscr{O}_X(1)$ ((3.2.7) and (3.2.9)); by Definition (8.6.1.1), C_X is thus the *vector bundle* $\mathbf{V}(\mathscr{L})$ on X, and its vertex is the *zero section* of this vector bundle.

8.8. Ample sheaves and contractions

(8.8.1). Let Y be a prescheme, $f : X \to Y$ a *separated* and *quasi-compact* morphism, and $\mathscr{L}$ an invertible $\mathscr{O}_X$-module that is *ample relative to* f. Consider the positively-graded $\mathscr{O}_Y$-algebra

(8.8.1.1) $$\mathscr{S} = \mathscr{O}_Y \oplus \bigoplus_{n\geqslant 1} f_*(\mathscr{L}^{\otimes n})$$

which is quasi-coherent (**I**, 9.2.2, a). There is a canonical homomorphism of graded $\mathscr{O}_X$-algebras **II** | 178

(8.8.1.2) $$\tau : f^*(\mathscr{S}) \longrightarrow \bigoplus_{n\geqslant 0} \mathscr{L}^{\otimes n}$$

which, in degrees $\geqslant 1$, agrees with the canonical homomorphism $\sigma : f^*(f_*(\mathscr{L}^{\otimes n})) \to \mathscr{L}^{\otimes n}$ (**0**, 4.4.3), and is the identity in degree 0. The hypothesis that $\mathscr{L}$ is f-ample then implies ((4.6.3) and (3.6.1)) that the corresponding Y-morphism

(8.8.1.3) $$r = r_{\mathscr{L},\tau} : X \longrightarrow P = \operatorname{Proj}(\mathscr{S})$$

is everywhere defined and is a *dominant open immersion*, and that

(8.8.1.4) $$r^*(\mathscr{O}_P(n)) = \mathscr{L}^{\otimes n} \qquad \text{for all } n \in \mathbf{Z}.$$

Proposition (8.8.2). — *Let $C = \operatorname{Spec}(\mathscr{S})$ be the affine cone defined by $\mathscr{S}$; if $\mathscr{L}$ is f-ample, then there exists a canonical Y-morphism*

(8.8.2.1) $$g : V = \mathbf{V}(\mathscr{L}) \longrightarrow C$$

such that the diagram

(8.8.2.2) $$\begin{tikzcd} X \arrow[r, "j"] \arrow[d, "f"'] & \mathbf{V}(\mathscr{L}) \arrow[r, "\pi"] \arrow[d, "g"] & X \arrow[d, "f"] \\ Y \arrow[r, "\varepsilon"'] & C \arrow[r, "\psi"'] & Y \end{tikzcd}$$

commutes, where ψ and π are the structure morphisms, and j and ε the canonical immersions sending X and Y (respectively) to the zero section of $\mathbf{V}(\mathscr{L})$ and the vertex prescheme of C (respectively). Furthermore, the restriction of g to $\mathbf{V}(\mathscr{L}) - j(X)$ is an open immersion

(8.8.2.3) $$\mathbf{V}(\mathscr{L}) - j(X) \longrightarrow E = C - \varepsilon(Y)$$

into the punctured affine cone E corresponding to $\mathscr{S}$.

Proof. With the notation of (8.8.1), let $\mathscr{S}_P^{\geqslant} = \bigoplus_{n\geqslant 0} \mathscr{O}_P(n)$ and $C_P = \operatorname{Spec}(\mathscr{S}_P^{\geqslant})$. We know (8.6.2) that there is a canonical morphism $h = \operatorname{Spec}(\alpha) : C_P \to C$ such that the diagram

(8.8.2.4) $$\begin{tikzcd} C_P \arrow[r] \arrow[d, "h"'] & P \arrow[d, "p"] \\ C \arrow[r, "\psi"'] & Y \end{tikzcd}$$

commutes; furthermore, if $\varepsilon_P : P \to C_P$ is the canonical immersion, then the diagram

(8.8.2.5) $$\begin{tikzcd} P \arrow[r, "\varepsilon_P"] \arrow[d, "p"'] & C_P \arrow[d, "h"] \\ Y \arrow[r, "\varepsilon"'] & C \end{tikzcd}$$

commutes (8.7.1.1), and, finally, the restriction of h to the punctured affine cone E_P is an *isomorphism* $E_P \xrightarrow{\sim} E$ (8.6.2). It follows from (8.8.1.4) that

$$r^*(\mathscr{S}_P^{\geqslant}) = \mathbf{S}_{\mathscr{O}_X}(\mathscr{L})$$

and so we have a canonical P-morphism $q : \mathbf{V}(\mathscr{L}) \to C_P$, with the commutative diagram **II** | 179

(8.8.2.6)
$$\begin{tikzcd} \mathbf{V}(\mathscr{L}) \arrow[r, "\pi"] \arrow[d, "q"'] & X \arrow[d, "r"] \\ C_P \arrow[r] & P \end{tikzcd}$$

identifying $\mathbf{V}(\mathscr{L})$ with the product $C_P \times_P X$ (1.5.2); since r is an open immersion, so too is q (**I**, 4.3.2). Furthermore, the restriction of q to $\mathbf{V}(\mathscr{L}) - j(X)$ sends this prescheme to E_P, by (8.5.2), and the diagram

(8.8.2.7)
$$\begin{tikzcd} X \arrow[r, "j"] \arrow[d, "r"'] & \mathbf{V}(\mathscr{L}) \arrow[d, "q"] \\ P \arrow[r, "\varepsilon_P"'] & C_P \end{tikzcd}$$

is commutative (since it is a particular case of (8.5.1.3)). The claims of (8.8.2) immediately follow from these facts, by taking g to be the composite morphism $h \circ q$. □

Remark (8.8.3). — Assume further that Y is a *Noetherian* prescheme, and that f is a *proper* morphism. Since r is then *proper* (5.4.4), and thus closed, and since it is also a dominant open immersion, r is necessarily an *isomorphism* $X \xrightarrow{\sim} P$. Furthermore, we will see, in Chapter III (**III**, 2.3.5.1), that $\mathscr{S}$ is then necessarily an $\mathscr{O}_Y$-algebra *of finite type*. It then follows that $\mathscr{S}^\natural$ is an $\mathscr{S}_0^\natural$-algebra *of finite type* ((8.2.10, i) and (8.7.2.7)); since C_P is C-isomorphic to $\operatorname{Proj}(\mathscr{S}^\natural)$ (8.7.3), we see that the morphism $h : C_P \to C$ is *projective*; since the morphism r is an isomorphism, so too is $q : \mathbf{V}(\mathscr{L}) \to C_P$, and we thus conclude that the morphism $g : \mathbf{V}(\mathscr{L}) \to C$ is *projective*. Furthermore, since the restriction of h to E_P is an isomorphism to E, and since q is an isomorphism, the restriction (8.8.2.3) of g is an isomorphism $\mathbf{V}(\mathscr{L}) - j(X) \xrightarrow{\sim} E$.

If we further assume that $\mathscr{L}$ is *very ample* for f, then, as we will also see in Chapter III (**III**, 2.3.5.1), there exists some integer $n_0 > 0$ such that $\mathscr{S}_n = \mathscr{S}_1^n$ for $n \geqslant n_0$. We then conclude, by (8.7.7), that $\mathbf{V}(\mathscr{L})$ can be identified with the prescheme Z given by *blowing up the vertex prescheme* (identified with Y) *in the affine cone* C, and that the *zero section* of $\mathbf{V}(\mathscr{L})$ (identified with X) is the *inverse image* of the vertex subprescheme Y of C.

Some of the above results can in fact be proven even without the Noetherian hypothesis:

Corollary (8.8.4). — *Let Y be a prescheme (resp. a quasi-compact scheme), $f : X \to Y$ a proper morphism, and $\mathscr{L}$ an invertible $\mathscr{O}_X$-module that is ample relative to f. Then the morphism in* (8.8.2.1) *is proper (resp. projective), and its restriction* (8.8.2.3) *is an isomorphism.*

Proof. To prove that g is proper, we can restrict to the case where Y is affine, and it then suffices to consider the case where Y is a quasi-compact scheme. The same arguments as in (8.8.3) first of all show that r is an *isomorphism* $X \xrightarrow{\sim} P$; then q is also an isomorphism, and, since the restriction of h to E_P is an isomorphism $E_P \xrightarrow{\sim} E$, we have already seen that (8.8.2.3) is an isomorphism. It remains only to prove that g is *projective*.

Since f is of finite type, by hypothesis, we can apply (3.8.5) to the homomorphism τ from (8.8.1.2): **II** | 180
there is an integer $d > 0$ and a quasi-coherent $\mathscr{O}_Y$-submodule $\mathscr{E}$ of finite type of $\mathscr{S}_d$ such that, if $\mathscr{S}'$ is the $\mathscr{O}_Y$-subalgebra of $\mathscr{S}$ generated by $\mathscr{E}$, and $\tau' = \tau \circ f^*(\phi)$ (where ϕ is the canonical injection $\mathscr{S}' \to \mathscr{S}$), then $r' = r_{\mathscr{L},\tau'}$ is an immersion

$$X \longrightarrow P' = \operatorname{Proj}(\mathscr{S}').$$

Furthermore, since ϕ is injective, r' is also a *dominant immersion* (3.7.6); the same argument as for r then shows that r' is a *surjective closed immersion*; since r' factors as $X \xrightarrow{r} \operatorname{Proj}(\mathscr{S}) \xrightarrow{\Phi} \operatorname{Proj}(\mathscr{S}')$, where $\Phi = \operatorname{Proj}(\phi)$, we thus conclude that Φ is also a *surjective closed immersion*. But this implies that Φ is an *isomorphism*; we can restrict to the case where $Y = \operatorname{Spec}(A)$ is affine, and $\mathscr{S} = \widetilde{S}$ and $\mathscr{S}' = \widetilde{S}'$, with S a graded A-algebra and S' a graded subalgebra of S. For every homogeneous element $t \in S'$, we have that $S'_{(t)}$ is a subring of $S_{(t)}$; if we return to the definition of $\operatorname{Proj}(\phi)$ (2.8.1), we see that it suffices to prove that, if B' is a subring of a ring B, and if the morphism $\operatorname{Spec}(B) \to \operatorname{Spec}(B')$ corresponding to the canonical injection $B' \to B$ is a closed immersion, then this morphism is necessarily an *isomorphism*; but this follows from (**I**, 4.2.3). Furthermore, $\Phi^*(\mathscr{O}_{P'}(n)) = \mathscr{O}_P(n)$ ((3.5.2, ii) and (3.5.4)), and so $r'^*(\mathscr{O}_{P'}(n))$ is isomorphic to $\mathscr{L}^{\otimes n}$ (4.6.3). Let $\mathscr{S}'' = \mathscr{S}'^{(d)}$, so that (3.1.8, i) X is canonically identified with $P'' = \operatorname{Proj}(\mathscr{S}'')$, and $\mathscr{L}'' = \mathscr{L}^{\otimes d}$ with $\mathscr{O}_{P''}(1)$ (3.2.9, ii).

Now, if $C'' = \operatorname{Spec}(\mathscr{S}'')$, then $\mathscr{S}_{P''}^{\geqslant} = \bigoplus_{n\geqslant 0} \mathscr{O}_{P''}(n)$ can be identified with $\bigoplus_{n\geqslant 0} \mathscr{L}''^{\otimes n}$, and thus $C_{P''} = \operatorname{Spec}(\mathscr{S}_{P''}^{\geqslant})$ with $\mathbf{V}(\mathscr{L}'')$; we also know (8.7.3) that $C_{P''}$ is C''-isomorphic to $\operatorname{Proj}(\mathscr{S}''^{\natural})$; by the definition of $\mathscr{S}''$, we know that $\mathscr{S}''^{\natural}$ is generated by $\mathscr{S}_1''^{\natural}$, and that $\mathscr{S}_1''^{\natural}$ is of finite type over $\mathscr{S}_0''^{\natural} = \mathscr{S}''$ ((8.2.10, i and iii)), and so $\operatorname{Proj}(\mathscr{S}''^{\natural})$ is *projective* over C'' (5.5.1). Consider the diagram

(8.8.4.1)
$$\begin{tikzcd} \mathbf{V}(\mathscr{L}) \arrow[r, "g"] \arrow[d, "u"'] & \operatorname{Spec}(\mathscr{S}) = C \arrow[d, "v"] \\ \mathbf{V}(\mathscr{L}'') \arrow[r, "g''"'] & \operatorname{Spec}(\mathscr{S}'') = C'' \end{tikzcd}$$

where g and g'' correspond, by (1.5.6), to the canonical f-morphisms

$$\mathscr{S} \longrightarrow \bigoplus_{n\geqslant 0} \mathscr{L}^{\otimes n} \quad \text{and} \quad \mathscr{S}'' \longrightarrow \bigoplus_{n\geqslant 0} \mathscr{L}''^{\otimes n}$$

(3.3.2.3) (see (8.8.5) below), and v and u to the inclusion morphisms $\mathscr{S}'' \to \mathscr{S}$ and $\bigoplus_{n\geqslant 0} \mathscr{L}^{\otimes nd} \to \bigoplus_{n\geqslant 0} \mathscr{L}^{\otimes n}$ (respectively); it is immediate (3.3.2) that this diagram is commutative. We have just seen that g'' is a projective morphism; we also know that u is a *finite* morphism. Since the question is local on X, we can assume that X is affine of ring A, and that $\mathscr{L} = \mathscr{O}_X$; everything then reduces to noting that the ring $A[T]$ is a module of finite type over its subring $A[T^d]$ (with T an indeterminate). Since Y is a quasi-compact scheme, and since C'' is affine over Y, we know that C'' is also a quasi-compact scheme, and so $g'' \circ u$ is a projective morphism (5.5.5, ii); by commutativity of (8.8.4.1), $v \circ g$ is also **II** | 181
projective, and, since v is affine, thus separated, we finally conclude that g is projective (5.5.5, v). □

(8.8.5). Consider again the situation in (8.8.1). We will see that the morphism $g : \mathbf{V}(\mathscr{L}) \to C$ can also be defined in a way that works for any invertible (but not necessarily ample) $\mathscr{O}_X$-module $\mathscr{L}$. For this, consider the f-morphism

(8.8.5.1)
$$\tau^\flat : \mathscr{S} \longrightarrow \bigoplus_{n\geqslant 0} \mathscr{L}^{\otimes n}$$

corresponding to the morphism τ from (8.8.1.2). This induces (1.5.6) a morphism $g' : V \to C$ such that, if $\pi : V \to X$ and $\psi : C \to Y$ are the structure morphisms, the diagrams

(8.8.5.2)
$$\begin{tikzcd} X \arrow[d, "f"'] & V \arrow[l, "\pi"'] \arrow[d, "g'"] \\ Y & C \arrow[l, "\psi"'] \end{tikzcd} \qquad \begin{tikzcd} X \arrow[r, "j"] \arrow[d, "f"'] & V \arrow[d, "g'"] \\ Y \arrow[r, "\varepsilon"'] & C \end{tikzcd}$$

commute ((8.5.1.2) and (8.5.1.3)). We will show that (if we assume that $\mathscr{L}$ is f-ample) *the morphisms g and g' are identical.*

Since the question is local on Y, we can assume that $Y = \operatorname{Spec}(A)$ is affine, and (by (8.8.1.3)) identify X with an open subset of $P = \operatorname{Proj}(S)$, where $S = A \oplus \bigoplus_{n\geqslant 1} \Gamma(X, \mathscr{L}^{\otimes n})$; we then deduce, by (8.8.1.4), that $\Gamma(X, \mathscr{O}_P(n)) = \Gamma(X, \mathscr{L}^{\otimes n})$ for all $n \in \mathbf{Z}$. Taking into account the definition of $h = \operatorname{Spec}(\alpha)$, where α is the canonical p-morphism $\widetilde{S} \to \mathscr{S}_P^{\geqslant}$ (8.6.1.2), we have to show that the restriction to X of $\alpha^\sharp : p^*(\widetilde{S}) \to \mathscr{S}_P^{\geqslant}$ is identical to τ. Taking (**0**, 4.4.3) into account, it suffices to show that, if we compose the canonical homomorphism $\alpha_n : S_n \to \Gamma(P, \mathscr{O}_P(n))$ with the restriction homomorphism $\Gamma(P, \mathscr{O}_P(n)) \to \Gamma(X, \mathscr{O}_P(n)) = \Gamma(X, \mathscr{L}^{\otimes n})$, then we obtain the identity, for all $n > 0$; but this follows immediately from the definition of the algebra S and of α_n (2.6.2).

Proposition (8.8.6). — *Assume (with the notation of (8.8.5)) that, if we write $f = (f_0, \lambda)$, then the homomorphism $\lambda : \mathscr{O}_Y \to f_*(\mathscr{O}_X)$ is bijective; then:*

(i) *if we write* $g = (g_0, \mu)$, *then* $\mu : \mathscr{O}_C \to g_*(\mathscr{O}_V)$ *is an isomorphism; and*
(ii) *if* X *is integral (resp. locally integral and normal), then* C *is integral (resp. normal).*

Proof. Indeed, the f-morphism $\tau^\flat$ is then an *isomorphism*

$$\tau^\flat : \mathscr{S} = \psi_*(\mathscr{O}_C) \longrightarrow f_*(\pi_*(\mathscr{O}_V)) = \psi_*(g_*(\mathscr{O}_V))$$

and the Y-morphism g can be considered as that for which the homomorphism $\mathscr{A}(g)$ (1.1.2) is equal to $\tau^\flat$. To see that μ is an isomorphism of $\mathscr{O}_C$-modules, it suffices (1.4.2) to see that $\mathscr{A}(\mu) : \psi_*(\mathscr{O}_C) \to \psi_*(g_*(\mathscr{O}_V))$ is an isomorphism. But, by Definition (1.1.2), we have that $\mathscr{A}(\mu) = \mathscr{A}(g)$, whence the conclusion of (i).

To prove (ii), we can restrict to the case where Y is affine, and so $\mathscr{S} = \widetilde{S}$, with $S = \bigoplus_{n \geqslant 0} \Gamma(X, \mathscr{L}^{\otimes n})$; the hypothesis that X is integral implies that the ring S is integral (**I**, 7.4.4), and thus so too is C (**I**, 5.1.4). To show that C is normal, we will use the following lemma: **II** | 182

Lemma (8.8.6.1). — *Let* Z *be a normal integral prescheme. Then the ring* $\Gamma(Z, \mathscr{O}_Z)$ *is integral and integrally closed.*

Proof. It follows from (**I**, 8.2.1.1) that $\Gamma(Z, \mathscr{O}_Z)$ is the intersection, in the field of rational functions $R(Z)$, of the integrally closed rings $\mathscr{O}_z$ over all $z \in Z$. □

With this in mind, we first show that V is *locally integral* and *normal*; for this, we can restrict to the case where $X = \operatorname{Spec}(A)$ is affine, with ring A integral and integrally closed (6.3.8), and where $\mathscr{L} = \mathscr{O}_X$. Since then $V = \operatorname{Spec}(A[T])$, and $A[T]$ is integral and integrally closed [Jaf60, p. 99], this proves our claim. For every affine open subset U of C, $g^{-1}(U)$ is quasi-compact, since the morphism g is quasi-compact; since V is locally integral, the connected components of $g^{-1}(U)$ are open integral preschemes in $g^{-1}(U)$, and thus finite in number, and, since V is normal, these preschemes are also normal (6.3.8). Then $\Gamma(U, \mathscr{O}_C)$, which is equal to $\Gamma(g^{-1}(U), \mathscr{O}_V)$, by (i), is the finite direct product of integral and integrally closed rings (8.8.6.1), which proves that C is normal (6.3.4). □

8.9. Grauert's ampleness criterion: statement We intend to show that the properties proven in (8.8.2) *characterise* f-ample $\mathscr{O}_X$-modules, and, more precisely, to prove the following criterion:

Theorem (8.9.1). — (Grauert's criterion). *Let* Y *be a prescheme,* $p : X \to Y$ *a separated and quasi-compact morphism, and* $\mathscr{L}$ *an invertible* $\mathscr{O}_X$*-module. For* $\mathscr{L}$ *to be ample relative to* p*, it is necessary and sufficient for there to exist a* Y*-prescheme* C*, a* Y*-section* $\varepsilon : Y \to C$ *of* C*, and a* Y*-morphism* $q : \mathbf{V}(\mathscr{L}) \to C$*, satisfying the following properties:*

(i) *the diagram*

(8.9.1.1)
$$\begin{tikzcd} X \arrow[r, "j"] \arrow[d, "p"'] & \mathbf{V}(\mathscr{L}) \arrow[d, "q"] \\ Y \arrow[r, "\varepsilon"'] & C \end{tikzcd}$$

commutes, where j *is the zero section of the vector bundle* $\mathbf{V}(\mathscr{L})$*; and*
(ii) *the restriction of* q *to* $\mathbf{V}(\mathscr{L}) - j(X)$ *is a quasi-compact open immersion*

$$\mathbf{V}(\mathscr{L}) - j(X) \longrightarrow C$$

whose image does not intersect $\varepsilon(Y)$*.*

Note that, if C is *separated* over Y, we can, in condition (ii), remove the hypothesis that the open immersion is quasi-compact; to see that this property (of quasi-compactness) is in fact a consequence of the other conditions, we can restrict to the case where Y is affine, and the claim then follows from (**I**, 5.5.1, i) and (**I**, 5.5.10). We can also remove the same hypothesis if we assume that X is Noetherian, **II** | 183
since then V is also Noetherian, and the claim follows from (**I**, 6.3.5).

Corollary (8.9.2). — *If the morphism* $p : X \to Y$ *is proper, then we can, in the statement of Theorem (8.9.1), assume that* q *is proper, and replace "open immersion" by "isomorphism".*

In a more suggestive manner, we can say (whenever $p : X \to Y$ is proper) that $\mathscr{L}$ *is ample relative to* p *if and only if we can* "contract" *the zero section of the vector bundle* $\mathbf{V}(\mathscr{L})$ *to the base prescheme* Y. An important particular case is that where Y is the spectrum of a field, and where the operation of "contraction" consists in contracting the zero section of $\mathbf{V}(\mathscr{L})$ *to a single point*.

(8.9.3). The necessity of the conditions in Theorem (8.9.1) and Corollary (8.9.2) follow immediately from (8.8.2) and (8.8.4).

To show that the conditions of (8.9.1) suffice, consider a slightly more general situation. For this, let (with the notation of (8.8.2))

$$\mathscr{S}' = \bigoplus_{n\geqslant 0} \mathscr{L}^{\otimes n}$$

and

$$V = \mathbf{V}(\mathscr{L}) = \operatorname{Spec}(\mathscr{S}').$$

The closed subprescheme $j(X)$, the zero section of $\mathbf{V}(\mathscr{L})$, is defined by the quasi-coherent sheaf of ideals $\mathscr{J} = (\mathscr{S}'_+)^\sim$ of $\mathscr{O}_V$ (1.4.10). This $\mathscr{O}_V$-module is *invertible*, since this property is local on X, and this reduces to remarking that the ideal $TA[T]$ in a ring of polynomials $A[T]$ is a free cyclic $A[T]$-module. Furthermore, it is immediate (again, because the question is local on X) that

$$\mathscr{L} = j^*(\mathscr{J})$$

and

$$j_*(\mathscr{L}) = \mathscr{J}/\mathscr{J}^2.$$

Now, if

$$\pi : \mathbf{V}(\mathscr{L}) \longrightarrow X$$

is the structure morphism, then $\pi_*(\mathscr{J}) = \mathscr{S}'_+$ and $\pi_*(\mathscr{J}/\mathscr{J}^2) = \mathscr{L}$; there are thus canonical homomorphisms $\mathscr{L} \to \pi_*(\mathscr{J}) \to \mathscr{L}$, the first being the canonical injection $\mathscr{L} \to \mathscr{S}'_+$, and the second the canonical projection from $\mathscr{S}'_+$ to $\mathscr{S}'_1 = \mathscr{L}$, and their composition being the identity. We can also canonically embed $\pi_*(\mathscr{J}) = \mathscr{S}'_+ = \bigoplus_{n\geqslant 1} \mathscr{L}^{\otimes n}$ into the *product* $\prod_{n\geqslant 1} \mathscr{L}^{\otimes n} = \varprojlim_n \pi_*(\mathscr{J}/\mathscr{J}^{n+1})$ (since $\pi_*(\mathscr{J}/\mathscr{J}^{n+1}) = \mathscr{L} \oplus \mathscr{L}^{\otimes 2} \oplus \ldots \oplus \mathscr{L}^{\otimes n}$), and we thus have canonical homomorphisms

$$\mathscr{L} \longrightarrow \varprojlim \pi_*(\mathscr{J}/\mathscr{J}^{n+1}) \longrightarrow \mathscr{L} \tag{8.9.3.1}$$

whose composition is the identity.

With this in mind, the generalisation of (8.9.1) that we are going to prove is the following:

Proposition (8.9.4). — *Let Y be a prescheme, V a Y-prescheme, and X a closed subprescheme of V defined by an ideal $\mathscr{J}$ of $\mathscr{O}_V$, which is an* invertible *$\mathscr{O}_V$-module; if $j : X \to V$ is the canonical injection, then let* **II | 184** *$\mathscr{L} = j^*(\mathscr{J}) = \mathscr{J} \otimes_{\mathscr{O}_V} \mathscr{O}_X$, so that $j_*(\mathscr{L}) = \mathscr{J}/\mathscr{J}^2$. Assume that the structure morphism $p : X \to Y$ is separated and quasi-compact, and that the following conditions are satisfied:*

- (i) *there exists a Y-morphism $\pi : V \to X$ of finite type such that $\pi \circ j = 1_X$, and so $\pi_*(\mathscr{J}/\mathscr{J}^2) = \mathscr{L}$;*
- (ii) *there exists a homomorphism of $\mathscr{O}_X$-modules $\phi : \mathscr{L} \to \varprojlim \pi_*(\mathscr{J}/\mathscr{J}^{n+1})$ such that the composition*

$$\mathscr{L} \xrightarrow{\phi} \varprojlim \pi_*(\mathscr{J}/\mathscr{J}^{n+1}) \xrightarrow{\alpha} \pi_*(\mathscr{J}/\mathscr{J}^2) = \mathscr{L}$$

(where α is the canonical homomorphism) is the identity;

- (iii) *there exists a Y-prescheme C, a Y-section ε of C, and a Y-morphism $q : V \to C$ such that the diagram*

$$\begin{tikzcd} X \arrow[r, "j"] \arrow[d, "p"'] & V \arrow[d, "q"] \\ Y \arrow[r, "\varepsilon"'] & C \end{tikzcd} \tag{8.9.4.1}$$

commutes; and

- (iv) *the restriction of q to $W = V - j(X)$ is a quasi-compact open immersion into C, whose image does not intersect $\varepsilon(Y)$.*

Then $\mathscr{L}$ is ample relative to p.

8.10. Grauert's ampleness criterion: proof

Lemma (8.10.1). — *Let $\pi : V \to X$ be a morphism, $j : X \to V$ an X-section of V that is also a closed immersion, and $\mathscr{J}$ a quasi-coherent ideal of $\mathscr{O}_V$ that defines the closed subprescheme of V associated to j. Then the following all hold true.*

(i) *For all $n \geqslant 0$, $\pi_*(\mathscr{O}_V/\mathscr{J}^{n+1})$ and $\pi_*(\mathscr{J}/\mathscr{J}^{n+1})$ are quasi-coherent $\mathscr{O}_X$-modules, and $\pi_*(\mathscr{O}_V/\mathscr{J}) = \mathscr{O}_X$ and $\pi_*(\mathscr{J}/\mathscr{J}^2) = j^*(\mathscr{J})$.*

(ii) *If $X = \{\xi\} = \operatorname{Spec}(k)$, where k is a field, then $\varprojlim \pi_*(\mathscr{O}_V/\mathscr{J}^{n+1})$ is isomorphic to the separated completion of the local ring $\mathscr{O}_{j(\xi)}$ for the $\mathfrak{m}_{j(\xi)}$-adic topology.*

(iii) *Assume that $\mathscr{J}$ is an invertible $\mathscr{O}_V$-module (which implies that*

$$\mathscr{L} = j^*(\mathscr{J}) = \pi_*(\mathscr{J}/\mathscr{J}^2)$$

is an invertible $\mathscr{O}_X$-module), and that there exists a homomorphism $\phi : \mathscr{L} \to \varprojlim \pi_*(\mathscr{J}/\mathscr{J}^{n+1})$ such that the composition $\mathscr{L} \xrightarrow{\phi} \varprojlim \pi_*(\mathscr{J}/\mathscr{J}^{n+1}) \xrightarrow{\alpha} \pi_*(\mathscr{J}/\mathscr{J}^2)$ (where α is the canonical homomorphism) is the identity. If we write $\mathscr{S} = \bigoplus_{n\geqslant 0}\mathscr{L}^{\otimes n}$, then ϕ canonically induces an isomorphism of $\mathscr{O}_X$-algebras from the completion $\widehat{\mathscr{S}}$ of $\mathscr{S}$ relative to its canonical filtration (the completion being isomorphic to the product $\prod_{n\geqslant 0}\mathscr{L}^{\otimes n}$) to $\varprojlim \pi_*(\mathscr{O}_V/\mathscr{J}^{n+1})$.

Proof. Note first of all that the support of the $\mathscr{O}_V$-module $\mathscr{O}_V/\mathscr{J}^{n+1}$ is $j(X)$, and the support of $\mathscr{J}/\mathscr{J}^{n+1}$ is contained in $j(X)$. In the case of (ii), $j(X)$ is a closed point $j(\xi)$ of V, and, by definition, **II** | 185 $\pi_*(\mathscr{O}_V/\mathscr{J}^{n+1})$ is the fibre of $\mathscr{O}_V/\mathscr{J}^{n+1}$ at the point $j(\xi)$, or, equivalently, setting $C = \mathscr{O}_{j(\xi)}$, and denoting by $\mathfrak{m}$ the maximal ideal of C, the C-module $C/\mathfrak{m}^{n+1}$; claim (ii) is then evident.

To prove (i), note that the question is local on X; we can thus restrict to the case where X is affine. Let U be an affine open subset of V; then $j(X)\cap U$ is an affine open subset of $j(X)$, so $U_0 = \pi(j(X)\cap U)$, which is isomorphic to it, is an affine open subset of X; for every affine open subset $W_0 \subset U_0$ in X, $W = \pi^{-1}(W_0)\cap U$ is an affine open subset of V, since X is a scheme (**I**, 5.5.10); in particular, $U' = U \cap \pi^{-1}(U_0)$ is an affine open subset of V, and clearly $\pi(U') = U_0$ and $j(U_0) = j(X)\cap U$. Then, by definition, $\Gamma(W_0, \pi_*(\mathscr{O}_V/\mathscr{J}^{n+1})) = \Gamma(\pi^{-1}(W_0), \mathscr{O}_V/\mathscr{J}^{n+1})$; but since every point of $\pi^{-1}(W_0)$ not belonging to $j(W_0)$ has an open neighbourhood in $\pi^{-1}(W_0)$ not intersecting $j(X)$, and in which $\mathscr{O}_V/\mathscr{J}^{n+1}$ is thus zero, it is clear that the sections of $\mathscr{O}_V/\mathscr{J}^{n+1}$ over $\pi^{-1}(W_0)$ and over W are in bijective correspondence. In other words, if π' is the restriction of π to U', then the $(\mathscr{O}_X|U_0)$-modules $\pi_*(\mathscr{O}_V/\mathscr{J}^{n+1})|U_0$ and $\pi'_*((\mathscr{O}_V/\mathscr{J}^{n+1})|U')$ are identical. Since U' and U_0 are affine, and since the U_0 cover X, we thus conclude (**I**, 1.6.3) that $\pi_*(\mathscr{O}_V/\mathscr{J}^{n+1})$ is quasi-coherent, and the proof is identical for $\pi_*(\mathscr{J}/\mathscr{J}^{n+1})$.

Finally, to prove (iii), note that $\mathscr{S}$ is exactly $\mathbf{S}_{\mathscr{O}_X}(\mathscr{L})$; so ϕ canonically induces a homomorphism of $\mathscr{O}_X$-algebras $\psi : \mathscr{S} \to \varprojlim \pi_*(\mathscr{O}_V/\mathscr{J}^{n+1})$ (1.7.4); furthermore, this homomorphism sends $\mathscr{L}^{\otimes n}$ to $\varprojlim_m \pi_*(\mathscr{J}^n/\mathscr{J}^{m+1})$, and is thus continuous for the topologies considered, and indeed then extends to a homomorphism $\widehat{\psi} : \widehat{\mathscr{S}} \to \varprojlim \pi_*(\mathscr{O}_V/\mathscr{J}^{n+1})$. To see that this is indeed an isomorphism, we can, as in the proof of (i), restrict to the case where $X = \operatorname{Spec}(A)$ and $V = \operatorname{Spec}(B)$ are affine, with $\mathscr{J} = \widetilde{\mathfrak{J}}$, where $\mathfrak{J}$ is an ideal of B; there is an injection $A \to B$ corresponding to π that identifies A with a subring of B complementary to $\mathfrak{J}$, and $\mathscr{L}$ (resp. $\pi_*(\mathscr{O}_V/\mathscr{J}^{n+1})$) is the quasi-coherent $\mathscr{O}_X$-module associated to the A-module $L = \mathfrak{J}/\mathfrak{J}^2$ (resp. $B/\mathfrak{J}^{n+1}$). Since $\mathscr{J}$ is an *invertible* $\mathscr{O}_V$-module, we can further assume that $\mathfrak{J} = Bt$, where t is not a zero divisor in B. From the fact that $B = A \oplus Bt$, we deduce that, for all $n > 0$,

$$B = A \oplus At \oplus At^2 \oplus \ldots \oplus At^n \oplus Bt^{n+1}$$

and so there exists a canonical A-isomorphism from the ring of formal series $A[[T]]$ to $C = \varprojlim B/\mathfrak{J}^{n+1}$ that sends T to t. We also have that $L = A\bar{t}$, where $\bar{t}$ is the class of t modulo Bt^2, and the homomorphism ϕ sends, by hypothesis, $\bar{t}$ to an element $t' \in C$ that is congruent to t modulo Ct^2. We thus deduce, by induction on n, that

$$A \oplus At' \oplus \ldots \oplus A(t')^n \oplus Ct^{n+1} = A \oplus At \oplus \ldots \oplus At^n \oplus Ct^{n+1}$$

which proves that the homomorphism $\widehat{\psi}$ does indeed correspond to an isomorphism from $\prod_{n\geqslant 0} L^{\otimes n}$ to C. □

Lemma (8.10.2). — *Under the hypotheses of Lemma (8.10.1), let $g : X' \to X$ be a morphism, write* II | 186
$V' = V \times_X X'$, and let $\pi' : V' \to X'$ and $g' : V' \to V$ be the canonical projections, so that we have the commutative diagram

$$\begin{tikzcd} V \arrow[d, "\pi"'] & V' \arrow[l, "g'"'] \arrow[d, "\pi'"] \\ X & X' \arrow[l, "g"'] \end{tikzcd}$$

Then $j' = j \times 1_{X'}$ is an X'-section of V' that is also a closed immersion, and $\mathscr{J}' = g'^*(\mathscr{J})\mathscr{O}_{V'}$ is the quasi-coherent ideal of $\mathscr{O}_{V'}$ that defines the closed subprescheme of V' associated to j'. Furthermore, $\pi'_*(\mathscr{O}_{V'}/\mathscr{J}'^{n+1}) = g^*(\pi_*(\mathscr{O}_V/\mathscr{J}^{n+1}))$. Finally, $\mathscr{J}'$ is an $\mathscr{O}_{V'}$-module that is canonically isomorphic to $g'^*(\mathscr{J})$, and is, in particular, invertible if $\mathscr{J}$ is an invertible $\mathscr{O}_V$-module.

Proof. The fact that j' is a closed immersion follows from (**I**, 4.3.1), and it is an X'-section of V' by functoriality of extension of the base prescheme. Furthermore, if Z (resp. Z') is the closed subprescheme of V (resp. V') associated to j (resp. j'), then $Z' = g'^{-1}(Z)$ (**I**, 4.3.1), and the second claim then follows from (**I**, 4.4.5). To prove the other claims, we see, as in (8.10.1), that we can restrict to the case where X, V, and X' (and thus also V') are affine; we keep the notation from the proof of (8.10.1), and let $X' = \operatorname{Spec}(A')$. Then $V' = \operatorname{Spec}(B')$, where $B' = B \otimes_A A'$, and $\mathscr{J}' = \widetilde{\mathfrak{J}}'$, where $\mathfrak{J}' = \operatorname{Im}(\mathfrak{J} \otimes_A A')$. Then $B'/\mathfrak{J}'^{n+1} = (B/\mathfrak{J}^{n+1}) \otimes_A A'$; furthermore, since $\mathfrak{J}$ is a direct factor (as an A-module) of B, $\mathfrak{J} \otimes_A A'$ is a direct factor (as an A'-module) of B', and is thus canonically identified with $\mathfrak{J}'$. □

Corollary (8.10.3). — *Assume that the hypotheses of Lemma (8.10.1) are satisfied, and assume further that π is of finite type, and that $\mathscr{J}$ is an invertible $\mathscr{O}_V$-module. Then, for all $x \in X$, the local ring at the point $j(x)$ of the fibre $\pi^{-1}(x)$ is a regular (thus integral) ring of dimension 1, whose completion is isomorphic to the formal series ring $k(x)[[T]]$ (where T is an indeterminate); furthermore, there exists exactly one irreducible component of $\pi^{-1}(x)$ that contains $j(x)$.*

Proof. Since $\pi^{-1}(x) = V \times_X \operatorname{Spec}(k(x))$, we are led, by (8.10.2), to the case where X is the spectrum of a field K. Since π is of finite type (**I**, 6.3.4, iv), $\mathscr{O}_{j(x)}$ is a Noetherian local ring, and thus separated for the $\mathfrak{m}_{j(x)}$-adic topology (**0**, 7.3.5); it follows from (8.10.1, ii and iii) that the completion of this ring is isomorphic to $K[[T]]$, and so $\mathscr{O}_{j(x)}$ is regular and of dimension 1 ([CC, p. 17-01, th. 1]); finally, since $\mathscr{O}_{j(x)}$ is integral, $j(x)$ belongs to exactly one of the (finitely many) irreducible components of $\pi^{-1}(x)$ (**I**, 5.1.4). □

Corollary (8.10.4). — *Suppose that the hypotheses of Lemma (8.10.1) are satisfied, and assume further that $\mathscr{J}$ is an invertible $\mathscr{O}_V$-module. Let $W = V - j(X)$; for every quasi-coherent ideal $\mathscr{K}$ of $\mathscr{O}_X$, let $\mathscr{K}_V = \pi^*(\mathscr{K})\mathscr{O}_V$ and $\mathscr{K}_W = \mathscr{K}_V|W$. Then $\mathscr{K}_V$ is the largest quasi-coherent ideal of $\mathscr{O}_V$ whose restriction to W is $\mathscr{K}_W$.*

Proof. Indeed, we see as in (8.10.1) that the question is local on X and V; we can thus reuse the notation from the proof of (8.10.1), with $\mathfrak{J} = Bt$, where t is not a zero divisor in B. Furthermore, we have $W = \operatorname{Spec}(B_t)$ and $\mathscr{K} = \widetilde{\mathfrak{K}}$, where $\mathfrak{K}$ is an ideal of A; whence $\pi^*(\mathscr{K})\mathscr{O}_V = (\mathfrak{K}.B)^\sim$ (**I**, 1.6.9),
$\mathscr{K}_W = (\mathfrak{K}.B_t)^\sim$, and the largest ideal of B whose canonical image in B_t is $\mathfrak{K}.B_t$ is the inverse image of II | 187
$\mathfrak{K}.B_t$, that is, the set of $s \in B$ such that, for some integer $n > 0$, we have $t^n s \in \mathfrak{K}.B$. We have to show that this last relation implies that $s \in \mathfrak{K}.B$, or again that the canonical image of t is not a zero divisor in $B/\mathfrak{K}B = (A/\mathfrak{K}) \otimes_A B$, which follows from (8.10.2) applied to $X' = \operatorname{Spec}(A/\mathfrak{K})$. □

Corollary (8.10.5). — *Suppose that the hypotheses of (8.10.3) are satisfied; let $W = V - j(X)$, x be a point of X, $\mathscr{K}$ a quasi-coherent ideal of $\mathscr{O}_X$, and z the generic point of the irreducible component of $\pi^{-1}(x)$ that contains $j(x)$ (8.10.3).*

(i) *Let g be a section of $\mathscr{O}_V$ over V such that $g|W$ is a section of $\mathscr{K}_W$ over W (using the notation from (8.10.4)). Then g is a section of $\mathscr{K}_V$; if further $g(z) \neq 0$, and if, for every integer $m > 0$, we denote by g_m^x the germ at the point x of the canonical image g_m of g in $\Gamma(X, \pi_*(\mathscr{O}_V/\mathscr{J}^{m+1}))$, then there exists an integer $m > 0$ such that the image of g_m^x in*

$$(\pi_*(\mathscr{O}_V/\mathscr{J}^{m+1}))_x \otimes_{\mathscr{O}_x} k(x)$$

is $\neq 0$.

(ii) *Suppose further that the conditions of (8.10.1, iii) are fulfilled. Then, if there exists a section g of $\mathscr{K}_V$ over V such that $g(z) \neq 0$, then there exists an integer $n \geqslant 0$ and a section f of $\mathscr{K}.\mathscr{L}^{\otimes n} = \mathscr{K} \otimes \mathscr{L}^{\otimes n} \subset \mathscr{L}^{\otimes n}$ such that $f(x) \neq 0$. If g is a section of $\mathscr{J}$, we can take $n > 0$.*

Proof.

(i) Since the ideal of $\mathscr{O}_W$ generated by $g|W$ is contained in $\mathscr{K}_W$ by hypothesis, the ideal of $\mathscr{O}_V$ generated by g is contained in $\mathscr{K}_V$ by (8.10.4), or, in other words, g is a section of $\mathscr{K}_V$. To prove the second claim of (i), we can again assume that X and V are affine, and reuse the notation from (8.10.1); the fibre $\pi^{-1}(x)$ is then affine of ring $B' = B \otimes_A k(x)$, and there exists in B' an element t' which is not a zero divisor and is such that $B' = k(x) \oplus B't'$. Since $j(x)$ is a specialisation of z and since $g(z) \neq 0$, we necessarily have that $g_{j(x)} \neq 0$. But $\mathscr{O}_{j(x)}$ is a separated local ring (8.10.3), and thus embeds into its completion, and the image of g in this completion is thus not null. But this completion is isomorphic to $\varprojlim_n (B'/B't'^{n+1})$ (8.10.3); if $g' = g \otimes 1 \in B'$, there then exists an integer m such that $g' \notin B't'^{m+1}$, or, again, the image g'_m of g' in $B'/B't'^{m+1}$ is nonzero. But since g'_m is exactly the image of g^x_m, our claim is proved.

(ii) By (8.10.1, iii), $\pi_*(\mathscr{O}_V/\mathscr{J}^{m+1})$ is isomorphic to the direct sum of the $\mathscr{L}^{\otimes k}$ for $0 \leqslant k \leqslant m$; we denote by f_k the section of $\mathscr{L}^{\otimes k}$ over X that is the component of the element of $\bigoplus_{k=0}^m \Gamma(X, \mathscr{L}^{\otimes k})$ which corresponds to g_m by this isomorphism. Choosing m as in (i), there is thus an index k such that $f_k(x) \neq 0$, by (i). To see that f_k is a section of $\mathscr{K}\mathscr{L}^{\otimes k}$, it suffices to consider, as above, the case where X and V are affine, and this follows immediately from the fact that $g \in \mathfrak{K}.B$ (with the notation from (8.10.4)). The final claim follows from the fact that the hypothesis $g \in \Gamma(V, \mathscr{J})$ implies that $f_0 = 0$.

□

(8.10.6). *Proof of* (8.9.4). The question is local on Y (4.6.4); since ε is a Y-section, we can thus replace C by an affine open neighbourhood U of a point of $\varepsilon(Y)$ such that $\varepsilon(Y) \cap U$ is closed in U. In other words, we can assume that C is affine, and that Y is a closed subprescheme of C (and thus also affine) defined by a quasi-coherent sheaf $\mathscr{I}$ of ideals of $\mathscr{O}_C$. Since p is separated and quasi-compact, **II** | 188
X is thus a quasi-compact scheme, and we are reduced to proving that $\mathscr{L}$ is *ample* (4.6.4). By criterion (4.5.2, a), we must thus prove the following: for every quasi-coherent ideal $\mathscr{K}$ of $\mathscr{O}_X$ and every point $x \in X$ not belonging to the support of $\mathscr{O}_X/\mathscr{K}$, there exists an integer $n > 0$ and a section f of $\mathscr{K} \otimes \mathscr{L}^{\otimes n}$ over X such that $f(x) \neq 0$.

For this, set

$$\mathscr{K}_V = \pi^*(\mathscr{K})\mathscr{O}_V$$
$$\mathscr{K}_W = \mathscr{K}_V|W$$

where $W = V - j(X)$; since the restriction of q to W is a quasi-compact open immersion into C, it follows from (**I**, 9.4.2) that $\mathscr{K}_W$ is the restriction to W of a quasi-coherent ideal $\mathscr{K}'_V$ of $\mathscr{O}_V$ of the form

$$\mathscr{K}'_V = q^*(\mathscr{K}_C)\mathscr{O}_V$$

where $\mathscr{K}_C$ is a quasi-coherent ideal of $\mathscr{O}_C$. Furthermore, since, by hypotheses, $q^{-1}(Y) \subset j(X)$, and since Y is defined by the ideal $\mathscr{I}$, the restriction to W of $q^*(\mathscr{I})\mathscr{O}_V$ is identical to that of $\mathscr{O}_V$, and so $\mathscr{K}_W$ is also the restriction to W of $q^*(\mathscr{I}\mathscr{K}_C)\mathscr{O}_V$, and we can thus suppose that $\mathscr{K}_C \subset \mathscr{I}$, whence

$$\mathscr{K}'_V \subset q^*(\mathscr{I})\mathscr{O}_V \subset \mathscr{J} \tag{8.10.6.1}$$

taking into account (**I**, 4.4.6) and the commutativity of (8.9.4.1). Furthermore, we deduce from (8.10.4) that

$$\mathscr{K}'_V \subset \mathscr{K}_V. \tag{8.10.6.2}$$

With this in mind, it follows from (8.10.3) that $j(x)$ belongs to exactly one irreducible component of $\pi^{-1}(x)$; let z be the generic point of this component, and let $z' = q(z)$. By (8.10.5), the proof will be finished (taking (8.10.6.1) and (8.10.6.2) into account) if we show the existence of a section g of $\mathscr{K}'_V$ over V such that $g(z) \neq 0$. But, by hypothesis, $\mathscr{K}$ has a restriction equal to that of $\mathscr{O}_X$ in an open neighbourhood of x; also, it follows from (8.10.3) that $z \neq j(x)$, and so $z \in W$, and thus

$(\mathscr{K}_W)_z = \mathscr{O}_{V,z}$, whence, by definition, $(\mathscr{K}_C)_{z'} = \mathscr{O}_{C,z'}$. Since C is affine, there is thus a section g' of $\mathscr{K}_C$ over C such that $g'(z') \neq 0$, and by taking g to be the section of $\mathscr{K}'_V$ corresponding canonically to g', we indeed have $g(z) \neq 0$, which finishes the proof.

Remark (8.10.7). — We ignore the question of whether or not condition (ii) in (8.9.4) is superfluous or not. In any case, the conclusion does not hold if we do not assume the existence of a Y-morphism $\pi : V \to X$ such that $\pi \circ j = 1_X$; we briefly point out how we can indeed construct a counterexample, whose details will not be developed until later on. We take $Y = \operatorname{Spec}(k)$, where k is a field, and $C = \operatorname{Spec}(A)$, where $A = k[T_1, T_2]$, and the Y-section ε corresponding to the augmentation homomorphism $A \to k$. We denote by C' the scheme induced by C by blowing up the closed point $a = \varepsilon(Y)$ of C; if D is the inverse image of a in C', we consider in D a closed point b, and we denote **II** | 189
by V the scheme induced by C' by blowing up b; X is the closed subprescheme of V given by the inverse image of a by the structure morphism $q : V \to C$. We now show that X is the union of two irreducible components, X_1 and X_2, where X_1 is the inverse image of b in V. It is immediate that the ideal $\mathscr{J}$ of $\mathscr{O}_V$ that defines X is again invertible, but we can show that $j^*(\mathscr{J}) = \mathscr{L}$ (where j is the canonical injection $X \to V$) is not ample, by considering the "degree" of the inverse image of $\mathscr{L}$ in X_1, which would be > 0 if $\mathscr{L}$ were ample, but which can be shown (by an elementary intersection calculation) to be equal to 0.

8.11. Uniqueness of contractions

Lemma (8.11.1). — *Let U and V be preschemes, and $h = (h_0, \lambda) : U \to V$ a surjective morphism. Suppose that*

(1) $\lambda : \mathscr{O}_V \to h_*(\mathscr{O}_U) = (h_0)_*(\mathscr{O}_U)$ is an isomorphism;

*(2) the underlying space of V can be identified with the quotient of the underlying space of U by the relation $h_0(x) = h_0(y)$ (*a condition which always holds whenever the morphism h is *open* or *closed*, or, *a fortiori* when h is *proper*.)

Then, for every prescheme W, the map

$$\operatorname{Hom}(V, W) \longrightarrow \operatorname{Hom}(U, W) \tag{8.11.1.1}$$

that, to each morphism $v = (v_0, \nu)$ from V to W, associates the morphism $u = v \circ h = (u_0, \mu)$, is a bijection from $\operatorname{Hom}(V, W)$ *to the set of u such that u_0 is constant on every fibre $h_0^{-1}(x)$.*

Proof. It is clear that, if $u = v \circ h$, so that $u_0 = v_0 \circ h_0$, then u_0 is constant on every set $h_0^{-1}(x)$. Conversely, if u has this property, we will show that there exists exactly one $v \in \operatorname{Hom}(V, W)$ such that $u = v \circ h$. The existence and uniqueness of the continuous map $v_0 : V \to W$ such that $u_0 = v_0 \circ h_0$ follows from the hypotheses, since h_0 can be identified with the canonical map from U to U/R. We can also, replacing V by some isomorphic prescheme if necessary, suppose that λ is the identity; by hypothesis, μ is then a homomorphism $\mu : \mathscr{O}_W \to (u_0)_*(\mathscr{O}_U) = (v_0)_*((h_0)_*(\mathscr{O}_U))$ such that the corresponding homomorphism $\mu^\sharp : u_0^*(\mathscr{O}_W) \to \mathscr{O}_U$ is *local* on every fibre. Since $(v_0)_*((h_0)_*(\mathscr{O}_U)) = (v_0)_*(\mathscr{O}_V)$, we necessarily have that $\nu = \mu$, and everything then reduces to showing that the corresponding homomorphism $\nu^\sharp : v_0^*(\mathscr{O}_W) \to \mathscr{O}_V$ is local on every fibre. But every $y \in V$ is of the form $h_0(x)$ for some $x \in U$; let $z = v_0(y) = u_0(x)$. Then (**0**, 3.5.5) the homomorphism $\mu_x^\sharp$ factors as

$$\mu_x^\sharp : \mathscr{O}_z \xrightarrow{\nu_y^\sharp} \mathscr{O}_y \xrightarrow{\lambda_x^\sharp} \mathscr{O}_x.$$

By hypothesis, $\lambda_x^\sharp$ and $\mu_x^\sharp$ are local homomorphisms; thus $\lambda_x^\sharp$ sends every invertible element of $\mathscr{O}_y$ to an invertible element of $\mathscr{O}_x$; if $\nu_y^\sharp$ sent a non-invertible element of $\mathscr{O}_z$ to an invertible element of $\mathscr{O}_y$, then $\mu_x^\sharp$ would send this element of $\mathscr{O}_z$ to an invertible element of $\mathscr{O}_x$, contradicting the hypothesis, whence the lemma. ☐

Corollary (8.11.2). — *Let U be an integral prescheme, and V a normal prescheme; then every morphism $h : U \to V$ that is universally closed, birational, and radicial, is also an isomorphism.*

Proof. If $h = (h_0, \lambda)$, then it follows from the hypotheses that h_0 is injective and closed, and that $h_0(U)$ is dense in V, and so h_0 is a *homeomorphism* from U to V. To prove the corollary, it will suffice **II** | 190
to show that $\lambda : \mathscr{O}_V \to (h_0)_*(\mathscr{O}_U)$ is an isomorphism: we can then apply (8.11.1), which proves that

the map (8.11.1.1) is bijective (the fibres $h_0^{-1}(x)$ each consisting of a single point); thus h will be an isomorphism. The question clearly being local on V, we can suppose that $V = \operatorname{Spec}(A)$ is affine, of an integral and integrally closed ring (8.8.6.1); h then corresponds (**I**, 2.2.4) to a homomorphism $\phi : A \to \Gamma(U, \mathscr{O}_U)$, and everything reduces to showing that ϕ is an isomorphism. But, if K is the field of fractions of A, then $\Gamma(U, \mathscr{O}_U)$ has, by hypothesis, K as its field of fractions, and A is a subring of $\Gamma(U, \mathscr{O}_U)$, with ϕ being the canonical injection (**I**, 8.2.7). Since the morphism h satisfies the hypotheses of (7.3.11), $\Gamma(U, \mathscr{O}_U)$ is a subring of the integral closure of A in K, and is thus identical to A by hypothesis. □

Remark (8.11.3). — We will see in chapter III (**III**, 4.4.11) that, whenever V is a *locally Noetherian* prescheme, every morphism $h : U \to V$ that is proper and quasi-finite (in particular, every morphism satisfying the hypotheses of (8.11.2)) is necessarily *finite*. The conclusion of (8.11.2) then follows in this case from (6.1.15).

(8.11.4). We will now see that, in Grauert's criterion, we can often prove that the prescheme C and the "contraction" q are determined in an *essentially unique* manner.

Lemma (8.11.5). — *Let Y be a prescheme, $p : X \to Y$ a proper morphism, $\mathscr{L}$ a p-ample invertible $\mathscr{O}_X$-module, C a Y-prescheme, $\varepsilon : Y \to C$ a Y-section, and $q : V = \mathbf{V}(\mathscr{L}) \to C$ a Y-morphism, all such that the diagram in (8.9.1.1) commutes. Suppose further that, if $p = (p_0, \theta)$, then $\theta : \mathscr{O}_Y \to p_*(\mathscr{O}_X)$ is an isomorphism. Let $\mathscr{S}' = \bigoplus_{n \geqslant 0} p_*(\mathscr{L}^{\otimes n})$ and $C' = \operatorname{Spec}(\mathscr{S}')$, and let $q' : \mathbf{V}(\mathscr{L}) \to C'$ be the canonical Y-morphism (8.8.5). Then there exists exactly one Y-morphism $u : C' \to C$ such that $q = u \circ q'$.*

Proof. The hypothesis on θ implies, in particular, that p is surjective; since, by (8.8.4), the restriction of q' to $\mathbf{V}(\mathscr{L}) - j(X)$ is an *isomorphism* to $C' - \varepsilon'(Y)$ (where ε' is the vertex section of C'), it follows from (8.8.4) that q' is *proper* and *surjective*; furthermore, by (8.8.6), if we let $q' = (q'_0, \tau)$, then $\tau : \mathscr{O}_{C'} \to q'_*(\mathscr{O}_V)$ is an isomorphism. We are thus in a situation where we can apply (8.11.1), and we will have proven the lemma if we show that q is constant on every fibre $q'^{-1}(z')$, where $z' \in C'$. But this condition is trivially satisfied for $z' \notin \varepsilon'(Y)$. If $z' \in \varepsilon'(Y)$, then there exists exactly one $y \in Y$ such that $z' = \varepsilon'(y)$, and, by commutativity of (8.8.5.2) and the fact that q' sends $\mathbf{V}(\mathscr{L}) - j(X)$ to $C' - \varepsilon'(Y)$, $q'^{-1}(z') = j(p^{-1}(y))$; the commutativity of the diagram in (8.9.1.1) then proves our claim. □

Corollary (8.11.6). — *Under the hypotheses of (8.11.5), suppose further that q is proper, and that the restriction of q to $\mathbf{V}(\mathscr{L}) - j(X)$ is an isomorphism to $C - \varepsilon(Y)$. Then the morphism u is universally closed, surjective, and radicial, and its restriction to $C' - \varepsilon'(Y)$ is an isomorphism to $C - \varepsilon(Y)$.*

Proof. Since q' is an isomorphism from $\mathbf{V}(\mathscr{L}) - j(X)$ to $C' - \varepsilon'(Y)$ (8.8.4), the last claim follows immediately from the fact that $q = u \circ q'$. Furthermore, the commutativity of the diagrams in (8.8.5.2) and (8.9.1.1) shows that the restriction of u to the closed subprescheme $\varepsilon'(Y)$ of C' is an isomorphism to the closed subprescheme $\varepsilon(Y)$ of C, from which we immediately deduce that, for all $z' \in \varepsilon'(Y)$, if $z = u(z')$, then u defines an isomorphism from $k(z)$ to $k(z')$. These remarks prove that u is bijective and radicial; furthermore, if $\psi : C \to Y$ and $\psi' : C' \to Y$ are the structure morphisms, then $\psi' = \psi \circ u$, and, since ψ' is separated (1.2.4), so too is u (**I**, 5.5.1, v). We have already seen, in the proof of (8.11.5), that q' is surjective; since $q = u \circ q'$ is proper, we finally conclude, from (5.4.3) and (5.4.9), that u is universally closed. □ **II** | 191

Proposition (8.11.7). — *Let Y be a prescheme, X an* integral *prescheme, $p : X \to Y$ a proper morphism, $\mathscr{L}$ a p-ample invertible $\mathscr{O}_X$-module, C a* normal *Y-prescheme, $\varepsilon : Y \to C$ a Y-section, and $q : V = \mathbf{V}(\mathscr{L}) \to C$ a Y-morphism, all such that the diagram in (8.9.1.1) commutes. Suppose further that, if $p = (p_0, \theta)$, then $\theta : \mathscr{O}_Y \to p_*(\mathscr{O}_X)$ is an isomorphism. Let $\mathscr{S}' = \bigoplus_{n \geqslant 0} p_*(\mathscr{L}^{\otimes n})$ and $C' = \operatorname{Spec}(\mathscr{S}')$, and let $q' : \mathbf{V}(\mathscr{L}) \to C'$ be the canonical Y-morphism (8.8.5). Then the unique Y-morphism $u : C' \to C$ such that $q = u \circ q'$ is an* isomorphism.

Proof. It follows from (8.8.6) that C' is integral; since u is a homeomorphism of the underlying subspaces $C' \to C$ (u being bijective and closed, by (8.11.6)), C is irreducible, thus integral, and, since the restriction of u to a non-empty open subset of C' is an isomorphism to an open subset of C, u is birational. Since C is assumed to be normal, it suffices to apply (8.11.2) to obtain the conclusion. □

Remark (8.11.8). — (i) The hypothesis that C is normal implies that X is also normal. Indeed, $C' = \operatorname{Spec}(\mathscr{S}')$ is then normal, being isomorphic to C, and integral, by (8.8.6); we thus conclude that $\operatorname{Proj}(\mathscr{S}')$ is *normal*. Indeed, the question is local on Y; if Y is affine, with $\mathscr{S}' = \widetilde{S}'$, then the ring $S' = \Gamma(C', \mathscr{O}_{C'})$ is integral and integrally closed (8.8.6.1), and so, for every homogeneous element $f \in S'_+$, the graded ring S'_f is integral and integrally closed [SZ60, t. I, p. 257 and 261], and thus so too is the ring $S'_{(f)}$ of its degree-zero terms, because the intersection of S'_f with the field of fractions of $S'_{(f)}$ is equal to $S'_{(f)}$; this proves our claim (6.3.4). Finally, since X is isomorphic to an open subprescheme of $\operatorname{Proj}(\mathscr{S}')$ (8.8.1), X is indeed normal. We can thus express (8.11.7) in the following form: *If X is integral and normal, and $p = (p_0, \theta) : X \to Y$ is a proper morphism such that $\theta : \mathscr{O}_Y \to p_*(\mathscr{O}_X)$ is an isomorphism, then, for every p-ample $\mathscr{O}_X$-module $\mathscr{L}$, there exists exactly one way of contracting the zero section of $V = \mathbf{V}(\mathscr{L})$ to obtain a normal Y-scheme C and a proper Y-morphism $q : V \to C$.*

(ii) When p is proper, the hypothesis $p_*(\mathscr{O}_X) = \mathscr{O}_Y$ can be considered as an auxiliary hypothesis, not really restricting the generality of the result. Indeed, if it is not satisfied, then it suffices to replace Y with the Y-scheme $Y' = \operatorname{Spec}(p_*(\mathscr{O}_X))$, and to consider X as a Y'-scheme. We will return to this general method in chapter III, § 4.

8.12. Quasi-coherent sheaves on projecting cones

(8.12.1). Let us use the hypotheses and notation of (8.3.1). Let $\mathscr{M}$ be a *quasi-coherent graded $\mathscr{S}$-module*; to avoid any confusion, we denote by $\widetilde{\mathscr{M}}$ the quasi-coherent $\mathscr{O}_C$-module associated to $\mathscr{M}$ **II | 192**
(1.4.3) when $\mathscr{M}$ is considered as a *non-graded* $\mathscr{S}$-module, and by $\mathscr{P}roj_0(\mathscr{M})$ the quasi-coherent $\mathscr{O}_X$-module associated to $\mathscr{M}$, $\mathscr{M}$ being considered this time as a graded $\mathscr{S}$-module (in other words, the $\mathscr{O}_X$-module denoted by $\widetilde{\mathscr{M}}$ in (3.2.2)). In addition, we set

$$\mathscr{M}_X = \mathscr{P}roj(\mathscr{M}) = \bigoplus_{n \in \mathbf{Z}} \mathscr{P}roj_0(\mathscr{M}(n)); \tag{8.12.1.1}$$

the quasi-coherent graded $\mathscr{O}_X$-algebra $\mathscr{S}_X$ being defined by (8.6.1.1), $\mathscr{P}roj(\mathscr{M})$ is equipped with a structure of a *(quasi-coherent) graded $\mathscr{S}_X$-module*, by means of the canonical homomorphisms (3.2.6.1)

$$\mathscr{O}_X(m) \otimes_{\mathscr{O}_X} \mathscr{P}roj_0(\mathscr{M}(n)) \longrightarrow \mathscr{P}roj_0(\mathscr{S}(m) \otimes_{\mathscr{S}} \mathscr{M}(n)) \longrightarrow \mathscr{P}roj_0(\mathscr{M}(m+n)), \tag{8.12.1.2}$$

the verification of the axioms of sheaves of modules being done using the commutative diagram in (2.5.11.4).

If $Y = \operatorname{Spec}(A)$ is affine, $\mathscr{S} = \widetilde{S}$, and $\mathscr{M} = \widetilde{M}$, where S is a graded A-algebra and M is a graded S-module, then, for every homogeneous element $f \in S_+$, we have

$$\Gamma(X_f, \mathscr{P}roj(\widetilde{M})) = M_f \tag{8.12.1.3}$$

by the definitions and (8.2.9.1).

Now consider the quasi-coherent graded $\widehat{\mathscr{S}}$-module

$$\widehat{\mathscr{M}} = \mathscr{M} \otimes_{\mathscr{S}} \widehat{\mathscr{S}} \tag{8.12.1.4}$$

($\widehat{\mathscr{S}}$ being defined by (8.3.1.1)); this induces a quasi-coherent graded $\mathscr{O}_{\widehat{C}}$-module $\mathscr{P}roj_0(\widehat{\mathscr{M}})$, which we will also denote by

$$\mathscr{M}^{\square} = \mathscr{P}roj_0(\widehat{\mathscr{M}}). \tag{8.12.1.5}$$

It is clear (3.2.4) that $\mathscr{M}^{\square}$ is an additive functor which is *exact* in $\mathscr{M}$, commuting with direct sums and with inductive limits.

Proposition (8.12.2). — *With the notation of (8.3.2), we have canonical functorial isomorphisms*

$$i^*(\mathscr{M}^{\square}) \xrightarrow{\sim} \widetilde{\mathscr{M}}, \quad j^*(\mathscr{M}^{\square}) \xrightarrow{\sim} \mathscr{P}roj_0(\mathscr{M}). \tag{8.12.2.1}$$

Indeed, $i^*(\mathscr{M}^{\square})$ is canonically identified with $(\widehat{\mathscr{M}}/(\mathbf{z}-1)\widehat{\mathscr{M}})^{\sim}$ on $\operatorname{Spec}(\widehat{\mathscr{S}}/(\mathbf{z}-1)\widehat{\mathscr{S}})$ by (3.2.3); the first of the canonical isomorphisms (8.12.2.1) is then immediately induced (1.4.1) by the canonical isomorphism $\widehat{\mathscr{M}}/(\mathbf{z}-1)\widehat{\mathscr{M}} \xrightarrow{\sim} \mathscr{M}$. The canonical immersion $j : X \to \widehat{C}$ corresponds to the canonical homomorphism $\widehat{\mathscr{S}} \to \mathscr{S}$ with kernel $\mathbf{z}\widehat{\mathscr{S}}$ (8.3.2); the second homomorphism (8.12.2.1) is the particular case of the canonical homomorphism (3.5.2, ii), since here we have $\widehat{\mathscr{M}} \otimes_{\widehat{\mathscr{S}}} \mathscr{S} = \mathscr{M}$; to verify that this is an isomorphism, we can *restrict to the case where $Y = \operatorname{Spec}(A)$ is affine, $\mathscr{S} = \widetilde{S}$, and $\mathscr{M} = \widetilde{M}$; by appealing to (2.8.8), the proof that, for all homogeneous f in S_+, the preceding homomorphism, restricted to X_f, restricts to an isomorphism, is then immediate.*

By an abuse of language, we again say, thanks to the existence of the first isomorphism (8.12.2.1), **II** | 193
that $\mathscr{M}^\square$ is the *projective closure* of the $\mathscr{O}_C$-module $\widetilde{\mathscr{M}}$ (it being implicit that the data of the $\mathscr{O}_C$-module $\widetilde{\mathscr{M}}$ includes the grading of the $\mathscr{S}$-module $\mathscr{M}$).

(8.12.3). With the notation of (8.3.5), we have a canonical functorial homomorphism

$$p^*(\mathscr{P}roj(\mathscr{M})) \longrightarrow \mathscr{M}^\square|\widehat{E}. \tag{8.12.3.1}$$

Indeed, this is a particular case of the homomorphism $\nu^\sharp$ defined more generally in (3.5.6). If $Y = \operatorname{Spec}(A)$ is affine, $\mathscr{S} = \widetilde{S}$, and $\mathscr{M} = \widetilde{M}$, then, by appealing to (2.8.8), the restriction of (8.12.3.1) to $p^{-1}(X_f) = \widehat{C}_f$ (for some homogeneous f in S_+) corresponds to the canonical homomorphism

$$M_{(f)} \otimes_{S_{(f)}} S_f^{\leqslant} \longrightarrow M_f^{\leqslant} \tag{8.12.3.2}$$

taking into account (8.2.3.2) and (8.2.5.2).

(8.12.4). Let us place ourselves in the settings of (8.5.1), and assume its hypotheses and keep its notation. It follows from (1.5.6) that, for every quasi-coherent graded $\mathscr{S}$-module $\mathscr{M}$, we have, on one hand, a canonical isomorphism

$$\Phi^*(\widetilde{\mathscr{M}}) \xrightarrow{\sim} (q^*(\mathscr{M}) \otimes_{q^*(\mathscr{S})} \mathscr{S}')^\sim \tag{8.12.4.1}$$

of $\mathscr{O}_{C'}$-modules; on the other hand, (3.5.6) implies the existence of a canonical $\operatorname{Proj}(\phi)$-morphism

$$\mathscr{P}roj_0(\mathscr{M}) \longrightarrow \mathscr{P}roj_0(q^*(\mathscr{M}) \otimes_{q^*(\mathscr{S})} \mathscr{S}')|G(\phi) \tag{8.12.4.2}$$

and also of a canonical $\widehat{\Phi}$-morphism

$$\mathscr{P}roj_0(\widehat{\mathscr{M}}) \longrightarrow \mathscr{P}roj_0(q^*(\widehat{\mathscr{M}}) \otimes_{q^*(\widehat{\mathscr{S}})} \widehat{\mathscr{S}'})|G(\widehat{\phi}). \tag{8.12.4.3}$$

(8.12.5). Consider now the setting of (8.6.1), with the same notation; we thus take $Y' = X$, the morphism $q : X \to Y$ being the structure morphism, and ϕ the canonical q-morphism (8.6.1.2). We then have a canonical isomorphism

$$q^*(\mathscr{M}) \otimes_{q^*(\mathscr{S})} \mathscr{S}_X^{\geqslant} \xrightarrow{\sim} \mathscr{M}_X^{\geqslant} \tag{8.12.5.1}$$

by setting $\mathscr{M}_X^{\geqslant} = \bigoplus_{n\geqslant 0} \mathscr{P}roj_0(\mathscr{M}(n))$. We can indeed restrict to the case where $Y = \operatorname{Spec}(A)$ is affine, $\mathscr{S} = \widetilde{S}$, and $\mathscr{M} = \widetilde{M}$, and define the isomorphism (8.12.5.1) on each of the affine open subsets X_f (where f is homogeneous in S_+), by verifying the compatibility with taking a homogeneous multiple of f. But the restriction to X_f of the left-hand side of (8.12.5.1) is $\widetilde{M}' = ((M \otimes_A S_{(f)}) \otimes_{S\otimes_A S_{(f)}} S_f^{\geqslant})^\sim$ by (8.6.2.1); since we have a canonical isomorphism from $M \otimes_A S_{(f)}$ to $M \otimes_S (S \otimes_A S_{(f)})$, we have an induced isomorphism from $\widetilde{M}'$ to $(M \otimes_S S_f^{\geqslant})^\sim$, and the latter is canonically isomorphic, by (8.2.9.1), to the restriction to X_f of the right-hand side of (8.12.5.1), and satisfies the required compatibility conditions. **II** | 194

Replacing $\mathscr{M}$ by $\widehat{\mathscr{M}}$, $\mathscr{S}$ by $\widehat{\mathscr{S}}$, and $\mathscr{S}_X$ by $(\mathscr{S}_X^{\geqslant})^\wedge$ in the previous argument, we similarly have a canonical isomorphism

$$q^*(\widehat{\mathscr{M}}) \otimes_{q^*(\widehat{\mathscr{S}})} (\mathscr{S}_X^{\geqslant})^\wedge \xrightarrow{\sim} (\mathscr{M}_X^{\geqslant})^\wedge. \tag{8.12.5.2}$$

If we recall (8.6.2) that the structure morphism $u : \operatorname{Proj}(\mathscr{S}_X^{\geqslant}) \to X$ is an isomorphism, then we deduce, first of all, from the above, that we have a canonical u-isomorphism

$$\mathscr{P}roj_0\mathscr{M} \xrightarrow{\sim} \mathscr{P}roj_0(\mathscr{M}_X^{\geqslant}) \tag{8.12.5.3}$$

as a particular case of (8.12.4.2). We note that, with the notation from the proof of (8.6.2), this reduces to seeing that the canonical homomorphism $M_{(f)} \otimes_{S_{(f)}} (S_f^{\geqslant})^{(d)} \to (M_f^{\geqslant})^{(d)}$ is an isomorphism whenever $f \in S_d$, which is immediate.

Secondly, the isomorphism (8.12.5.2) gives us, by this time applying (8.12.4.3) to the canonical morphism $r = \operatorname{Proj}(\widehat{\alpha}) : \widehat{C}_X \to \widehat{C}$, a canonical r-morphism

$$\mathscr{M}^{\square} \longrightarrow (\mathscr{M}_X^{\geqslant})^{\square}. \tag{8.12.5.4}$$

Recall now (8.6.2) that the restrictions of r to the punctured cones $\widehat{E}_X$ and E_X are *isomorphisms* to $\widehat{E}$ and E (respectively). Furthermore:

Proposition (8.12.6). — *The restrictions to $\widehat{E}_X$ and E_X of the canonical r-morphism (8.12.5.4) are isomorphisms*

$$\mathscr{M}^{\square}|\widehat{E} \xrightarrow{\sim} (\mathscr{M}_X^{\geqslant})^{\square}|\widehat{E}_X \tag{8.12.6.1}$$

$$\widetilde{\mathscr{M}}|E \xrightarrow{\sim} (\mathscr{M}_X^{\geqslant})^{\sim}|E_X. \tag{8.12.6.2}$$

Proof. We restrict to the case where Y is affine, as in the proof of (8.6.2) (whose notation we adopt); by reducing to definitions (2.8.8), we have to show that the canonical homomorphism

$$\widehat{M}_{(f)} \otimes_{\widehat{S}_{(f)}} (S_f^{\geqslant})^{\wedge}_{(f/1)} \longrightarrow (M \otimes_S S_f^{\geqslant})^{\wedge}_{(f/1)}$$

is an isomorphism; but, by (8.2.3.2) and (8.2.5.2), the left-hand side is canonically identified with $M_f^{\leqslant} \otimes_{S_f^{\leqslant}} (S_f^{\geqslant})^{\leqslant}_{f/1}$, and thus with $M_f^{\leqslant}$, by (8.2.7.2), and the right-hand side with $(M_f^{\geqslant})^{\leqslant}_{f/1}$, and thus also with $M_f^{\leqslant}$, by (8.2.9.2), whence the conclusion concerning (8.12.6.1); (8.12.6.2) then follows from (8.12.6.1) and (8.12.2.1). □

Corollary (8.12.7). — *With the identifications of (8.6.3), the restriction of $(\mathscr{M}_X^{\geqslant})^{\square}$ to $\widehat{E}_X$ can be identified with $(\mathscr{M}_X^{\leqslant})^{\sim}$, and the restriction of $(\mathscr{M}_X^{\geqslant})^{\square}$ to E_X with $\widetilde{\mathscr{M}}_X$.*

Proof. We can restrict to the affine case, and this follows from the identification of $(M_f^{\geqslant})^{\leqslant}_{f/1}$ with $M_f^{\leqslant}$, and of $(M_f^{\geqslant})_{f/1}$ with M_f (8.2.9.2). □

Proposition (8.12.8). — *Under the hypotheses of (8.6.4), the canonical homomorphism (8.12.3.1) is an isomorphism.*

Proof. Taking into account the fact that $\operatorname{Proj}(\mathscr{S}_X^{\geqslant}) \to X$ is an isomorphism (8.6.2), and the isomorphisms (8.12.5.4) and (8.12.6.1), we are led to proving the corresponding proposition for the canonical homomorphism $p_X^*(\mathscr{P}roj_0(\mathscr{M}_X^{\geqslant})) \to (\mathscr{M}_X^{\geqslant})^{\square}|\widehat{E}_X$, or, in other words, we can restrict to the case where $\mathscr{S}_1$ is an invertible $\mathscr{O}_Y$-module, and where $\mathscr{S}$ is generated by $\mathscr{S}_1$. With the notation of (8.12.3), we then have, for some $f \in S_1$, that $S_f^{\leqslant} = S_{(f)}[1/f]$, and the canonical homomorphism $M_{(f)} \otimes_{S_{(f)}} S_f^{\leqslant} \to M_f^{\leqslant}$ is an isomorphism, by the definition of $M_f^{\leqslant}$. □ **II | 195**

(8.12.9). Consider now the quasi-coherent $\mathscr{S}$-modules

$$\mathscr{M}_{[n]} = \bigoplus_{m \geqslant n} \mathscr{M}_m$$

and (with the notation of (8.7.2)) the quasi-coherent graded $\mathscr{S}^{\natural}$-module

$$\mathscr{M}^{\natural} = \left(\bigoplus_{n \geqslant 0} \mathscr{M}_{[n]} \right)^{\sim}. \tag{8.12.9.1}$$

We have seen (8.7.3) that there exists a canonical C-isomorphism $h : C_X \xrightarrow{\sim} \operatorname{Proj}(\mathscr{S}^{\natural})$. Furthermore:

Proposition (8.12.10). — *There exists a canonical h-isomorphism*

$$\mathscr{P}roj_0(\mathscr{M}^{\natural}) \xrightarrow{\sim} \widetilde{\mathscr{M}}_X. \tag{8.12.10.1}$$

Proof. We argue as in (8.7.3), this time using the existence of the di-isomorphism (8.2.9.3) instead of (8.2.7.3). We leave the details to the reader. □

8.13. Projective closures of subsheaves and closed subschemes

(8.13.1). With hypotheses and notation as in (8.12.1), consider a *not-necessarily graded* quasi-coherent sub-$\mathscr{S}$-module $\mathscr{N}$ of $\mathscr{M}$. We can then consider the quasi-coherent $\mathscr{O}_C$-module $\widetilde{\mathscr{N}}$ associated to $\mathscr{N}$, which is a sub-$\mathscr{O}_C$-module of $\widetilde{\mathscr{M}}$. We have seen elsewhere (8.12.2.1) that $\widetilde{\mathscr{M}}$ can be identified with the restriction of $\mathscr{M}^\square$ to C. Since the canonical injection $i : C \to \widehat{C}$ is an affine morphism (8.3.2), and *a fortiori* quasi-compact, the *canonical extension* $(\widetilde{\mathscr{N}})^-$, the largest sub-$\mathscr{O}_{\widehat{C}}$-module contained in $\mathscr{M}^\square$ and inducing $\widetilde{\mathscr{N}}$ on C, is a *quasi-coherent* $\mathscr{O}_{\widehat{C}}$-module (**I**, 9.4.2). We will give a more explicit description by using a graded $\widehat{\mathscr{S}}$-module.

(8.13.2). For this, consider, for every integer $n \geqslant 0$, the homomorphism $\bigoplus_{i\leqslant n} \mathscr{M}_i \to \mathscr{M}$ which, for every open U of Y, sends the family

$$(s_i) \in \bigoplus_{i\leqslant n} \Gamma(U, \mathscr{M}_i)$$

to the section $\sum_i s_i \in \Gamma(U, \mathscr{M})$. Denote by $\mathscr{N}'_n$ the inverse image of $\mathscr{N}$ by this homomorphism, which is a quasi-coherent sub-$\mathscr{O}_Y$-module of $\bigoplus_{i\leqslant n} \mathscr{M}_i$. Now consider the homomorphism $\bigoplus_{i\leqslant n} \mathscr{M}_i \to \widehat{\mathscr{M}} = \mathscr{M}[\mathbf{z}]$ which sends (s_i) to the section $\sum_{i\leqslant n} s_i \mathbf{z}^{n-i} \in \Gamma(U, \widehat{\mathscr{M}_n})$, and let $\mathscr{N}_n$ be the image of $\mathscr{N}'_n$ under this homomorphism; we immediately have that $\overline{\mathscr{N}} = \bigoplus_{n\geqslant 0} \mathscr{N}_n$ is a (quasi-coherent) sub-$\widehat{\mathscr{S}}$-module of $\widehat{\mathscr{M}}$; we say that $\overline{\mathscr{N}}$ is induced from $\mathscr{N}$ by *homogenisation*, via the "homogenising variable" $\mathbf{z}$. We note that, if $\mathscr{N}$ is already a *graded* sub-$\mathscr{S}$-module of $\mathscr{M}$, then $\overline{\mathscr{N}}$ can be identified **II** | 196
with the direct sum of the components $\widehat{\mathscr{N}_n}$ of degree $n \geqslant 0$ in $\widehat{\mathscr{N}} = \mathscr{N}[\mathbf{z}]$.

Proposition (8.13.3). — *The $\mathscr{O}_{\widehat{C}}$-module $\mathscr{P}roj_0(\overline{\mathscr{N}})$ is the canonical extension $(\widetilde{\mathscr{N}})^-$ of $\widetilde{\mathscr{N}}$ to $\widehat{C}$.*

Proof. The question is local on Y and $\widehat{C}$ by the definition of the canonical extension (**I**, 9.4.1). We can thus already suppose that $Y = \operatorname{Spec}(A)$ is affine, with $\mathscr{S} = \widetilde{S}$, $\mathscr{M} = \widetilde{M}$, and $\mathscr{N} = \widetilde{N}$, where N is a non-necessarily-graded sub-S-module of M. Furthermore (8.3.2.6), $\widehat{C}$ is a union of affine opens $\widehat{C}_z = C$ and $\widehat{C}_f = \operatorname{Spec}(S_f^{\leqslant})$ (with f homogeneous in S_+). It thus suffices to show that: (1) the restriction of $\mathscr{P}roj_0(\overline{\mathscr{N}})$ to C is $\widetilde{\mathscr{N}}$; (2) the restriction of $\mathscr{P}roj_0(\overline{\mathscr{N}})$ to each $\widehat{C}_f$ is the canonical extension of the restriction of $\widetilde{\mathscr{N}}$ to $C \cap \widehat{C}_f = \operatorname{Spec}(S_f)$ (8.3.2.6). For the first point, note that $\mathscr{P}roj_0(\overline{\mathscr{N}})|C$ can be identified with $(\overline{N}_{(\mathbf{z})})^\sim$ (8.3.2.4); but $\overline{N}_{(\mathbf{z})}$ is canonically identified (2.2.5) with the image of $\overline{N}$ in $\widehat{M}/(\mathbf{z}-1)\widehat{M}$, and by the canonical isomorphism of the latter with M (8.2.5), this image can be identified with N, by the definition of $\overline{N}$ given in (8.13.2).

To prove the second point, note that the injection $i : C \cap \widehat{C}_f \to \widehat{C}_f$ corresponds to the canonical injection $S_f^{\leqslant} \to S_f$ (8.3.2.6); we also have that $\Gamma(\widehat{C}_f, \mathscr{M}^\square) = M_f^{\leqslant}$, that $\Gamma(\widehat{C}_f, i_*(\widetilde{\mathscr{N}})) = N_f$, and, by (8.12.2.1), that $\Gamma(\widehat{C}_f, i_*(i^*(\mathscr{M}^\square))) = M_f$. Taking (**I**, 9.4.2) into account, we are thus led to showing that $\overline{N}_{(f)} \subset \widehat{M}_{(f)} = M_f^{\leqslant}$ is canonically identified with the inverse image of N_f under the canonical injection $M_f^{\leqslant} \to M_f$. Indeed, let $d = \deg(f) > 0$, and suppose that an element $(\sum_{k\leqslant md} x_k)/f^m$ of M_f (with $x_k \in M_k$) is of the form y/f^m with $y \in N$. By multiplying y and the x_k by one single suitable f^h, we can already assume that $\sum_{k\leqslant md} x_k = y$. But in the identification of (8.2.5.2), $(\sum_{k\leqslant md} x_k)/f^m$ corresponds to $\sum_{k\leqslant md} x_k \mathbf{z}^{md-k}/f^m$, and this is indeed an element of $\overline{N}_{(f)}$, since $\sum_{k\leqslant md} x_k \in N$; the converse is evident. □

Remark (8.13.4). — (i) The most important case of application of (8.13.3) is that where $\mathscr{M} = \mathscr{S}$, with $\widetilde{\mathscr{N}}$ then being an *arbitrary* quasi-coherent sheaf of ideals $\mathscr{J}$ of $\mathscr{O}_C$ (1.4.3), corresponding bijectively to a *closed subprescheme* Z of C. Then the canonical extension $(\mathscr{J})^-$ of $\mathscr{J}$ is the quasi-coherent sheaf of ideals of $\mathscr{O}_{\widehat{C}}$ that defines the *closure* $\overline{Z}$ of Z in $\widehat{C}$ (**I**, 9.5.10); Proposition (8.13.3) gives a canonical way of defining $\overline{Z}$ by using a graded ideal in $\widehat{\mathscr{S}} = \mathscr{S}[\mathbf{z}]$.

(ii) Suppose, to simplify things, that Y is affine, and adopt the notation from the proof of (8.13.3). For every non-zero $x \in N$, let $d(x)$ be the largest degree of the homogeneous components x_i of x in M; by definition, $\overline{N}$ is the submodule of $\widehat{M}$ consisting of 0 and elements of the form $h(x,k) = \mathbf{z}^k \sum_{i \leqslant d(x)} x_i \mathbf{z}^{d(x)-i}$ (for integral $k \geqslant 0$); it is thus generated, as a module over $\widehat{S} = S[\mathbf{z}]$, by the elements of the form

$$h(x,0) = \sum_{i \leqslant d(x)} x_i \mathbf{z}^{d(x)-i}.$$

We say that $h(x,0)$ is induced from x by *homogenisation* via the "homogenising variable" $\mathbf{z}$. **II** | 197
But since $h(x,0)$ does not depend additively on x (nor *a fortiori* S-linearly), *we will refrain from believing* (even when $M = S$) that the $h(x,0)$ form a *system of generators* of the graded $\widehat{S}$-module $\overline{N}$ when we let x run over a *system of generators* of the S-module N. This is, however, the case when N is a *free cyclic* S-module (the only case considered in elementary algebraic geometry), since, if t is a basis of N, then $h(t,0)$ generates the $\widehat{S}$-module $\overline{N}$.

8.14. Supplement on sheaves associated to graded $\mathscr{S}$-modules

(8.14.1). Let Y be a prescheme, $\mathscr{S}$ a *positively-graded* quasi-coherent $\mathscr{O}_Y$-algebra, $X = \operatorname{Proj}(\mathscr{S})$, and $q : X \to Y$ the structure morphism (which is separated, by (3.1.3)). Using the notation of (8.12.1), we have defined a functor $\mathscr{M}_X = \mathscr{P}roj(\mathscr{M})$ in $\mathscr{M}$, from the category of quasi-coherent graded $\mathscr{S}$-modules to the category of quasi-coherent graded $\mathscr{S}_X$-modules; it is further clear (3.2.4) that this is an *additive* and *exact* functor, commuting with inductive limits.

Note, furthermore, that it follows immediately from the definition (8.12.1.1) that we have

$$\mathscr{P}roj(\mathscr{M}(n)) = (\mathscr{P}roj(\mathscr{M}))(n) \quad \text{for all } n \in \mathbf{Z}. \tag{8.14.1.1}$$

(8.14.2). We will first extend the canonical homomorphisms λ and μ, defined in (3.2.6), to $\mathscr{S}_X$-modules of the form $\mathscr{P}roj(\mathscr{M})$. For this, note that, for any $m \in \mathbf{Z}$ and $n \in \mathbf{Z}$, we have, by (2.1.2.1), a canonical homomorphism of $\mathscr{O}_X$-modules

$$\lambda_{mn} : \mathscr{P}roj_0(\mathscr{M}(m)) \otimes_{\mathscr{O}_X} \mathscr{P}roj_0(\mathscr{N}(n)) \longrightarrow \mathscr{P}roj_0((\mathscr{M} \otimes_{\mathscr{S}} \mathscr{N})(m+n)), \tag{8.14.2.1}$$

and likewise, by (2.1.2.2), a canonical homomorphism of $\mathscr{O}_X$-modules

$$\mu_{mn} : \mathscr{P}roj_0((\mathscr{H}om_{\mathscr{S}}(\mathscr{M},\mathscr{N}))(n-m)) \longrightarrow \mathscr{H}om_{\mathscr{O}_X}(\mathscr{P}roj_0(\mathscr{M}(m)), \mathscr{P}roj_0(\mathscr{N}(n))) \tag{8.14.2.2}$$

for any quasi-coherent graded $\mathscr{S}$-modules $\mathscr{M}$ and $\mathscr{N}$. This induces a homomorphism

$$\mu_k : \mathscr{P}roj_0((\mathscr{H}om_{\mathscr{S}}(\mathscr{M},\mathscr{N}))(k)) \longrightarrow (\mathscr{H}om_{\mathscr{S}_X}(\mathscr{P}roj(\mathscr{M}), \mathscr{P}roj(\mathscr{N})))_k$$

given by sending every $u \in \Gamma(U, \mathscr{P}roj_0((\mathscr{H}om_{\mathscr{S}}(\mathscr{M},\mathscr{N}))(k)))$ to the homomorphism $\mu_k(u)$, of degree k, of graded $\mathbf{Z}$-modules $\Gamma(U, \mathscr{P}roj(\mathscr{M})) \to \Gamma(U, \mathscr{P}roj(\mathscr{N}))$ (where U is open in X) which, in each $\Gamma(U, \mathscr{P}roj_0(\mathscr{M}(m)))$, agrees with $\mu_{m,m+k}(u)$; furthermore, by returning to the definition of the μ_{mn} (2.5.12.1), we immediately see that $\mu_k(u)$ is in fact a homomorphism of degree k of graded $\Gamma(U, \mathscr{S}_X)$-modules, and, furthermore, that the μ_k define a homomorphism of *graded $\mathscr{S}_X$-modules*

$$\mathscr{P}roj(\mathscr{H}om_{\mathscr{S}}(\mathscr{M},\mathscr{N})) \longrightarrow \mathscr{H}om_{\mathscr{S}_X}(\mathscr{P}roj(\mathscr{M}), \mathscr{P}roj(\mathscr{N})). \tag{8.14.2.3}$$

Similarly, taking the associativity diagram (2.5.11.4) into account, the homomorphisms (8.14.2.1) give a homomorphism of *graded $\mathscr{S}_X$-modules*

$$\lambda : \mathscr{P}roj(\mathscr{M}) \otimes_{\mathscr{S}_X} \mathscr{P}roj(\mathscr{N}) \longrightarrow \mathscr{P}roj(\mathscr{M} \otimes_{\mathscr{S}} \mathscr{N}). \tag{8.14.2.4}$$

II | 198

Proposition (8.14.3). — *The homomorphism* (8.14.2.4) *is bijective; so too is* (8.14.2.3) *whenever the graded $\mathscr{S}$-module $\mathscr{M}$ admits a finite presentation* (3.1.1).

Proof. The question is clearly local on X and Y; we can thus suppose that $Y = \operatorname{Spec}(A)$ is affine, with $\mathscr{S} = \widetilde{S}$, $\mathscr{M} = \widetilde{M}$, and $\mathscr{N} = \widetilde{N}$, where S is a positively-graded A-algebra, and M and N are graded S-modules. If f is a homogeneous element of S_+, then the homomorphisms (8.14.2.1) and (8.14.2.2), restricted to the affine open $D_+(f)$, correspond to the canonical homomorphisms (2.5.11.1) and (2.5.12.1):

$$M(m)_{(f)} \otimes_{S_{(f)}} N(n)_{(f)} \longrightarrow (M \otimes_S N)(m+n)_{(f)}$$
$$(\operatorname{Hom}_S(M,N))(n-m)_{(f)} \longrightarrow \operatorname{Hom}_{S_{(f)}}(M(m)_{(f)}, N(n)_{(f)}).$$

If we refer to the definitions of these homomorphisms, we thus see (taking (8.2.9.1) into account) that the restriction of (8.14.2.4) to $D_+(f)$ corresponds to the canonical homomorphism

$$M_f \otimes_{S_f} N_f \longrightarrow (M \otimes_S N)_f$$

defined in (**0**, 1.3.4), and we know that this latter homomorphism is an isomorphism. Similarly, the restriction of (8.14.2.3) to $D_+(f)$ corresponds to the canonical homomorphism (**0**, 1.3.5)

$$(\mathrm{Hom}_S(M,N))_f \longrightarrow \mathrm{Hom}_{S_f}(M_f, N_f)$$

taking into account the fact that, since M is of finite type, the module $\mathrm{Hom}_S(M,N)$, the direct sum of the subgroups consisting of *homogeneous* homomorphisms of S-modules (2.1.2), agrees with the set of *all* homomorphisms $M \to N$ of S-modules. The hypothesis that M admits a finite presentation then implies (**0**, 1.3.5) that the canonical homomorphism in question is indeed an isomorphism. □

Proposition (8.14.4). — *If U is a quasi-compact open of X, then there exists an integer d such that, for every integer n that is a multiple of d, $\mathscr{O}_X(n)|U$ is invertible, with its inverse being $\mathscr{O}_X(-n)|U$.*

Proof. Since $q(U)$ is quasi-compact, it is covered by a finite number of affine opens V_i, and so every $x \in U$ is contained in some affine open of the form $D_+(f)$, where f is a homogeneous element of degree > 0 of one of the rings $\Gamma(V_i, \mathscr{S})$. Since U is quasi-compact, we can cover it by a finite number of such opens $D_+(f_j)$; let d be a common multiple of the degrees of the f_j. This d satisfies the desired property, by (2.5.17). □

(8.14.5). With the hypotheses and notation of (8.14.1), we defined, in (3.3.2), canonical homomorphisms of $\mathscr{O}_Y$-modules

(8.14.5.1) $$\alpha_n : \mathscr{M}_n \longrightarrow q_*(\mathscr{P}roj_0(\mathscr{M}(n))) \qquad (n \in \mathbf{Z}).$$

Generalising the notation of (3.3.1), we set, for every *graded $\mathscr{S}_X$-module $\mathscr{F}$*,

(8.14.5.2) $$\mathbf{\Gamma}_*(\mathscr{F}) = \bigoplus_{n\in\mathbf{Z}} q_*(\mathscr{F}_n).$$

In particular, $\mathbf{\Gamma}_*(\mathscr{S}_X) = \bigoplus_{n\in\mathbf{Z}} q_*(\mathscr{O}_X(n))$ is the graded $\mathscr{O}_Y$-algebra denoted by $\mathbf{\Gamma}_*(\mathscr{O}_X)$ in (3.3.1.2); it is clear that $\mathbf{\Gamma}_*(\mathscr{F})$ is a *graded* $\mathbf{\Gamma}_*(\mathscr{S}_X)$*-module* (**0**, 4.2.2). When we take $\mathscr{M} = \mathscr{S}$ in the homomorphisms (8.14.5.1), we obtain the homomorphism of graded $\mathscr{O}_Y$-algebras **II | 199**

(8.14.5.3) $$\alpha : \mathscr{S} \longrightarrow \mathbf{\Gamma}_*(\mathscr{S}_X)$$

previously defined in (3.3.2), and which makes $\mathbf{\Gamma}_*(\mathscr{F})$ a *graded $\mathscr{S}$-module*; the homomorphisms (8.14.5.1) then define a homomorphism (of degree 0) of *graded $\mathscr{S}$-modules*

(8.14.5.4) $$\alpha : \mathscr{M} \longrightarrow \mathbf{\Gamma}_*(\mathscr{P}roj(\mathscr{M})).$$

(8.14.6). In general, for a quasi-coherent graded $\mathscr{S}_X$-module $\mathscr{F}$, it is not certain that the graded $\mathscr{S}$-module $\mathbf{\Gamma}_*(\mathscr{F})$ will necessarily be quasi-coherent. Consider an open X' of X such that the restriction $q' : X' \to Y$ of q to X' is a *quasi-compact* morphism. Since q' is further separated, $q'_*(\mathscr{F}')$ is then a quasi-coherent $\mathscr{O}_Y$-module for every quasi-coherent $\mathscr{O}_{X'}$-module $\mathscr{F}'$ (**I**, 9.2.2, b). We set

(8.14.6.1) $$\mathscr{S}_{X'} = \mathscr{S}_X|X' = \bigoplus_{n\in\mathbf{Z}} \mathscr{O}_X(n)|X'$$

and, for every graded $\mathscr{S}_{X'}$-module $\mathscr{F}'$,

(8.14.6.2) $$\mathbf{\Gamma}'_*(\mathscr{F}') = \bigoplus_{n\in\mathbf{Z}} q'_*(\mathscr{F}'_n).$$

The previous remark then shows that, if $\mathscr{F}'$ is a quasi-coherent $\mathscr{S}_{X'}$-module, then $\mathbf{\Gamma}'_*(\mathscr{F}')$ is a graded *quasi-coherent* $\mathscr{S}$-module (**I**, 9.6.1).

We note also that the canonical injection $j : X' \to X$ is *quasi-compact*, because $q' = q \circ j$ is quasi-compact and q is separated (**I**, 6.6.4, v). Then $\mathscr{F} = j_*(\mathscr{F}')$ is a quasi-coherent graded $\mathscr{S}_X$-module for every quasi-coherent graded $\mathscr{S}_{X'}$-module $\mathscr{F}'$, and it follows from the previous definitions that

(8.14.6.3) $$\mathbf{\Gamma}'_*(\mathscr{F}') = \mathbf{\Gamma}_*(\mathscr{F}).$$

With the same hypotheses on X', for every quasi-coherent graded $\mathscr{S}$-module $\mathscr{M}$, we set

$$\mathscr{P}\mathit{roj}'(\mathscr{M}) = \mathscr{P}\mathit{roj}(\mathscr{M})|X' \tag{8.14.6.4}$$

which is a quasi-coherent graded $\mathscr{S}_{X'}$-module. The canonical homomorphism

$$\mathscr{P}\mathit{roj}(\mathscr{M}) \longrightarrow j_*(\mathscr{P}\mathit{roj}'(\mathscr{M}))$$

(0, 4.4.3) thus gives a canonical homomorphism $\mathbf{\Gamma}_*(\mathscr{P}\mathit{roj}(\mathscr{M})) \to \mathbf{\Gamma}'_*(\mathscr{P}\mathit{roj}'(\mathscr{M}))$ of graded $\mathscr{S}$-modules, and, by composition with (8.14.5.4), we obtain a functorial canonical homomorphism (of degree 0) of quasi-coherent graded $\mathscr{S}$-modules

$$\alpha' : \mathscr{M} \longrightarrow \mathbf{\Gamma}'_*(\mathscr{P}\mathit{roj}'(\mathscr{M})). \tag{8.14.6.5}$$

(8.14.7). Keeping the hypotheses on X' from (8.14.6), let $\mathscr{F}'$ be a *quasi-coherent graded $\mathscr{S}_{X'}$-module*, so that $\mathscr{P}\mathit{roj}'(\mathbf{\Gamma}'_*(\mathscr{F}'))$ is also a graded *quasi-coherent* $\mathscr{S}_{X'}$-module. We will define a functorial canonical **II** | 200
homomorphism (of degree 0) of graded $\mathscr{S}_{X'}$-modules

$$\beta' : \mathscr{P}\mathit{roj}'(\mathbf{\Gamma}'_*(\mathscr{F}')) \longrightarrow \mathscr{F}'. \tag{8.14.7.1}$$

Suppose first of all that $Y = \operatorname{Spec}(A)$ is affine, and that $\mathscr{S} = \widetilde{S}$, where S is a positively-graded A-algebra; then $\mathbf{\Gamma}'_*(\mathscr{F}') = \widetilde{M}$, where $M = \bigoplus_{n\in\mathbf{Z}} \Gamma(X', \mathscr{F}'_n)$ is a graded S-module. Let $f \in S_d$ be such that $D_+(f) \subset X'$; by definition (2.6.2), $\alpha_d(f)$ restricted to $D_+(f)$ is the section of $\mathscr{O}_X(d)$ over $D_+(f)$ corresponding to the element $f/1$ of $(S(d))_{(f)}$, and is thus invertible; thus so too is $\alpha_{nd}(f^n)$ for every $n > 0$. From this, we immediately conclude that we have defined an S_f-homomorphism (of degree 0) of graded modules $\beta_f : M_f \to \Gamma(D_+(f), \mathscr{F}')$ by sending each element $z/f^n \in M_f$ (where $z \in M$) to the section $(z|D_+(f))(\alpha_{nd}(f^n)|D_+(f))^{-1}$ of $\mathscr{F}'$ over $D_+(f)$. Furthermore, we have a commutative diagram corresponding to (2.6.4.1), whence the definition of β' in this case. To pass to the general case, we must consider an A-algebra A', the graded A'-algebra $S' = S \otimes_A A'$, and use the commutative diagram analogous to (2.8.13.2); we leave the details to the reader.

Proposition (8.14.8). — *If X' is an open of $X = \operatorname{Proj}(\mathscr{S})$ such that $q' : X' \to Y$ is quasi-compact, then the homomorphism β' defined in* (8.14.7) *is bijective.*

Proof. We can clearly restrict to the case where Y is affine, and everything then reduces to proving (with the notation of (8.14.7)) that the homomorphism $\beta_f : M_f \to \Gamma(D_+(f), \mathscr{F}')$ is an isomorphism. But replacing f by one of its powers changes neither $D_+(f)$ nor β_f; since X' is *quasi-compact* by hypothesis, we can always assume, by (8.14.4), that the sheaf $\mathscr{O}_X(d)$ is *invertible*. Since X' is a scheme (because q' is separated), the proposition is then exactly (**I**, 9.3.1). □

Corollary (8.14.9). — *Under the hypotheses of* (8.14.8), *every quasi-coherent graded $\mathscr{S}_{X'}$-module is isomorphic to a graded $\mathscr{S}_{X'}$-module of the form $\mathscr{P}\mathit{roj}'(\mathscr{M})$, where $\mathscr{M}$ is a quasi-coherent graded $\mathscr{S}$-module. Further, if $\mathscr{F}'$ is of finite type, and if we assume that Y is a quasi-compact scheme, or a prescheme whose underlying space is Noetherian, then we can assume that $\mathscr{M}$ is of finite type.*

Proof. The proof starting from (8.14.8) follows exactly the same route as the proof of (3.4.5) starting from (3.4.4), and we leave the details to the reader. □

Proposition (8.14.10). — *Under the hypotheses of* (8.14.7), *let $\mathscr{M}$ be a quasi-coherent graded $\mathscr{S}$-module, and $\mathscr{F}'$ a quasi-coherent graded $\mathscr{S}_{X'}$-module; the composite homomorphisms*

$$\mathscr{P}\mathit{roj}'(\mathscr{M}) \xrightarrow{\mathscr{P}\mathit{roj}'(\alpha')} \mathscr{P}\mathit{roj}'(\mathbf{\Gamma}'_*(\mathscr{P}\mathit{roj}'(\mathscr{M}))) \xrightarrow{\beta'} \mathscr{P}\mathit{roj}'(\mathscr{M}) \tag{8.14.10.1}$$

$$\mathbf{\Gamma}'_*(\mathscr{F}') \xrightarrow{\alpha'} \mathbf{\Gamma}'_*(\mathscr{P}\mathit{roj}'(\mathbf{\Gamma}'_*(\mathscr{F}'))) \xrightarrow{\mathbf{\Gamma}'_*(\beta')} \mathbf{\Gamma}'_*(\mathscr{F}') \tag{8.14.10.2}$$

are the identity isomorphisms.

Proof. The question is local on Y, and the proof follows as in (2.6.5); we leave the details to the reader. □

Remark (8.14.11). — In chapter III (III, 2.3.1), we will see that, when Y is *locally Noetherian*, and $\mathscr{S}$ is a quasi-coherent graded $\mathscr{O}_Y$-algebra *of finite type* (in which case we can take $X' = X$), then **II** | 201
the homomorphism α (8.14.5.4) is **(TN)**-*bijective* for every quasi-coherent graded $\mathscr{S}$-module $\mathscr{M}$ satisfying condition **(TF)**.

Remark (8.14.12). — The situation described in (8.14.4) is a particular case of the following. Let X be a ringed space, and $\mathscr{S}$ a (positively- and negatively-) graded $\mathscr{O}_X$-algebra; suppose that there exists an integer $d > 0$ such that $\mathscr{S}_d$ and $\mathscr{S}_{-d}$ are *invertible*, with the canonical homomorphism

$$\mathscr{S}_d \otimes_{\mathscr{O}_X} \mathscr{S}_{-d} \longrightarrow \mathscr{O}_X \tag{8.14.12.1}$$

being an *isomorphism* (such that $\mathscr{S}_{-d}$ is identified with $\mathscr{S}_d^{-1}$). We then say that the graded $\mathscr{O}_X$-algebra $\mathscr{S}$ is *periodic*, *of period* d. This nomenclature stems from the following property: *under the preceding hypotheses, for every graded* $\mathscr{S}$*-module* $\mathscr{F}$, *the canonical homomorphism*

$$\mathscr{S}_d \otimes_{\mathscr{O}_X} \mathscr{F}_n \longrightarrow \mathscr{F}_{n+d} \tag{8.14.12.2}$$

is an isomorphism for all $n \in \mathbf{Z}$. Indeed, the question is local on X, and we can assume that $\mathscr{S}_d$ has an *invertible* section s over X, with its inverse s' being a section of $\mathscr{S}_{-d}$. The homomorphism $\mathscr{F}_{n+d} \to \mathscr{S}_d \otimes \mathscr{F}_n$, which sends each section $z \in \Gamma(U, \mathscr{F}_{n+d})$ to the section $(s|U) \otimes (s'|U)z$ of $\mathscr{S}_d \otimes \mathscr{F}_n$ over U, is then the inverse of (8.14.12.2), whence our claim. This induces, for all $k \in \mathbf{Z}$, a canonical isomorphism

$$(\mathscr{S}_d)^{\otimes k} \otimes \mathscr{F}_n \xrightarrow{\sim} \mathscr{F}_{n+kd}.$$

Then *the data of a graded* $\mathscr{S}$*-module* $\mathscr{F}$ *is equivalent to the data of* $\mathscr{S}_0$*-modules* $\mathscr{F}_i$ *(*$0 \leqslant i \leqslant d-1$*) and canonical homomorphisms*

$$\mathscr{S}_i \otimes \mathscr{F}_j \longrightarrow \mathscr{F}_{i+j} \qquad \text{for } 0 \leqslant i, j \leqslant d-1$$

(setting $\mathscr{F}_{i+j} = \mathscr{S}_d \otimes_{\mathscr{S}_0} \mathscr{F}_{i+j-d}$ whenever $i+j \geqslant d$). Of course, for these homomorphisms to give a well-defined $\mathscr{S}$-module structure on the direct sum of the $(\mathscr{S}_d)^{\otimes k} \otimes \mathscr{F}_i$ ($k \in \mathbf{Z}$, $0 \leqslant i \leqslant d-1$), they should satisfy some associativity conditions that we will not explain.

In the case where $d = 1$ (which is the one considered in (3.3)), we can thus say that the category of graded $\mathscr{S}$-modules (resp. quasi-coherent $\mathscr{S}$-modules if X is a prescheme and $\mathscr{S}$ is quasi-coherent) is *equivalent* to the category of arbitrary $\mathscr{S}_0$-modules (resp. quasi-coherent $\mathscr{S}_0$-modules); it is in this way that we can think of the results of this paragraph as generalising those of §3. Furthermore, we see that, under suitable finiteness conditions, the results of this paragraph (along with (8.14.11)) reduce, in some sense, the study of quasi-coherent graded algebras on a prescheme, and graded modules "modulo **(TN)**" on such algebras, to the study of the particular case where the algebras in question are *periodic* (and where condition **(TN)** for $\mathscr{M}$ (3.4.2) thus implies that $\mathscr{M} = 0$).

Remark (8.14.13). — Under the hypotheses of (8.14.1), let d be an integer > 0; we have defined a canonical Y-isomorphism h from X to $X^{(d)} = \operatorname{Proj}(\mathscr{S}^{(d)})$ (3.1.8). For every quasi-coherent graded **II** | 202
$\mathscr{S}$-module $\mathscr{M}$ and every integer k such that $0 \leqslant k \leqslant d-1$, we also have (with the notation of (3.1.1)) a canonical h-isomorphism

$$(\mathscr{P}roj(\mathscr{M}))^{(d,k)} \xleftarrow{\sim} \mathscr{P}roj(\mathscr{M}^{(d,k)}). \tag{8.14.13.1}$$

Suppose, first of all, that $Y = \operatorname{Spec}(A)$ is affine, $\mathscr{S} = \widetilde{S}$, and $\mathscr{M} = \widetilde{M}$, where S is a positively-graded A-algebra, and M a graded S-module. We know, for every $f \in S_e$ ($e > 0$), that h sends $D_+(f)$ to $D_+(f^d)$, and corresponds to the canonical isomorphism $S_{(f^d)} \to S_{(f)}$ (2.2.2). The restriction of (8.14.13.1) to $D_+(f^d)$ then corresponds to the canonical di-isomorphism $M_{f^d} \to M_f$ restricted to the elements of M_{f^d} whose degree is congruent to k (modulo d). We leave to the reader the task of showing that these isomorphisms are compatible with passing from f to some homogeneous multiple fg, and then that there is an analogous compatibility with passing from S to a graded A'-algebra $S' = S \otimes_A A'$, where A' is some A-algebra. In particular, this gives us an h-isomorphism

$$(\mathscr{S}^{(d)})_{X^{(d)}} \xrightarrow{\sim} (\mathscr{S}_X)^{(d)} \tag{8.14.13.2}$$

that respects the multiplicative structures of both the source and the target, and that, thanks to (8.14.13.1), becomes an h-di-isomorphism from a graded $(\mathscr{S}^{(d)})_{X^{(d)}}$-module to a graded $(\mathscr{S}_X)^{(d)}$-module. Similarly, we have an h-isomorphism

$$\mathscr{P}roj_0(\mathscr{S}^{(d,k)}(n)) \xrightarrow{\sim} \mathscr{O}_X(nd+k), \tag{8.14.13.3}$$

which completes the result of (3.2.9, ii).

The isomorphism in (8.14.13.1) immediately induces an isomorphism of graded $\mathscr{S}^{(d)}$-modules

$$\Gamma_*^{(d)}(\mathscr{P}roj(\mathscr{M}^{(d,k)})) \xrightarrow{\sim} \Gamma_*((\mathscr{P}roj(\mathscr{M}))^{(d,k)}) \tag{8.14.13.4}$$

where $\Gamma_*^{(d)}$ corresponds to the structure morphism $q^{(d)} : X^{(d)} \to Y$; it can be immediately verified that the canonical homomorphism α (8.14.5.4), and the analogous homomorphism $\alpha^{(d)}$ for $X^{(d)}$, make the following diagram commute:

$$\begin{tikzcd} & \mathscr{M}^{(d,k)} \arrow[dl, "\alpha^{(d)}"'] \arrow[dr, "\alpha"] & \\ \Gamma_*^{(d)}(\mathscr{P}roj(\mathscr{M}^{(d,k)})) \arrow[rr, "\sim"] & & \Gamma_*((\mathscr{P}roj(\mathscr{M}))^{(d,k)}) \end{tikzcd} \tag{8.14.13.5}$$

the verification being carried out by supposing that Y is affine and then calculating the restrictions of the images under $\alpha^{(d)}$ and α of a single element of $M^{(d,k)}$ to the open subsets $D_+(f^d)$ and $D_+(f)$ (using the same notation as above).

Proposition (8.14.14). — *Let Y be a quasi-compact prescheme, $\mathscr{S}$ a quasi-coherent graded $\mathscr{O}_Y$-algebra of finite type, and $\mathscr{M}$ a quasi-coherent graded $\mathscr{S}$-module satisfying condition* **(TF)***; let $X = \operatorname{Proj}(\mathscr{S})$. Then $\mathscr{S}_X$ is a periodic graded $\mathscr{O}_X$-algebra (8.14.12), and there exists some period d of $\mathscr{S}_X$ such that the $(\mathscr{P}roj(\mathscr{M}))^{(d,k)}$* **II | 203** *$(0 \leqslant k \leqslant d-1)$ are $(\mathscr{S}_X)^{(d)}$-modules of finite type.*

Proof. Indeed, (3.1.10) proves that there exists some d such that $\mathscr{S}^{(d)}$ is generated by $\mathscr{S}_d = (\mathscr{S}^{(d)})_1$, with the latter being an $\mathscr{S}_0$-module of finite type. To prove the first claim, we can thus, by (8.14.13.2), restrict to the case where $d = 1$, and the proposition then follows from (3.2.7). Furthermore, taking (8.14.13.1) into account, the second claim is a consequence of (2.1.6, iii) and (3.4.3). □

(List 1)

Chapter 0

(0, 2.1.3). On line 15 from the bottom of p. 21, replace "inter-section" by "intersection".
(0, 2.1.6). On line 13 of p. 22, replace

$$Z_i \cap C\left(\bigcup_{j\neq i} Z_j\right) \quad \text{by} \quad \bigcup_{j\neq i} Z_j.$$

(0, 3.1.6). On line 17 from the bottom of p. 25, replace $\Gamma(U,\mathscr{F})$ by $\Gamma(V,\mathscr{F})$.
(0, 4.1.1). On line 12 of p. 36, replace $\mathscr{G}\to\mathscr{F}$ by $\mathscr{B}\to\mathscr{A}$.
(0, 4.2.1). On line 11 from the bottom of p. 39, replace "sheaves" by "sheaf".
(0, 5.1.2). After line 14 of p. 45, add:

If $\mathscr{G}$ is an $\mathscr{O}_Y$-module generated by its sections over Y, then $f^*(\mathscr{G})$ is generated by its sections over X, since f^* is a right-exact functor.

(0, 5.2.4). On line 18 from the bottom of p. 46, replace f_U by f_U^*.
(0, 5.3.4). Before line 16 from the bottom of p. 47, add:

If

$$\mathscr{A}\longrightarrow\mathscr{B}\longrightarrow\mathscr{C}\longrightarrow\mathscr{D}\longrightarrow\mathscr{E}$$

is an exact sequence of $\mathscr{O}_X$-modules, and if $\mathscr{A},\mathscr{B},\mathscr{D},\mathscr{E}$ are coherent, then $\mathscr{C}$ is coherent.

(0, 5.4.1). After line 2 of p. 49, add:

Suppose that $\mathscr{O}_X$ is coherent, and let $\mathscr{F}$ be a coherent $\mathscr{O}_X$-module. If, at a point $x\in X$, $\mathscr{F}_x$ is a free $\mathscr{O}_x$-module of rank n, then there exists a neighbourhood U of x such that $\mathscr{F}|U$ is locally free of rank n; indeed, $\mathscr{F}_x$ is then isomorphic to $\mathscr{O}_x^n$, and the assertion follows from (0, 5.2.7).

(0, 6.6.2). Replace lines 10 and 11 of p. 59 by:

Indeed, this follows from (0, 6.4.1, d).

(0, 6.7.1). Before line 10 from the bottom of p. 59, add:

If f is a flat morphism, we also say that X is *flat over Y*, or *Y-flat*.

(0, 7.2.9). On line 11 from the bottom of p. 65, replace M_n by M_{n-1}.

Chapter I

(I, 1.2.1). On line 18 of p. 83, replace K by k (twice).
(I, 1.2.7). On line 16 from the bottom of p. 84, replace A by A' (twice) and $\mathfrak{r}$ by $\mathfrak{r}'$; on line 17 from the bottom, replace X by X'.
(I, 1.7.3) and (I, 2.2.4). The statements given under these numbers can, in accordance with a remark of J. Tate, be generalized as follows.

1.8. Morphisms from locally ringed spaces to affine schemes

Proposition (1.8.1). — *Let $(S,\mathscr{O}_S)$ be an affine scheme and $(X,\mathscr{O}_X)$ a locally ringed space. There is a canonical bijection from the set of ring homomorphisms* **II | 218**

$$\Gamma(S,\mathscr{O}_S)\longrightarrow\Gamma(X,\mathscr{O}_X)$$

to the set of morphisms of ringed spaces $(\psi,\theta):(X,\mathscr{O}_X)\to(S,\mathscr{O}_S)$ such that, for every $x\in X$, $\theta_x^\sharp:\mathscr{O}_{\psi(x)}\to\mathscr{O}_x$ is a local homomorphism.

Proof. First note that, if $(X,\mathscr{O}_X)$ and $(S,\mathscr{O}_S)$ are any two ringed spaces, a morphism (ψ,θ) from $(X,\mathscr{O}_X)$ to $(S,\mathscr{O}_S)$ canonically defines a ring homomorphism

$$\Gamma(\theta):\Gamma(S,\mathscr{O}_S)\longrightarrow\Gamma(X,\mathscr{O}_X),$$

and hence a first map

$$\rho:\operatorname{Hom}((X,\mathscr{O}_X),(S,\mathscr{O}_S))\longrightarrow\operatorname{Hom}(\Gamma(S,\mathscr{O}_S),\Gamma(X,\mathscr{O}_X)). \tag{1.8.1.1}$$

Conversely, under the hypotheses of the proposition, put $A=\Gamma(S,\mathscr{O}_S)$ and consider a ring homomorphism $\phi:A\to\Gamma(X,\mathscr{O}_X)$. For every $x\in X$, the set of $f\in A$ such that $\phi(f)(x)=0$ is a prime ideal of A, since $\mathscr{O}_x/\mathfrak{m}_x = k(x)$ is a field. It is therefore an element of $S = \operatorname{Spec}(A)$, which we again denote by ${}^a\phi(x)$. Moreover, for every $f \in A$, by definition (0, 5.5.2),

$$ {}^a\phi^{-1}(D(f)) = X_f, $$

which proves that ${}^a\phi$ is a continuous map $X \to S$.

We next define a homomorphism of $\mathscr{O}_S$-modules

$$ \widetilde{\phi} : \mathscr{O}_S \longrightarrow {}^a\phi_*(\mathscr{O}_X). $$

For every $f \in A$, one has $\Gamma(D(f), \mathscr{O}_S) = A_f$ (I, 1.3.6); to $s/f \in A_f$ associate

$$ (\phi(s)|X_f)(\phi(f)|X_f)^{-1} \in \Gamma(X_f, \mathscr{O}_X) = \Gamma(D(f), {}^a\phi_*(\mathscr{O}_X)). $$

Passing from $D(f)$ to $D(fg)$ shows at once that this defines a homomorphism of sheaves and hence a morphism of ringed spaces $({}^a\phi, \widetilde{\phi})$. With the same notation, and writing $y = {}^a\phi(x)$, one has (0, 3.7.1)

$$ \widetilde{\phi}_x^\sharp(s_y/f_y) = (\phi(s)_x)(\phi(f)_x)^{-1}. $$

Since $s_y \in \mathfrak{m}_y$ is, by definition, equivalent to $\phi(s)_x \in \mathfrak{m}_x$, the homomorphism $\widetilde{\phi}_x^\sharp : \mathscr{O}_y \to \mathscr{O}_x$ is local. We have therefore defined a second map

$$ \sigma : \operatorname{Hom}(\Gamma(S, \mathscr{O}_S), \Gamma(X, \mathscr{O}_X)) \longrightarrow \mathfrak{L}, $$

where $\mathfrak{L}$ denotes the set of morphisms $(\psi, \theta) : (X, \mathscr{O}_X) \to (S, \mathscr{O}_S)$ for which $\theta_x^\sharp$ is local for every $x \in X$.

It remains to prove that σ and the restriction of ρ to $\mathfrak{L}$ are inverses. The definition of $\widetilde{\phi}$ immediately gives $\Gamma(\widetilde{\phi}) = \phi$, and hence $\rho \circ \sigma$ is the identity. To see that $\sigma \circ \rho$ is the identity, begin with $(\psi, \theta) \in \mathfrak{L}$ and put $\phi = \Gamma(\theta)$. The hypothesis on $\theta_x^\sharp$ gives, after passage to residue fields, a monomorphism

$$ \theta^x : k(\psi(x)) \longrightarrow k(x) $$

such that, for every $f \in A = \Gamma(S, \mathscr{O}_S)$,

$$ \theta^x(f(\psi(x))) = \phi(f)(x). $$

Thus $f(\psi(x)) = 0$ is equivalent to $\phi(f)(x) = 0$, which proves that ${}^a\phi = \psi$. On the other hand, the definitions make the diagram

$$ \begin{tikzcd} A \arrow[r, "\phi"] \arrow[d] & \Gamma(X, \mathscr{O}_X) \arrow[d] \\ A_{\psi(x)} \arrow[r, "\theta_x^\sharp"] & \mathscr{O}_x \end{tikzcd} $$

commutative; the analogous diagram with $\theta_x^\sharp$ replaced by $\widetilde{\phi}_x^\sharp$ is also commutative. It follows from (0, 1.2.4) that $\widetilde{\phi}_x^\sharp = \theta_x^\sharp$, and consequently that $\widetilde{\phi} = \theta$. □

(1.8.2). When $(X, \mathscr{O}_X)$ and $(Y, \mathscr{O}_Y)$ are locally ringed spaces, we shall consider morphisms $(\psi, \theta) : (X, \mathscr{O}_X) \to (Y, \mathscr{O}_Y)$ such that, for every $x \in X$, $\theta_x^\sharp : \mathscr{O}_{\psi(x)} \to \mathscr{O}_x$ is a local homomorphism.

Whenever we speak henceforth of a *morphism of locally ringed spaces*, we shall always mean a morphism of this kind. With this definition of morphisms, locally ringed spaces form a category. For two objects X, Y of this category, $\operatorname{Hom}(X, Y)$ will therefore denote the set of morphisms of locally ringed spaces from X to Y (the set denoted $\mathfrak{L}$ in (1.8.1)). When we wish to consider the set of morphisms of ringed spaces from X to Y, we shall write $\operatorname{Hom}_{\mathrm{rs}}(X, Y)$ to avoid ambiguity. The map (1.8.1.1) is thus written **II** | 219

(1.8.2.1) $$ \rho : \operatorname{Hom}_{\mathrm{rs}}(X, Y) \longrightarrow \operatorname{Hom}(\Gamma(Y, \mathscr{O}_Y), \Gamma(X, \mathscr{O}_X)), $$

and its restriction

(1.8.2.2) $$ \rho' : \operatorname{Hom}(X, Y) \longrightarrow \operatorname{Hom}(\Gamma(Y, \mathscr{O}_Y), \Gamma(X, \mathscr{O}_X)) $$

is functorial in X and Y in the category of locally ringed spaces.

Corollary (1.8.3). — *Let $(Y, \mathscr{O}_Y)$ be a locally ringed space. For Y to be an affine scheme, it is necessary and sufficient that, for every locally ringed space $(X, \mathscr{O}_X)$, the map (1.8.2.2) be bijective.*

Proof. Proposition (1.8.1) shows that the condition is necessary. Conversely, suppose it holds and put $A = \Gamma(Y, \mathscr{O}_Y)$. The hypothesis and (1.8.1) show that the functors

$$X \longmapsto \mathrm{Hom}(X, Y) \quad \text{and} \quad X \longmapsto \mathrm{Hom}(X, \mathrm{Spec}(A))$$

from locally ringed spaces to sets are isomorphic. This implies the existence of a canonical isomorphism $Y \to \mathrm{Spec}(A)$ (cf. 0, 8). □

(1.8.4). Let $S = \mathrm{Spec}(A)$ be an affine scheme. Denote by (S', A') the ringed space whose underlying space consists of one point and whose structure sheaf A' is the (necessarily simple) sheaf on S' defined by the ring A. Let $\pi : S \to S'$ be the unique map. For every open subset U of S, the canonical map

$$\Gamma(S', A') = \Gamma(S, \mathscr{O}_S) \longrightarrow \Gamma(U, \mathscr{O}_S)$$

defines a π-morphism $\iota : A' \to \mathscr{O}_S$ of sheaves of rings. Thus there is a canonical morphism of ringed spaces

$$i = (\pi, \iota) : (S, \mathscr{O}_S) \longrightarrow (S', A').$$

For every A-module M, denote by M' the simple sheaf on S' defined by M, which is evidently an A'-module. It is clear that $i_*(\widetilde{M}) = M'$ (I, 1.3.7).

Lemma (1.8.5). — *With the notation of (1.8.4), for every A-module M, the canonical functorial $\mathscr{O}_S$-homomorphism (0, 4.4.3.3)*

(1.8.5.1) $$i^*(i_*(\widetilde{M})) \longrightarrow \widetilde{M}$$

is an isomorphism.

Proof. Both sides of (1.8.5.1) are right exact in M (the functor $M \mapsto i_*(\widetilde{M})$ being evidently exact) and commute with direct sums. By viewing M as the cokernel of a homomorphism $A^{(I)} \to A^{(J)}$, one is reduced to the case $M = A$, where the assertion is immediate. □

Corollary (1.8.6). — *Let $(X, \mathscr{O}_X)$ be a ringed space and let $u : X \to S$ be a morphism of ringed spaces. For every A-module M, there is, with the notation of (1.8.4), a canonical functorial isomorphism of $\mathscr{O}_X$-modules* II | 220

(1.8.6.1) $$u^*(\widetilde{M}) \simeq u^*(i^*(M')).$$

Corollary (1.8.7). — *Under the hypotheses of (1.8.6), for every A-module M and every $\mathscr{O}_X$-module $\mathscr{F}$, there is a canonical isomorphism, functorial in M and $\mathscr{F}$,*

(1.8.7.1) $$\mathrm{Hom}_{\mathscr{O}_S}(\widetilde{M}, u_*(\mathscr{F})) \simeq \mathrm{Hom}_A(M, \Gamma(X, \mathscr{F})).$$

Proof. By (0, 4.4.3) and Lemma (1.8.5), there is a canonical isomorphism of bifunctors

$$\mathrm{Hom}_{\mathscr{O}_S}(\widetilde{M}, u_*(\mathscr{F})) \simeq \mathrm{Hom}_{A'}(M', i_*(u_*(\mathscr{F}))).$$

The right-hand side is plainly $\mathrm{Hom}_A(M, \Gamma(X, \mathscr{F}))$. Under the canonical homomorphism (1.8.7.1), an $\mathscr{O}_S$-homomorphism $h : \widetilde{M} \to u_*(\mathscr{F})$ (equivalently, a u-morphism $\widetilde{M} \to \mathscr{F}$) corresponds to

$$\Gamma(h) : M \longrightarrow \Gamma(S, u_*(\mathscr{F})) = \Gamma(X, \mathscr{F}).$$

□

(1.8.8). With the notation of (1.8.4), it is clear from (0, 4.1.1) that every morphism of ringed spaces $(\psi, \theta) : X \to S'$ is equivalent to the data of a ring homomorphism $A \to \Gamma(X, \mathscr{O}_X)$. Proposition (1.8.1) may therefore be interpreted as giving a canonical bijection

$$\mathrm{Hom}(X, S) \simeq \mathrm{Hom}(X, S'),$$

where the right-hand side means morphisms of ringed spaces, since A is not in general a local ring.

More generally, let X, Y be locally ringed spaces and let (Y', A') be the ringed space whose underlying space is one point and whose sheaf of rings is the simple sheaf defined by $\Gamma(Y, \mathscr{O}_Y)$. Then (1.8.2.1) may be interpreted as a map

(1.8.8.1) $$\rho : \mathrm{Hom}_{\mathrm{rs}}(X, Y) \longrightarrow \mathrm{Hom}(X, Y').$$

Corollary (1.8.3) says that affine schemes are characterized among locally ringed spaces as those for which the restriction of ρ to $\mathrm{Hom}(X, Y)$,

$$\rho' : \mathrm{Hom}(X, Y) \longrightarrow \mathrm{Hom}(X, Y'), \tag{1.8.8.2}$$

is bijective for every locally ringed space X. In a later chapter we shall generalize this definition, thereby associating to an arbitrary ringed space Z (and not only to one whose underlying space is a point) a locally ringed space which we shall again call $\mathrm{Spec}(Z)$. This will be the starting point of a "relative" theory of preschemes over arbitrary ringed spaces, extending the results of Chapter I.

(1.8.9). The pairs $(X, \mathscr{F})$, where X is a locally ringed space and $\mathscr{F}$ an $\mathscr{O}_X$-module, form a category: a morphism $(X, \mathscr{F}) \to (Y, \mathscr{G})$ is a pair (u, h) consisting of a morphism of locally ringed spaces $u : X \to Y$ and a u-morphism $h : \mathscr{G} \to \mathscr{F}$ of modules. For fixed $(X, \mathscr{F})$ and $(Y, \mathscr{G})$, these morphisms form a set denoted $\mathrm{Hom}((X, \mathscr{F}), (Y, \mathscr{G}))$. The assignment $(u, h) \mapsto (\rho'(u), \Gamma(h))$ is a canonical map **II | 221**

$$\begin{aligned}\mathrm{Hom}((X, \mathscr{F}), (Y, \mathscr{G})) \longrightarrow \mathrm{Hom}\big((\Gamma(Y, \mathscr{O}_Y), \Gamma(Y, \mathscr{G})), \\ (\Gamma(X, \mathscr{O}_X), \Gamma(X, \mathscr{F}))\big),\end{aligned} \tag{1.8.9.1}$$

functorial in $(X, \mathscr{F})$ and $(Y, \mathscr{G})$; the right-hand side is the set of di-homomorphisms corresponding to the rings and modules in question (0, 1.0.2).

Corollary (1.8.10). — *Let Y be a locally ringed space and $\mathscr{G}$ an $\mathscr{O}_Y$-module. For Y to be an affine scheme and $\mathscr{G}$ a quasi-coherent $\mathscr{O}_Y$-module, it is necessary and sufficient that, for every pair $(X, \mathscr{F})$ consisting of a locally ringed space X and an $\mathscr{O}_X$-module $\mathscr{F}$, the canonical map (1.8.9.1) be bijective.*

We leave to the reader the task of spelling out the proof, which is modelled on that of (1.8.3) and uses (1.8.1) and (1.8.7).

Remark (1.8.11). — The statements (I, 1.7.3), (I, 1.7.4), and (I, 2.2.4), as well as the definition (I, 1.6.1), are special cases of (1.8.1); similarly, (I, 2.2.5) follows from (1.8.7). Corollary (1.8.7) also gives (I, 1.6.3), and hence (I, 1.6.4), as a special case. Indeed, if X is affine and $\Gamma(X, \mathscr{F}) = N$, the functors

$$M \longmapsto \mathrm{Hom}_{\mathscr{O}_S}(\widetilde{M}, u_*(\widetilde{N})) \quad \text{and} \quad M \longmapsto \mathrm{Hom}_{\mathscr{O}_S}(\widetilde{M}, (N_{[\phi]})^{\sim})$$

(where $\phi : A \to \Gamma(X, \mathscr{O}_X)$ corresponds to u) are isomorphic by (1.8.7) and (I, 1.3.8). Finally, (I, 1.6.5), and hence (I, 1.6.6), follows from (1.8.6) and from the fact that, for every $f \in A$, the A_f-modules

$$N' \otimes_{A'} A_f \quad \text{and} \quad (N' \otimes_{A'} A)_f$$

(with the notation of (I, 1.6.5)) are canonically isomorphic.

Insert after (I, 3.2.8):

(3.2.9). It follows from (1.8.1) that (I, 3.2.2) may be sharpened as follows. The prescheme

$$Z = \mathrm{Spec}(B \otimes_A C)$$

is not only a product of $X = \mathrm{Spec}(B)$ and $Y = \mathrm{Spec}(C)$ in the category of S-preschemes, but also in the category of locally ringed spaces over S (with the definition of S-morphisms modelled on (I, 2.5.2)). The proof of (I, 3.2.6) also shows that, for arbitrary S-preschemes X, Y, the prescheme $X \times_S Y$ is not only their product in the category of S-preschemes, but also in the category of locally ringed spaces over the prescheme S.

(I, 4.4.5). On line 14 from the bottom of p. 126, replace B by A; on line 13 from the bottom, replace "A-algebra" by "B-algebra".

(I, 5.3.5). On line 2 from the bottom of p. 132, replace $Y \to S$ by $g : Y \to S$.

(I, 6.3.2.1). On line 6 from the bottom of p. 144, read

$$D(g_i) \subset W.$$

(I, 7.3.8). Replace the present text, which is erroneous, by the following:

Let X, Y be integral preschemes; then $\mathscr{R}(X)$ and $\mathscr{R}(Y)$ are respectively a quasi-coherent $\mathscr{O}_X$-module and a quasi-coherent $\mathscr{O}_Y$-module (I, 7.3.3). If $f : X \to Y$ is a dominant morphism, there is a canonical homomorphism of $\mathscr{O}_X$-modules **II** | 222

$$\tau : f^*(\mathscr{R}(Y)) \longrightarrow \mathscr{R}(X). \tag{7.3.8.1}$$

First suppose that $X = \operatorname{Spec}(A)$ and $Y = \operatorname{Spec}(B)$ are affine, with A, B integral domains. Then f corresponds to an injective homomorphism $B \to A$, which extends to a monomorphism $L \to K$ from the fraction field L of B into the fraction field K of A. The homomorphism (7.3.8.1) then corresponds to the canonical homomorphism

$$L \otimes_B A \longrightarrow K$$

of (I, 1.6.5).

In the general case, for every pair of nonempty affine open subsets $U \subset X$, $V \subset Y$ such that $f(U) \subset V$, the preceding construction defines a homomorphism $\tau_{U,V}$. If $U' \subset U$, $V' \subset V$, and $f(U') \subset V'$, then $\tau_{U,V}$ extends $\tau_{U',V'}$; the assertion follows by gluing. If x, y are the generic points of X, Y, respectively, then $f(x) = y$ and

$$\big(f^*(\mathscr{R}(Y))\big)_x = \mathscr{O}_y \otimes_{\mathscr{O}_y} \mathscr{O}_x = \mathscr{O}_x$$

by (0, 4.3.1), so τ_x is an isomorphism.

(I, 9.5.2). In the last three lines of p. 176 and the first five lines of p. 177, replace X' everywhere by Y' and X'' by Y''.

(I, 10.5.4). On line 11 from the bottom of p. 187, replace (10.3.4) by (10.3.5).

(I, 10.6.3). On line 3 from the bottom of p. 189, replace X by $\mathfrak{X}$.

(I, 10.14.2). On line 5 of p. 210, replace "coherent $\mathscr{O}_X$-module" by "coherent ideal of $\mathscr{O}_X$"; on line 7, replace "coherent $\mathscr{O}_X$-modules" by "coherent ideals of $\mathscr{O}_X$".

III | 81

Summary

This chapter gives the fundamental theorems concerning the cohomology of coherent algebraic sheaves, with the exception of theorems explaining the theory of residues (duality theorems), which will be the subject of a later chapter. Amongst all those included here, there are essentially six fundamental theorems, and each one is the subject of one of the first six sections. These results will prove to be essential tools in all that follows, even in questions which are not truly cohomological in their nature; the reader will see the first such examples starting from §4. §7 gives some more technical results, but ones which are constantly used in applications. Finally, in §§8–11, we will develop certain results, related to the duality of coherent sheaves, that are particularly important for applications, and which can be explained even before the introduction of the full general theory of residues.

The content of §§1 and 2 is due to J.-P. Serre, and the reader will observe that we have had only to follow (FAC). §8 and 9 are equally inspired by (FAC) (the changes necessitated by the different contexts, however, being less evident). Finally, as we said in the Introduction, §4 should be considered as the formalisation, in modern language, of the fundamental "invariance theorem" of Zariski's "theory of holomorphic functions". III | 82

We draw attention to the fact that the results of n°3.4 (and the preliminary propositions of (**0**, 13.4) to (**0**, 13.7)) will not be used in what follows Chapter III, and can thus be skipped in a first reading.

§1. Cohomology of affine schemes

1.1. Review of the exterior algebra complex

(1.1.1). Let A be a ring, $\mathbf{f} = (f_i)_{1\leqslant i\leqslant r}$ a system of r elements of A. The *exterior algebra complex* $K_\bullet(\mathbf{f})$ corresponding to $\mathbf{f}$ is a chain complex (G, I, 2.2) defined in the following way: the graded A-module $K_\bullet(\mathbf{f})$ is equal to the *exterior algebra* $\wedge(A^r)$, graded in the usual way, and the boundary map is the *interior multiplication* $i_\mathbf{f}$ by $\mathbf{f}$ considered as an element of the dual $(A^r)^\vee$; we recall that $i_\mathbf{f}$ is an *antiderivation* of degree -1 of $\wedge(A^r)$, and if $(\mathbf{e}_i)_{1\leqslant i\leqslant r}$ is the canonical basis of A^r, then we have $i_\mathbf{f}(\mathbf{e}_i) = f_i$; the verification of the condition $i_\mathbf{f} \circ i_\mathbf{f} = 0$ is immediate.

An equivalent definition is the following: for each i, we consider a chain complex $K_\bullet(f_i)$ defined as follows: $K_0(f_i) = K_1(f_i) = A$, $K_n(f_i) = 0$ for $n \neq 0, 1$: the boundary map is defined by the condition that $d_1 : A \to A$ is *multiplication by* f_i. We then take $K_\bullet(\mathbf{f})$ to be the *tensor product* $K_\bullet(f_1) \otimes K_\bullet(f_2) \otimes \cdots \otimes K_\bullet(f_r)$ (G, I, 2.7) with its total degree; the verification of the isomorphism from this complex to the complex defined above is immediate.

[1]EGA IV does not depend on §§8–11, and will probably be published before these chapters. *[Trans.] These last four chapters were never published.*

(1.1.2). For every A-module M, we define the *chain complex*

$$K_\bullet(\mathbf{f}, M) = K_\bullet(\mathbf{f}) \otimes_A M \tag{1.1.2.1}$$

and the *cochain complex* (G, I, 2.2)

$$K^\bullet(\mathbf{f}, M) = \mathrm{Hom}_A(K_\bullet(\mathbf{f}), M). \tag{1.1.2.2}$$

If g is a k-cochain of this latter complex, and if we set

$$g(i_1, \ldots, i_k) = g(\mathbf{e}_{i_1} \wedge \cdots \wedge \mathbf{e}_{i_k}),$$

then g identifies with an *alternating* map from $[1, r]^k$ to M, and it follows from the above definitions that we have

$$d^k g(i_1, i_2, \ldots, i_{k+1}) = \sum_{h=1}^{k+1} (-1)^{h-1} f_{i_h} g(i_1, \ldots, \widehat{i_h}, \ldots, i_{k+1}). \tag{1.1.2.3}$$

(1.1.3). From the above complexes, we deduce as usual the *homology and cohomology A-modules* (G, I, 2.2) **III** | 83

$$\mathrm{H}_\bullet(\mathbf{f}, M) = \mathrm{H}_\bullet(K_\bullet(\mathbf{f}, M)), \tag{1.1.3.1}$$

$$\mathrm{H}^\bullet(\mathbf{f}, M) = \mathrm{H}^\bullet(K^\bullet(\mathbf{f}, M)). \tag{1.1.3.2}$$

We define an *A-isomorphism* $K_i(\mathbf{f}, M) \simeq K^{r-i}(\mathbf{f}, M)$ by sending each chain $z = \sum(\mathbf{e}_{i_1} \wedge \cdots \wedge \mathbf{e}_{i_k}) \otimes z_{i_1,\ldots,i_k}$ to the cochain g_z such that $g_z(j_1, \ldots, j_{r-k}) = \varepsilon z_{i_1,\ldots,i_k}$, where $(j_h)_{1\leqslant h\leqslant r-k}$ is the strictly increasing sequence complementary to the strictly increasing sequence $(i_h)_{1\leqslant h\leqslant k}$ in $[1, r]$ and $\varepsilon = (-1)^\nu$, where ν is the number of inversions of the permutation $i_1, \ldots, i_k, j_1, \ldots, j_{r-k}$ of $[1, r]$. We verify that $g_{dz} = d(g_z)$, which gives an isomorphism

$$\mathrm{H}^i(\mathbf{f}, M) \simeq \mathrm{H}_{r-i}(\mathbf{f}, M) \text{ for } 0 \leqslant i \leqslant r. \tag{1.1.3.3}$$

In this chapter, we will especially consider the cohomology modules $\mathrm{H}^\bullet(\mathbf{f}, M)$.

For a given $\mathbf{f}$, it is immediate (G, I, 2.1) that $M \mapsto \mathrm{H}^\bullet(\mathbf{f}, M)$ is a *cohomological functor* (T, II, 2.1) from the category of A-modules to the category of graded A-modules, zero in degrees < 0 and $> r$. In addition, we have

$$\mathrm{H}^0(\mathbf{f}, M) = \mathrm{Hom}_A(A/(\mathbf{f}), M), \tag{1.1.3.4}$$

denoting by $(\mathbf{f})$ the ideal of A generated by $f_1, \ldots, f_r$; this follows immediately from (1.1.2.3), and it is clear that $\mathrm{H}^0(\mathbf{f}, M)$ identifies with the submodule of M *killed by* $(\mathbf{f})$. Similarly, we have by (1.1.2.3) that

$$\mathrm{H}^r(\mathbf{f}, M) = M/\left(\sum_{i=1}^r f_i M\right) = (A/(\mathbf{f})) \otimes_A M. \tag{1.1.3.5}$$

We will use the following known result, which we will recall a proof of to be complete:

Proposition (1.1.4). — *Let A be a ring, $\mathbf{f} = (f_i)_{1\leqslant i\leqslant r}$ a finite family of elements of A, and M an A-module. If, for $1 \leqslant i \leqslant r$, the scaling $z \mapsto f_i \cdot z$ on $M_{i-1} = M/(f_1 M + \cdots + f_{i-1} M)$ is injective, then we have $\mathrm{H}^i(\mathbf{f}, M) = 0$ for $i \neq r$.*

Proof. It suffices to prove that $\mathrm{H}_i(\mathbf{f}, M) = 0$ for all $i > 0$ according to (1.1.3.3). We argue by induction on r, the case $r = 0$ being trivial. Set $\mathbf{f}' = (f_i)_{1\leqslant i\leqslant r-1}$; this family satisfies the conditions in the statement, so if we set $L_\bullet = K_\bullet(\mathbf{f}', M)$, then we have $\mathrm{H}_i(L_\bullet) = 0$ for $i > 0$ by hypothesis, and $\mathrm{H}_0(L_\bullet) = M_{r-1}$ by virtue of (1.1.3.3) and (1.1.3.5). To abbreviate, set $K_\bullet = K_\bullet(f_r) = K_0 \oplus K_1$, with $K_0 = K_1 = A$, $d_1 : K_1 \to K_0$ multiplication by f_r; we have by definition (1.1.1) that $K_\bullet(\mathbf{f}, M) = K_\bullet \otimes_A L_\bullet$. We have the following lemma:

Lemma (1.1.4.1). — *Let $K_\bullet$ be a chain complex of free A-modules, zero except in dimensions* 0 *and* 1*. For every chain complex $L_\bullet$ of A-modules, we have an exact sequence*

$$0 \longrightarrow \mathrm{H}_0(K_\bullet \otimes \mathrm{H}_p(L_\bullet)) \longrightarrow \mathrm{H}_p(K_\bullet \otimes L_\bullet) \longrightarrow \mathrm{H}_1(K_\bullet \otimes \mathrm{H}_{p-1}(L_\bullet)) \longrightarrow 0$$

for every index p.

This is a particular case of an exact sequence of low-order terms of the Künneth spectral sequence (M, XVII, 5.2 (a) and G, I, 5.5.2); it can be proved directly as follows. Consider K_0 and K_1 as chain complexes (zero in dimensions $\neq 0$ and $\neq 1$ respectively); we then have an exact sequence of complexes **III | 84**

$$0 \longrightarrow K_0 \otimes L_\bullet \longrightarrow K_\bullet \otimes L_\bullet \longrightarrow K_1 \otimes L_\bullet \longrightarrow 0,$$

to which we can apply the exact sequence in homology

$$\cdots \longrightarrow \mathrm{H}_{p+1}(K_1 \otimes L_\bullet) \xrightarrow{\partial} \mathrm{H}_p(K_0 \otimes L_\bullet) \longrightarrow \mathrm{H}_p(K_\bullet \otimes L_\bullet)$$
$$\longrightarrow \mathrm{H}_p(K_1 \otimes L_\bullet) \xrightarrow{\partial} \mathrm{H}_{p-1}(K_0 \otimes L_\bullet) \longrightarrow \cdots.$$

But it is evident that $\mathrm{H}_p(K_0 \otimes L_\bullet) = K_0 \otimes \mathrm{H}_p(L_\bullet)$ and $\mathrm{H}_p(K_1 \otimes L_\bullet) = K_1 \otimes \mathrm{H}_{p-1}(L_\bullet)$ for all p; in addition, we verify immediately that the operator $\partial : K_1 \otimes \mathrm{H}_p(L_\bullet) \to K_0 \otimes \mathrm{H}_p(L_\bullet)$ is none other than $d_1 \otimes 1$; the lemma thus follows from the above exact sequence and the definition of $\mathrm{H}_0(K_\bullet \otimes \mathrm{H}_p(L_\bullet))$ and $\mathrm{H}_1(K_\bullet \otimes \mathrm{H}_{p-1}(L_\bullet))$.

The lemma having been established, the end of the proof of Proposition (1.1.4) is immediate: the induction hypothesis of Lemma (1.1.4.1) gives $\mathrm{H}_p(K_\bullet \otimes L_\bullet) = 0$ for $p \geqslant 2$; in addition if we show that $\mathrm{H}_1(K_\bullet, \mathrm{H}_0(L_\bullet)) = 0$, then we also deduce from Lemma (1.1.4.1) that $\mathrm{H}_1(K_\bullet \otimes L_\bullet) = 0$; but by definition, $\mathrm{H}_1(K_\bullet, \mathrm{H}_0(L_\bullet))$ is none other than the kernel of the scaling $z \mapsto f_r \cdot z$ on M_{r-1}, and as by hypothesis this kernel is zero, this finishes the proof. □

(1.1.5). Let $\mathbf{g} = (g_i)_{1 \leqslant i \leqslant r}$ be a second sequence of r elements of A, and set $\mathbf{fg} = (f_i g_i)_{1 \leqslant i \leqslant r}$. We can define a canonical homomorphism of complexes

$$\phi_{\mathbf{g}} : K_\bullet(\mathbf{fg}) \longrightarrow K_\bullet(\mathbf{f}) \tag{1.1.5.1}$$

as the canonical extension to the exterior algebra $\wedge(A^r)$ of the A-linear map $(x_1, \ldots, x_r) \mapsto (g_1 x_1, \ldots, g_r x_r)$ from A^r to itself. To see that we have a homomorphism of complexes, it suffices to note, in general, that if $u : E \to F$ is an A-linear map, and if $\mathbf{x} \in F^\vee$ and $\mathbf{y} = {}^t u(\mathbf{x}) \in E^\vee$, then we have the formula

$$(\wedge u) \circ i_{\mathbf{y}} = i_{\mathbf{x}} \circ (\wedge u); \tag{1.1.5.2}$$

indeed, both sides are antiderivations of $\wedge F$, and it suffices to check that they coincide on F, which follows immediately from the definitions.

When we identify $K_\bullet(\mathbf{f})$ with the tensor product of the $K_\bullet(f_i)$ (1.1.1), $\phi_{\mathbf{g}}$ is the tensor product of the ϕ_{g_i}, where ϕ_{g_i} is the identity in degree 0 and multiplication by g_i in degree 1.

(1.1.6). In particular, for every pair of integers m and n such that $0 \leqslant n \leqslant m$, we have homomorphisms of complexes

$$\phi_{\mathbf{f}^{m-n}} : K_\bullet(\mathbf{f}^m) \longrightarrow K_\bullet(\mathbf{f}^n) \tag{1.1.6.1}$$

and as a result, homomorphisms

$$\phi_{\mathbf{f}^{m-n}} : K^\bullet(\mathbf{f}^n, M) \longrightarrow K^\bullet(\mathbf{f}^m, M), \tag{1.1.6.2}$$

$$\phi_{\mathbf{f}^{m-n}} : \mathrm{H}^\bullet(\mathbf{f}^n, M) \longrightarrow \mathrm{H}^\bullet(\mathbf{f}^m, M). \tag{1.1.6.3}$$

The latter homomorphisms evidently satisfy the transitivity condition $\phi_{\mathbf{f}^{m-p}} = \phi_{\mathbf{f}^{m-n}} \circ \phi_{\mathbf{f}^{n-p}}$ for $p \leqslant n \leqslant m$; they therefore define two *inductive systems* of A-modules; we set **III | 85**

$$\mathrm{C}^\bullet((\mathbf{f}), M) = \varinjlim_n K^\bullet(\mathbf{f}^n, M), \tag{1.1.6.4}$$

$$\mathrm{H}^\bullet((\mathbf{f}), M) = \mathrm{H}^\bullet(\mathrm{C}^\bullet((\mathbf{f}), M)) = \varinjlim_n \mathrm{H}^\bullet(\mathbf{f}^n, M), \tag{1.1.6.5}$$

the last equality following from the fact that passing to the inductive limit commutes with the functor $\mathrm{H}^\bullet$ (G, I, 2.1). We will later see (1.4.3) that $\mathrm{H}^\bullet((\mathbf{f}), M)$ does not depend on the *ideal* $(\mathbf{f})$ of A (and similarly on the $(\mathbf{f})$-pre-adic topology on A), which justifies the notations.

It is clear that $M \mapsto \mathrm{C}^\bullet((\mathbf{f}), M)$ is an exact A-linear functor, and $M \mapsto \mathrm{H}^\bullet((\mathbf{f}), M)$ is a cohomological functor.

(1.1.7). Set $\mathbf{f} = (f_i) \in A^r$ and $\mathbf{g} = (g_i) \in A^r$; denote by $e_{\mathbf{g}}$ the left multiplication by the vector $\mathbf{g} \in A^r$ on the exterior algebra $\wedge(A^r)$; we know that we have the *homotopy formula*

$$i_{\mathbf{f}} e_{\mathbf{g}} + e_{\mathbf{g}} i_{\mathbf{f}} = \langle \mathbf{g}, \mathbf{f} \rangle 1 \tag{1.1.7.1}$$

in the A-module $\wedge(A^r)$ (1 denotes the identity automorphism of $\wedge(A^r)$); this relation also implies that *in the complex $K_\bullet(\mathbf{f})$* we have

$$d e_{\mathbf{g}} + e_{\mathbf{g}} d = \langle \mathbf{g}, \mathbf{f} \rangle 1. \tag{1.1.7.2}$$

If the ideal $(\mathbf{f})$ is equal to A, then there exists a $\mathbf{g} \in A^r$ such that $\langle \mathbf{g}, \mathbf{f} \rangle = \sum_{i=1}^r g_i f_i = 1$. As a result (G, I, 2.4):

Proposition (1.1.8). — *Suppose that the ideal $(\mathbf{f})$ generated by the f_i is equal to A. Then the complex $K_\bullet(\mathbf{f})$ is homotopically trivial, and so are the complexes $K_\bullet(\mathbf{f}, M)$ and $K^\bullet(\mathbf{f}, M)$ for every A-module M.*

Corollary (1.1.9). — *If $(\mathbf{f}) = A$, then we have $\mathrm{H}^\bullet(\mathbf{f}, M) = 0$ and $\mathrm{H}^\bullet((\mathbf{f}), M) = 0$ for every A-module M.*

Proof. Indeed, we then have $(\mathbf{f}^n) = A$ for all n. □

Remark (1.1.10). — With the same notations as above, set $X = \operatorname{Spec}(A)$ and Y the closed subprescheme of X defined by the ideal $(\mathbf{f})$. We will prove in §9 that $\mathrm{H}^\bullet((\mathbf{f}), M)$ is isomorphic to the cohomology $\mathrm{H}^\bullet_Y(X, \widetilde{M})$ corresponding to the antifilter Φ of closed subsets of Y (T, 3.2). We will also show that Proposition (1.2.3) applied to X and to $\mathscr{F} = \widetilde{M}$ is a particular case of an exact sequence in cohomology

$$\cdots \longrightarrow \mathrm{H}^p_Y(X, \mathscr{F}) \longrightarrow \mathrm{H}^p(X, \mathscr{F}) \longrightarrow \mathrm{H}^p(X - Y, \mathscr{F}) \longrightarrow \mathrm{H}^{p+1}_Y(X, \mathscr{F}) \longrightarrow \cdots.$$

1.2. Čech cohomology of an open cover

Notation (1.2.1). — In this section, we denote:

(1) X a prescheme;
(2) $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-module; **III** | 86
(3) $A = \Gamma(X, \mathscr{O}_X)$, $M = \Gamma(X, \mathscr{F})$;
(4) $\mathbf{f} = (f_i)_{1 \leqslant i \leqslant r}$ a finite system of elements of A;
(5) $U_i = X_{f_i}$, the open set (0, 5.5.2) of the $x \in X$ such that $f_i(x) \neq 0$;
(6) $U = \bigcup_{i=1}^r U_i$;
(7) $\mathfrak{U}$ the cover $(U_i)_{1 \leqslant i \leqslant r}$ of U.

(1.2.2). Suppose that X is either a prescheme whose underlying space is *Noetherian* or a *scheme* whose underlying space is *quasi-compact*. We then know (I, 9.3.3) that we have $\Gamma(U_i, \mathscr{F}) = M_{f_i}$. We set

$$U_{i_0 i_1 \cdots i_p} = \bigcap_{k=0}^{p} U_{i_k} = X_{f_{i_0} f_{i_1} \cdots f_{i_p}}$$

(0, 5.5.3); so we also have

$$\Gamma(U_{i_0 i_1 \cdots i_p}, \mathscr{F}) = M_{f_{i_0} f_{i_1} \cdots f_{i_p}}. \tag{1.2.2.1}$$

We have (0, 1.6.1) that $M_{f_{i_0} f_{i_1} \cdots f_{i_p}}$ identifies with the inductive limit $\varinjlim_n M^{(n)}_{i_0 i_1 \cdots i_p}$, where the inductive system is formed by the $M^{(n)}_{i_0 i_1 \cdots i_p} = M$, the homomorphisms $\phi_{nm} : M^{(m)}_{i_0 i_1 \cdots i_p} \to M^{(n)}_{i_0 i_1 \cdots i_p}$ being multiplication by $(f_{i_0} f_{i_1} \cdots f_{i_p})^{n-m}$ for $m \leqslant n$. We denote by $C^p_n(M)$ the set of *alternating* maps from $[1, r]^{p+1}$ to M (for all n); these A-modules also form an inductive system with respect to the ϕ_{nm}. If $C^p(\mathfrak{U}, \mathscr{F})$ is the group of *alternating* Čech p-cochains relative to the cover $\mathfrak{U}$, with coefficients in $\mathscr{F}$ (G, II, 5.1), then it follows from the above that we can write

$$C^p(\mathfrak{U}, \mathscr{F}) = \varinjlim_n C^p_n(M). \tag{1.2.2.2}$$

With the notations of (1.1.2), $C^p_n(M)$ identifies with $K^{p+1}(\mathbf{f}^n, M)$, and the map ϕ_{nm} identifies with the map $\phi_{\mathbf{f}^{n-m}}$ defined in (1.1.6). We thus have, for every $p \geqslant 0$, a canonical functorial isomorphism

$$C^p(\mathfrak{U}, \mathscr{F}) \simeq C^{p+1}((\mathbf{f}), M). \tag{1.2.2.3}$$

In addition, the formula (1.1.2.3) and the definition of the cohomology of a cover (G, II, 5.1) show that the isomorphisms (1.2.2.3) are compatible with the coboundary maps.

Proposition (1.2.3). — *If X is a prescheme whose underlying space is Noetherian or a scheme whose underlying space is quasi-compact, then there exists a canonical functorial isomorphism in $\mathscr{F}$*

(1.2.3.1) $$\mathrm{H}^p(\mathfrak{U},\mathscr{F}) \simeq \mathrm{H}^{p+1}((\mathbf{f}),M) \text{ for } p \geqslant 1.$$

In addition, we have a functorial exact sequence in $\mathscr{F}$

(1.2.3.2) $$0 \longrightarrow \mathrm{H}^0((\mathbf{f}),M) \longrightarrow M \longrightarrow \mathrm{H}^0(\mathfrak{U},\mathscr{F}) \longrightarrow \mathrm{H}^1((\mathbf{f}),M) \longrightarrow 0.$$

III | 87

Proof. The isomorphisms (1.2.3.1) are immediate consequences of what we saw in (1.2.2). On the other hand, we have $C^0(\mathfrak{U},\mathscr{F}) = C^1((\mathbf{f}),M)$; as a result, $\mathrm{H}^0(\mathfrak{U},\mathscr{F})$ identifies with the subgroup of 1-cocycles of $C^1((\mathbf{f}),M)$; as $M = C^0((\mathbf{f}),M)$, the exact sequence (1.2.3.2) is none other than the one given by the definition of the cohomology groups $\mathrm{H}^0((\mathbf{f}),M)$ and $\mathrm{H}^1((\mathbf{f}),M)$. □

Corollary (1.2.4). — *Suppose that the X_{f_i} are quasi-compact and that there exists $g_i \in \Gamma(U,\mathscr{O}_X)$ such that $\sum_i g_i(f_i|U) = 1|U$. Then for every quasi-coherent $(\mathscr{O}_X|U)$-module $\mathscr{G}$, we have $\mathrm{H}^p(\mathfrak{U},\mathscr{G}) = 0$ for $p > 0$; if in addition $U = X$, then the canonical homomorphism (1.2.3.2) $\Gamma(X,\mathscr{G}) \to \mathrm{H}^0(\mathfrak{U},\mathscr{G})$ is bijective.*

Proof. As by hypothesis the $U_i = X_{f_i}$ are quasi-compact, so is U, and we can reduce to the case where $U = X$; setting $N = \Gamma(X,\mathscr{G})$, the hypothesis then implies that $\mathrm{H}^p((\mathbf{f}),N) = 0$ for all $p \geqslant 0$ (1.1.9). The corollary then follows immediately from (1.2.3.1) and (1.2.3.2). □

We note that since $\mathrm{H}^0(\mathfrak{U},\mathscr{F}) = \mathrm{H}^0(U,\mathscr{F})$ (G, II, 5.2.2), we have again proved (I, 1.3.7) as a special case.

Remark (1.2.5). — Suppose that X is an *affine scheme*; then the $U_i = X_{f_i} = D(f_i)$ are affine open sets, as well as the $U_{i_0i_1\cdots i_p}$ (but U is not necessarily affine). In this case, the functors $\Gamma(X,\mathscr{F})$ and $\Gamma(U_{i_0i_1\cdots i_p},\mathscr{F})$ are exact in $\mathscr{F}$ (I, 1.3.11). If we have an exact sequence $0 \to \mathscr{F}' \to \mathscr{F} \to \mathscr{F}'' \to 0$ of quasi-coherent $\mathscr{O}_X$-modules, then the sequence of complexes

$$0 \longrightarrow C^\bullet(\mathfrak{U},\mathscr{F}') \longrightarrow C^\bullet(\mathfrak{U},\mathscr{F}) \longrightarrow C^\bullet(\mathfrak{U},\mathscr{F}'') \longrightarrow 0$$

is exact, and thus gives an exact sequence in cohomology

$$\cdots \longrightarrow \mathrm{H}^p(\mathfrak{U},\mathscr{F}') \longrightarrow \mathrm{H}^p(\mathfrak{U},\mathscr{F}) \longrightarrow \mathrm{H}^p(\mathfrak{U},\mathscr{F}'') \xrightarrow{\partial} \mathrm{H}^{p+1}(\mathfrak{U},\mathscr{F}') \longrightarrow \cdots.$$

On the other hand, if we set $M' = \Gamma(X,\mathscr{F}')$ and $M'' = \Gamma(X,\mathscr{F}'')$, then the sequence $0 \to M' \to M \to M'' \to 0$ is exact; as $C^\bullet((\mathbf{f}),M)$ is an exact functor in M, we also have the exact sequence in cohomology

$$\cdots \longrightarrow \mathrm{H}^p((\mathbf{f}),M') \longrightarrow \mathrm{H}^p((\mathbf{f}),M) \longrightarrow \mathrm{H}^p((\mathbf{f}),M'') \xrightarrow{\partial} \mathrm{H}^{p+1}((\mathbf{f}),M') \longrightarrow \cdots.$$

This being so, as the diagram

$$\begin{tikzcd}
0 \arrow[r] & C^\bullet(\mathfrak{U},\mathscr{F}') \arrow[r] \arrow[d] & C^\bullet(\mathfrak{U},\mathscr{F}) \arrow[r] \arrow[d] & C^\bullet(\mathfrak{U},\mathscr{F}'') \arrow[r] \arrow[d] & 0 \\
0 \arrow[r] & C^\bullet((\mathbf{f}),M') \arrow[r] & C^\bullet((\mathbf{f}),M) \arrow[r] & C^\bullet((\mathbf{f}),M'') \arrow[r] & 0
\end{tikzcd}$$

is commutative, we conclude that the diagrams III | 88

(1.2.5.1) $$\begin{tikzcd}
\mathrm{H}^p(\mathfrak{U},\mathscr{F}'') \arrow[r, "\partial"] \arrow[d] & \mathrm{H}^{p+1}(\mathfrak{U},\mathscr{F}') \arrow[d] \\
\mathrm{H}^{p+1}((\mathbf{f}),M'') \arrow[r, "\partial"] & \mathrm{H}^{p+2}((\mathbf{f}),M')
\end{tikzcd}$$

are commutative for all p (G, I, 2.1.1).

1.3. Cohomology of an affine scheme

Theorem (1.3.1). — *Let X be an affine scheme. For every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$, we have* $\mathrm{H}^p(X, \mathscr{F}) = 0$ *for all $p > 0$.*

Proof. Let $\mathfrak{U}$ be a finite cover of X by the affine open sets $X_{f_i} = D(f_i)$ $(1 \leqslant i \leqslant r)$; we then know that the ideal of $A = \Gamma(X, \mathscr{O}_X)$ generated by the f_i is equal to A. We thus conclude from Corollary (1.2.4) that we have $\mathrm{H}^p(\mathfrak{U}, \mathscr{F}) = 0$ for $p > 0$. As there are finite covers of X by affine open sets which are arbitrarily fine (**I**, 1.1.10), the definition of Čech cohomology (G, II, 5.8) shows that we also have $\check{\mathrm{H}}^p(X, \mathscr{F}) = 0$ for $p > 0$. But this also applies to every prescheme X_f for $f \in A$ (**I**, 1.3.6), hence $\check{\mathrm{H}}^p(X_f, \mathscr{F}) = 0$ for $p > 0$. As we have $X_f \cap X_g = X_{fg}$, we deduce that we also have $\mathrm{H}^p(X, \mathscr{F}) = 0$ for all $p > 0$, by virtue of (G, II, 5.9.2). □

Corollary (1.3.2). — *Let Y be a prescheme, $f : X \to Y$ an affine morphism* (**II**, 1.6.1)*. For every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$, we have $\mathrm{R}^q f_*(\mathscr{F}) = 0$ for $q > 0$.*

Proof. By definition $\mathrm{R}^q f_*(\mathscr{F})$ is the $\mathscr{O}_Y$-module associated to the presheaf $U \mapsto \mathrm{H}^q(f^{-1}(U), \mathscr{F})$, where U varies over the open subsets of Y. But the affine open sets form a basis for Y, and for such an open set U, $f^{-1}(U)$ is affine (**II**, 1.3.2), hence $\mathrm{H}^q(f^{-1}(U), \mathscr{F}) = 0$ by Theorem (1.3.1), which proves the corollary. □

Corollary (1.3.3). — *Let Y be a prescheme, $f : X \to Y$ an affine morphism. For every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$, the canonical homomorphism $\mathrm{H}^p(Y, f_*(\mathscr{F})) \to \mathrm{H}^p(X, \mathscr{F})$ (**0**, 12.1.3.1) is bijective for all p.*

Proof. It suffices (by (**0**, 12.1.7)) to show that the edge homomorphisms $''E_2^{p0} = \mathrm{H}^p(Y, f_*(\mathscr{F})) \to \mathrm{H}^p(X, \mathscr{F})$ of the second spectral sequence of the composite functor Γf_* are bijective. But the E_2-term of this spectral sequence is given by $''E_2^{pq} = \mathrm{H}^p(Y, \mathrm{R}^q f_*(\mathscr{F}))$ (G, II, 4.17.1), so it follows from Corollary (1.3.2) that $''E_2^{pq} = 0$ for $q > 0$, and the spectral sequence degenerates; hence our assertion (**0**, 11.1.6). □

Corollary (1.3.4). — *Let $f : X \to Y$ be an affine morphism, $g : Y \to Z$ a morphism. For every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$, the canonical homomorphism $\mathrm{R}^p g_*(f_*(\mathscr{F})) \to \mathrm{R}^p (g \circ f)_*(\mathscr{F})$ (**0**, 12.2.5.1) is bijective for all p.* **III** | 89

Proof. It suffices to note that, according to Corollary (1.3.3), for every affine open subset W of Z, the canonical homomorphism $\mathrm{H}^p(g^{-1}(W), f_*(\mathscr{F})) \to \mathrm{H}^p(f^{-1}(g^{-1}(W)), \mathscr{F})$ is bijective; this proves that the homomorphism of presheaves defining the canonical homomorphism $\mathrm{R}^p g_*(f_*(\mathscr{F})) \to \mathrm{R}^p (g \circ f)_*(\mathscr{F})$ is bijective (**0**, 12.2.5). □

1.4. Application to the cohomology of arbitrary preschemes

Proposition (1.4.1). — *Let X be a scheme, $\mathfrak{U} = (U_\alpha)$ be a cover of X by affine open sets. For every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$, the cohomology modules $\mathrm{H}^\bullet(X, \mathscr{F})$ and $\mathrm{H}^\bullet(\mathfrak{U}, \mathscr{F})$ (over $\Gamma(X, \mathscr{O}_X)$) are canonically isomorphic.*

Proof. As X is a scheme, every finite intersection V of open sets in the cover $\mathfrak{U}$ is affine (**I**, 5.5.6), so $\mathrm{H}^q(V, \mathscr{F}) = 0$ for $q \geqslant 1$ by Theorem (1.3.1). The proposition then follows from a theorem of Leray (G, II, 5.4.1). □

Remark (1.4.2). — We note that the result of Proposition (1.4.1) is still true when the finite intersections of the sets U_α are affine, even when we do not necessarily assume that X is a scheme.

Corollary (1.4.3). — *Let X be a scheme with quasi-compact underlying space, $A = \Gamma(X, \mathscr{O}_X)$, and $\mathbf{f} = (f_i)_{1 \leqslant i \leqslant r}$ a finite sequence of elements of A such that the X_{f_i} (notation of (1.2.1)) are affine. Then (with the notations of (1.2.1)), for every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$, we have a canonical isomorphism which is functorial in $\mathscr{F}$*

(1.4.3.1) $$\mathrm{H}^q(U, \mathscr{F}) \simeq \mathrm{H}^{q+1}((\mathbf{f}), M) \text{ for } q \geqslant 1,$$

and an exact sequence which is functorial in $\mathscr{F}$

(1.4.3.2) $$0 \longrightarrow \mathrm{H}^0((\mathbf{f}), M) \longrightarrow M \longrightarrow \mathrm{H}^0(U, \mathscr{F}) \longrightarrow \mathrm{H}^1((\mathbf{f}), M) \longrightarrow 0.$$

Proof. This follows immediately from Propositions (1.4.1) and (1.2.3). □

(1.4.4). If X is an *affine scheme*, then it follows from Remark (1.2.5) and Proposition (1.4.1) that for all $q \geqslant 0$, the diagrams

$$\begin{tikzcd} \mathrm{H}^q(U,\mathscr{F}'') \arrow[r, "\partial"] \arrow[d] & \mathrm{H}^{q+1}(U,\mathscr{F}') \arrow[d] \\ \mathrm{H}^{q+1}((\mathbf{f}),M'') \arrow[r, "\partial"] & \mathrm{H}^{q+2}((\mathbf{f}),M') \end{tikzcd} \tag{1.4.4.1}$$

corresponding to an exact sequence $0 \to \mathscr{F}' \to \mathscr{F} \to \mathscr{F}'' \to 0$ of quasi-coherent $\mathscr{O}_X$-modules (with the notations of Remark (1.2.5)) are commutative.

Proposition (1.4.5). — *Let X be a quasi-compact scheme, $\mathscr{L}$ an invertible $\mathscr{O}_X$-module, and consider the graded ring $A_\bullet = \Gamma_\bullet(\mathscr{L})$ (**0**, 5.4.6); then $\mathrm{H}^\bullet(\mathscr{F},\mathscr{L}) = \bigoplus_{n\in\mathbf{Z}} \mathrm{H}^\bullet(X,\mathscr{F}\otimes\mathscr{L}^{\otimes n})$ is a graded $A_\bullet$-module, and for all $f \in A_n$, we have a canonical isomorphism* III | 90

$$\mathrm{H}^\bullet(X_f,\mathscr{F}) \simeq (\mathrm{H}^\bullet(\mathscr{F},\mathscr{L}))_{(f)} \tag{1.4.5.1}$$

of $(A_\bullet)_{(f)}$-modules.

Proof. As X is a quasi-compact scheme, we can calculate the cohomology of all the $\mathscr{O}_X$-modules $\mathscr{F}\otimes\mathscr{L}^{\otimes n}$ using the same finite cover $\mathfrak{U} = (U_i)$ consisting of the affine open sets such that the restriction $\mathscr{L}|U_i$ is isomorphic to $\mathscr{O}_X|U_i$ for each i (1.4.1). It is then immediate that the $U_i \cap X_f$ are affine open sets (**I**, 1.3.6), and we can thus calculate the cohomology $\mathrm{H}^\bullet(X_f,\mathscr{F}\otimes\mathscr{L}^{\otimes n})$ using the cover $\mathfrak{U}|X_f = (U_i \cap X_f)$ (1.4.1). It is immediate that for all $f \in A_n$, multiplication by f defines a homomorphism $C^\bullet(\mathfrak{U},\mathscr{F}\otimes\mathscr{L}^m) \to C^\bullet(\mathfrak{U},\mathscr{F}\otimes\mathscr{L}^{\otimes(m+n)})$, hence a homomorphism $\mathrm{H}^\bullet(\mathfrak{U},\mathscr{F}\otimes\mathscr{L}^{\otimes m}) \to \mathrm{H}^\bullet(\mathfrak{U},\mathscr{F}\otimes\mathscr{L}^{\otimes(m+n)})$, which establishes the first assertion. On the other hand, for a given $f \in A_n$, it follows from (**I**, 9.3.2) that we have an isomorphism of complexes of $(A_\bullet)_{(f)}$-modules

$$C^\bullet(\mathfrak{U}|X_f,\mathscr{F}) \simeq \left(C^\bullet\left(\mathfrak{U}, \bigoplus_{n\in\mathbf{Z}} \mathscr{F}\otimes\mathscr{L}^{\otimes n}\right)\right)_{(f)},$$

taking into account (**I**, 1.3.9, ii). Passing to the cohomology of these complexes, we induce the isomorphism (1.4.5.1), recalling that the functor $M \mapsto M_{(f)}$ is exact on the category of graded $A_\bullet$-modules. □

Corollary (1.4.6). — *Suppose that the hypotheses of Proposition (1.4.5) are satisfied, and in addition suppose that $\mathscr{L} = \mathscr{O}_X$. If we set $A = \Gamma(X,\mathscr{O}_X)$, then for all $f \in A$, we have a canonical isomorphism $\mathrm{H}^\bullet(X_f,\mathscr{F}) \simeq (\mathrm{H}^\bullet(X,\mathscr{F}))_f$ of A_f-modules.*

Corollary (1.4.7). — *Let X be a quasi-compact scheme, f an element of $\Gamma(X,\mathscr{O}_X)$.*

(i) *Suppose that the open set X_f is affine. Then for every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$, every $i > 0$, and every $\xi \in \mathrm{H}^i(X,\mathscr{F})$, there exists an integer $n > 0$ such that $f^n\xi = 0$.*
(ii) *Conversely, suppose that X_f is quasi-compact and that for every quasi-coherent sheaf of ideals $\mathscr{J}$ of $\mathscr{O}_X$ and every $\zeta \in \mathrm{H}^1(X,\mathscr{J})$, there exists an $n > 0$ such that $f^n\zeta = 0$. Then X_f is affine.*

Proof.

(i) If X_f is affine, then we have $\mathrm{H}^i(X_f,\mathscr{F}) = 0$ for all $i > 0$ (1.3.1), so the assertion follows directly from Corollary (1.4.6).
(ii) By virtue of Serre's criterion (**II**, 5.2.1), it suffices to prove that for every quasi-coherent sheaf of ideals $\mathscr{K}$ of $\mathscr{O}_X|X_f$, we have $\mathrm{H}^1(X_f,\mathscr{K}) = 0$. As X_f is a quasi-compact open set in a quasi-compact scheme X, there exists a quasi-coherent sheaf of ideals $\mathscr{J}$ of $\mathscr{O}_X$ such that $\mathscr{K} = \mathscr{J}|X_f$ (**I**, 9.4.2). According to Corollary (1.4.6), we have $\mathrm{H}^1(X_f,\mathscr{K}) = (\mathrm{H}^1(X,\mathscr{J}))_f$, and the hypothesis implies that the right hand side is zero, hence the assertion.

□

Remark (1.4.8). — We note that Corollary (1.4.7, i) gives a simpler proof of the relation (**II**, 4.5.13.2).

Lemma (1.4.9). — *Let X be a quasi-compact scheme, $\mathfrak{U} = (U_i)_{1\leqslant i\leqslant n}$ a finite cover of X by affine open sets, and $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-module. The complex of sheaves $\mathscr{C}^\bullet(\mathfrak{U},\mathscr{F})$ defined by the cover $\mathfrak{U}$ (G, II, 5.2) is then a quasi-coherent $\mathscr{O}_X$-module.* III | 91

Proof. It follows from the definitions (G, II, 5.2) that $\mathscr{C}^p(\mathfrak{U},\mathscr{F})$ is the direct sum of the direct image sheaves of the $\mathscr{F}|U_{i_0\cdots i_p}$ under the canonical injection $U_{i_0\cdots i_p} \to X$. The hypothesis that X is a scheme implies that these injections are affine morphisms (**I**, 5.5.6), hence the $\mathscr{C}^p(\mathfrak{U},\mathscr{F})$ are quasi-coherent (**II**, 1.2.6). □

Proposition (1.4.10). — *Let $u : X \to Y$ be a separated and quasi-compact morphism. For every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$, the $\mathrm{R}^q u_*(\mathscr{F})$ are quasi-coherent $\mathscr{O}_Y$-modules.*

Proof. The question is local on Y, so we can suppose that Y is affine. Then X is a finite union of affine open sets U_i ($1 \leqslant i \leqslant n$); let $\mathfrak{U}$ be the cover (U_i). In addition, as Y is a scheme, it follows from (**I**, 5.5.10) that for every affine open $V \subset Y$, the canonical injection $u^{-1}(V) \to X$ is an affine morphism; we conclude (Proposition (1.4.1) and (G, II, 5.2)) that we have a canonical isomorphism

(1.4.10.1) $$\mathrm{H}^\bullet(u^{-1}(V),\mathscr{F}) \simeq \mathrm{H}^\bullet(\Gamma(V,\mathscr{K}^\bullet)),$$

where we set $\mathscr{K}^\bullet = u_*(\mathscr{C}^\bullet(\mathfrak{U},\mathscr{F}))$. According to Lemma (1.4.9) and (**I**, 9.2.2), $\mathscr{K}^\bullet$ is a quasi-coherent $\mathscr{O}_Y$-module; moreover, it constitutes a *complex of sheaves* since so is $\mathscr{C}^\bullet(\mathfrak{U},\mathscr{F})$. It then follows from the definition of the cohomology $\mathscr{H}^\bullet(\mathscr{K}^\bullet)$ (G, II, 4.1) that the latter consists of quasi-coherent $\mathscr{O}_Y$-modules (**I**, 4.1.1). As (for V affine in Y) the functor $\Gamma(V,\mathscr{G})$ is exact in $\mathscr{G}$ on the category of quasi-coherent $\mathscr{O}_Y$-modules, we have (G, II, 4.1)

(1.4.10.2) $$\mathrm{H}^\bullet(\Gamma(V,\mathscr{K}^\bullet)) = \Gamma(V,\mathscr{H}^\bullet(\mathscr{K}^\bullet)).$$

Finally, we note that it follows from the definition of the canonical homomorphism

$$\mathrm{H}^\bullet(\mathfrak{U},\mathscr{F}) \longrightarrow \mathrm{H}^\bullet(X,\mathscr{F}),$$

given in (G, II, 5.2), that if $V' \subset V$ is a second affine open subset of Y, then the diagram

$$\begin{tikzcd}
\mathrm{H}^\bullet(u^{-1}(V),\mathscr{F}) \arrow[r, "\sim"] \arrow[d] & \mathrm{H}^\bullet(\Gamma(V,\mathscr{K}^\bullet)) \arrow[d] \\
\mathrm{H}^\bullet(u^{-1}(V'),\mathscr{F}) \arrow[r, "\sim"] & \mathrm{H}^\bullet(\Gamma(V',\mathscr{K}^\bullet))
\end{tikzcd}$$

is commutative. We thus conclude from the above that the isomorphisms (1.4.10.1) define an isomorphism of $\mathscr{O}_Y$-modules

(1.4.10.3) $$\mathrm{R}^\bullet u_*(\mathscr{F}) \simeq \mathscr{H}^\bullet(\mathscr{K}^\bullet),$$

and as a result, $\mathrm{R}^\bullet u_*(\mathscr{F})$ is quasi-coherent. □ III | 92

In addition, it follows from (1.4.10.3), (1.4.10.2), and (1.4.10.1) that:

Corollary (1.4.11). — *Under the hypotheses of Proposition (1.4.10), for every affine open set V of Y, the canonical homomorphism*

(1.4.11.1) $$\mathrm{H}^q(u^{-1}(V),\mathscr{F}) \longrightarrow \Gamma(V,\mathrm{R}^q u_*(\mathscr{F}))$$

is an isomorphism for all $q \geqslant 0$.

Corollary (1.4.12). — *Suppose that the hypotheses of Proposition (1.4.10) are satisfied, and in addition suppose that Y is quasi-compact. Then there exists an integer $r > 0$ such that for every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$ and every integer $q > r$, we have $\mathrm{R}^q u_*(\mathscr{F}) = 0$. If Y is affine, then we can take for r an integer such that there exists a cover of X consisting of r affine open sets.*

Proof. As we can cover Y by a finite number of affine open sets, we can reduce to proving the second assertion, by virtue of Corollary (1.4.11). If $\mathfrak{U}$ is a cover of X by r affine open sets, then we have $\mathrm{H}^q(\mathfrak{U},\mathscr{F}) = 0$ for $q > r$, since the cochains of $C^q(\mathfrak{U},\mathscr{F})$ are alternating; the assertion thus follows from Proposition (1.4.1). □

Corollary (1.4.13). — *Suppose that the hypotheses of Proposition (1.4.10) are satisfied, and in addition suppose that $Y = \operatorname{Spec}(A)$ is affine. Then for every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$ and every $f \in A$, we have*

$$\Gamma(Y_f, \mathrm{R}^q u_*(\mathscr{F})) = (\Gamma(Y, \mathrm{R}^q u_*(\mathscr{F})))_f$$

up to canonical isomorphism.

Proof. This follows from the fact that $\mathrm{R}^q u_*(\mathscr{F})$ is a quasi-coherent $\mathscr{O}_Y$-module (**I**, 1.3.7). □

Proposition (1.4.14). — *Let $f : X \to Y$ be a separated and quasi-compact morphism, $g : Y \to Z$ an affine morphism. For every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$, the canonical homomorphism $\mathrm{R}^p(g \circ f)_*(\mathscr{F}) \to g_*(\mathrm{R}^p f_*(\mathscr{F}))$ (**0**, 12.2.5.2) is bijective for all p.*

Proof. For every affine open subset W of Z, $g^{-1}(W)$ is an affine open subset of Y. The homomorphism of presheaves defining the canonical homomorphism

$$\mathrm{R}^p(g \circ f)_*(\mathscr{F}) \longrightarrow g_*(\mathrm{R}^p f_*(\mathscr{F}))$$

(**0**, 12.2.5) is thus bijective by Corollary (1.4.11). □

Proposition (1.4.15). — *Let $u : X \to Y$ be a separated morphism of finite type, $v : Y' \to Y$ a flat morphism of preschemes (**0**, 6.7.1); let $u' = u_{(Y')}$, such that we have the commutative diagram*

(1.4.15.1)
$$\begin{tikzcd} X \arrow[d, "u"'] & X' = X_{(Y')} \arrow[l, "v'"'] \arrow[d, "u'"] \\ Y & Y'. \arrow[l, "v"'] \end{tikzcd}$$

Then for every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$, $\mathrm{R}^q u'_*(\mathscr{F}')$ is canonically isomorphic to $\mathrm{R}^q u_*(\mathscr{F}) \otimes_{\mathscr{O}_Y} \mathscr{O}_{Y'} = v^*(\mathrm{R}^q u_*(\mathscr{F}))$ for all $q \geqslant 0$, where $\mathscr{F}' = v'^*(\mathscr{F}) = \mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{O}_{Y'}$.

III | 93

Proof. The canonical homomorphism $\rho : \mathscr{F} \to v'_*(v'^*(\mathscr{F}))$ (**0**, 4.4.3.2) defines by functoriality a homomorphism

(1.4.15.2)
$$\mathrm{R}^q u_*(\mathscr{F}) \longrightarrow \mathrm{R}^q u_*(v'_*(\mathscr{F}')).$$

On the other hand, we have, by setting $w = u \circ v' = v \circ u'$, the canonical homomorphisms (**0** ,12.2.5.1 and 12.2.5.2)

(1.4.15.3)
$$\mathrm{R}^q u_*(v'_*(\mathscr{F}')) \longrightarrow \mathrm{R}^q w_*(\mathscr{F}') \longrightarrow v_*(\mathrm{R}^q u'_*(\mathscr{F}')).$$

Composing (1.4.15.3) and (1.4.15.2), we have a homomorphism

$$\psi : \mathrm{R}^q u_*(\mathscr{F}) \longrightarrow v_*(\mathrm{R}^q u'_*(\mathscr{F}')),$$

and finally we obtain a canonical homomorphism (whose definition does not make *any assumptions* on v)

(1.4.15.4)
$$\psi^\sharp : v^*(\mathrm{R}^q u_*(\mathscr{F})) \longrightarrow \mathrm{R}^q u'_*(\mathscr{F}'),$$

and it is necessary to prove that it is an isomorphism when v is *flat*. It is clear that the question is local on Y and Y', and we can therefore suppose that $Y = \operatorname{Spec}(A)$ and $Y' = \operatorname{Spec}(B)$; we will also use the following lemma:

Lemma (1.4.15.5). — *Let $\phi : A \to B$ be a ring homomorphism, $Y = \operatorname{Spec}(A)$, $X = \operatorname{Spec}(B)$, $f : X \to Y$ the morphism corresponding to ϕ, and M a B-module. For the $\mathscr{O}_X$-module $\widetilde{M}$ to be f-flat (**0**, 6.7.1), it is necessary and sufficient for M to be a flat A-module. In particular, for the morphism f to be flat, it is necessary and sufficient for B to be a flat A-module.*

This follows from the definition (**0**, 6.7.1) and from (**0**, 6.3.3), taking into account (**I**, 1.3.4).

This being so, it follows from (1.4.11.1) and the definitions of the homomorphisms (1.4.15.3) (cf. (**0**, 12.2.5)) that ψ then corresponds to the composite morphism

$$\mathrm{H}^q(X, \mathscr{F}) \xrightarrow{\rho_q} \mathrm{H}^q(X, v'_*(v'^*(\mathscr{F}))) \xrightarrow{\theta_q} \mathrm{H}^q(X', v'^*(v'_*(v'^*(\mathscr{F})))) \xrightarrow{\sigma_q} \mathrm{H}^q(X', v'^*(\mathscr{F})),$$

where ρ_q and σ_q are the homomorphisms in cohomology corresponding to the canonical morphisms ρ and $\sigma : v'^*(v'_*(\mathscr{G}')) \to \mathscr{G}'$, and θ_q is the ϕ-morphism (**0**, 12.1.3.1) relative to the $\mathscr{O}_X$-module $v'_*(v'^*(\mathscr{F}))$. But by the functoriality of θ_q, we have the commutative diagram

$$\begin{tikzcd}
\mathrm{H}^q(X,\mathscr{F}) \arrow[r, "\rho_q"] \arrow[d, "\theta_q"'] & \mathrm{H}^q(X, v'_*(v'^*(\mathscr{F}))) \arrow[d, "\theta_q"] \\
\mathrm{H}^q(X', v'^*(\mathscr{F})) \arrow[r, "v'^*(\rho_q)"] & \mathrm{H}^q(X', v'^*(v'_*(v'^*(\mathscr{F})))),
\end{tikzcd}$$

and as by definition (0, 4.4.3) $v'^*(\rho)$ is the inverse of σ, we see that the composite morphism considered above is finally none other than θ_q; as a result, $\psi^\sharp$ is the associated B-homomorphism $\mathrm{H}^q(X,\mathscr{F}) \otimes_A B \to \mathrm{H}^q(X',\mathscr{F}')$. As u is of finite type, X is a finite union of affine open sets U_i $(1 \leqslant i \leqslant r)$; let $\mathfrak{U}$ be the cover (U_i). As v is an affine morphism, so is v' (**II**, 1.6.2, iii), and as a result the $U'_i = v'^{-1}(U_i)$ form an affine open cover $\mathfrak{U}'$ of X'. We then know (0, 12.1.4.2) that the diagram **III** | 94

$$\begin{tikzcd}
\mathrm{H}^q(\mathfrak{U},\mathscr{F}) \arrow[r, "\theta_q"] \arrow[d] & \mathrm{H}^q(\mathfrak{U}',\mathscr{F}') \arrow[d] \\
\mathrm{H}^q(X,\mathscr{F}) \arrow[r, "\theta_q"] & \mathrm{H}^q(X',\mathscr{F}')
\end{tikzcd}$$

is commutative, and the vertical arrows are isomorphisms since X and X' are schemes (1.4.1). As a result, it suffices to prove that the canonical ϕ-morphism $\theta_q : \mathrm{H}^q(\mathfrak{U},\mathscr{F}) \to \mathrm{H}^q(\mathfrak{U}',\mathscr{F}')$ is such that the associated B-homomorphism

$$\mathrm{H}^q(\mathfrak{U},\mathscr{F}) \otimes_A B \longrightarrow \mathrm{H}^q(\mathfrak{U}',\mathscr{F}')$$

is an isomorphism. For every sequence $\mathbf{s} = (i_k)_{0 \leqslant k \leqslant p}$ of $p+1$ indices of $[1,r]$, set $U_{\mathbf{s}} = \bigcap_{k=0}^p U_{i_k}$, $U'_{\mathbf{s}} = \bigcap_{k=0}^p U'_{i_k} = v'^{-1}(U_{\mathbf{s}})$, $M_{\mathbf{s}} = \Gamma(U_{\mathbf{s}},\mathscr{F})$, and $M'_{\mathbf{s}} = \Gamma(U'_{\mathbf{s}},\mathscr{F}')$. The canonical map $M_{\mathbf{s}} \otimes_A B \to M'_{\mathbf{s}}$ is an isomorphism (**I**, 1.6.5), hence the canonical map $C^p(\mathfrak{U},\mathscr{F}) \otimes_A B \to C^p(\mathfrak{U}',\mathscr{F}')$ is an isomorphism, by which $d \otimes 1$ identifies with the coboundary map $C^p(\mathfrak{U}',\mathscr{F}') \to C^{p+1}(\mathfrak{U}',\mathscr{F}')$. As B is a *flat* A-module, it follows from the definition of the cohomology modules that the canonical map $\mathrm{H}^q(\mathfrak{U},\mathscr{F}) \otimes_A B \to \mathrm{H}^q(\mathfrak{U}',\mathscr{F}')$ is an isomorphism (0, 6.1.1). This result will later be generalized in §6. □

Corollary (1.4.16). — *Let A be a ring, X an A-scheme of finite type, and B an A-algebra which is faithfully flat over A. For X to be affine, it is necessary and sufficient for $X \otimes_A B$ to be.*

Proof. The condition is evidently necessary (**I**, 3.2.2); we show that it is sufficient. As X is separated over A and the morphism $\mathrm{Spec}(B) \to \mathrm{Spec}(A)$ is flat, it follows from Proposition (1.4.15) that we have

(1.4.16.1) $$\mathrm{H}^i(X \otimes_A B, \mathscr{F} \otimes_A B) = \mathrm{H}^i(X,\mathscr{F}) \otimes_A B$$

for every $i \geqslant 0$ and every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$. If $X \otimes_A B$ is affine, the left hand side of (1.4.16.1) is zero for $i = 1$, hence so is $\mathrm{H}^1(X,\mathscr{F})$ since B is a faithfully flat A-module. As X is a quasi-compact scheme, we finish the proof by Serre's criterion (**II**, 5.2.1). □

Proposition (1.4.17). — *Let X be a prescheme, $0 \to \mathscr{F} \xrightarrow{u} \mathscr{G} \xrightarrow{v} \mathscr{H} \to 0$ an exact sequence of $\mathscr{O}_X$-modules. If $\mathscr{F}$ and $\mathscr{H}$ are quasi-coherent, then so is $\mathscr{G}$.*

III | 95

Proof. The question is local on X, so we can suppose that $X = \mathrm{Spec}(A)$ is affine, and it then suffices to prove that $\mathscr{G}$ satisfies the conditions (d1) and (d2) of (**I**, 1.4.1) (with $V = X$). The verification of (d2) is immediate, because if $t \in \Gamma(X,\mathscr{G})$ is zero when restricted to $D(f)$, then so is its image $v(t) \in \Gamma(X,\mathscr{H})$; therefore there exists an $m > 0$ such that $f^m v(t) = v(f^m t) = 0$ (**I**, 1.4.1), and as Γ is left exact, $f^m t = u(s)$, where $s \in \Gamma(X, \mathscr{F})$; as u is injective, the restriction of s to $D(f)$ is zero, hence (**I**, 1.4.1) there exists an integer $n > 0$ such that $f^n s = 0$; we finally deduce that $f^{m+n} t = u(f^n s) = 0$.

We now check (d1); let $t' \in \Gamma(D(f), \mathscr{G})$; as $\mathscr{H}$ is quasi-coherent, there exists an integer m such that $f^m v(t') = v(f^m t')$ extends to a section $z \in \Gamma(X, \mathscr{H})$ (**I**, 1.4.1). But in virtue of Theorem (1.3.1) (or (**I**, 5.1.9.2)) applied to the quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$, the sequence $\Gamma(X, \mathscr{G}) \to \Gamma(X, \mathscr{H}) \to 0$ is exact, so there exists $t \in \Gamma(X, \mathscr{G})$ such that $z = v(t)$; we thus see that $v(f^m t' - t'') = 0$, denoting by t'' the restriction of t to $D(f)$; thus we have $f^m t' - t'' = u(s')$, where $s' \in \Gamma(D(f), \mathscr{F})$. But as $\mathscr{F}$ is quasi-coherent, there exists an integer $n > 0$ such that $f^n s'$ extends to a section $s \in \Gamma(X, \mathscr{F})$; as $f^{m+n} t' - f^n t'' = u(f^n s')$, we see that $f^{m+n} t'$ is the restriction to $D(f)$ of a section $f^n t + u(s) \in \Gamma(X, \mathscr{G})$, which finishes the proof. $\square$

§2. COHOMOLOGICAL STUDY OF PROJECTIVE MORPHISMS

2.1. Explicit calculations of certain cohomology groups

(2.1.1). Let X be a prescheme, $\mathscr{L}$ an invertible $\mathscr{O}_X$-module; consider the graded ring (**0**, 5.4.6) III | 95

(2.1.1.1)
$$S = \Gamma_*(X, \mathscr{L}) = \bigoplus_{n \in \mathbf{Z}} \Gamma(X, \mathscr{L}^{\otimes n}).$$

Let $(f_i)_{1 \leqslant i \leqslant r}$ be a finite family of *homogeneous* elements of S, say $f_i \in S_{d_i}$; set $U_i = X_{f_i}$, $U = \bigcup_i U_i$, and denote by $\mathfrak{U}$ the covering (U_i) of U. For every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$, we set

(2.1.1.2)
$$\mathrm{H}^\bullet(U, \mathscr{F}(*)) = \bigoplus_{n \in \mathbf{Z}} \mathrm{H}^\bullet(U, \mathscr{F} \otimes \mathscr{L}^{\otimes n})$$

(2.1.1.3)
$$\mathrm{H}^\bullet(\mathfrak{U}, \mathscr{F}(*)) = \bigoplus_{n \in \mathbf{Z}} \mathrm{H}^\bullet(\mathfrak{U}, \mathscr{F} \otimes \mathscr{L}^{\otimes n}).$$

The abelian groups (2.1.1.2) and (2.1.1.3) are *bigraded*, by taking

$$(\mathrm{H}^\bullet(U, \mathscr{F}(*)))_{mn} = \mathrm{H}^m(U, \mathscr{F} \otimes \mathscr{L}^{\otimes n})$$

and an analogous definition for (2.1.1.3). For the second grading, it is clear that these groups are graded S-modules, as follows, for example, from the fact that $\mathscr{F} \mapsto \mathrm{H}^m(U, \mathscr{F})$ and $\mathscr{F} \mapsto \mathrm{H}^m(\mathfrak{U}, \mathscr{F})$ are functors.

(2.1.2). Consider now the graded S-module (**0**, 5.4.6)

(2.1.2.1)
$$M = \Gamma_*(\mathscr{L}, \mathscr{F}) = \mathrm{H}^0(X, \mathscr{F}(*)) = \bigoplus_{n \in \mathbf{Z}} \Gamma(X, \mathscr{F} \otimes \mathscr{L}^{\otimes n}).$$

If X is a prescheme whose underlying space is Noetherian, or a quasi-compact scheme, it follows from (**I**, 9.3.1) that, setting as usual $U_{i_0 i_1 \cdots i_p} = \bigcap_{k=0}^p U_{i_k}$, we have, up to canonical isomorphism, III | 96

$$\Gamma(U_{i_0 i_1 \cdots i_p}, \mathscr{F}(*)) = \mathrm{H}^0(U_{i_0 i_1 \cdots i_p}, \mathscr{F}(*)) = M_{f_{i_0} f_{i_1} \cdots f_{i_p}}.$$

We can further, with the notation of (1.2.2), identify $M_{f_{i_0} f_{i_1} \cdots f_{i_p}}$ with $\varinjlim_n M^{(n)}_{i_0 i_1 \cdots i_p}$. This identification is an isomorphism of *graded* S-modules if we define the degree of a homogeneous element $z \in \varinjlim_n M^{(n)}_{i_0 i_1 \cdots i_p}$ as follows: z is the canonical image of a homogeneous element $x \in M^{(n)}_{i_0 i_1 \cdots i_p} = M$ of degree m, and we take the degree of z to be the number $m - n(d_{i_0} + d_{i_1} + \cdots + d_{i_p})$. Taking into account the definition of the homomorphisms $\phi_{kh} : M^{(h)}_{i_0 i_1 \cdots i_p} \to M^{(k)}_{i_0 i_1 \cdots i_p}$ (1.2.2), we see immediately that this definition does not depend on the "representative" x of z that was chosen. Denoting, as in (1.2.2), by $C^p_n(M)$ the set of alternating maps from $[1, r]^{p+1}$ to M (for every n), we similarly define a graded S-module structure on $\varinjlim_n C^p_n(M)$; as in (1.2.2), we then have

(2.1.2.2)
$$C^p(\mathfrak{U}, \mathscr{F}(*)) = \varinjlim_n C^p_n(M)$$

with the isomorphism between the two sides *respecting degrees*. We also have, as in (1.2.2),

(2.1.2.3)
$$C^p(\mathfrak{U}, \mathscr{F}(*)) = C^{p+1}((\mathbf{f}), M) = \varinjlim_n K^{p+1}(\mathbf{f}^n, M)$$

with the isomorphism *preserving degrees*: the degree of an element of $\varinjlim_n K^{p+1}(\mathbf{f}^n, M)$, which is the canonical image of a cochain $g \in K^{p+1}(\mathbf{f}^n, M)$ whose values $g(i_0, \ldots, i_p)$ lie in one and the same homogeneous component M_m of M, is $m - n(d_{i_0} + \cdots + d_{i_p})$, independently of the choice of this cochain as a representative of the element in question.

Since the preceding isomorphisms are compatible with the coboundary operators, we conclude, as in (1.2.2), that:

Proposition (2.1.3). — *Let X be a prescheme whose underlying space is Noetherian, or a quasi-compact scheme. There is a canonical isomorphism, functorial in $\mathscr{F}$,*

$$\text{(2.1.3.1)} \qquad \mathrm{H}^p(\mathfrak{U}, \mathscr{F}(*)) \xrightarrow{\sim} \mathrm{H}^{p+1}((\mathbf{f}), M) \qquad \textit{for every } p \geqslant 1.$$

Moreover, there is an exact sequence, functorial in $\mathscr{F}$,

$$\text{(2.1.3.2)} \qquad 0 \longrightarrow \mathrm{H}^0((\mathbf{f}), M) \longrightarrow M \longrightarrow \mathrm{H}^0(\mathfrak{U}, \mathscr{F}(*)) \longrightarrow \mathrm{H}^1((\mathbf{f}), M) \longrightarrow 0.$$

All the homomorphisms introduced are of degree 0 for the graded S-module structures, where S is the ring (2.1.1.1).

Corollary (2.1.4). — *If X is a quasi-compact scheme and the $U_i = X_{f_i}$ are affine, there is a canonical isomorphism, functorial in $\mathscr{F}$ and of degree 0,* **III** | 97

$$\text{(2.1.4.1)} \qquad \mathrm{H}^p(U, \mathscr{F}(*)) \xrightarrow{\sim} \mathrm{H}^{p+1}((\mathbf{f}), M) \qquad \textit{for every } p \geqslant 1,$$

and an exact sequence, functorial in $\mathscr{F}$,

$$\text{(2.1.4.2)} \qquad 0 \longrightarrow \mathrm{H}^0((\mathbf{f}), M) \longrightarrow M \longrightarrow \mathrm{H}^0(U, \mathscr{F}(*)) \longrightarrow \mathrm{H}^1((\mathbf{f}), M) \longrightarrow 0,$$

in which all the homomorphisms are of degree 0.

Proof. It suffices to apply (1.4.1) to the result of (2.1.3). □

The "local" proposition analogous to (2.1.3) is the following.

Proposition (2.1.5). — *Let S be a positively graded ring, let the f_i ($1 \leqslant i \leqslant r$) be homogeneous elements of S_+ of degrees d_i, and let M be a graded S-module. Let $X = \mathrm{Proj}(S)$ be the homogeneous prime spectrum of S, and set $U_i = \mathrm{D}_+(f_i)$, $U = \bigcup_i U_i$, and $\mathrm{H}^\bullet(U, \widetilde{M}(*)) = \bigoplus_{n \in \mathbf{Z}} \mathrm{H}^\bullet(U, (M(n))^\sim)$. There are canonical isomorphisms, functorial in M and of degree 0 for the graded S-module structures,*

$$\text{(2.1.5.1)} \qquad \mathrm{H}^p(U, \widetilde{M}(*)) \xrightarrow{\sim} \mathrm{H}^{p+1}((\mathbf{f}), M) \qquad \textit{for every } p \geqslant 1,$$

and an exact sequence, functorial in M,

$$\text{(2.1.5.2)} \qquad 0 \longrightarrow \mathrm{H}^0((\mathbf{f}), M) \longrightarrow M \longrightarrow \mathrm{H}^0(U, \widetilde{M}(*)) \longrightarrow \mathrm{H}^1((\mathbf{f}), M) \longrightarrow 0,$$

in which all the homomorphisms are of degree 0.

Proof. Indeed, by definition (II, 2.5.2),

$$\Gamma(U_{i_0 i_1 \cdots i_p}, (M(n))^\sim) = (M_{f_{i_0} \cdots f_{i_p}})_n,$$

and therefore $\Gamma(U_{i_0 i_1 \cdots i_p}, \widetilde{M}(*)) = M_{f_{i_0} \cdots f_{i_p}}$. The rest of the argument is the same as in the proof of (2.1.4), taking into account that X is a scheme. □

(2.1.6). *Remarks.* — (i) Under the hypotheses of (2.1.5), the functors $\Gamma(U_{i_0 i_1 \cdots i_p}, \widetilde{M}(*))$ are exact in M, by (**0**, 1.3.2). The same argument as in (1.2.5) therefore shows that, if $0 \to M' \to M \to M'' \to 0$ is an exact sequence of graded S-modules whose homomorphisms have degree 0, then for every $p \geqslant 0$ there are commutative diagrams

$$\text{(2.1.6.1)} \qquad \begin{array}{ccc} \mathrm{H}^p(U, \widetilde{M''}(*)) & \xrightarrow{\partial} & \mathrm{H}^{p+1}(U, \widetilde{M'}(*)) \\ \downarrow & & \downarrow \\ \mathrm{H}^{p+1}((\mathbf{f}), M'') & \xrightarrow{\partial} & \mathrm{H}^{p+2}((\mathbf{f}), M') \end{array}$$

(ii) Proposition (2.1.5) is especially useful when S is an A-algebra generated by finitely many elements of degree 1, with A Noetherian; in that case every quasi-coherent $\mathscr{O}_X$-module is of the form $\widetilde{M}$ (II, 2.7.7).

(2.1.7). We now apply (2.1.5) in the case $S = A[\mathrm{T}_0, \dots, \mathrm{T}_r]$, where A is an arbitrary ring and the T_i are indeterminates, taking $M = S$ and $f_i = \mathrm{T}_i$. We are thus essentially reduced to computing $\mathrm{H}^\bullet((\mathbf{T}), S)$, where $\mathbf{T} = (\mathrm{T}_i)_{0\leqslant i\leqslant r}$. III | 98

Lemma (2.1.8). — *If $S = A[\mathrm{T}_0, \dots, \mathrm{T}_r]$, then, with $\mathbf{T} = (\mathrm{T}_i)_{0\leqslant i\leqslant r}$,*

(2.1.8.1) $$\mathrm{H}^i(\mathbf{T}^n, S) = 0 \qquad \text{if } i \neq r+1,$$

(2.1.8.2) $$\mathrm{H}^{r+1}(\mathbf{T}^n, S) = S/(\mathbf{T}^n).$$

The A-module $\mathrm{H}^{r+1}(\mathbf{T}^n, S)$ therefore has an A-basis formed by the classes modulo $(\mathbf{T}^n)$ of the monomials

$$\mathrm{T}_{\mathbf{p}} = \mathrm{T}_0^{p_0} \cdots \mathrm{T}_r^{p_r}, \qquad \mathbf{p} = (p_0, \dots, p_r), \quad 0 \leqslant p_i < n \text{ for every } i.$$

Proof. This follows immediately from (1.1.3.5) and Proposition (1.1.4), whose hypotheses are trivially satisfied. □

(2.1.9). Passing to the inductive limit over n, relations (2.1.8.1) give $\mathrm{H}^i((\mathbf{T}), S) = 0$ for $i \neq r+1$. For $i = r+1$, the inductive system consists of the modules $S/(\mathbf{T}^n)$, the homomorphism

$$\phi_{nm} : S/(\mathbf{T}^n) \longrightarrow S/(\mathbf{T}^m) \qquad (0 \leqslant n \leqslant m)$$

being multiplication by $(\mathrm{T}_0 \cdots \mathrm{T}_r)^{m-n}$. For $n \geqslant \sup(p_i)_{0\leqslant i\leqslant r}$, denote by $\xi_{\mathbf{p}}^{(n)} = \xi_{p_0,\dots,p_r}^{(n)}$ the class of $\mathrm{T}_0^{n-p_0} \cdots \mathrm{T}_r^{n-p_r}$ modulo $(\mathbf{T}^n)$. Then $\phi_{nm}(\xi_{\mathbf{p}}^{(n)}) = \xi_{\mathbf{p}}^{(m)}$, so these elements have the same canonical image $\xi_{\mathbf{p}} = \xi_{p_0,\dots,p_r}$ in the inductive limit $\mathrm{H}^{r+1}((\mathbf{T}), S)$. By the definition of degree in (2.1.2), the degree of $\xi_{\mathbf{p}}$ is $-|\mathbf{p}| = -(p_0 + p_1 + \cdots + p_r)$. It is clear that the $\xi_{\mathbf{p}}^{(n)}$ with $0 < p_i \leqslant n$ for $0 \leqslant i \leqslant r$ form a basis of $S/(\mathbf{T}^n)$. We therefore deduce immediately from (2.1.8):

Corollary (2.1.10). — *With the notation of (2.1.8),*

(2.1.10.1) $$\mathrm{H}^i((\mathbf{T}), S) = 0 \qquad \text{for } i \neq r+1,$$

and $\mathrm{H}^{r+1}((\mathbf{T}), S)$ is a free A-module with basis the elements $\xi_{p_0,\dots,p_r}$ such that $p_i > 0$ for $0 \leqslant i \leqslant r$.

(2.1.11). *Remark.* — Let N be any A-module and let $M = S \otimes_A N$. The argument of (2.1.8) shows more generally that

(2.1.11.1) $$\mathrm{H}^i(\mathbf{T}^n, M) = 0 \qquad \text{if } i \neq r+1,$$

(2.1.11.2) $$\mathrm{H}^{r+1}(\mathbf{T}^n, M) = (S/(\mathbf{T}^n)) \otimes_A N.$$

Indeed, the latter formula follows directly from (1.1.3.5). Moreover, it is clear that

$$M/(\mathrm{T}_0^n M + \cdots + \mathrm{T}_{i-1}^n M) = \big(S/(\mathrm{T}_0^n S + \cdots + \mathrm{T}_{i-1}^n S)\big) \otimes_A N,$$

since the ideal $\mathrm{T}_0^n S + \cdots + \mathrm{T}_{i-1}^n S$ is a direct summand of the A-module S. This permits us to apply (1.1.4) to M, and yields (2.1.11.1).

Combining (2.1.10) and (2.1.5), we obtain:

Proposition (2.1.12). — *Let A be a ring, let r be an integer > 0, and let $X = \mathbf{P}_A^r$ (**II**, 4.1.1). Then:*

(i) $\mathrm{H}^i(X, \mathscr{O}_X(*)) = 0$ *for $i \neq 0, r$.*
(ii) *The canonical homomorphism $\alpha : S \to \mathrm{H}^0(X, \mathscr{O}_X(*))$ (**II**, 2.6.2) is bijective.* III | 99
(iii) $\mathrm{H}^r(X, \mathscr{O}_X(*))$ *is a free A-module with basis the elements $\xi_{p_0,\dots,p_r}$, where $p_i > 0$ for $0 \leqslant i \leqslant r$; the element $\xi_{p_0,\dots,p_r}$ has degree $-|\mathbf{p}| = -(p_0 + \cdots + p_r)$, and*

$$\mathrm{T}_i \xi_{p_0,\dots,p_r} = \xi_{p_0,\dots,p_{i-1},p_i-1,p_{i+1},\dots,p_r}.$$

Proof. In the exact sequence (2.1.5.2) applied to $M = S = A[\mathrm{T}_0, \dots, \mathrm{T}_r]$, we have $\mathrm{H}^0((\mathbf{T}), S) = 0$ and $\mathrm{H}^1((\mathbf{T}), S) = 0$ by (2.1.10.1); moreover, Proposition (2.1.5) applies with $U = X$, since X is the union of the $\mathrm{D}_+(\mathrm{T}_i)$ (**II**, 2.3.14). It remains to identify the map $S \to \mathrm{H}^0(X, \mathscr{O}_X(*))$ in (2.1.5.2) with the canonical map α. This follows from the canonical identification of $\mathrm{H}^0(U, \mathscr{O}_X(*))$ and $\mathrm{H}^0(\mathfrak{U}, \mathscr{O}_X(*))$. □

Corollary (2.1.13). — *The only pairs (i, n) for which $\mathrm{H}^i(X, \mathscr{O}_X(n)) \neq 0$ can occur are $i = 0$, $n \geqslant 0$, and $i = r$, $n \leqslant -(r+1)$.*

If $A \neq 0$, then $\mathrm{H}^i(X, \mathscr{O}_X(n)) \neq 0$ does indeed hold for all the pairs listed in (2.1.13). This follows from (2.1.12), since $S_n \neq 0$ for every degree $n \geqslant 0$.

In the applications made in this chapter, we will mostly use the following less precise result.

Corollary (2.1.14). — *The A-modules $\mathrm{H}^i(X, \mathscr{O}_X(n))$ are free of finite type; if $i > 0$, they vanish for $n > 0$.*

Proposition (2.1.15). — *Let Y be a prescheme, let $\mathscr{E}$ be a locally free $\mathscr{O}_Y$-module of rank $r+1$, let $X = \mathbf{P}(\mathscr{E})$ be the projective bundle defined by $\mathscr{E}$, and let $f : X \to Y$ be the structural morphism. The only values of i and n for which $\mathrm{R}^i f_*(\mathscr{O}_X(n)) \neq 0$ can occur are $i = 0$, $n \geqslant 0$, and $i = r$, $n \leqslant -(r+1)$. Moreover, the canonical homomorphism* (**II**, 3.3.2)

$$\alpha : \mathbf{S}_{\mathscr{O}_Y}(\mathscr{E}) \longrightarrow \Gamma_*(\mathscr{O}_X) = \mathrm{R}^0 f_*(\mathscr{O}_X(*)) = \bigoplus_{n \in \mathbf{Z}} f_*(\mathscr{O}_X(n))$$

is an isomorphism.

Proof. The question is local on Y, so we may assume that Y is affine with ring A and that $\mathscr{E} = \widetilde{E}$, where $E = A^{r+1}$. We are then immediately reduced to (2.1.12), taking (1.4.11) into account. ☐

(2.1.16). *Remark.* — We will later complete the results of (2.1.15) by proving the following propositions. Set

$$\boldsymbol{\omega} = f^*\big(\bigwedge^{r+1} \mathscr{E}\big)(-r-1),$$

which is an invertible $\mathscr{O}_X$-module. Then:

(i) There is a canonical isomorphism

$$\rho : \mathscr{O}_Y \xrightarrow{\sim} \mathrm{R}^r f_*(\boldsymbol{\omega}). \tag{2.1.16.1}$$

(ii) The cup-product pairing (**0**, 12.2.2)

$$\mathrm{R}^r f_*(\mathscr{O}_X(n)) \times \mathrm{R}^0 f_*(\boldsymbol{\omega}(-n)) \longrightarrow \mathrm{R}^r f_*(\boldsymbol{\omega}), \tag{2.1.16.2}$$

composed with ρ^{-1}, defines an *isomorphism* from $\mathrm{R}^r f_*(\mathscr{O}_X(n))$ onto the *dual* of the locally free $\mathscr{O}_Y$-module

$$\mathrm{R}^0 f_*(\boldsymbol{\omega}(-n)) = \big(\bigwedge^{r+1} \mathscr{E}\big) \otimes_{\mathscr{O}_Y} \big(\mathbf{S}_{\mathscr{O}_Y}(\mathscr{E})\big)_{-n}.$$

2.2. The fundamental theorem of projective morphisms **III | 100**

Theorem (2.2.1). — *(Serre). Let Y be a Noetherian prescheme, let $f : X \to Y$ be a proper morphism, and let $\mathscr{L}$ be an invertible $\mathscr{O}_X$-module ample relative to f. For every $\mathscr{O}_X$-module $\mathscr{F}$, set*

$$\mathscr{F}(n) = \mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{L}^{\otimes n} \qquad (n \in \mathbf{Z}).$$

Then, for every coherent $\mathscr{O}_X$-module $\mathscr{F}$:

(i) *the $\mathscr{O}_Y$-modules $\mathrm{R}^q f_*(\mathscr{F})$ are coherent;*

(ii) *there exists an integer N such that, for $n \geqslant N$,*

$$\mathrm{R}^q f_*(\mathscr{F}(n)) = 0 \qquad \text{for every } q > 0;$$

(iii) *there exists an integer N such that, for $n \geqslant N$, the canonical homomorphism*

$$f^*\big(f_*(\mathscr{F}(n))\big) \longrightarrow \mathscr{F}(n)$$

is surjective.

Proof. First note that if the theorem is true after replacing $\mathscr{L}$ by $\mathscr{L}^{\otimes d}$, where $d > 0$, then it is true in its original form. Indeed, writing

$$\mathscr{F}(n) = \big(\mathscr{F} \otimes \mathscr{L}^{\otimes r}\big) \otimes \mathscr{L}^{\otimes hd}, \qquad h > 0, \quad 0 \leqslant r < d,$$

the hypothesis gives, for each r, an integer N_r such that (ii) and (iii) hold for $\mathscr{F} \otimes \mathscr{L}^{\otimes r}$ whenever $h \geqslant N_r$. Taking N to be the largest of the integers dN_r, assertions (ii) and (iii) therefore hold for $n \geqslant N$.

We may consequently suppose that $\mathscr{L}$ is very ample relative to f (**II**, 4.6.11). There is then a dominant open immersion over Y

$$i : X \longrightarrow P, \qquad P = \mathrm{Proj}(\mathscr{S}),$$

where $\mathscr{S}$ is a quasi-coherent $\mathscr{O}_Y$-algebra graded in positive degrees, $\mathscr{S}_1$ is of finite type and generates $\mathscr{S}$, and $\mathscr{L}$ is isomorphic to $i^*(\mathscr{O}_P(1))$ (**II**, 4.4.7). Since f is proper, i is proper as well (**II**, 5.4.4), and hence is an isomorphism $X \xrightarrow{\sim} P$. We are thus reduced to the case $X = \mathrm{Proj}(\mathscr{S})$ and $\mathscr{L} = \mathscr{O}_X(1)$. The theorem is then a consequence of the following proposition. □

Proposition (2.2.2). — *Let A be a Noetherian ring and let S be an A-algebra graded in positive degrees such that the A-module S_1 has a system of $r+1$ generators and generates the algebra S. Set $X = \mathrm{Proj}(S)$. For every coherent $\mathscr{O}_X$-module $\mathscr{F}$:*

(i) *the A-modules $\mathrm{H}^q(X, \mathscr{F})$ are of finite type;*
(ii) *$\mathrm{H}^q(X, \mathscr{F}) = 0$ for $q > r$;*
(iii) *there exists an integer N such that, for $n \geqslant N$,*

$$\mathrm{H}^q(X, \mathscr{F}(n)) = 0 \qquad \textit{for every } q > 0;$$

(iv) *there exists an integer N such that, for $n \geqslant N$, $\mathscr{F}(n)$ is generated by its sections over X.*

Proof. Let us first show how (2.2.2) implies (2.2.1). In the special case $X = \mathrm{Proj}(\mathscr{S})$ to which (2.2.1) was reduced above, Y is quasi-compact. It can therefore be covered by finitely many affine open subsets U_α, with Noetherian rings, such that the restriction of $\mathscr{S}_1$ to each U_α is generated by finitely many sections over U_α. Once (2.2.2) is known, it is enough to take in parts (ii) and (iii) of (2.2.1) the largest of the corresponding integers for the U_α, taking (1.4.11) and (**II**, 3.4.7) into account.

To prove (2.2.2), observe that X identifies with a closed subprescheme of $P = \mathbf{P}^r_A$ (**II**, 3.6.2). Moreover, if $j : X \to P$ is the canonical injection, then $j_*(\mathscr{F})$ is a coherent $\mathscr{O}_P$-module and

$$j_*(\mathscr{F}(n)) = (j_*\mathscr{F})(n)$$

by (**II**, 3.4.5) and (**II**, 3.5.2). In view of (G, II, Corollary to Theorem 4.9.1), we are therefore reduced to proving (2.2.2) in the special case

$$X = \mathbf{P}^r_A, \qquad S = A[T_0, \ldots, T_r].$$

Since X is covered by the $r+1$ affine open subsets $D_+(T_i)$, assertion (ii) follows from (1.4.12). **III** | 101
Assertion (iv) has already been proved in (**II**, 2.7.9).

We now prove (i) and (iii) simultaneously. They hold for $\mathscr{F} = \mathscr{O}_X(m)$ by (2.1.13), and hence also when $\mathscr{F}$ is a direct sum of finitely many $\mathscr{O}_X$-modules of the form $\mathscr{O}_X(m_j)$. They are trivially true for $q > r$ by (ii). We proceed by descending induction on q.

The sheaf $\mathscr{F}$ is isomorphic to a quotient of a direct sum $\mathscr{E}$ of finitely many sheaves $\mathscr{O}_X(m_j)$ (**II**, 2.7.10). Thus there is an exact sequence

$$0 \longrightarrow \mathscr{R} \longrightarrow \mathscr{E} \longrightarrow \mathscr{F} \longrightarrow 0,$$

where $\mathscr{R}$ is coherent (**0**, 5.3.3) and $\mathscr{E}$ satisfies (i) and (iii). Since twisting is exact, for every $n \in \mathbf{Z}$ we also have an exact sequence

$$0 \longrightarrow \mathscr{R}(n) \longrightarrow \mathscr{E}(n) \longrightarrow \mathscr{F}(n) \longrightarrow 0,$$

and hence an exact cohomology sequence

$$\mathrm{H}^{q-1}(X, \mathscr{E}(n)) \longrightarrow \mathrm{H}^{q-1}(X, \mathscr{F}(n)) \longrightarrow \mathrm{H}^q(X, \mathscr{R}(n)).$$

Because $\mathscr{E}(n)$ is a direct sum of sheaves $\mathscr{O}_X(n + m_j)$ (**II**, 2.5.14), the module $\mathrm{H}^{q-1}(X, \mathscr{E}(n))$ is of finite type. The module $\mathrm{H}^q(X, \mathscr{R}(n))$ is likewise of finite type by the induction hypothesis. Since A is Noetherian, it follows that $\mathrm{H}^{q-1}(X, \mathscr{F}(n))$ is of finite type, proving (i).

By the induction hypothesis we may choose N so that $\mathrm{H}^q(X, \mathscr{R}(n)) = 0$ for $n \geqslant N$. We may also choose N so that $\mathrm{H}^{q-1}(X, \mathscr{E}(n)) = 0$ for $n \geqslant N$, since $\mathscr{E}$ satisfies (iii). The exact cohomology sequence then gives

$$\mathrm{H}^{q-1}(X, \mathscr{F}(n)) = 0 \qquad (n \geqslant N),$$

which completes the proof. □

Corollary (2.2.3). — *Under the hypotheses of (2.2.1), let*

$$\mathscr{F} \longrightarrow \mathscr{G} \longrightarrow \mathscr{H}$$

be an exact sequence of coherent $\mathscr{O}_X$-modules. There exists an integer N such that, for $n \geqslant N$, the sequence

$$f_*(\mathscr{F}(n)) \longrightarrow f_*(\mathscr{G}(n)) \longrightarrow f_*(\mathscr{H}(n))$$

is exact.

Proof. Let $\mathscr{F}'$, $\mathscr{G}'$, and $\mathscr{G}''$ be respectively the kernel, image, and cokernel of $\mathscr{F} \to \mathscr{G}$. Then $\mathscr{G}'$ is the kernel and $\mathscr{G}''$ the image of $\mathscr{G} \to \mathscr{H}$; let $\mathscr{H}''$ be the cokernel of this latter homomorphism. All these $\mathscr{O}_X$-modules are coherent (**0**, 5.3.4). Since twisting is exact, it is enough to prove that, for n sufficiently large, each of the sequences

$$0 \longrightarrow f_*(\mathscr{F}'(n)) \longrightarrow f_*(\mathscr{F}(n)) \longrightarrow f_*(\mathscr{G}'(n)) \longrightarrow 0,$$
$$0 \longrightarrow f_*(\mathscr{G}'(n)) \longrightarrow f_*(\mathscr{G}(n)) \longrightarrow f_*(\mathscr{G}''(n)) \longrightarrow 0,$$
$$0 \longrightarrow f_*(\mathscr{G}''(n)) \longrightarrow f_*(\mathscr{H}(n)) \longrightarrow f_*(\mathscr{H}''(n)) \longrightarrow 0$$

is exact. Consequently, we may suppose that

$$0 \longrightarrow \mathscr{F} \longrightarrow \mathscr{G} \longrightarrow \mathscr{H} \longrightarrow 0$$

is exact. The cohomology sequence is then

$$0 \longrightarrow f_*(\mathscr{F}(n)) \longrightarrow f_*(\mathscr{G}(n)) \longrightarrow f_*(\mathscr{H}(n)) \longrightarrow \mathrm{R}^1 f_*(\mathscr{F}(n)) \longrightarrow \cdots,$$

and the conclusion follows from (2.2.1), (ii). □

III | 102

Corollary (2.2.4). — *Let Y be a Noetherian prescheme, let $f : X \to Y$ be a morphism of finite type, and let $\mathscr{L}$ be an invertible $\mathscr{O}_X$-module ample relative to f. For every $\mathscr{O}_X$-module $\mathscr{F}$, set*

$$\mathscr{F}(n) = \mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{L}^{\otimes n} \qquad (n \in \mathbf{Z}).$$

Let

$$\mathscr{F} \longrightarrow \mathscr{G} \longrightarrow \mathscr{H}$$

*be an exact sequence of coherent $\mathscr{O}_X$-modules such that the supports of $\mathscr{F}$ and $\mathscr{H}$ are proper over Y (**II**, 5.4.10). Then there exists an integer N such that, for $n \geqslant N$, the sequence*

$$f_*(\mathscr{F}(n)) \longrightarrow f_*(\mathscr{G}(n)) \longrightarrow f_*(\mathscr{H}(n))$$

is exact.

Proof. The argument at the beginning of (2.2.1) shows that if the corollary is true for $\mathscr{L}^{\otimes d}$, where $d > 0$, then it is true for $\mathscr{L}$. We may therefore suppose that $\mathscr{L}$ is very ample relative to f (**II**, 4.6.11). We can then identify X with an open subset of a Y-prescheme

$$Z = \mathrm{Proj}(\mathscr{S}),$$

where $\mathscr{S}$ is a quasi-coherent $\mathscr{O}_Y$-algebra graded in positive degrees, $\mathscr{S}_1$ is of finite type and generates $\mathscr{S}$, and

$$\mathscr{L} = i^*(\mathscr{O}_Z(1)),$$

with $i : X \to Z$ the canonical immersion (**II**, 4.4.7).

Now $\mathrm{Supp}(\mathscr{G})$ is closed in X and contained in

$$\mathrm{Supp}(\mathscr{F}) \cup \mathrm{Supp}(\mathscr{H});$$

it is therefore proper over Y. The supports of $\mathscr{F}$, $\mathscr{G}$, and $\mathscr{H}$ are consequently closed in Z (**II**, 5.4.10). Thus

$$\mathscr{F}' = i_*(\mathscr{F}), \qquad \mathscr{G}' = i_*(\mathscr{G}), \qquad \mathscr{H}' = i_*(\mathscr{H})$$

are coherent $\mathscr{O}_Z$-modules, and the sequence

$$\mathscr{F}' \longrightarrow \mathscr{G}' \longrightarrow \mathscr{H}'$$

is exact. If $g : Z \to Y$ is the structural morphism, then $f = g \circ i$, and clearly

$$\mathscr{F}'(n) = i_*(\mathscr{F}(n)),$$

with analogous identities for $\mathscr{G}'$ and $\mathscr{H}'$. The conclusion follows from (2.2.3), applied to $\mathscr{F}'$, $\mathscr{G}'$, and $\mathscr{H}'$. □

(2.2.5). *Remarks.*

(i) Assertion (i) of (2.2.1) remains true if one assumes only that Y is *locally Noetherian*. Indeed, the property is plainly local on Y. Moreover, the hypotheses of (2.2.1) imply that, for every open subset $U \subset Y$, the restriction of f to $f^{-1}(U)$ is a projective morphism

$$f^{-1}(U) \longrightarrow U$$

(**II**, 5.5.5, iii), and $\mathscr{L}|_{f^{-1}(U)}$ is ample for this morphism (**II**, 4.6.4).

(ii) Assertion (iii) of (2.2.1) remains valid, as we have seen, if one assumes only that X is a quasi-compact scheme, or a prescheme whose underlying space is Noetherian, and that $f : X \to Y$ is quasi-compact (**II**, 4.6.8). It should be noted, however, that even when Y is the *spectrum of a field* K and f is *quasi-projective*, assertion (ii) of (2.2.1) need no longer hold.

For example, let

$$X' = \operatorname{Spec}(K[T_0, \ldots, T_r])$$

and let X be the union of the affine open subsets $D(T_i)$ of X', for $0 \leqslant i \leqslant r$. Since the immersion $X \to X'$ is quasi-compact, the structural morphism $f : X \to Y$ is quasi-affine (**II**, 5.1.10), and hence $\mathscr{O}_X$ is very ample relative to f (**II**, 5.1.6). But

$$\Gamma(X, \mathscr{O}_X) = \bigcap_{i=0}^{r} (K[T_0, \ldots, T_r])_{T_i} = K[T_0, \ldots, T_r]$$

by (**I**, 8.2.1.1). It follows from (1.4.3.1) and (1.1.3.5) that

$$\mathrm{H}^r(X, \mathscr{O}_X^{\otimes n}) = \mathrm{H}^r(X, \mathscr{O}_X) = A \neq 0$$

for every n.

2.3. Application to graded sheaves of algebras and modules

Theorem (2.3.1). — *Let Y be a Noetherian prescheme, let $\mathscr{S}$ be a quasi-coherent $\mathscr{O}_Y$-algebra of finite type, graded in positive degrees, let*

$$X = \operatorname{Proj}(\mathscr{S}),$$

and let $q : X \to Y$ be the structural morphism. Let $\mathscr{M}$ be a quasi-coherent graded $\mathscr{S}$-module satisfying condition **(TF)**. *There then exists an integer N such that, for $n \geqslant N$, the canonical homomorphism* (**II**, 8.14.5.1)

$$\alpha_n : \mathscr{M}_n \longrightarrow q_*\big(\mathscr{P}roj_0(\mathscr{M}(n))\big) = q_*\big((\mathscr{P}roj(\mathscr{M}))_n\big)$$

is bijective. In other words, the canonical homomorphism **III** | 103

$$\alpha : \mathscr{M} \longrightarrow \mathbf{\Gamma}_*(\mathscr{P}roj(\mathscr{M}))$$

is a **(TN)***-isomorphism.*

Proof. We may restrict to the case in which $\mathscr{M}$ is an $\mathscr{S}$-module of finite type (**II**, 3.4.2). Since Y is quasi-compact, there is an integer $d > 0$ such that $\mathscr{S}^{(d)}$ is generated by the quasi-coherent $\mathscr{O}_Y$-module $\mathscr{S}_d$, which is of finite type (**II**, 3.1.10), and hence coherent because Y is Noetherian. Now $\mathscr{M}$ is the direct sum of the $\mathscr{M}^{(d,k)}$, for $0 \leqslant k < d$, and each $\mathscr{M}^{(d,k)}$ is a quasi-coherent $\mathscr{S}^{(d)}$-module of finite type, by (**II**, 2.1.6, iii). Since the question is local on Y, it plainly suffices to prove that each canonical homomorphism

$$\alpha : \mathscr{M}^{(d,k)} \longrightarrow \mathbf{\Gamma}_*\big((\mathscr{P}roj(\mathscr{M}))^{(d,k)}\big)$$

is a **(TN)**-isomorphism. Taking (**II**, 8.14.13) into account, and in particular diagram (**II**, 8.14.13.4), we are thus reduced to proving the theorem when $\mathscr{S}$ is generated by $\mathscr{S}_1$ and $\mathscr{S}_1$ is a coherent $\mathscr{O}_Y$-module.

Since Y is Noetherian, the argument used at the beginning of the proof of (2.2.2) shows that we may reduce to the case

$$Y = \operatorname{Spec}(A), \qquad \mathscr{S} = \widetilde{S}, \qquad \mathscr{M} = \widetilde{M},$$

where A is a Noetherian ring, S_1 is an A-module of finite type, and M is a graded S-module of finite type. We shall show that it then suffices to prove the theorem for $M = S$. Indeed, in the general case there is an exact sequence

$$L' \longrightarrow L \longrightarrow M \longrightarrow 0,$$

where L and L' are direct sums of graded modules of the form $S(m)$. If the result holds for $M = S$, it also holds for $M = S(m)$, and hence for L and L'. Consider the commutative diagram

$$\begin{tikzcd} \widetilde{L'_n} \arrow[r] \arrow[d, "\alpha_n"'] & \widetilde{L_n} \arrow[r] \arrow[d, "\alpha_n"] & \widetilde{M_n} \arrow[r] \arrow[d, "\alpha_n"] & 0 \\ q_*(\widetilde{L'}(n)) \arrow[r] & q_*(\widetilde{L}(n)) \arrow[r] & q_*(\widetilde{M}(n)) \arrow[r] & 0. \end{tikzcd}$$

The second row is exact by (2.2.3) once n is sufficiently large. The same is true of the first row, and since the two left-hand vertical arrows are isomorphisms, the third is as well. **III** | 104

It therefore remains to prove the theorem for $M = S$. Suppose first that

$$S = A[T_0, \ldots, T_r],$$

where the T_i are indeterminates. In this case the assertion is precisely (2.1.11, ii). In the general case, S identifies with a quotient of a ring

$$S' = A[T_0, \ldots, T_r]$$

by a graded ideal, so X is a closed subscheme of

$$X' = \mathbf{P}^r_A$$

(**II**, 2.9.2). If $j : X \to X'$ is the canonical injection, then $j_*(\widetilde{S}(n))$ is the $\mathscr{O}_{X'}$-module

$$(\mathscr{P}\!roj(\widetilde{S}))(n),$$

where S is regarded as a graded S'-module; this follows at once from (**II**, 2.8.7). Since $j_*(\widetilde{S}(n))$ is an $\mathscr{O}_{X'}$-module satisfying **(TF)**, the canonical homomorphism

$$\alpha_n : S_n \longrightarrow \Gamma\big(X', j_*(\widetilde{S}(n))\big)$$

is bijective for all sufficiently large n, by the polynomial case just proved. This completes the proof, since

$$\Gamma\big(X', j_*(\widetilde{S}(n))\big) = \Gamma(X, \widetilde{S}(n)).$$

□

Corollary (2.3.2). — *Under the hypotheses of (2.3.1), let*

$$\mathscr{S}_X = \bigoplus_{n\in\mathbf{Z}} \mathscr{O}_X(n),$$

*and let $\mathscr{F}$ be a quasi-coherent graded $\mathscr{S}_X$-module of finite type. Then $\mathbf{\Gamma}_*(\mathscr{F})$ satisfies condition **(TF)**.*

Proof. In the proof of (2.3.1) we saw that X, which is isomorphic to $\operatorname{Proj}(\mathscr{S}^{(d)})$ (**II**, 3.1.8), is of finite type over Y (**II**, 3.4.1). It follows from (**II**, 8.14.9) that $\mathscr{F}$ is isomorphic to a graded $\mathscr{S}_X$-module of the form $\mathscr{P}\!roj(\mathscr{M})$, where $\mathscr{M}$ is a quasi-coherent graded $\mathscr{S}$-module of finite type. By (2.3.1), $\mathbf{\Gamma}_*(\mathscr{F})$ is **(TN)**-isomorphic to $\mathscr{M}$ and consequently satisfies **(TF)**. □

(2.3.3). *Scholium.* Let Y be a Noetherian prescheme, let $\mathscr{S}$ be a graded $\mathscr{O}_Y$-algebra satisfying the hypotheses of (2.3.1), and let $X = \operatorname{Proj}(\mathscr{S})$. Let $\mathtt{K}_{\mathscr{S}}$ be the abelian category of quasi-coherent graded $\mathscr{S}$-modules satisfying **(TF)**, and let $\mathtt{K}'_{\mathscr{S}}$ be the subcategory of $\mathtt{K}_{\mathscr{S}}$ consisting of the $\mathscr{S}$-modules satisfying **(TN)**. Finally, let $\mathtt{K}_X$ be the category of quasi-coherent graded $\mathscr{S}_X$-modules $\mathscr{F}$ of finite type; since $\mathscr{S}_X$ is periodic (**II**, 8.14.4) and (**II**, 8.14.12), this is equivalent to requiring the $\mathscr{F}_i$ to be coherent $\mathscr{O}_X$-modules.

By (**II**, 8.14.8), (**II**, 8.14.10), and (2.3.2), the functors

$$\mathscr{M} \longmapsto \mathscr{P}\!roj(\mathscr{M}), \qquad \mathscr{F} \longmapsto \mathbf{\Gamma}_*(\mathscr{F})$$

define an equivalence (T, I, 1.2) between the quotient category

$$\mathtt{K}_{\mathscr{S}} / \mathtt{K}'_{\mathscr{S}}$$

(T, I, 1.11) and the category $\mathtt{K}_X$. When $\mathscr{S}$ is generated by $\mathscr{S}_1$, the category $\mathtt{K}_X$ may be replaced by the category of coherent $\mathscr{O}_X$-modules (**II**, 8.14.12).

Proposition (2.3.4). — *Let Y be a Noetherian prescheme.*

(i) Let $\mathscr{S}$ be a quasi-coherent $\mathscr{O}_Y$-algebra of finite type, graded in positive degrees. Set

$$X = \operatorname{Proj}(\mathscr{S}), \qquad \mathscr{S}_X = \mathscr{P}roj(\mathscr{S}) = \bigoplus_{n\in\mathbf{Z}} \mathscr{O}_X(n).$$

*Then $\mathscr{S}_X$ is a periodic quasi-coherent graded $\mathscr{O}_X$-algebra (**II**, 8.14.12), its homogeneous components*

$$(\mathscr{S}_X)_n = \mathscr{O}_X(n)$$

are coherent $\mathscr{O}_X$-modules, and, if $d > 0$ is a period of $\mathscr{S}_X$, then

$$(\mathscr{S}_X)_d = \mathscr{O}_X(d)$$

is an invertible Y-ample $\mathscr{O}_X$-module. Moreover, the canonical homomorphism

$$\alpha : \mathscr{S} \longrightarrow \mathbf{\Gamma}_*(\mathscr{S}_X)$$

*is a **(TN)**-isomorphism.*

(ii) Conversely, let $q : X \to Y$ be a projective morphism, and let $\mathscr{S}'$ be a graded $\mathscr{O}_X$-algebra whose homogeneous components $\mathscr{S}'_n$, for $n \in \mathbf{Z}$, are coherent $\mathscr{O}_X$-modules. Suppose that $\mathscr{S}'$ has a period $d > 0$ such that $\mathscr{S}'_d$ is an invertible $\mathscr{O}_X$-module ample for q. Then

$$\mathscr{S} = \bigoplus_{n\geqslant 0} q_*(\mathscr{S}'_n)$$

is a quasi-coherent $\mathscr{O}_Y$-algebra of finite type, graded in positive degrees, and there is a Y-isomorphism

$$r : X \xrightarrow{\sim} \operatorname{Proj}(\mathscr{S})$$

such that $r^*(\mathscr{P}roj(\mathscr{S}))$ is isomorphic to $\mathscr{S}'$ as a graded $\mathscr{O}_X$-algebra.

Proof. (i) Almost all the assertions have already been proved, the last being a special case of (2.3.2). The periodicity of $\mathscr{S}_X$ was proved in (**II**, 8.14.14), and the assertion that there is a period $d > 0$ for which $\mathscr{O}_X(d)$ is invertible and Y-ample is precisely (**II**, 4.6.18). Finally, for $0 \leqslant k < d$, $(\mathscr{S}_X)^{(d,k)}$ is an $(\mathscr{S}_X)^{(d)}$-module of finite type (**II**, 8.14.14). It follows that each $(\mathscr{S}_X)_n$ is a quasi-coherent $\mathscr{O}_X$-module of finite type (**II**, 2.1.6, ii); since $\mathscr{O}_X$ is coherent, so is each $(\mathscr{S}_X)_n$.

(ii) After replacing the period d by one of its multiples, we may suppose that

$$\mathscr{L} = \mathscr{S}'_d$$

is very ample relative to q (**II**, 4.6.11). By hypothesis,

$$\mathscr{S}'^{(d)} = \bigoplus_{n\in\mathbf{Z}} \mathscr{L}^{\otimes n},$$

and hence

$$\mathscr{S}^{(d)} = \bigoplus_{n\geqslant 0} q_*(\mathscr{L}^{\otimes n}).$$

By (**II**, 3.1.8) and (**II**, 3.2.9), there is a Y-isomorphism

$$s : X' = \operatorname{Proj}(\mathscr{S}) \xrightarrow{\sim} X'' = \operatorname{Proj}(\mathscr{S}^{(d)})$$

such that **III** | 105

$$s^*(\mathscr{O}_{X''}(n)) = \mathscr{O}_{X'}(nd)$$

for every n (**II**, 3.5.2). We shall therefore establish the existence of a Y-isomorphism $X \xrightarrow{\sim} X'$ by proving the following assertion.

(2.3.4.1). Let Y be a Noetherian prescheme, let $q : X \to Y$ be a projective morphism, and let $\mathscr{L}$ be an invertible $\mathscr{O}_X$-module very ample for q. Then

$$\mathscr{S} = \bigoplus_{n\geqslant 0} q_*(\mathscr{L}^{\otimes n})$$

is a quasi-coherent graded $\mathscr{O}_Y$-algebra of finite type such that

$$\mathscr{S}_n = \mathscr{S}_1^n$$

for all sufficiently large n, and there is a Y-isomorphism

$$r : X \xrightarrow{\sim} P = \mathrm{Proj}(\mathscr{S})$$

such that

$$\mathscr{L} = r^*(\mathscr{O}_P(1)).$$

Since q is projective, it follows from (**II**, 5.4.4) and (**II**, 4.4.7) that there is a Y-isomorphism

$$r' : X \xrightarrow{\sim} P' = \mathrm{Proj}(\mathscr{T}),$$

where $\mathscr{T}$ is a quasi-coherent $\mathscr{O}_Y$-algebra, $\mathscr{T}_1$ is of finite type and generates $\mathscr{T}$, and

$$\mathscr{L} = r'^*(\mathscr{O}_{P'}(1)).$$

If $q' : P' \to Y$ is the structural morphism, then

$$\mathscr{S} = \bigoplus_{n\geqslant 0} q'_*(\mathscr{O}_{P'}(n)).$$

By (2.3.1), the canonical homomorphism

$$\alpha_n : \mathscr{T}_n \longrightarrow \mathscr{S}_n = q'_*(\mathscr{O}_{P'}(n))$$

is bijective for all sufficiently large n. Since $\mathscr{T}_n = \mathscr{T}_1^n$, it follows *a fortiori* that $\mathscr{S}_n = \mathscr{S}_1^n$ for all sufficiently large n.

The canonical homomorphism $\alpha : \mathscr{T} \to \mathscr{S}$ of graded $\mathscr{O}_Y$-algebras is a **(TN)**-isomorphism. Consequently

$$\Phi = \mathrm{Proj}(\alpha) : \mathrm{Proj}(\mathscr{S}) \longrightarrow \mathrm{Proj}(\mathscr{T})$$

is an isomorphism (**II**, 3.6.1). Moreover, (**II**, 3.5.2) and the fact that the graded $\mathscr{T}$-modules obtained from $\mathscr{S}(n)$ by restriction of scalars are **(TN)**-isomorphic to $\mathscr{T}(n)$ give

$$\Phi_*(\mathscr{O}_P(n)) = \mathscr{O}_{P'}(n)$$

for every n (**II**, 3.4.2). It remains only to show that $\mathscr{S}$ is of finite type over $\mathscr{O}_Y$. The modules

$$\mathscr{S}_n = q'_*(\mathscr{O}_{P'}(n))$$

are coherent by (2.2.1); and if $\mathscr{S}_n = \mathscr{S}_1^n$ for $n \geqslant n_0$, then $\mathscr{S}$ is generated by the coherent module

$$\bigoplus_{i\leqslant n_0} \mathscr{S}_i.$$

This proves the assertion (**I**, 9.6.2).

We return to the proof of (2.3.4), retaining its notation. We have proved that there is a Y-isomorphism

$$r'' : X \xrightarrow{\sim} X''$$

such that

$$r''_*(\mathscr{L}^{\otimes n}) = \mathscr{O}_{X''}(n)$$

for every $n \in \mathbf{Z}$. Let $q'' : X'' \to Y$ be the structural morphism. The algebra $\mathscr{S}'$ is the direct sum of the graded $\mathscr{S}'^{(d)}$-modules $\mathscr{S}'^{(d,k)}$. Each of these is a quasi-coherent $\mathscr{S}'^{(d)}$-module of finite type, by the periodicity of $\mathscr{S}'$ and the hypothesis that the $\mathscr{S}'_n$ are $\mathscr{O}_X$-modules of finite type (**II**, 8.14.12). Set

$$\mathscr{F}^{(k)} = r''_*(\mathscr{S}'^{(d,k)}),$$

so that the $\mathscr{F}^{(k)}$ are quasi-coherent graded $\mathscr{S}_{X''}$-modules of finite type. By (**II**, 8.14.8), the canonical homomorphism

$$\beta : \mathscr{P}roj(\mathbf{\Gamma}_*(\mathscr{F}^{(k)})) \longrightarrow \mathscr{F}^{(k)}$$

is an isomorphism of $\mathscr{S}_{X''}$-modules. On the other hand,

$$q''_*\big((\mathscr{F}^{(k)})_n\big) = q_*\big((\mathscr{S}'^{(d,k)})_n\big),$$

and for $n \geqslant 0$ the last $\mathscr{O}_Y$-module is, by definition, equal to $(\mathscr{S}^{(d,k)})_n$. In other words, the canonical injection

$$\mathscr{S}^{(d,k)} \longrightarrow \mathbf{\Gamma}_*(\mathscr{F}^{(k)})$$

is a **(TN)**-isomorphism. Hence

$$\mathscr{P}roj(\mathscr{S}^{(d,k)}) = \mathscr{P}roj(\mathbf{\Gamma}_*(\mathscr{F}^{(k)})),$$

and consequently

$$r''^*\big(\mathscr{P}roj(\mathscr{S}^{(d,k)})\big) \simeq \mathscr{S}'^{(d,k)}.$$

It remains to observe that, up to canonical isomorphism,

$$\mathscr{P}roj(\mathscr{S}^{(d,k)}) = s_*\big((\mathscr{P}roj(\mathscr{S}))^{(d,k)}\big)$$

(**II**, 8.14.13.1); this proves that $r^*(\mathscr{P}roj(\mathscr{S}))$ is isomorphic to $\mathscr{S}'$.

Finally, by (2.3.2), each $\mathbf{\Gamma}_*(\mathscr{F}^{(k)})$ satisfies condition **(TF)**, and hence so does each $\mathscr{S}^{(d,k)}$. Moreover, the $\mathscr{S}_n = q_*(\mathscr{S}'_n)$ are coherent by (2.2.1), because the $\mathscr{S}'_n$ are coherent. It follows at once that the $\mathscr{S}^{(d,k)}$ are $\mathscr{S}^{(d)}$-modules of finite type. Since (2.3.4.1) shows that $\mathscr{S}^{(d)}$ is an $\mathscr{O}_Y$-algebra of finite type, $\mathscr{S}$ is likewise an $\mathscr{O}_Y$-algebra of finite type. □

III | 106

Proposition (2.3.5). — *Let Y be an integral Noetherian prescheme, let X be an integral prescheme, and let*

$$f : X \longrightarrow Y$$

be a projective birational morphism. There is then a coherent fractional ideal

$$\mathscr{J} \subset \mathscr{R}(Y)$$

(**II**, 8.1.2) *such that X is Y-isomorphic to the prescheme obtained by blowing up $\mathscr{J}$* (**II**, 8.1.3). *Moreover, there is an open subset U of Y such that the restriction of f to $f^{-1}(U)$ is an isomorphism from $f^{-1}(U)$ onto U (cf. **I**, 6.5.5), and such that $\mathscr{J}|U$ is invertible.*

Proof. There is an invertible $\mathscr{O}_X$-module $\mathscr{L}$ very ample for f (**II**, 4.4.2) and (**II**, 5.3.2). Applying (2.3.4.1), we identify X with $\operatorname{Proj}(\mathscr{S})$, where

$$\mathscr{S} = \bigoplus_{n\geqslant 0} f_*(\mathscr{L}^{\otimes n}).$$

The modules $f_*(\mathscr{L}^{\otimes n})$ are torsion-free over $\mathscr{O}_Y$ (**I**, 7.4.5). Thus $\mathscr{S}$ identifies canonically with a sub-$\mathscr{O}_Y$-module of

$$\mathscr{S} \otimes_{\mathscr{O}_Y} \mathscr{R}(Y)$$

(**I**, 7.4.1). The latter is a simple sheaf (**I**, 7.3.6), and is therefore determined by its restriction to a nonempty open subset.

Choose a nonempty open subset $U' \subset U$ on which $\mathscr{L}|f^{-1}(U')$ is isomorphic to $\mathscr{O}_X|f^{-1}(U')$, and hence to $\mathscr{O}_Y|U'$. The restrictions $f_*(\mathscr{L}^{\otimes n})|U'$ are then isomorphic to $\mathscr{O}_Y|U'$. It follows that

$$\mathscr{S} \otimes_{\mathscr{O}_Y} \mathscr{R}(Y) \simeq \mathscr{R}(Y)[T],$$

where T is an indeterminate. By (2.3.4.1), $\mathscr{S}$ is **(TN)**-isomorphic to the sub-$\mathscr{O}_Y$-algebra generated by the canonical image of $f_*(\mathscr{L})$ in this polynomial algebra. Under the displayed identification, that image is $\mathscr{J} \cdot T$, where $\mathscr{J}$ is a coherent sub-$\mathscr{O}_Y$-module of $\mathscr{R}(Y)$ (2.2.1). Its restriction to U' is isomorphic to $\mathscr{O}_Y|U'$, and, after shrinking U if necessary, $\mathscr{J}|U$ is invertible. Consequently

$$\mathscr{S} \quad \text{is **(TN)**-isomorphic to} \quad \bigoplus_{n\geqslant 0} \mathscr{J}^n,$$

which completes the proof. □

Corollary (2.3.6). — *Under the hypotheses of (2.3.5), suppose in addition that for every nonzero coherent sub-$\mathscr{O}_Y$-module*

$$\mathscr{J} \subset \mathscr{R}(Y)$$

there is an invertible $\mathscr{O}_Y$-module $\mathscr{L}$ such that

$$\Gamma\big(Y, \mathscr{L} \otimes_{\mathscr{O}_Y} \mathscr{H}om(\mathscr{J}, \mathscr{O}_Y)\big) \neq 0.$$

Then, in the statement of (2.3.5), $\mathscr{J}$ may be taken to be an ideal of $\mathscr{O}_Y$. This additional condition is always satisfied if there exists an ample $\mathscr{O}_Y$-module.

Proof. Indeed, by (**0**, 5.4.2),

$$\mathscr{L} \otimes \mathscr{H}om(\mathscr{J}, \mathscr{O}_Y) = \mathscr{H}om(\mathscr{L}^{-1}, \mathscr{H}om(\mathscr{J}, \mathscr{O}_Y)) = \mathscr{H}om(\mathscr{J} \otimes \mathscr{L}^{-1}, \mathscr{O}_Y).$$

The hypothesis therefore says that there is a nonzero homomorphism

$$u : \mathscr{J} \otimes \mathscr{L}^{-1} \longrightarrow \mathscr{O}_Y.$$

For every $y \in Y$, the module $(\mathscr{J} \otimes \mathscr{L}^{-1})_y$ identifies with a sub-$\mathscr{O}_y$-module of the field of fractions $\mathscr{R}(Y)_y$ of $\mathscr{O}_y$ (**I**, 7.1.5). Thus u_y is necessarily injective, and u identifies $\mathscr{J} \otimes \mathscr{L}^{-1}$ with an ideal $\mathscr{J}'$ of $\mathscr{O}_Y$. But

$$\operatorname{Proj}\left(\bigoplus_{n\geqslant 0} \mathscr{J}^n\right) \quad \text{and} \quad \operatorname{Proj}\left(\bigoplus_{n\geqslant 0} (\mathscr{J} \otimes \mathscr{L}^{-1})^n\right)$$

are Y-isomorphic (**II**, 3.1.8); this proves the first assertion.

For the second, note that

$$\mathscr{F} = \mathscr{H}om_{\mathscr{O}_Y}(\mathscr{J}, \mathscr{O}_Y)$$

is coherent and nonzero, since there is an open subset U of Y on which $\mathscr{J}|U$ is invertible. If $\mathscr{L}$ is an ample $\mathscr{O}_Y$-module, there is an integer n such that

$$\mathscr{F}(n) = \mathscr{F} \otimes \mathscr{L}^{\otimes n}$$

is generated by its sections over Y (**II**, 4.5.5). *A fortiori*,

$$\Gamma(Y, \mathscr{F}(n)) \neq 0,$$

which proves the assertion. □

Corollary (2.3.7). — *Let X and Y be integral schemes projective over a field k, and let*

$$f : X \longrightarrow Y$$

be a birational k-morphism. Then X is k-isomorphic to a Y-scheme obtained by blowing up a closed subscheme Y' of Y, not necessarily reduced.

Proof. Indeed, f is projective (**II**, 5.5.5, v), and since Y is projective over k, the additional condition of (2.3.6) is satisfied. It therefore suffices to take the closed subscheme Y' of Y defined by the coherent ideal $\mathscr{J}$ of (2.3.6). □ **III** | 107

(2.3.8). *Remark.* In Chapter IV, in studying the notion of divisor, we shall see that if, in the statement of (2.3.5), the local rings $\mathscr{O}_y$, for $y \in Y$, are assumed factorial—as is the case, for example, when Y is nonsingular—then X may be obtained from Y by blowing up a closed subprescheme Y' of Y whose underlying space is contained in $Y - U$.

2.4. A generalisation of the fundamental theorem

Theorem (2.4.1). — *Let Y be a Noetherian prescheme, let $\mathscr{S}$ be a quasi-coherent $\mathscr{O}_Y$-algebra of finite type, let*

$$f : X \longrightarrow Y$$

be a projective morphism, set $\mathscr{S}' = f^*(\mathscr{S})$, and let $\mathscr{M}$ be a quasi-coherent $\mathscr{S}'$-module of finite type. Then:

(i) *For every $p \in \mathbf{Z}$, $\mathrm{R}^p f_*(\mathscr{M})$ is an $\mathscr{S}$-module of finite type.*

(ii) *Suppose in addition that $\mathscr{L}$ is an invertible $\mathscr{O}_X$-module ample for f, and, for every $n \in \mathbf{Z}$, set*

$$\mathscr{M}(n) = \mathscr{M} \otimes \mathscr{L}^{\otimes n}.$$

There is an integer N such that, for $n \geqslant N$,

$$\mathrm{R}^p f_*(\mathscr{M}(n)) = 0 \tag{2.4.1.1}$$

for every $p > 0$, and the canonical homomorphism

$$f^*(f_*(\mathscr{M}(n))) \longrightarrow \mathscr{M}(n)$$

(**0**, 4.4.3) *is surjective.*

Proof. Set

$$Y' = \mathrm{Spec}(\mathscr{S}), \qquad X' = \mathrm{Spec}(\mathscr{S}'),$$

so that $X' = X \times_Y Y'$ (**II**, 1.5.5). Let

$$g : Y' \longrightarrow Y, \qquad g' : X' \longrightarrow X$$

be the structural morphisms, which are affine by definition, and let

$$f' = f_{(Y')} : X' \longrightarrow Y'.$$

We thus have a commutative diagram

$$\begin{tikzcd} X \arrow[d, "f"'] & X' \arrow[l, "g'"'] \arrow[d, "f'"] \arrow[dl, "h"] \\ Y & Y', \arrow[l, "g"] \end{tikzcd}$$

where f' is projective (**II**, 5.5.5, iii) and

$$h = f \circ g' = g \circ f'.$$

(i) Let $\widetilde{\mathscr{M}}$ be the $\mathscr{O}_{X'}$-module associated with the quasi-coherent $\mathscr{S}'$-module $\mathscr{M}$ when X' is regarded as an affine X-scheme (**II**, 1.4.3); thus

$$\mathscr{M} = g'_*(\widetilde{\mathscr{M}}).$$

Since $\mathscr{M}$ is an $\mathscr{S}'$-module of finite type, $\widetilde{\mathscr{M}}$ is an $\mathscr{O}_{X'}$-module of finite type (**II**, 1.4.5). Moreover, h is of finite type, since g and f' are of finite type (**II**, 1.3.7) and (**I**, 6.3.4, ii). Hence X' is Noetherian (**I**, 6.3.7), and $\widetilde{\mathscr{M}}$ is therefore coherent.

Since g' is affine, the canonical homomorphism

$$\mathrm{R}^p f_*(\mathscr{M}) \longrightarrow \mathrm{R}^p h_*(\widetilde{\mathscr{M}})$$

is bijective (1.3.4). It is moreover a homomorphism of $\mathscr{S}$-modules. Indeed, the canonical homomorphism

(2.4.1.2) $$g'_*(\mathscr{O}_{X'}) \otimes_{\mathscr{O}_X} g'_*(\widetilde{\mathscr{M}}) \longrightarrow g'_*(\widetilde{\mathscr{M}})$$

defines the $\mathscr{S}'$-module structure on $\mathscr{M}$, since

$$\mathscr{S}' = g'_*(\mathscr{O}_{X'}).$$

It canonically gives rise to a homomorphism

$$f_*\big(g'_*(\mathscr{O}_{X'})\big) \otimes \mathrm{R}^p f_*\big(g'_*(\widetilde{\mathscr{M}})\big) \longrightarrow \mathrm{R}^p f_*\big(g'_*(\widetilde{\mathscr{M}})\big).$$

By (**0**, 12.2.2), and because (2.4.1.2) itself is obtained, by applying (**0**, 4.2.2.1), from the homomorphism **III** | 108

$$\mathscr{O}_{X'} \otimes \widetilde{\mathscr{M}} \longrightarrow \widetilde{\mathscr{M}}$$

that defines the $\mathscr{O}_{X'}$-module structure on $\widetilde{\mathscr{M}}$, the diagram

$$\begin{tikzcd} f_*\big(g'_*(\mathscr{O}_{X'})\big) \otimes \mathrm{R}^p f_*\big(g'_*(\widetilde{\mathscr{M}})\big) \arrow[r] \arrow[d] & \mathrm{R}^p f_*\big(g'_*(\widetilde{\mathscr{M}})\big) \arrow[d] \\ h_*(\mathscr{O}_{X'}) \otimes \mathrm{R}^p h_*(\widetilde{\mathscr{M}}) \arrow[r] & \mathrm{R}^p h_*(\widetilde{\mathscr{M}}) \end{tikzcd}$$

is commutative (**0**, 12.2.6). Composing the horizontal arrows with the homomorphism induced by the canonical homomorphism

$$\mathscr{S} \longrightarrow f_*(f^*(\mathscr{S})) = f_*(\mathscr{S}') = f_*\big(g'_*(\mathscr{O}_{X'})\big) = h_*(\mathscr{O}_{X'}),$$

we obtain the assertion.

On the other hand, since g is affine and f' is separated and quasi-compact, the canonical homomorphism

$$\mathrm{R}^p h_*(\widetilde{\mathscr{M}}) \longrightarrow g_*\big(\mathrm{R}^p f'_*(\widetilde{\mathscr{M}})\big)$$

is bijective (1.4.14). As above, it is an isomorphism of $\mathscr{S}$-modules, this time by using the commutativity in (**0**, 12.6.2). Now f' is projective and $\widetilde{\mathscr{M}}$ is coherent, so $\mathrm{R}^p f'_*(\widetilde{\mathscr{M}})$ is a coherent $\mathscr{O}_{Y'}$-module by (2.2.1). It follows that

$$g_*\big(\mathrm{R}^p f'_*(\widetilde{\mathscr{M}})\big)$$

is an $\mathscr{S}$-module of finite type (**II**, 1.4.5).

(ii) Put

$$\mathscr{L}' = g'^*(\mathscr{L}),$$

an invertible $\mathscr{O}_{X'}$-module. For every $n \in \mathbf{Z}$, up to canonical isomorphism,

$$g'_*\big(\widetilde{\mathscr{M}} \otimes \mathscr{L}'^{\otimes n}\big) = g'_*(\widetilde{\mathscr{M}}) \otimes \mathscr{L}^{\otimes n} = \mathscr{M}(n)$$

(**0**, 5.4.10). Applying the argument of *(i)* to

$$\widetilde{\mathscr{M}} \otimes \mathscr{L}'^{\otimes n}$$

shows that

$$\mathrm{R}^p f_*\big(g'_*(\widetilde{\mathscr{M}} \otimes \mathscr{L}'^{\otimes n})\big) \simeq g_*\big(\mathrm{R}^p f'_*(\widetilde{\mathscr{M}} \otimes \mathscr{L}'^{\otimes n})\big).$$

Now $\mathscr{L}'$ is ample for f' (**II**, 4.6.13, iii). It follows from (2.2.1) that there is an integer N such that

$$\mathrm{R}^p f'_*\big(\widetilde{\mathscr{M}} \otimes \mathscr{L}'^{\otimes n}\big) = 0$$

for every $p > 0$ and every $n \geqslant N$. This proves (2.4.1.1).

It follows once more from (2.2.1) that N may be chosen so that, for $n \geqslant N$, the canonical homomorphism

$$f'^*\big(f'_*(\widetilde{\mathscr{M}} \otimes \mathscr{L}'^{\otimes n})\big) \longrightarrow \widetilde{\mathscr{M}} \otimes \mathscr{L}'^{\otimes n}$$

is surjective. Since g'_* is exact (**II**, 1.4.4), the corresponding homomorphism

$$g'_*\Big(f'^*\big(f'_*(\widetilde{\mathscr{M}} \otimes \mathscr{L}'^{\otimes n})\big)\Big) \longrightarrow g'_*\big(\widetilde{\mathscr{M}} \otimes \mathscr{L}'^{\otimes n}\big) = \mathscr{M}(n)$$

is surjective. But (**II**, 1.5.2) gives

$$g'_*\Big(f'^*\big(f'_*(\widetilde{\mathscr{M}} \otimes \mathscr{L}'^{\otimes n})\big)\Big) = f^*\Big(g_*\big(f'_*(\widetilde{\mathscr{M}} \otimes \mathscr{L}'^{\otimes n})\big)\Big),$$

and $g_* \circ f'_* = f_* \circ g'_*$. Consequently,

$$g'_*\Big(f'^*\big(f'_*(\widetilde{\mathscr{M}} \otimes \mathscr{L}'^{\otimes n})\big)\Big) = f^*\big(f_*(\mathscr{M}(n))\big),$$

which completes the proof. □

(2.4.2). We shall apply (2.4.1), in particular, when $\mathscr{S}$ is an $\mathscr{O}_Y$-algebra graded in positive degrees and

$$\mathscr{M} = \bigoplus_{k\in\mathbf{Z}} \mathscr{M}_k$$

is a graded $\mathscr{S}'$-module. Under the same finiteness hypotheses on $\mathscr{S}$ and $\mathscr{M}$, it follows from (2.4.1) that **III** | 109

$$\bigoplus_{k\in\mathbf{Z}} \mathrm{R}^p f_*(\mathscr{M}_k)$$

is an $\mathscr{S}$-module of finite type for every p. Under the additional hypotheses of (2.4.1, ii), there is moreover an integer N such that, for $n \geqslant N$,

$$\mathrm{R}^p f_*(\mathscr{M}_k(n)) = 0$$

for every $p > 0$ and every $k \in \mathbf{Z}$, and the canonical homomorphism

$$f^*\big(f_*(\mathscr{M}_k(n))\big) \longrightarrow \mathscr{M}_k(n)$$

is surjective for every $k \in \mathbf{Z}$.

2.5. Euler–Poincaré characteristic and the Hilbert polynomial

(2.5.1). Let A be an Artinian ring and let X be an A-scheme projective over

$$Y = \mathrm{Spec}(A).$$

For every coherent $\mathscr{O}_X$-module $\mathscr{F}$, the A-modules

$$\mathrm{H}^i(X, \mathscr{F}) \qquad (i \geqslant 0)$$

are of finite type (2.2.1), and hence have finite length, since A is Artinian. Moreover, (2.2.1) shows that $\mathrm{H}^i(X, \mathscr{F}) = 0$ for all but finitely many $i \geqslant 0$. Thus the integer

$$\chi_A(\mathscr{F}) = \sum_{i=0}^{\infty}(-1)^i \operatorname{length}_A(\mathrm{H}^i(X, \mathscr{F})) \tag{2.5.1.1}$$

is defined for every coherent $\mathscr{O}_X$-module $\mathscr{F}$. When A is an Artinian local ring, $\chi_A(\mathscr{F})$ is called the *Euler–Poincaré characteristic* of $\mathscr{F}$ with respect to A. For $\mathscr{F} = \mathscr{O}_X$, the integer $\chi_A(\mathscr{O}_X)$ is called the *arithmetic genus* of X with respect to A.

Proposition (2.5.2). — *Let*

$$0 \longrightarrow \mathscr{F}' \longrightarrow \mathscr{F} \longrightarrow \mathscr{F}'' \longrightarrow 0$$

be an exact sequence of coherent $\mathscr{O}_X$-modules. Then

$$\chi_A(\mathscr{F}) = \chi_A(\mathscr{F}') + \chi_A(\mathscr{F}''). \tag{2.5.2.1}$$

Proof. The cohomology modules of $\mathscr{F}$, $\mathscr{F}'$, and $\mathscr{F}''$ vanish in all sufficiently large degrees. There is therefore an integer $r > 0$ for which the long exact cohomology sequence has the form

$$0 \longrightarrow \mathrm{H}^0(X, \mathscr{F}') \longrightarrow \mathrm{H}^0(X, \mathscr{F}) \longrightarrow \mathrm{H}^0(X, \mathscr{F}'') \longrightarrow \mathrm{H}^1(X, \mathscr{F}') \longrightarrow \cdots$$

$$\cdots \longrightarrow \mathrm{H}^r(X, \mathscr{F}') \longrightarrow \mathrm{H}^r(X, \mathscr{F}) \longrightarrow \mathrm{H}^r(X, \mathscr{F}'') \longrightarrow 0.$$

In an exact sequence of A-modules of finite length with zero terms at both ends, the alternating sum of the lengths is zero (**0**, 11.10.1). Applying this fact gives (2.5.2.1) immediately. □

The result of (2.5.2) applies whenever X is a quasi-compact A-scheme and the A-modules $\mathrm{H}^i(X, \mathscr{F})$ are of finite type for every coherent $\mathscr{O}_X$-module $\mathscr{F}$ (1.4.12).

Theorem (2.5.3). — *Let A be an Artinian local ring, let X be a scheme projective over*

$$Y = \mathrm{Spec}(A),$$

let $\mathscr{L}$ be an invertible $\mathscr{O}_X$-module very ample relative to Y, and let $\mathscr{F}$ be a coherent $\mathscr{O}_X$-module. For every $n \in \mathbf{Z}$, put

$$\mathscr{F}(n) = \mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{L}^{\otimes n}.$$

(i) *There is a unique polynomial $P \in \mathbf{Q}[T]$ such that*

$$\chi_A(\mathscr{F}(n)) = P(n)$$

for every $n \in \mathbf{Z}$. The polynomial P is called the Hilbert polynomial *of $\mathscr{F}$ with respect to A.*

(ii) *For all sufficiently large n,*

$$\chi_A(\mathscr{F}(n)) = \operatorname{length}_A \Gamma(X, \mathscr{F}(n)).$$

(iii) *The coefficient of the highest-degree term of $\chi_A(\mathscr{F}(n))$ is nonnegative.*

We shall moreover prove in Chapter IV, in the section devoted to dimension, that *the degree of $\chi_A(\mathscr{F}(n))$ equals the dimension of the support of $\mathscr{F}$.*

Proof. For all sufficiently large n, we have

$$\mathrm{H}^i(X, \mathscr{F}(n)) = 0$$

for every $i > 0$ (2.2.1). Consequently, **III** | 110

$$\chi_A(\mathscr{F}(n)) = \operatorname{length}_A \mathrm{H}^0(X, \mathscr{F}(n)) = \operatorname{length}_A \Gamma(X, \mathscr{F}(n))$$

for all sufficiently large n, which proves *(ii)*. It follows that $\chi_A(\mathscr{F}(n)) \geqslant 0$ for all sufficiently large n, and *(iii)* therefore follows from *(i)*. The uniqueness assertion in *(i)* is immediate, so it remains to prove the existence of P.

We first show that we may assume

$$\mathfrak{m}\mathscr{F} = 0,$$

where $\mathfrak{m}$ is the maximal ideal of A. Indeed, there is an integer $s > 0$ such that $\mathfrak{m}^s = 0$, and $\mathscr{F}(n)$ therefore has the finite filtration

$$\mathscr{F}(n) \supset \mathfrak{m}\mathscr{F}(n) \supset \cdots \supset \mathfrak{m}^{s-1}\mathscr{F}(n) \supset 0.$$

Induction using (2.5.2.1) gives

$$\chi_A(\mathscr{F}(n)) = \sum_{k=1}^{s} \chi_A\left(\mathfrak{m}^{k-1}\mathscr{F}(n)/\mathfrak{m}^k\mathscr{F}(n)\right).$$

But

$$\mathfrak{m}^{k-1}\mathscr{F}(n)/\mathfrak{m}^k\mathscr{F}(n) = \mathscr{F}'_k(n), \qquad \mathscr{F}'_k = \mathfrak{m}^{k-1}\mathscr{F}/\mathfrak{m}^k\mathscr{F},$$

which proves the reduction.

Suppose, then, that $\mathfrak{m}\mathscr{F} = 0$. Let X' be the closed subscheme of X obtained as the inverse image, under the structural morphism

$$X \longrightarrow \operatorname{Spec}(A),$$

of the unique closed point of $\operatorname{Spec}(A)$, and let $j : X' \to X$ be the canonical injection. Then

$$\mathscr{F} = j_*(\mathscr{F}')$$

for a coherent $\mathscr{O}_{X'}$-module $\mathscr{F}'$, and X' is projective over $\operatorname{Spec}(K)$, where

$$K = A/\mathfrak{m}.$$

If $\mathscr{L}' = j^*(\mathscr{L})$, then $\mathscr{L}'$ is very ample relative to $\operatorname{Spec}(K)$ (**II**, 4.4.10), and

$$\mathscr{F}(n) = j_*(\mathscr{F}'(n)), \qquad \mathscr{F}'(n) = \mathscr{F}' \otimes_{\mathscr{O}_{X'}} \mathscr{L}'^{\otimes n}$$

(**0**, 5.4.10). It follows that

$$\chi_A(\mathscr{F}(n)) = \chi_K(\mathscr{F}'(n))$$

(G, II, 4.9.1), and we are reduced to the case in which A is a field.

Now X may be regarded as a closed subscheme of

$$P = \mathbf{P}^r_A$$

for a suitable r (**II**, 5.5.4, ii). If $i : X \to P$ is the canonical injection, the same argument gives

$$\chi_A(\mathscr{F}(n)) = \chi_A\big(i_*(\mathscr{F})(n)\big).$$

We may therefore restrict to the case

$$X = \mathbf{P}^r_A = \operatorname{Proj}(S), \qquad S = A[T_0, \ldots, T_r],$$

where A is a field.

In this case $\mathscr{F} = \widetilde{M}$ for a graded S-module M of finite type (**II**, 2.7.8). By the Hilbert syzygy theorem (M, VIII, 6.5), M has a finite resolution by graded free S-modules of finite type:

$$0 \longrightarrow L_q \longrightarrow L_{q-1} \longrightarrow \cdots \longrightarrow L_1 \longrightarrow M \longrightarrow 0.$$

Since the functor $M \mapsto \widetilde{M}$ is exact (**II**, 2.5.4), we obtain an exact sequence

$$0 \longrightarrow \widetilde{L}_q \longrightarrow \widetilde{L}_{q-1} \longrightarrow \cdots \longrightarrow \widetilde{L}_1 \longrightarrow \widetilde{M} \longrightarrow 0,$$

and hence, for every $n \in \mathbf{Z}$, an exact sequence

$$0 \longrightarrow \widetilde{L}_q(n) \longrightarrow \widetilde{L}_{q-1}(n) \longrightarrow \cdots \longrightarrow \widetilde{L}_1(n) \longrightarrow \widetilde{M}(n) \longrightarrow 0.$$

Induction on q, using (2.5.2), yields

$$\chi_A(\widetilde{M}(n)) = \sum_{j=1}^{q} (-1)^{j+1} \chi_A(\widetilde{L}_j(n)).$$

To prove *(i)*, we are therefore reduced to the case in which M is graded, free, and of finite type, and hence to the case

$$M = S(h)$$

for some $h \in \mathbf{Z}$. Then

$$\widetilde{M}(n) = \widetilde{M(n)} = \widetilde{S(n+h)}$$

(**II**, 2.5.15), so the theorem follows from the lemma below. □

III | 111

Lemma (2.5.3.1). — *Let A be a field, let $r > 0$ be an integer, and let*

$$X = \mathbf{P}^r_A.$$

Then

$$\chi_A(\mathscr{O}_X(n)) = \binom{n+r}{r}$$

for every $n \in \mathbf{Z}$.

Proof. For $n \geqslant 0$,

$$\chi_A(\mathscr{O}_X(n)) = \operatorname{length}_A \mathrm{H}^0(X, \mathscr{O}_X(n)),$$

which is the number of monomials in the T_i of total degree n, namely

$$\binom{n+r}{r}$$

(2.1.12).

For $n \leqslant -r-1$, we likewise have

$$\chi_A(\mathscr{O}_X(n)) = (-1)^r \operatorname{length}_A \mathrm{H}^r(X, \mathscr{O}_X(n)).$$

Writing $n = -r-h$, the dimension of $\mathrm{H}^r(X, \mathscr{O}_X(n))$ over A is the number of sequences

$$(p_i)_{0 \leqslant i \leqslant r}$$

of positive integers satisfying

$$\sum_{i=0}^{r} p_i = r + h$$

(2.1.12). Equivalently, it is the number of sequences of nonnegative integers

$$(q_i)_{0 \leqslant i \leqslant r}$$

such that

$$\sum_{i=0}^{r} q_i = h - 1.$$

This number is

$$\binom{h+r-1}{r} = (-1)^r \binom{n+r}{r}.$$

Finally, if $-r \leqslant n < 0$, then

$$\binom{n+r}{r} = 0,$$

and $\mathrm{H}^i(X, \mathscr{O}_X(n)) = 0$ for every $i \geqslant 0$ (2.1.12). This proves the lemma. □

Corollary (2.5.4). — *Let A be an Artinian local ring, let S be a graded A-algebra of finite type generated by S_1, let M be a graded S-module of finite type, and let*

$$X = \operatorname{Proj}(S).$$

Then, for all sufficiently large n,

$$\chi_A(\widetilde{M}(n)) = \operatorname{length}_A(M_n).$$

Proof. For all sufficiently large n, the modules

$$M_n \quad \text{and} \quad \Gamma(X, \widetilde{M}(n))$$

are isomorphic (2.3.1). □

2.6. Application: ampleness criteria

Proposition (2.6.1). — *Let Y be a Noetherian prescheme, let $f : X \to Y$ be a proper morphism, and let $\mathscr{L}$ be an invertible $\mathscr{O}_X$-module. The following conditions are equivalent:*

a) *$\mathscr{L}$ is ample for f.*

b) *For every coherent $\mathscr{O}_X$-module $\mathscr{F}$, there exists an integer N such that, for $n \geqslant N$,*

$$\mathrm{R}^q f_*(\mathscr{F} \otimes \mathscr{L}^{\otimes n}) = 0$$

for every $q > 0$.

c) *For every coherent ideal $\mathscr{J}$ of $\mathscr{O}_X$, there exists an integer N such that, for $n \geqslant N$,*

$$\mathrm{R}^1 f_*(\mathscr{J} \otimes \mathscr{L}^{\otimes n}) = 0.$$

Proof. We have seen that *a)* implies *b)* (2.2.1), (ii). It is immediate that *b)* implies *c)*, and it remains to prove that *c)* implies *a)*. We may restrict to the case where Y is affine (**II**, 4.6.4). It is enough to show that, as h ranges through the sections of $\mathscr{L}^{\otimes n}$ over X, with $n > 0$, the affine open subsets X_h form a covering of X (**II**, 4.5.2).

For this purpose, let x be a closed point of X and let U be an affine open neighbourhood of x. We shall find an integer n and a section

$$h \in \Gamma(X, \mathscr{L}^{\otimes n})$$

such that $x \in X_h \subset U$. The open subset X_h will then be affine (**I**, 1.3.6). The union of all such X_h is an open subset of X containing every closed point, and therefore is all of X, since X is Noetherian (**I**, 6.3.7) and (**0**, 2.1.3).

Let $\mathscr{J}$, respectively $\mathscr{J}'$, be the quasi-coherent ideal of $\mathscr{O}_X$ defining the reduced closed sub-prescheme whose underlying space is $X - U$, respectively $(X - U) \cup \{x\}$ (**I**, 5.2.1). The ideals $\mathscr{J}$ and $\mathscr{J}'$ are coherent (**I**, 6.1.1), $\mathscr{J}' \subset \mathscr{J}$, and

$$\mathscr{J}'' = \mathscr{J} / \mathscr{J}'$$

is a coherent $\mathscr{O}_X$-module (**0**, 5.3.3), supported by $\{x\}$, with $\mathscr{J}''_x = k(x)$. Since $\mathscr{L}$ is locally free, the sequence

$$0 \longrightarrow \mathscr{J}' \otimes \mathscr{L}^{\otimes n} \longrightarrow \mathscr{J} \otimes \mathscr{L}^{\otimes n} \longrightarrow \mathscr{J}'' \otimes \mathscr{L}^{\otimes n} \longrightarrow 0$$

is exact for every n. By hypothesis, for all sufficiently large n,

$$\mathrm{H}^1(X, \mathscr{J}' \otimes \mathscr{L}^{\otimes n}) = 0.$$

The exact cohomology sequence therefore shows that **III** | 112

$$\Gamma(X, \mathscr{J} \otimes \mathscr{L}^{\otimes n}) \longrightarrow \Gamma(X, \mathscr{J}'' \otimes \mathscr{L}^{\otimes n})$$

is surjective. A section g of $\mathscr{J}'' \otimes \mathscr{L}^{\otimes n}$ over X such that $g(x) \neq 0$ is consequently the image of a section

$$h \in \Gamma(X, \mathscr{J} \otimes \mathscr{L}^{\otimes n}) \subset \Gamma(X, \mathscr{L}^{\otimes n});$$

the inclusion follows from (**0**, 5.4.1). By construction, $h(x) \neq 0$, while $h(z) = 0$ for every $z \notin U$. Thus $x \in X_h \subset U$, which proves the assertion. □

Proposition (2.6.2). — *Let Y be a Noetherian prescheme, let $f : X \to Y$ be a morphism of finite type, let $g : X' \to X$ be a finite surjective morphism, let $\mathscr{L}$ be an invertible $\mathscr{O}_X$-module, and set*

$$\mathscr{L}' = g^*(\mathscr{L}).$$

*Suppose that there exists a subset Z of X, proper over Y (**II**, 5.4.10), such that, for every $x \in X - Z$, either X is normal at x, or*

$$\big(g_*(\mathscr{O}_{X'})\big)_x$$

is a free $\mathscr{O}_{X,x}$-module. Then $\mathscr{L}$ is ample for f if and only if $\mathscr{L}'$ is ample for $f \circ g$.

Proof.

(2.6.2.1). Since g is affine, the condition is necessary (**II**, 5.1.12). To prove that it is sufficient, we may suppose that Y is affine (**II**, 4.6.4). We first show that we may also restrict to the case in which X is reduced.

Let $j : X_{\mathrm{red}} \to X$ be the canonical immersion, and put

$$X_1 = X_{\mathrm{red}}, \qquad X'_1 = X' \times_X X_1.$$

We then have the commutative diagram

$$\begin{tikzcd} X' \arrow[d, "g"'] & X'_1 \arrow[l, "j'"'] \arrow[d, "g_1"] \\ X & X_1 \arrow[l, "j"] \end{tikzcd} \tag{2.6.2.2}$$

The morphism $f \circ j$ is of finite type (**I**, 6.3.4), and g_1 is finite (**II**, 6.1.5), (iii). If $\mathscr{L}'$ is ample for $f \circ g$, then $j'^*(\mathscr{L}')$ is ample for $f \circ g \circ j'$, because j' is a closed immersion (**II**, 5.1.12) and (**I**, 4.3.2). If $Z_1 = j^{-1}(Z)$, then Z_1 is proper over Y (**II**, 5.4.10). Moreover, if X is normal at a point x, then so is X_{red} at that point; and if $\big(g_*(\mathscr{O}_{X'})\big)_x$ is a free $\mathscr{O}_{X,x}$-module, then (**II**, 1.5.2) shows that

$$\big((g_1)_*(\mathscr{O}_{X'_1})\big)_x$$

is a free $\mathscr{O}_{X_1,x}$-module. Finally, since X is Noetherian (**I**, 6.3.7), the ampleness of $j^*(\mathscr{L})$ implies that of $\mathscr{L}$ (**II**, 4.5.14). As

$$j'^*(\mathscr{L}') = g_1^*(j^*(\mathscr{L})),$$

this proves the announced reduction. Henceforth we suppose that Y is affine and that X is reduced.

The hypotheses of (**II**, 6.6.11) are now satisfied. There exist a reduced Y-prescheme X_2 and a finite birational Y-morphism

$$h : X_2 \longrightarrow X$$

whose restriction to $h^{-1}(X - Z)$ is an isomorphism onto $X - Z$, and such that $h^*(\mathscr{L})$ is ample. Replacing X' by X_2, we are reduced to proving the proposition under the additional assumption that g has the properties just listed for h. We continue to write Z for a closed subprescheme of X, proper over Y (**II**, 5.4.10), whose underlying space is the given subset Z.

(2.6.2.3). Let X_1 be a closed subprescheme of X, let $j : X_1 \to X$ be the canonical immersion, and let

$$X'_1 = g^{-1}(X_1) = X' \times_X X_1,$$

with canonical immersion $j' : X'_1 \to X'$. The corresponding square is again (2.6.2.2). Put

$$\mathscr{L}_1 = j^*(\mathscr{L}), \qquad \mathscr{L}'_1 = j'^*(\mathscr{L}') = g_1^*(\mathscr{L}_1).$$

Then $\mathscr{L}'_1$ is ample for $f \circ g \circ j'$ (**II**, 5.1.12). If $Z_1 = j^{-1}(Z)$, the closed subprescheme Z_1 of X_1 is proper over Y (**II**, 5.4.2), (ii). In other words, the hypotheses of (2.6.2) hold for X_1, $\mathscr{L}_1$, g_1, and Z_1.

This permits us to prove (2.6.2) by Noetherian induction (**0**, 2.2.2) when the restriction of g to $g^{-1}(X - Z)$ is an isomorphism onto $X - Z$; as seen in (2.6.2.1), that case is sufficient. It is enough to show that if the conclusion of (2.6.2) holds for $\mathscr{L}_1$ on every closed subprescheme X_1 of X whose underlying space is not X, then it also holds for $\mathscr{L}$. **III** | 113

(2.6.2.4). Set

$$\mathscr{A} = \mathscr{O}_X, \qquad \mathscr{B} = g_*(\mathscr{O}_{X'}).$$

Since g is birational and X is reduced, $\mathscr{B}$ is a sub-$\mathscr{A}$-algebra of the sheaf $\mathscr{R}(X)$ of total quotient rings, and it is a coherent $\mathscr{A}$-module. Moreover,

$$\mathscr{B}|_{X-Z} = \mathscr{A}|_{X-Z}.$$

Let $\mathscr{K}$ be the conductor of $\mathscr{B}$ over $\mathscr{A}$, that is, the largest quasi-coherent sub-$\mathscr{A}$-module of $\mathscr{A}$ such that

$$\mathscr{B}\mathscr{K} \subset \mathscr{A}.$$

Equivalently, $\mathscr{K}$ is the annihilator of the $\mathscr{A}$-module $\mathscr{B}/\mathscr{A}$ (**0**, 5.3.7). It follows that

$$\mathscr{B}\mathscr{K} = \mathscr{K}.$$

Clearly $\mathscr{K}_x = \mathscr{A}_x$ at every point admitting a neighbourhood W_x on which $g : g^{-1}(W_x) \to W_x$ is an isomorphism. This holds in particular at every point of $X - Z$, and in a neighbourhood of every generic point of an irreducible component of X.

Let

$$Z_1 = \operatorname{Spec}(\mathscr{A}/\mathscr{K})$$

be the closed subprescheme of X defined by $\mathscr{K}$. It is proper over Y, because its underlying space is closed in Z (**II**, 5.4.10). The definition of $\mathscr{K}$ also gives

$$\mathscr{B}|_{X-Z_1} = \mathscr{A}|_{X-Z_1}.$$

We may therefore reduce to the case

$$Z = \operatorname{Spec}(\mathscr{A}/\mathscr{K}).$$

Since $X - Z_1$ is a nonempty open subset of X, we may in addition suppose that the underlying space of Z is distinct from X.

(2.6.2.5). Regard X' as $\operatorname{Spec}(\mathscr{B})$, since g is affine, and let

$$\mathscr{K}' = \widetilde{\mathscr{K}}.$$

This is a coherent ideal of $\mathscr{O}_{X'}$ satisfying $g_*(\mathscr{K}') = \mathscr{K}$ (**II**, 1.4.1). The closed subprescheme

$$Z' = g^{-1}(Z) = Z \times_X X'$$

of X' is defined by $\mathscr{K}'$ and is equal to

$$\operatorname{Spec}(\mathscr{B}/\mathscr{K})$$

(**II**, 1.4.10). The morphism $h : Z' \to Z$ is finite (**II**, 6.1.5), (iii); consequently Z' is proper over Y (**II**, 6.1.11) and (**II**, 5.4.2), (ii).

We must prove that, for every $x \in X$ and every open neighbourhood U of x, there exist an integer $n > 0$ and a section s of $\mathscr{L}^{\otimes n}$ over X such that

$$x \in X_s \subset U$$

(**II**, 4.5.2). We distinguish two cases.

1° Suppose first that $x \in X - Z$. We may clearly suppose that $U \subset X - Z$, so that $U' = g^{-1}(U)$ does not meet Z'. Since $\mathscr{L}'$ is ample, there exist $n > 0$ and a section s' of $\mathscr{L}'^{\otimes n}$ over X' such that

$$x' = g^{-1}(x) \in X'_{s'} \subset g^{-1}(U)$$

(**II**, 4.5.2). We may also suppose that $\mathscr{K}' \otimes \mathscr{L}'^{\otimes n}$ is generated by its global sections (**II**, 4.5.5). As $\mathscr{K}'_{x'} = \mathscr{O}_{X',x'}$, one of these sections, say s'', is nonzero at x'. Multiplying it by s', and thus replacing n by $2n$, we may arrange that

$$x' \in X'_{s''} \subset g^{-1}(U).$$

By (**0**, 5.4.10), there is a canonical isomorphism

$$\Gamma(X, \mathscr{K} \otimes \mathscr{L}^{\otimes n}) \xrightarrow{\sim} \Gamma(X', \mathscr{K}' \otimes \mathscr{L}'^{\otimes n}).$$

The section s of $\mathscr{K} \otimes \mathscr{L}^{\otimes n}$ corresponding to s'' plainly has the required properties.

2° Suppose now that $x \in Z$. Let $\mathscr{J}$ be the coherent ideal of $\mathscr{O}_X$ defining the reduced closed subprescheme whose underlying space is $X - U$, and consider in $\mathscr{B}$ the coherent ideals **III** | 114

$$\mathscr{J}\mathscr{B} \qquad \text{and} \qquad \mathscr{J}\mathscr{K} = \mathscr{J}(\mathscr{K}\mathscr{B}) = \mathscr{K}(\mathscr{J}\mathscr{B}).$$

We have the diagram of inclusions

(2.6.2.6)

$$\begin{tikzcd}
\mathscr{J}\mathscr{B} \arrow[r, hook] & \mathscr{B} \\
\mathscr{J} \arrow[u, hook] \arrow[r, hook] & \mathscr{A} \arrow[u, hook] \\
\mathscr{J}\mathscr{K}\mathscr{B} = \mathscr{J}\mathscr{K} \arrow[u, hook] \arrow[r, hook] & \mathscr{K} \arrow[u, hook]
\end{tikzcd}$$

Let $\mathscr{J}' = (\mathscr{J}\mathscr{B})^{\sim}$ be the coherent ideal of $\mathscr{O}_{X'}$ such that

$$g_*(\mathscr{J}') = \mathscr{J}\mathscr{B}.$$

Then

$$\mathscr{J}'\mathscr{K}' = (\mathscr{J}\mathscr{K}\mathscr{B})^{\sim}, \qquad \mathscr{J}'/\mathscr{J}'\mathscr{K}' = (\mathscr{J}\mathscr{B}/\mathscr{J}\mathscr{K}\mathscr{B})^{\sim}$$

(**II**, 1.4.4). Since $\mathscr{J}|_V = \mathscr{J}\mathscr{K}|_V$ on every open subset V disjoint from Z, the support of $\mathscr{J}'/\mathscr{J}'\mathscr{K}'$ is contained in Z'. Because Z' is proper over Y, (2.2.4) shows that, for all sufficiently large n, the canonical map

$$\Gamma(X', \mathscr{J}' \otimes \mathscr{L}'^{\otimes n}) \longrightarrow \Gamma\big(X', (\mathscr{J}'/\mathscr{J}'\mathscr{K}') \otimes \mathscr{L}'^{\otimes n}\big)$$

is surjective. By (**0**, 5.4.10), it follows that the canonical map

$$\Gamma(X, \mathscr{J}\mathscr{B} \otimes \mathscr{L}^{\otimes n}) \longrightarrow \Gamma\big(X, (\mathscr{J}\mathscr{B}/\mathscr{J}\mathscr{K}\mathscr{B}) \otimes \mathscr{L}^{\otimes n}\big)$$

is surjective.

Let $i : Z \to X$ and $i' : Z' \to X'$ be the canonical immersions. They fit into the commutative diagram

$$\begin{tikzcd} X' \arrow[d, "g"'] & Z' \arrow[l, "i'"'] \arrow[d, "h"] \\ X & Z \arrow[l, "i"] \end{tikzcd}$$

Put

$$\mathscr{M} = i^*(\mathscr{L}), \qquad \mathscr{M}' = i'^*(\mathscr{L}').$$

Since $\mathscr{L}'$ is ample, $\mathscr{M}'$ is ample (**II**, 5.1.12), and

$$\mathscr{M}' = h^*(\mathscr{M}).$$

The Noetherian induction hypothesis, applied because $Z \neq X$, now shows that $\mathscr{M}$ is ample. Consequently, for all sufficiently large n,

$$i^*(\mathscr{J}/\mathscr{J}\mathscr{K}) \otimes \mathscr{M}^{\otimes n}$$

is generated by its sections over Z (**II**, 4.5.5). Since

$$\mathscr{J}/\mathscr{J}\mathscr{K} = i_*\big(i^*(\mathscr{J}/\mathscr{J}\mathscr{K})\big),$$

(**0**, 5.4.10) gives a section s of

$$(\mathscr{J}/\mathscr{J}\mathscr{K}) \otimes \mathscr{L}^{\otimes n}$$

over X, for some sufficiently large n, such that $s(x) \neq 0$. Indeed, $\mathscr{J}_x = \mathscr{A}_x$ by the definition of $\mathscr{J}$, whereas $\mathscr{K}_x \neq \mathscr{A}_x$ by hypothesis.

The diagram (2.6.2.6) shows that s is also a section of

$$(\mathscr{J}\mathscr{B}/\mathscr{J}\mathscr{K}\mathscr{B}) \otimes \mathscr{L}^{\otimes n}$$

over X. It is therefore the canonical image of a section

$$t \in \Gamma(X, \mathscr{J}\mathscr{B} \otimes \mathscr{L}^{\otimes n}).$$

By definition, the image of t modulo $\mathscr{J}\mathscr{K}\mathscr{B} \otimes \mathscr{L}^{\otimes n}$ lies in

$$\frac{\mathscr{J} \otimes \mathscr{L}^{\otimes n}}{\mathscr{J}\mathscr{K}\mathscr{B} \otimes \mathscr{L}^{\otimes n}}.$$

The diagram (2.6.2.6) therefore implies that t is a section of $\mathscr{J} \otimes \mathscr{L}^{\otimes n}$, hence in particular a section of $\mathscr{L}^{\otimes n}$. We have $t(x) \neq 0$, so $x \in X_t$. By the definition of $\mathscr{J}$, the section t vanishes on $X - U$, the support of $\mathscr{O}_X/\mathscr{J}$. Thus $X_t \subset U$, and the proof is complete.

□

III | 115

(2.6.3). *Remark.* When X is proper over Y, Proposition (2.6.2) can be proved more simply by arguing as in Chevalley's theorem (**II**, 6.7.1), with the aid of Proposition (2.6.1) and the lemma (**II**, 6.7.1.1).

§3. Finiteness theorem for proper morphisms

3.1. The dévissage lemma

Definition (3.1.1). — Let C be an abelian category. We say that a subset C' of the set of objects of C is *exact* if $0 \in \mathsf{C}'$ and if, for every exact sequence $0 \to A' \to A \to A'' \to 0$ in C such that two of the objects A, A', A'' are in C', then the third is also in C'.

Theorem (3.1.2). — *Let X be a Noetherian prescheme; we denote by C the abelian category of coherent $\mathscr{O}_X$-modules. Let C' be an exact subset of C, X' a closed subset of the underlying space of X. Suppose that for every closed irreducible subset Y of X', with generic point y, there exists an $\mathscr{O}_X$-module $\mathscr{G} \in \mathsf{C}'$ such that $\mathscr{G}_y$ is a $k(y)$-vector space of dimension 1. Then every coherent $\mathscr{O}_X$-module with support contained in X' is in C' (and in particular, if $X' = X$, then we have $\mathsf{C}' = \mathsf{C}$).*

Proof. Consider the following property $\mathbf{P}(Y)$ of a closed subset Y of X': every coherent $\mathscr{O}_X$-module with support contained in Y is in C'. By virtue of the principle of Noetherian induction (**0**, 2.2.2), we see that we can reduce to showing that *if Y is a closed subset of X' such that the property $\mathbf{P}(Y')$ is true for every closed subset Y' of Y, distinct from Y, then $\mathbf{P}(Y)$ is true*.

Therefore, let $\mathscr{F} \in \mathsf{C}$ have support contained in Y, and we show that $\mathscr{F} \in \mathsf{C}'$. Denote also by Y the closed reduced subprescheme of X having Y for its underlying space (**I**, 5.2.1); it is defined by a coherent sheaf of ideals $\mathscr{J}$ of $\mathscr{O}_X$. We know (**I**, 9.3.4) that there exists an integer $n > 0$ such that $\mathscr{J}^n\mathscr{F} = 0$; for $1 \leqslant k \leqslant n$, we thus have an exact sequence

$$0 \longrightarrow \mathscr{J}^{k-1}\mathscr{F} / \mathscr{J}^k\mathscr{F} \longrightarrow \mathscr{F} / \mathscr{J}^k\mathscr{F} \longrightarrow \mathscr{F} / \mathscr{J}^{k-1}\mathscr{F} \longrightarrow 0$$

of coherent $\mathscr{O}_X$-modules ((**I**, 5.3.6) and (**I**, 5.3.3)); as C' is exact, we see, by induction on k, that it suffices to show that each of the $\mathscr{F}_k = \mathscr{J}^{k-1}\mathscr{F} / \mathscr{J}^k\mathscr{F}$ is in C'. We thus reduce to proving that $\mathscr{F} \in \mathsf{C}'$ under the additional hypothesis that $\mathscr{J}\mathscr{F} = 0$; it is equivalent to say that $\mathscr{F} = j_*(j^*(\mathscr{F}))$, where j is the canonical injection $Y \to X$. Let us now consider two cases:

(a) Y is *reducible*. Let $Y = Y' \cup Y''$, where Y' and Y'' are closed subsets of Y, distinct from Y; denote also by Y' and Y'' the closed reduced subpreschemes of X having Y' and Y'' for their respective underlying spaces, which are defined respectively by sheaves of ideals $\mathscr{J}'$ and $\mathscr{J}''$ of $\mathscr{O}_X$. Set $\mathscr{F}' = \mathscr{F} \otimes_{\mathscr{O}_X} (\mathscr{O}_X / \mathscr{J}')$ and $\mathscr{F}'' = \mathscr{F} \otimes_{\mathscr{O}_X} (\mathscr{O}_X / \mathscr{J}'')$. The canonical homomorphisms $\mathscr{F} \to \mathscr{F}'$ and $\mathscr{F} \to \mathscr{F}''$ thus define a homomorphism $u : \mathscr{F} \to \mathscr{F}' \oplus \mathscr{F}''$. We show that for every $z \notin Y' \cap Y''$, the homomorphism $u_z : \mathscr{F}_z \to \mathscr{F}'_z \oplus \mathscr{F}''_z$ is *bijective*. Indeed, we have $\mathscr{J}' \cap \mathscr{J}'' = \mathscr{J}$, since the question is local and the above equality follows from ((**I**, 5.2.1) and (**I**, 1.1.5)); if $z \notin Y''$, then we have $\mathscr{J}'_z = \mathscr{J}_z$, hence $\mathscr{F}'_z = \mathscr{F}_z$ and $\mathscr{F}''_z = 0$, which establishes our assertion in this case; we reason similarly for $z \notin Y'$. As a result, the kernel and cokernel of u, which are in C (**0**, 5.3.4), have their support in $Y' \cap Y''$, and thus are in C' by hypothesis; for the same reason, $\mathscr{F}'$ and $\mathscr{F}''$ are in C', hence also $\mathscr{F}' \oplus \mathscr{F}''$, as C' is exact. The conclusion then follows from the consideration of the two exact sequences **III | 116**

$$0 \longrightarrow \operatorname{Im} u \longrightarrow \mathscr{F}' \oplus \mathscr{F}'' \longrightarrow \operatorname{Coker} u \longrightarrow 0,$$

$$0 \longrightarrow \operatorname{Ker} u \longrightarrow \mathscr{F} \longrightarrow \operatorname{Im} u \longrightarrow 0,$$

and the hypothesis that C' is exact.

(b) Y is irreducible, and as a result, the subprescheme Y of X is *integral*. If y is its generic point, then we have $(\mathscr{O}_Y)_y = k(y)$, and as $j^*(\mathscr{F})$ is a coherent $\mathscr{O}_Y$-module, $\mathscr{F}_y = (j^*(\mathscr{F}))_y$ is a $k(y)$-vector space of finite dimension m. By hypothesis, there is a coherent $\mathscr{O}_X$-module $\mathscr{G} \in \mathsf{C}'$ (necessarily of support Y) such that $\mathscr{G}_y$ is a $k(y)$-vector space of dimension 1. As a result, there is a $k(y)$-isomorphism $(\mathscr{G}_y)^m \simeq \mathscr{F}_y$, which is also an $\mathscr{O}_Y$-isomorphism, and as $\mathscr{G}^m$ and $\mathscr{F}$ are coherent, there exists an open neighbourhood W of y in X and an isomorphism $\mathscr{G}^m|W \simeq \mathscr{F}|W$ (**0**, 5.2.7). Let $\mathscr{H}$ be the graph of this isomorphism, which is a coherent $(\mathscr{O}_X|W)$-submodule of $(\mathscr{G}^m \oplus \mathscr{F})|W$, canonically isomorphic to $\mathscr{G}^m|W$ and to $\mathscr{F}|W$; there thus exists a coherent $\mathscr{O}_X$-submodule $\mathscr{H}_0$ of $\mathscr{G}^m \oplus \mathscr{F}$, inducing $\mathscr{H}$ on W and 0 on $X - Y$, since $\mathscr{G}^m$ and $\mathscr{F}$ have Y for their support (**I**, 9.4.7). The restrictions $v : \mathscr{H}_0 \to \mathscr{G}^m$ and $w : \mathscr{H}_0 \to \mathscr{F}$ of the canonical projections of $\mathscr{G}^m \oplus \mathscr{F}$ are then homomorphisms of coherent $\mathscr{O}_X$-modules, which, on W and on $X - Y$, reduce to isomorphisms; in other words, the kernels and cokernels of v and w have their support in the closed set $Y - (Y \cap W)$, distinct from Y. They are in $\mathtt{C}'$; on the other hand, we have $\mathscr{G}^m \in \mathtt{C}'$ since $\mathscr{G} \in \mathtt{C}'$ and since $\mathtt{C}'$ is exact. We conclude successively, by the exactness of $\mathtt{C}'$, that $\mathscr{H}_0 \in \mathtt{C}'$, then $\mathscr{F} \in \mathtt{C}'$. Q.E.D. □

Corollary (3.1.3). — *Suppose that the exact subset $\mathtt{C}'$ of $\mathtt{C}$ has in addition the property that any coherent direct factor of a coherent $\mathscr{O}_X$-module $\mathscr{M} \in \mathtt{C}'$ is also in $\mathtt{C}'$. In this case, the conclusion of Theorem (3.1.2) is still valid when the condition "$\mathscr{G}_y$ is a $k(y)$-vector space of dimension 1" is replaced by $\mathscr{G}_y \neq 0$ (this is equivalent to $\operatorname{Supp}(\mathscr{G}) = Y$).*

Proof. The reasoning of Theorem (3.1.2) must be modified only in the case (b); now $\mathscr{G}_y$ is a $k(y)$-vector space of dimension $q > 0$, and as a result, we have an $\mathscr{O}_Y$-isomorphism $(\mathscr{G}_y)^m \simeq (\mathscr{F}_y)^q$; the end of the reasoning in Theorem (3.1.2) then proves that $\mathscr{F}^q \in \mathtt{C}'$, and the additional hypothesis on $\mathtt{C}'$ implies that $\mathscr{F} \in \mathtt{C}'$. □

3.2. The finiteness theorem: the case of usual schemes

Theorem (3.2.1). — *Let Y be a locally Noetherian prescheme, $f : X \to Y$ a proper morphism. For every coherent $\mathscr{O}_X$-module $\mathscr{F}$, the $\mathscr{O}_Y$-modules $\mathrm{R}^q f_*(\mathscr{F})$ are coherent for $q \geqslant 0$.*

Proof. Since the question is local on Y, we can suppose Y Noetherian, thus X Noetherian (**I**, 6.3.7). The coherent $\mathscr{O}_X$-modules $\mathscr{F}$ for which the conclusion of Theorem (3.2.1) is true form an *exact* subset $\mathtt{C}'$ of the category $\mathtt{C}$ of coherent $\mathscr{O}_X$-modules. Indeed, let $0 \to \mathscr{F}' \to \mathscr{F} \to \mathscr{F}'' \to 0$ be an exact **III** | 117
sequence of coherent $\mathscr{O}_X$-modules; suppose for example that $\mathscr{F}'$ and $\mathscr{F}''$ belong to $\mathtt{C}'$; we have the long exact sequence in cohomology

$$\mathrm{R}^{q-1} f_*(\mathscr{F}'') \xrightarrow{\partial} \mathrm{R}^q f_*(\mathscr{F}') \longrightarrow \mathrm{R}^q f_*(\mathscr{F}) \longrightarrow \mathrm{R}^q f_*(\mathscr{F}'') \xrightarrow{\partial} \mathrm{R}^{q+1} f_*(\mathscr{F}'),$$

in which by hypothesis the outer four terms are coherent; it is the same for the middle term $\mathrm{R}^q f_*(\mathscr{F})$ by ((**0**, 5.3.4) and (**0**, 5.3.3)). We show in the same way that when $\mathscr{F}$ and $\mathscr{F}'$ (resp. $\mathscr{F}$ and $\mathscr{F}''$) are in $\mathtt{C}'$, then so is $\mathscr{F}''$ (resp. $\mathscr{F}'$). In addition, every coherent *direct factor* $\mathscr{F}'$ of an $\mathscr{O}_X$-module $\mathscr{F} \in \mathtt{C}'$ belongs to $\mathtt{C}'$: indeed, $\mathrm{R}^q f_*(\mathscr{F}')$ is then a direct factor of $\mathrm{R}^q f_*(\mathscr{F})$ (G, II, 4.4.4), therefore it is of finite type, and as it is quasi-coherent (1.4.10), it is coherent, as Y is Noetherian. By virtue of Corollary (3.1.3), we reduce to proving that when X is *irreducible* with generic point x, there exists *one* coherent $\mathscr{O}_X$-module $\mathscr{F}$ belonging to $\mathtt{C}'$, such that $\mathscr{F}_x \neq 0$: indeed, if this point is established, then it can be applied to any irreducible closed subprescheme Y of X, since if $j : Y \to X$ is the canonical injection, then $f \circ j$ is proper (**II**, 5.4.2), and if $\mathscr{G}$ is a coherent $\mathscr{O}_Y$-module with support Y, then $j_*(\mathscr{G})$ is a coherent $\mathscr{O}_X$-module such that $\mathrm{R}^q(f \circ j)_*(\mathscr{G}) = \mathrm{R}^q f_*(j_*(\mathscr{G}))$ (G, II, 4.9.1), therefore we can apply Corollary (3.1.3).

By virtue of Chow's lemma (**II**, 5.6.2), there exists an irreducible prescheme X' and a *projective* and surjective morphism $g : X' \to X$ such that $f \circ g : X' \to Y$ is *projective*. There exists an ample $\mathscr{O}_{X'}$-module $\mathscr{L}$ for g (**II**, 5.3.1); we apply the fundamental theorem of projective morphisms (2.2.1) to $g : X' \to X$ and with $\mathscr{L}$: there thus exists an integer n such that $\mathscr{F} = g_*(\mathscr{O}_{X'}(n))$ is a coherent $\mathscr{O}_X$-module and $\mathrm{R}^q g_*(\mathscr{O}_{X'}(n)) = 0$ for all $q > 0$; in addition, as $g^*(g_*(\mathscr{O}_{X'}(n))) \to \mathscr{O}_{X'}(n)$ is surjective for n large enough (2.2.1), we see that we can suppose, at the generic point x of X, that we have $\mathscr{F}_x \neq 0$ (**II**, 3.4.7). On the other hand, as $f \circ g$ is projective and Y is Noetherian, the $\mathrm{R}^q(f \circ g)_*(\mathscr{O}_{X'}(n))$ are *coherent* (2.2.1). This being so, $\mathrm{R}^\bullet(f \circ g)_*(\mathscr{O}_{X'}(n))$ is the abutment of a Leray spectral sequence, whose E_2-term is given by $E_2^{pq} = \mathrm{R}^p f_*(\mathrm{R}^q g_*(\mathscr{O}_{X'}(n)))$; the above shows that this spectral sequence degenerates, and we then know (**0**, 11.1.6) that $E_2^{p0} = \mathrm{R}^p f_*(\mathscr{F})$ is isomorphic to $\mathrm{R}^p(f \circ g)_*(\mathscr{O}_{X'}(n))$, which finishes the proof. □

Corollary (3.2.2). — *Let Y be a locally Noetherian prescheme. For every proper morphism $f : X \to Y$, the direct image under f of any coherent $\mathscr{O}_X$-module is a coherent $\mathscr{O}_Y$-module.*

Corollary (3.2.3). — *Let A be a Noetherian ring, X a proper scheme over A; for every coherent $\mathscr{O}_X$-module $\mathscr{F}$, the $\mathrm{H}^p(X, \mathscr{F})$ are A-modules of finite type, and there exists an integer $r > 0$ such that for every coherent $\mathscr{O}_X$-module $\mathscr{F}$ and all $p > r$, $\mathrm{H}^p(X, \mathscr{F}) = 0$.*

Proof. The second assertion has already been proved (1.4.12); the first follows from the finiteness theorem (3.2.1), taking into account Corollary (1.4.11). □

In particular, if X is a *proper algebraic scheme* over a field k, then, for every coherent $\mathscr{O}_X$-module $\mathscr{F}$, the $\mathrm{H}^p(X, \mathscr{F})$ are *finite-dimensional* k-vector spaces.

Corollary (3.2.4). — *Let Y be a locally Noetherian prescheme, $f : X \to Y$ a morphism of finite type. For every coherent $\mathscr{O}_X$-module $\mathscr{F}$ whose support is proper over Y (**II**, 5.4.10), the $\mathscr{O}_Y$-modules $\mathrm{R}^q f_*(\mathscr{F})$ are coherent.*

III | 118

Proof. Since the question is local on Y, we can suppose Y Noetherian, and it is the same for X (**I**, 6.3.7). By hypothesis, every closed subprescheme Z of X whose underlying space is $\mathrm{Supp}(\mathscr{F})$ is proper over Y, in other words, if $j : Z \to X$ is the canonical injection, then $f \circ j : Z \to Y$ is proper. We can suppose that Z is such that $\mathscr{F} = j_*(\mathscr{G})$, where $\mathscr{G} = j^*(\mathscr{F})$ is a coherent $\mathscr{O}_Z$-module (**I**, 9.3.5); as we have $\mathrm{R}^q f_*(\mathscr{F}) = \mathrm{R}^q(f \circ j)_*(\mathscr{G})$ by Corollary (1.3.4), the conclusion follows immediately from Theorem (3.2.1). □

3.3. Generalization of the finiteness theorem (usual schemes)

Proposition (3.3.1). — *Let Y be a Noetherian prescheme, $\mathscr{S}$ a quasi-coherent $\mathscr{O}_Y$-algebra of finite type, graded in positive degrees, $Y' = \mathrm{Proj}(\mathscr{S})$, and $g : Y' \to Y$ the structure morphism. Let $f : X \to Y$ be a proper morphism, $\mathscr{S}' = f^*(\mathscr{S})$, $\mathscr{M} = \bigoplus_{k \in \mathbf{Z}} \mathscr{M}_k$ a quasi-coherent graded $\mathscr{S}'$-module of finite type. Then the $\mathrm{R}^p f_*(\mathscr{M}) = \bigoplus_{k \in \mathbf{Z}} \mathrm{R}^p f_*(\mathscr{M}_k)$ are graded $\mathscr{S}$-modules of finite type for all p. Suppose in addition that $\mathscr{S}$ is generated by $\mathscr{S}_1$; then, for every $p \in \mathbf{Z}$, there exists an integer k_p such that for all $k \geqslant k_p$ and all $r \geqslant 0$, we have*

$$\mathrm{R}^p f_*(\mathscr{M}_{k+r}) = \mathscr{S}_r \mathrm{R}^p f_*(\mathscr{M}_k). \tag{3.3.1.1}$$

Proof. The first assertion is identical to the statement of Theorem (2.4.1, i), where we have simply replaced "projective morphism" by "proper morphism". In the proof of Theorem (2.4.1, i), the hypothesis on f was only used to show (with the notation of this proof) that $\mathrm{R}^p f'_*(\widetilde{\mathscr{M}})$ is a coherent $\mathscr{O}_{Y'}$-module. With the hypothesis of Proposition (3.3.1), f' is proper (**II**, 5.4.2, iii), so we can resume without change in the proof of Theorem (2.4.1, i), thanks to the finiteness theorem (3.2.1).

As for the second assertion, it suffices to remark that there is a finite affine open cover (U_i) of Y such that the restrictions to the U_i of the two sides of (3.3.1.1) are equal for all $k \geqslant k_{p,i}$ (**II**, 2.1.6, ii); it suffices to take for k_p the largest of the $k_{p,i}$. □

Corollary (3.3.2). — *Let A be a Noetherian ring, $\mathfrak{m}$ an ideal of A, X a proper A-scheme, and $\mathscr{F}$ a coherent $\mathscr{O}_X$-module. Then, for all $p \geqslant 0$, the direct sum $\bigoplus_{k \geqslant 0} \mathrm{H}^p(X, \mathfrak{m}^k \mathscr{F})$ is a module of finite type over the ring $S = \bigoplus_{k \geqslant 0} \mathfrak{m}^k$; in particular, there exists an integer $k_p \geqslant 0$ such that for all $k \geqslant k_p$ and all $r \geqslant 0$, we have*

$$\mathrm{H}^p(X, \mathfrak{m}^{k+r} \mathscr{F}) = \mathfrak{m}^r \mathrm{H}^p(X, \mathfrak{m}^k \mathscr{F}). \tag{3.3.2.1}$$

Proof. It suffices to apply Proposition (3.3.1) with $Y = \mathrm{Spec}(A)$, $\mathscr{S} = \widetilde{S}$, $\mathscr{M}_k = \mathfrak{m}^k \mathscr{F}$, taking into account Corollary (1.4.11). □

It should be remembered that the S-module structure on $\bigoplus_{k \geqslant 0} \mathrm{H}^p(X, \mathfrak{m}^k \mathscr{F})$ is obtained by considering, for every $a \in \mathfrak{m}^r$, the map $\mathrm{H}^p(X, \mathfrak{m}^k \mathscr{F}) \to \mathrm{H}^p(X, \mathfrak{m}^{k+r} \mathscr{F})$, which comes from the passage to cohomology of the multiplication map $\mathfrak{m}^k \mathscr{F} \to \mathfrak{m}^{k+r} \mathscr{F}$ defined by a (2.4.1).

3.4. Finiteness theorem: the case of formal schemes The results of this section (except the definition (3.4.1)) will not be used in the rest of this chapter. **III** | 119

(3.4.1). Let $\mathfrak{X}$ and $\mathfrak{S}$ be two locally Noetherian formal preschemes (**I**, 10.4.2), $f : \mathfrak{X} \to \mathfrak{S}$ a morphism of formal preschemes. We say that f is a *proper* morphism if it satisfies the following conditions:

1st. *f is a morphism of finite type* (**I**, 10.13.3).

2nd. *If $\mathscr{K}$ is a sheaf of ideals of definition for $\mathfrak{S}$ and if we set $\mathscr{J} = f^*(\mathscr{K})\mathscr{O}_{\mathfrak{X}}$, $X_0 = (\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{J})$, $S_0 = (\mathfrak{S}, \mathscr{O}_{\mathfrak{S}}/\mathscr{K})$, then the morphism $f_0 : X_0 \to S_0$ induced by f* (**I**, 10.5.6) *is proper*.

It is immediate that this definition does not depend on the sheaf of ideals of definition $\mathscr{K}$ for $\mathscr{S}$ considered; indeed, if $\mathscr{K}'$ is a second sheaf of ideals of definition such that $\mathscr{K}' \subset \mathscr{K}$, and if we set $\mathscr{J}' = f^*(\mathscr{K}')\mathscr{O}_{\mathfrak{X}}$, $X'_0 = (\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{J}')$, $S'_0 = (\mathscr{S}, \mathscr{O}_{\mathfrak{S}}/\mathscr{K}')$, then the morphism $f'_0 : X'_0 \to S'_0$ induced by f is such that the diagram

$$\begin{tikzcd} X_0 \arrow[r, "f_0"] \arrow[d, "i"'] & S_0 \arrow[d, "j"] \\ X'_0 \arrow[r, "f'_0"'] & S'_0 \end{tikzcd}$$

is commutative, i and j being surjective immersions; it is equivalent to say that f_0 or f'_0 is proper, by virtue of (**II**, 5.4.5).

We note that, for all $n \geqslant 0$, if we set $X_n = (\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{J}^{n+1})$, $S_n = (\mathfrak{S}, \mathscr{O}_{\mathfrak{S}}/\mathscr{K}^{n+1})$, then the morphism $f_n : X_n \to S_n$ induced by f (**I**, 10.5.6) is proper for all n whenever it is for $n = 0$ (**II**, 5.4.6).

If $g : Y \to Z$ is a proper morphism of locally Noetherian usual preschemes, Z' a closed subset of Z, Y' a closed subset of Y such that $g(Y') \subset Z'$, then the extension $\widehat{g} : Y_{/Y'} \to Z_{/Z'}$ of g to the completions (**I**, 10.9.1) is a proper morphism of formal preschemes, as it follows from the definition and from (**II**, 5.4.5).

Let $\mathfrak{X}$ and $\mathfrak{S}$ be two locally Noetherian formal preschemes, $f : \mathfrak{X} \to \mathfrak{S}$ a morphism *of finite type* (**I**, 10.13.3); the notation being the same as above, we say that a subset Z of the underlying space of $\mathfrak{X}$ is *proper* over $\mathfrak{S}$ (or proper for f) if, considered as a subset of X_0, Z is *proper over* S_0 (**II**, 5.4.10). All the properties of proper subsets of usual preschemes stated in (**II**, 5.4.10) are still true for the proper subsets of formal preschemes, as it follows immediately from the definitions.

Theorem (3.4.2). — *Let $\mathfrak{X}$ and $\mathfrak{Y}$ be locally Noetherian formal preschemes, $f : \mathfrak{X} \to \mathfrak{Y}$ a proper morphism. For every coherent $\mathscr{O}_{\mathfrak{X}}$-module $\mathscr{F}$, the $\mathscr{O}_{\mathfrak{Y}}$-modules $\mathrm{R}^q f_*(\mathscr{F})$ are coherent for all $q \geqslant 0$.*

Let $\mathscr{J}$ be a sheaf of ideals of definition for $\mathfrak{Y}$, $\mathscr{K} = f^*(\mathscr{J})\mathscr{O}_{\mathfrak{X}}$, and consider the $\mathscr{O}_{\mathfrak{X}}$-modules

(3.4.2.1) $$\mathscr{F}_k = \mathscr{F} \otimes_{\mathscr{O}_{\mathfrak{Y}}} (\mathscr{O}_{\mathfrak{Y}}/\mathscr{J}^{k+1}) = \mathscr{F}/\mathscr{K}^{k+1}\mathscr{F} \quad (k \geqslant 0)$$

which evidently form a *projective system* of topological $\mathscr{O}_{\mathfrak{X}}$-modules, such that **III** | 120

$$\mathscr{F} = \varprojlim_k \mathscr{F}_k$$

by (**I**, 10.11.3). On the other hand, it follows from Theorem (3.4.2) that each of the $\mathrm{R}^q f_*(\mathscr{F})$, being coherent, is naturally equipped with a topological $\mathscr{O}_{\mathfrak{Y}}$-module structure (**I**, 10.11.6), and so are the $\mathrm{R}^q f_*(\mathscr{F}_k)$. The canonical homomorphisms $\mathscr{F} \to \mathscr{F}_k = \mathscr{F}/\mathscr{K}^{k+1}\mathscr{F}$ canonically correspond to homomorphisms

$$\mathrm{R}^q f_*(\mathscr{F}) \longrightarrow \mathrm{R}^q f_*(\mathscr{F}_k),$$

which are necessarily continuous for the topological $\mathscr{O}_{\mathfrak{Y}}$-module structures above (**I**, 10.11.6), and form a projective system, giving the limit a canonical functorial homomorphism

(3.4.2.2) $$\mathrm{R}^q f_*(\mathscr{F}) \longrightarrow \varprojlim_k \mathrm{R}^q f_*(\mathscr{F}_k),$$

which will be a continuous homomorphism of topological $\mathscr{O}_{\mathfrak{Y}}$-modules. We will prove along with Theorem (3.4.2) the

Corollary (3.4.3). — *Each of the homomorphisms (3.4.2.2) is a topological isomorphism. In addition, if $\mathfrak{Y}$ is Noetherian, then the projective system $(\mathrm{R}^q f_*(\mathscr{F}/\mathscr{K}^{k+1}\mathscr{F}))_{k \geqslant 0}$ satisfies the* (ML)*-condition* (**0**, 13.1.1).

We will begin by establishing Theorem (3.4.2) and Corollary (3.4.3) when Y is a Noetherian formal affine scheme (**I**, 10.4.1):

Corollary (3.4.4). — *Under the hypotheses of Theorem (3.4.2), suppose in addition that $\mathfrak{Y} = \mathrm{Spf}(A)$, where A is an adic Noetherian ring. Let $\mathfrak{J}$ be an ideal of definition for A, and set $\mathscr{F}_k = \mathscr{F}/\mathfrak{J}^{k+1}\mathscr{F}$ for $k \geqslant 0$. Then the $\mathrm{H}^n(\mathfrak{X}, \mathscr{F})$ are A-modules of finite type; the projective system $(\mathrm{H}^n(\mathfrak{X}, \mathscr{F}_k))_{k\geqslant 0}$ satisfies the* (ML)*-condition for all n; if we set*

$$N_{n,k} = \mathrm{Ker}\left(\mathrm{H}^n(\mathfrak{X}, \mathscr{F}) \longrightarrow \mathrm{H}^n(\mathfrak{X}, \mathscr{F}_k)\right) \tag{3.4.4.1}$$

*(also equal to $\mathrm{Im}(\mathrm{H}^n(\mathfrak{X}, \mathfrak{J}^{k+1}\mathscr{F}) \to \mathrm{H}^n(\mathfrak{X}, \mathscr{F}))$ by the exact sequence in cohomology), then the $N_{n,k}$ define on $\mathrm{H}^n(\mathfrak{X}, \mathscr{F})$ a $\mathfrak{J}$-good filtration (**0**, 13.7.7); finally, the canonical homomorphism*

$$\mathrm{H}^n(\mathfrak{X}, \mathscr{F}) \longrightarrow \varprojlim_k \mathrm{H}^n(\mathfrak{X}, \mathscr{F}_k) \tag{3.4.4.2}$$

is a topological isomorphism for all n (the left hand side being equipped with the $\mathfrak{J}$-adic topology, the $\mathrm{H}^n(\mathfrak{X}, \mathscr{F}_k)$ with the discrete topology).

Set

$$S = \mathrm{gr}(A) = \bigoplus_{k\geqslant 0} \mathfrak{J}^k/\mathfrak{J}^{k+1}, \; \mathscr{M} = \mathrm{gr}(\mathscr{F}) = \bigoplus_{k\geqslant 0} \mathfrak{J}^k\mathscr{F}/\mathfrak{J}^{k+1}\mathscr{F}.$$

We know that $\mathfrak{J}^\Delta$ is a sheaf of ideals of definition for $\mathfrak{Y}$ (**I**, 10.3.1); let $\mathscr{K} = f^*(\mathfrak{J}^\Delta)\mathscr{O}_{\mathfrak{X}}$, $X_0 = (\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{K})$, $Y_0 = (\mathfrak{Y}, \mathscr{O}_{\mathfrak{Y}}/\mathfrak{J}^\Delta) = \mathrm{Spec}(A_0)$, with $A_0 = A/\mathfrak{J}$. It is clear that the $\mathscr{M}_k = \mathfrak{J}^k\mathscr{F}/\mathfrak{J}^{k+1}\mathscr{F}$ are coherent $\mathscr{O}_{X_0}$-modules (**I**, 10.11.3). Consider on the other hand the quasi-coherent graded $\mathscr{O}_{X_0}$-algebra

$$\mathscr{S} = \mathscr{O}_{X_0} \otimes_{A_0} S = \mathrm{gr}(\mathscr{O}_{\mathfrak{X}}) = \bigoplus_{k\geqslant 0} \mathscr{K}^k/\mathscr{K}^{k+1}. \tag{3.4.4.4}$$

The hypothesis that $\mathscr{F}$ is an $\mathscr{O}_{\mathfrak{X}}$-module of finite type implies first that $\mathscr{M}$ is a graded $\mathscr{S}$-module *of finite type*. Indeed, the question is local on $\mathfrak{X}$, and we can thus suppose that $\mathfrak{X} = \mathrm{Spf}(B)$, where B is an adic Noetherian ring, and $\mathscr{F} = N^\Delta$, where N is a B-module of finite type (**I**, 10.10.5); we have in addition $X_0 = \mathrm{Spec}(B_0)$, where $B_0 = B/\mathfrak{J}B$, and the quasi-coherent $\mathscr{O}_{X_0}$-modules $\mathscr{S}$ and $\mathscr{M}$ are respectively equal to $\widetilde{S'}$ and $\widetilde{M'}$, where $S' = \bigoplus_{k\geqslant 0}((\mathfrak{J}^k/\mathfrak{J}^{k+1}) \otimes_{A_0} B_0)$ and $M' = \bigoplus_{k\geqslant 0}((\mathfrak{J}^k/\mathfrak{J}^{k+1}) \otimes_{A_0} N_0)$, with $N_0 = N/\mathfrak{J}N$; we then evidently have $M' = S' \otimes_{B_0} N_0$, and as N_0 is a B_0-module of finite type, M' is a S'-module of finite type, hence our assertion (**I**, 1.3.13). **III** | 121

As the morphism $f_0 : X_0 \to Y_0$ is *proper* by hypothesis, we can apply Corollary (3.3.2) to $\mathscr{S}$, $\mathscr{M}$, and the morphism f_0: taking into account Corollary (1.4.11), we conclude that for *all* $n \geqslant 0$, $\bigoplus_{k\geqslant 0} \mathrm{H}^n(X_0, \mathscr{M}_k)$ is a graded S-module *of finite type*. This proves that the condition (F_n) of (**0**, 13.7.7) is satisfied for *all* $n \geqslant 0$, when we consider the strict projective system $(\mathscr{F}/\mathfrak{J}^k\mathscr{F})_{k\geqslant 0}$ of sheaves of abelian groups on X_0, each equipped with its natural "filtered A-module" structure. We can thus apply (**0**, 13.7.7), which proves that:

1st. The projective system $(\mathrm{H}^n(\mathfrak{X}, \mathscr{F}_k))_{k\geqslant 0}$ satisfies the (ML)-condition.
2nd. If $\mathrm{H}'^n = \varprojlim_k \mathrm{H}^n(\mathfrak{X}, \mathscr{F}_k)$, then H'^n is an A-module of finite type.
3rd. The filtration defined on H'^n by the kernels of the canonical homomorphisms $\mathrm{H}'^n \to \mathrm{H}^n(\mathfrak{X}, \mathscr{F}_k)$ is $\mathfrak{J}$-good.

Note that on the other hand, if we set $X_k = (\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{K}^{k+1})$, then $\mathscr{F}_k$ is a coherent $\mathscr{O}_{X_k}$-module (**I**, 10.11.3), and if U is an affine open set in X_0, then U is also an affine open set in each of the X_k (**I**, 5.1.9), so $\mathrm{H}^n(U, \mathscr{F}_k) = 0$ for all $n > 0$ and all k (1.3.1) and $\mathrm{H}^0(U, \mathscr{F}_k) \to \mathrm{H}^0(U, \mathscr{F}_h)$ is surjective for $h \leqslant k$ (**I**, 1.3.9). We are thus in the conditions of (**0**, 13.3.2) and applying (**0**, 13.3.1) proves that H'^n canonically identifies with $\mathrm{H}^n(\mathfrak{X}, \varprojlim_k \mathscr{F}_k) = \mathrm{H}^n(\mathfrak{X}, \mathscr{F})$; this finishes the proof of Corollary (3.4.4).

(3.4.5). We return to the proof of (3.4.2) and (3.4.3). We first prove the propositions for the case $\mathfrak{Y} = \mathrm{Spf}(A)$ envisaged in (3.4.4); for this, for all $g \in A$, apply (3.4.4) to the Noetherian affine formal scheme induced on the open set $\mathfrak{Y}_g = \mathfrak{D}(g)$ of $\mathfrak{Y}$, which is equal to $\mathrm{Spf}(A_{\{g\}})$, and to the formal prescheme induced by $\mathfrak{X}$ on $f^{-1}(\mathfrak{Y}_g)$; note that $\mathfrak{Y}_g$ is also an affine open set in the prescheme $Y_k = (\mathfrak{Y}, \mathscr{O}_{\mathfrak{Y}}/(\mathfrak{J}^{\Delta})^{k+1})$, and as $\mathscr{F}_k$ is a coherent $\mathscr{O}_{X_k}$-module, we have

$$\mathrm{H}^n(f^{-1}(\mathfrak{Y}_g), \mathscr{F}_k) = \Gamma(\mathfrak{Y}_g, \mathrm{R}^n f_*(\mathscr{F}_k))$$

for all $k \geqslant 0$ by virtue of Corollary (1.4.11). The canonical homomorphism

$$\mathrm{H}^n(f^{-1}(\mathfrak{Y}_g), \mathscr{F}) \longrightarrow \varprojlim_k \Gamma(\mathfrak{Y}_g, \mathrm{R}^n f_*(\mathscr{F}_k))$$

is an isomorphism; but we have (**0**, 3.2.6)

$$\varprojlim_k \Gamma(\mathfrak{Y}_g, \mathrm{R}^n f_*(\mathscr{F}_k)) = \Gamma(\mathfrak{Y}_g, \varprojlim_k \mathrm{R}^n f_*(\mathscr{F}_k)),$$

and as the sheaf $\mathrm{R}^n f_*(\mathscr{F})$ is the sheaf associated to the presheaf $\mathfrak{Y}_g \mapsto \mathrm{H}^n(f^{-1}(\mathfrak{Y}_g), \mathscr{F})$ on the $\mathfrak{Y}_g$ (**0**, 3.2.1), we have shown that the homomorphism (3.4.2.2) is *bijective*. Let us now prove that $\mathrm{R}^n f_*(\mathscr{F})$ is a coherent $\mathscr{O}_{\mathfrak{Y}}$-module, and more precisely that we have **III | 122**

(3.4.5.1) $$\mathrm{R}^n f_*(\mathscr{F}) = \left(\mathrm{H}^n(\mathfrak{X}, \mathscr{F})\right)^{\Delta}.$$

With the above notation, we have, since $\mathscr{F}_k$ is a coherent $\mathscr{O}_{X_k}$-module (1.4.13),

$$\Gamma(\mathfrak{Y}_g, \mathrm{R}^n f_*(\mathscr{F}_k)) = (\Gamma(\mathfrak{Y}, \mathrm{R}^n f_*(\mathscr{F}_k)))_g = (\mathrm{H}^n(\mathfrak{X}, \mathscr{F}_k))_g.$$

Now the $\mathrm{H}^n(\mathfrak{X}, \mathscr{F}_k)$ form a projective system satisfying (ML), and their projective limit $\mathrm{H}^n(\mathfrak{X}, \mathscr{F})$ is an A-module of finite type. We conclude (**0**, 13.7.8) that we have

$$\varprojlim_k \left((\mathrm{H}^n(\mathfrak{X}, \mathscr{F}_k))_g\right) = \mathrm{H}^n(\mathfrak{X}, \mathscr{F}) \otimes_A A_{\{g\}} = \Gamma(\mathfrak{Y}_g, (\mathrm{H}^n(\mathfrak{X}, \mathscr{F}))^{\Delta}),$$

taking into account (**I**, 10.10.8) applied to A and $A_{\{g\}}$; this proves (3.4.5.1) since $\Gamma(\mathfrak{Y}_g, \mathrm{R}^n f_*(\mathscr{F})) = \varprojlim_k \Gamma(\mathfrak{Y}_g, \mathrm{R}^n f_*(\mathscr{F}_k))$.

As (3.4.2.2) is then an isomorphism of coherent $\mathscr{O}_{\mathfrak{Y}}$-modules, it is necessarily a *topological* isomorphism (**I**, 10.11.6). Finally, it follows from the relations $\mathrm{R}^n f_*(\mathscr{F}_k) = (\mathrm{H}^n(\mathfrak{X}, \mathscr{F}_k))^{\Delta}$ that the projective system $(\mathrm{R}^n f_*(\mathscr{F}_k))_{k \geqslant 0}$ satisfies (ML) (**I**, 10.10.2).

Once (3.4.2) and (3.4.3) are proved in the case where the formal prescheme $\mathfrak{Y}$ is affine Noetherian, it is immediate to pass to the general case for (3.4.2) and the first assertion of (3.4.3), which are local on $\mathfrak{Y}$. As for the second assertion of (3.4.3), it suffices, $\mathfrak{Y}$ being Noetherian, to cover it by a finite number of Noetherian affine open sets U_i and to note that the restrictions of the projective system $(\mathrm{R}^q f_*(\mathscr{F}_k))$ to each of the U_i satisfies (ML).

Along the way, we have in addition proved:

Corollary (3.4.6). — *Under the hypotheses of Corollary (3.4.4), the canonical homomorphism*

(3.4.6.1) $$\mathrm{H}^q(\mathfrak{X}, \mathscr{F}) \longrightarrow \Gamma(\mathfrak{Y}, \mathrm{R}^q f_*(\mathscr{F}))$$

is bijective.

§4. The fundamental theorem of proper morphisms. Applications

4.1. The fundamental theorem

(4.1.1). Let X and Y be Noetherian usual preschemes, let $f : X \to Y$ be a proper morphism, let Y' be a closed subset of Y, and let

$$X' = f^{-1}(Y').$$

We denote by $\widehat{X}$ and $\widehat{Y}$ the formal preschemes $X_{/X'}$ and $Y_{/Y'}$, obtained by completing X and Y along X' and Y', respectively (**I**, 10.8.5). We denote by $\widehat{f} : \widehat{X} \to \widehat{Y}$ the extension of f to these completions (**I**, 10.9.1). For every coherent $\mathscr{O}_X$-module $\mathscr{F}$, we denote by **III | 123**

$$\widehat{\mathscr{F}} = \mathscr{F}_{/X'}$$

its completion along X' (**I**, 10.8.4); this is a coherent $\mathscr{O}_{\widehat{X}}$-module (**I**, 10.8.8).

(4.1.2). Let $\mathscr{J}$ be a coherent ideal of $\mathscr{O}_Y$ such that

$$\mathrm{Supp}(\mathscr{O}_Y/\mathscr{J}) = Y'$$

(**I**, 5.2.1). We know (**I**, 4.4.5) that

$$\mathscr{K} = f^*(\mathscr{J})\mathscr{O}_X$$

is a coherent ideal of $\mathscr{O}_X$ satisfying

$$\mathrm{Supp}(\mathscr{O}_X/\mathscr{K}) = X'.$$

For every $k \geqslant 0$, consider the coherent $\mathscr{O}_X$-module

$$\mathscr{F}_k = \mathscr{F} \otimes_{\mathscr{O}_Y} (\mathscr{O}_Y/\mathscr{J}^{k+1}) = \mathscr{F}/\mathscr{K}^{k+1}\mathscr{F}.$$

The $\mathscr{O}_Y$-modules

$$\mathrm{R}^n f_*(\mathscr{F}) \quad \text{and} \quad \mathrm{R}^n f_*(\mathscr{F}_k)$$

are coherent for every n (3.2.1). For every $k \geqslant 0$ and every n, the canonical homomorphism $\mathscr{F} \to \mathscr{F}_k$ induces, by functoriality, a homomorphism

$$\mathrm{R}^n f_*(\mathscr{F}) \longrightarrow \mathrm{R}^n f_*(\mathscr{F}_k). \tag{4.1.2.1}$$

Since $\mathscr{F}_k$ is an $\mathscr{O}_X/\mathscr{K}^{k+1}$-module, $\mathrm{R}^n f_*(\mathscr{F}_k)$ is an $\mathscr{O}_Y/\mathscr{J}^{k+1}$-module (**0**, 12.2.1). We therefore deduce from (4.1.2.1) a homomorphism

$$\mathrm{R}^n f_*(\mathscr{F}) \otimes_{\mathscr{O}_Y} (\mathscr{O}_Y/\mathscr{J}^{k+1}) \longrightarrow \mathrm{R}^n f_*(\mathscr{F}_k). \tag{4.1.2.2}$$

The two sides of (4.1.2.2) form projective systems. The projective limit of the left-hand side is the completion

$$\big(\mathrm{R}^n f_*(\mathscr{F})\big)_{/Y'},$$

which we shall denote by

$$\mathrm{R}^n \widehat{f_*(\mathscr{F})}.$$

The homomorphisms (4.1.2.2) are compatible with the projective systems and hence define, on passing to the limit, a canonical homomorphism

$$\phi_n : \mathrm{R}^n \widehat{f_*(\mathscr{F})} \longrightarrow \varprojlim_k \mathrm{R}^n f_*(\mathscr{F}_k). \tag{4.1.2.3}$$

Moreover, (4.1.2.2) is a homomorphism of $\mathscr{O}_Y/\mathscr{J}^{k+1}$-modules. By (**I**, 10.8.3), it may therefore be regarded as a continuous homomorphism of topological $\mathscr{O}_{\widehat{Y}}$-modules endowed with their pseudo-discrete topologies (**0**, 3.8.1). Consequently, ϕ_n is a continuous homomorphism of topological $\mathscr{O}_{\widehat{Y}}$-modules.

(4.1.3). Let $i : \widehat{X} \to X$ be the canonical morphism of ringed spaces defined in (**I**, 10.8.7). We have the commutative diagram

$$\begin{tikzcd} X_k \arrow[r, "h_k"] \arrow[dr, "i_k"'] & \widehat{X} \arrow[d, "i"] \\ & X \end{tikzcd} \tag{4.1.3.1}$$

where X_k is the closed subprescheme of X defined by $\mathscr{K}^{k+1}$, i_k is the canonical immersion, and h_k is the morphism of ringed spaces corresponding to the identity on the underlying spaces and to the canonical homomorphism

$$\mathscr{O}_{\widehat{X}} \longrightarrow \mathscr{O}_X/\mathscr{K}^{k+1}$$

(**I**, 10.5.2). Moreover,

$$\widehat{\mathscr{F}} = i^*(\mathscr{F})$$

up to canonical isomorphism (**I**, 10.8.8). We have

$$\mathrm{H}^n(X_k, i_k^*(\mathscr{F}_k)) = \mathrm{H}^n(X, \mathscr{F}_k) \tag{4.1.3.2}$$

up to canonical isomorphism.

Indeed, **III** | 124

$$\mathscr{F}_k = (i_k)_*(i_k^*(\mathscr{F}_k))$$

(G, II, 4.9.1). The canonical homomorphism

$$\mathrm{H}^n(\widehat{X},\widehat{\mathscr{F}}) \longrightarrow \mathrm{H}^n(X_k, h_k^*(\widehat{\mathscr{F}}))$$

(**0**, 12.1.3.5) may thus also be written

$$\mathrm{H}^n(\widehat{X},\widehat{\mathscr{F}}) \longrightarrow \mathrm{H}^n(X,\mathscr{F}_k). \tag{4.1.3.3}$$

These homomorphisms form a projective system and therefore define a canonical homomorphism

$$\psi_{n,X} : \mathrm{H}^n(\widehat{X},\widehat{\mathscr{F}}) \longrightarrow \varprojlim_k \mathrm{H}^n(X,\mathscr{F}_k). \tag{4.1.3.4}$$

Replacing X by an open subset of the form $f^{-1}(V)$, where V is an affine open subset of Y, and taking (1.4.11) into account, we obtain homomorphisms

$$\psi_{n,V} : \mathrm{H}^n(\widehat{X}\cap f^{-1}(V),\widehat{\mathscr{F}}) \longrightarrow \varprojlim_k \Gamma(V,\mathrm{R}^n f_*(\mathscr{F}_k)). \tag{4.1.3.5}$$

These homomorphisms plainly commute with restriction from V to a smaller affine open subset. They therefore define a canonical homomorphism of sheaves

$$\psi_n : \mathrm{R}^n \widehat{f}_*(\widehat{\mathscr{F}}) \longrightarrow \varprojlim_k \mathrm{R}^n f_*(\mathscr{F}_k). \tag{4.1.3.6}$$

(4.1.4). Finally, let $j : \widehat{Y} \to Y$ be the canonical morphism of ringed spaces (**I**, 10.8.7). Since $\mathrm{R}^n f_*(\mathscr{F})$ is a coherent $\mathscr{O}_Y$-module (3.2.1), we have, up to canonical isomorphism,

$$j^*(\mathrm{R}^n f_*(\mathscr{F})) = \widehat{\mathrm{R}^n f_*(\mathscr{F})}$$

(**I**, 10.8.8). There is consequently a canonical homomorphism

$$\rho_n : \widehat{\mathrm{R}^n f_*(\mathscr{F})} = j^*(\mathrm{R}^n f_*(\mathscr{F})) \longrightarrow \mathrm{R}^n \widehat{f}_*(i^*(\mathscr{F})) = \mathrm{R}^n \widehat{f}_*(\widehat{\mathscr{F}}) \tag{4.1.4.1}$$

defined for ringed spaces in general; see the proof of (1.4.15). We shall show that the diagram

$$\begin{tikzcd} \widehat{\mathrm{R}^n f_*(\mathscr{F})} \arrow[rr, "\rho_n"] \arrow[dr, "\phi_n"'] & & \mathrm{R}^n \widehat{f}_*(\widehat{\mathscr{F}}) \arrow[dl, "\psi_n"] \\ & \varprojlim_k \mathrm{R}^n f_*(\mathscr{F}_k) & \end{tikzcd} \tag{4.1.4.2}$$

is commutative. It is enough to prove the commutativity of the diagram formed by the corresponding homomorphisms of presheaves. We may therefore restrict to the case where Y is affine, and it is enough to prove that

$$\begin{tikzcd} \widehat{\mathrm{H}^n(X,\mathscr{F})} \arrow[rr, "\rho_n"] \arrow[dr, "\phi_n"'] & & \mathrm{H}^n(\widehat{X},\widehat{\mathscr{F}}) \arrow[dl, "\psi_{n,X}"] \\ & \varprojlim_k \mathrm{H}^n(X,\mathscr{F}_k) & \end{tikzcd} \tag{4.1.4.3}$$

is commutative. The commutativity of (4.1.3.1), together with the relations between cohomology groups established in (4.1.3), gives the commutative diagram

III | 125

$$\begin{tikzcd} \mathrm{H}^n(X,\mathscr{F}) \arrow[r] \arrow[dr] & \mathrm{H}^n(\widehat{X},\widehat{\mathscr{F}}) = \mathrm{H}^n(\widehat{X},i^*(\mathscr{F})) \arrow[d] \\ & \mathrm{H}^n(X,\mathscr{F}_k) = \mathrm{H}^n(X_k,i_k^*(\mathscr{F})). \end{tikzcd}$$

The commutativity of (4.1.4.3) follows immediately.

Theorem (4.1.5). — *Let $f : X \to Y$ be a proper morphism of Noetherian preschemes, let Y' be a closed subset of Y, and put $X' = f^{-1}(Y')$. Then, for every coherent $\mathscr{O}_X$-module $\mathscr{F}$,*

$$\mathrm{R}^n \widehat{f}_*(\widehat{\mathscr{F}})$$

is a coherent $\mathscr{O}_{\widehat{Y}}$-module, and the homomorphisms ϕ_n, ψ_n, and ρ_n in diagram (4.1.4.2) *are topological isomorphisms.*

Proof. It is enough to prove that ϕ_n and ψ_n are isomorphisms. Indeed, $\mathrm{R}^n f_*(\mathscr{F})$ is coherent (3.2.1), so its completion $\widehat{\mathrm{R}^n f_*(\mathscr{F})}$ is coherent (**I**, 10.8.8); the bicontinuity of ϕ_n, ψ_n, and ρ_n is then automatic (**I**, 10.11.6). □

(4.1.6). *Remarks.*

(i) Put

$$\widehat{\mathscr{F}_k} = \widehat{\mathscr{F}}/\widehat{\mathscr{K}}^{k+1}\widehat{\mathscr{F}}.$$

Then, immediately,

$$\mathscr{F}_k = i_*(\widehat{\mathscr{F}_k}),$$

and the canonical homomorphism (4.1.3.6) is precisely the homomorphism already defined in (3.4.2.2):

$$\mathrm{R}^n \widehat{f}_*(\widehat{\mathscr{F}}) \longrightarrow \varprojlim_k \mathrm{R}^n \widehat{f}_*(\widehat{\mathscr{F}_k}). \tag{4.1.6.1}$$

Thus the fact that ψ_n is an isomorphism is a special case of (3.4.3). We shall nevertheless give a direct proof below, avoiding the delicate considerations concerning projective limits of spectral sequences (**0**, 13.7) on which the general theorem (3.4.3) rests.

(ii) Since the ψ_n are isomorphisms, saying that the ϕ_n are isomorphisms is equivalent to saying that

$$\rho_n = \psi_n^{-1} \circ \phi_n$$

are isomorphisms. Theorem (4.1.5) states, in particular, that the formation of $\mathrm{R}^n f_*$ commutes with completion; it may therefore be called the first comparison theorem between the "algebraic" and the "formal" theories.

We shall begin by proving the affine form of (4.1.5).

Corollary (4.1.7). — *Under the hypotheses of* (4.1.5)*, suppose in addition that $Y = \mathrm{Spec}(A)$, where A is Noetherian, and that $\mathscr{J} = \widetilde{\mathfrak{J}}$, where $\mathfrak{J}$ is an ideal of A, so that*

$$\mathscr{F}_k = \mathscr{F}/\mathfrak{J}^{k+1}\mathscr{F}.$$

The canonical homomorphism

$$\phi_n : \widehat{\mathrm{H}^n(X, \mathscr{F})} \longrightarrow \varprojlim_k \mathrm{H}^n(X, \mathscr{F}_k) \tag{4.1.7.1}$$

where the first term is the separated completion of $\mathrm{H}^n(X, \mathscr{F})$ for the $\mathfrak{J}$-preadic topology, is an isomorphism. For every n, the projective system

$$\big(\mathrm{H}^n(X, \mathscr{F}_k)\big)_{k \geqslant 0}$$

satisfies condition (ML)*, and the canonical homomorphism*

$$\psi_n : \mathrm{H}^n(\widehat{X}, \widehat{\mathscr{F}}) \longrightarrow \varprojlim_k \mathrm{H}^n(X, \mathscr{F}_k) \tag{4.1.7.2}$$

is an isomorphism. Finally, the filtration on $\mathrm{H}^n(X, \mathscr{F})$ defined by the kernels of the canonical homomorphisms **III** | 126

$$\mathrm{H}^n(X, \mathscr{F}) \longrightarrow \mathrm{H}^n(X, \mathscr{F}_k)$$

is $\mathfrak{J}$-good (**0**, 13.7.7)*, and ϕ_n is a topological isomorphism.*[2]

[2] The following proof, which is simpler than the original proof, and the supplement concerning the filtration of $\mathrm{H}^n(X, \mathscr{F})$, were communicated to us by J.-P. Serre.

Proof. Fix $n \geqslant 0$ throughout this proof and, for simplicity, put

$$\mathrm{H} = \mathrm{H}^n(X, \mathscr{F}), \qquad \mathrm{H}_k = \mathrm{H}^n(X, \mathscr{F}_k). \tag{4.1.7.3}$$

Put also

$$\mathrm{R}_k = \mathrm{Ker}(\mathrm{H} \longrightarrow \mathrm{H}_k), \qquad \text{a sub-}A\text{-module of H.} \tag{4.1.7.4}$$

The cohomology exact sequence

$$\mathrm{H}^n(X, \mathfrak{J}^{k+1}\mathscr{F}) \longrightarrow \mathrm{H}^n(X, \mathscr{F}) \longrightarrow \mathrm{H}^n(X, \mathscr{F}_k) \xrightarrow{\partial} \mathrm{H}^{n+1}(X, \mathfrak{J}^{k+1}\mathscr{F}) \longrightarrow \mathrm{H}^{n+1}(X, \mathscr{F})$$

shows that

$$\mathrm{R}_k = \mathrm{Im}\big(\mathrm{H}^n(X, \mathfrak{J}^{k+1}\mathscr{F}) \longrightarrow \mathrm{H}^n(X, \mathscr{F})\big).$$

We put

$$\begin{aligned} \mathrm{Q}_k &= \mathrm{Ker}\big(\mathrm{H}^{n+1}(X, \mathfrak{J}^{k+1}\mathscr{F}) \longrightarrow \mathrm{H}^{n+1}(X, \mathscr{F})\big) \\ &= \mathrm{Im}\big(\mathrm{H}^n(X, \mathscr{F}_k) \longrightarrow \mathrm{H}^{n+1}(X, \mathfrak{J}^{k+1}\mathscr{F})\big). \end{aligned} \tag{4.1.7.5}$$

We therefore have the exact sequence

$$0 \longrightarrow \mathrm{R}_k \longrightarrow \mathrm{H} \longrightarrow \mathrm{H}_k \longrightarrow \mathrm{Q}_k \longrightarrow 0. \tag{4.1.7.6}$$

(4.1.7.7). Let $x \in \mathfrak{J}^m$, where $m \geqslant 0$. Multiplication by x on $\mathfrak{J}^k\mathscr{F}$ is a homomorphism

$$\mathfrak{J}^k\mathscr{F} \longrightarrow \mathfrak{J}^{k+m}\mathscr{F},$$

and hence gives a homomorphism

$$\mu_{x,m} : \mathrm{H}^n(X, \mathfrak{J}^k\mathscr{F}) \longrightarrow \mathrm{H}^n(X, \mathfrak{J}^{k+m}\mathscr{F}). \tag{4.1.7.8}$$

Let

$$S = \bigoplus_{k \geqslant 0} \mathfrak{J}^k$$

be the graded A-algebra. We know that the multiplications $\mu_{x,m}$ endow

$$\mathrm{E} = \bigoplus_{k \geqslant 0} \mathrm{H}^n(X, \mathfrak{J}^k\mathscr{F})$$

with the structure of a graded S-module of finite type (3.3.2); the graded ring S is Noetherian (**II**, 2.1.5).

Lemma (4.1.7.9). — *The submodules* R_k *of* H *define a* $\mathfrak{J}$*-good filtration on* H.

Proof. First let us show that

$$\mathfrak{J}^m\mathrm{R}_k \subset \mathrm{R}_{k+m}, \tag{4.1.7.10}$$

where multiplication on $\mathrm{H} = \mathrm{H}^n(X, \mathscr{F})$ by an element $x \in \mathfrak{J}^m$ is the map $\mu_{x,0}$. For every $x \in \mathfrak{J}^m$, the diagram

$$\begin{tikzcd} \mathfrak{J}^{k+1}\mathscr{F} \arrow[r, "x"] \arrow[d] & \mathfrak{J}^{k+m+1}\mathscr{F} \arrow[d] \\ \mathscr{F} \arrow[r, "x"'] & \mathscr{F} \end{tikzcd} \tag{4.1.7.11}$$

is commutative; its horizontal arrows are multiplication by x, and its vertical arrows are the **III** | 127
canonical injections. Consequently, the corresponding diagram

$$\begin{tikzcd} \mathrm{H}^n(X, \mathfrak{J}^{k+1}\mathscr{F}) \arrow[r, "\mu_{x,m}"] \arrow[d] & \mathrm{H}^n(X, \mathfrak{J}^{k+m+1}\mathscr{F}) \arrow[d] \\ \mathrm{H}^n(X, \mathscr{F}) \arrow[r, "\mu_{x,0}"'] & \mathrm{H}^n(X, \mathscr{F}) \end{tikzcd}$$

is commutative. The interpretation of R_k as the image of

$$\mathrm{H}^n(X, \mathfrak{J}^{k+1}\mathscr{F}) \longrightarrow \mathrm{H}^n(X, \mathscr{F})$$

therefore proves (4.1.7.10). It also shows that the graded S-module

$$\mathrm{R} = \bigoplus_{k\geqslant 0} \mathrm{R}_k$$

is a quotient of the sub-S-module

$$\mathrm{M} = \bigoplus_{k\geqslant 0} \mathrm{H}^n(X, \mathfrak{J}^{k+1}\mathscr{F})$$

of E. The preceding observation thus shows that R is an S-module of finite type. This is equivalent to the assertion of the lemma (Bourbaki, *Alg. comm.*, Chap. III, §3, no. 1, Th. 1). □

(4.1.7.12). Consider now the graded S-module

$$\mathrm{N} = \bigoplus_{k\geqslant 0} \mathrm{H}^{n+1}(X, \mathfrak{J}^{k+1}\mathscr{F}),$$

defined as in (4.1.7.8). It too is an S-module of finite type by (3.3.2). By (4.1.7.5), we have $\mathrm{Q}_k \subset \mathrm{N}_k$ for every k, and diagram (4.1.7.11), with n replaced by $n+1$, shows that

$$S_m \mathrm{Q}_k = \mathfrak{J}^m \mathrm{Q}_k \subset \mathrm{Q}_{k+m}.$$

In other words, Q is a graded sub-S-module of N and is therefore of finite type.

(4.1.7.13). Let α_m denote the canonical injection

$$\mathfrak{J}^m \longrightarrow A,$$

which may also be written $S_m \to S_0$. Since $\mathfrak{J}^{k+1}\mathscr{F}_k = 0$, the A-module $\mathrm{H}^n(X, \mathscr{F}_k)$ is annihilated by $\mathfrak{J}^{k+1}$. As Q_k is the image of the A-homomorphism

$$\mathrm{H}^n(X, \mathscr{F}_k) \longrightarrow \mathrm{H}^{n+1}(X, \mathfrak{J}^{k+1}\mathscr{F}),$$

Q_k is likewise annihilated by $\mathfrak{J}^{k+1}$. Equivalently, in the S-module Q,

$$\alpha_{k+1}(S_{k+1})\mathrm{Q}_k = 0. \tag{4.1.7.14}$$

Since Q is an S-module of finite type, there exist integers k_0 and h such that

$$\mathrm{Q}_{k+h} = S_h \mathrm{Q}_k \qquad (k \geqslant k_0)$$

(II, 2.1.6, ii). This relation and (4.1.7.14) imply that there exists an integer $r > 0$ such that

$$\alpha_r(S_r)\mathrm{Q} = 0. \tag{4.1.7.15}$$

(4.1.7.16). The canonical injection

$$\mathfrak{J}^{k+m}\mathscr{F} \longrightarrow \mathfrak{J}^k\mathscr{F}$$

induces in cohomology an A-homomorphism

$$\nu_m : \mathrm{H}^{n+1}(X, \mathfrak{J}^{k+m}\mathscr{F}) \longrightarrow \mathrm{H}^{n+1}(X, \mathfrak{J}^k\mathscr{F}). \tag{4.1.7.17}$$

For every $x \in \mathfrak{J}^m$, we plainly have the factorization

$$\mathrm{H}^{n+1}(X, \mathfrak{J}^k\mathscr{F}) \xrightarrow{\mu_{x,m}} \mathrm{H}^{n+1}(X, \mathfrak{J}^{k+m}\mathscr{F}) \xrightarrow{\nu_m} \mathrm{H}^{n+1}(X, \mathfrak{J}^k\mathscr{F}), \tag{4.1.7.18}$$

whose composite is $\mu_{x,0}$.

It follows that, for every sub-A-module P of $\mathrm{H}^{n+1}(X, \mathfrak{J}^k\mathscr{F})$, we have in the S-module N **III** | 128

$$\nu_m(S_m \mathrm{P}) = \alpha_m(S_m)\mathrm{P}. \tag{4.1.7.19}$$

Lemma (4.1.7.20). — *There exists an integer $m > 0$ such that*

$$\nu_m(\mathrm{Q}_{k+m}) = 0$$

for every $k \geqslant k_0$.

Proof. Take m to be a multiple of h with $m \geqslant r$. Since

$$Q_{k+m} = S_m Q_k \qquad (k \geqslant k_0),$$

relations (4.1.7.19) and (4.1.7.15) give

$$\nu_m(Q_{k+m}) = \alpha_m(S_m)Q_k \subset \alpha_r(S_r)Q_k = 0.$$

□

(4.1.7.21). The commutative diagram

$$\begin{tikzcd}
H^n(X,\mathscr{F}) \arrow[r] & H^n(X,\mathscr{F}_k) \arrow[r, "\partial"] & H^{n+1}(X,\mathfrak{J}^{k+1}\mathscr{F}) \arrow[r] & H^{n+1}(X,\mathscr{F}) \\
H^n(X,\mathscr{F}) \arrow[r] \arrow[u] & H^n(X,\mathscr{F}_{k+m}) \arrow[r, "\partial"] \arrow[u] & H^{n+1}(X,\mathfrak{J}^{k+m+1}\mathscr{F}) \arrow[r] \arrow[u] & H^{n+1}(X,\mathscr{F}) \arrow[u]
\end{tikzcd}$$

itself comes from the commutative diagram

$$\begin{tikzcd}
0 \arrow[r] & \mathfrak{J}^{k+1}\mathscr{F} \arrow[r] & \mathscr{F} \arrow[r] & \mathscr{F}_k \arrow[r] & 0 \\
0 \arrow[r] & \mathfrak{J}^{k+m+1}\mathscr{F} \arrow[r] \arrow[u] & \mathscr{F} \arrow[r] \arrow[u] & \mathscr{F}_{k+m} \arrow[r] \arrow[u] & 0.
\end{tikzcd}$$

Here the vertical arrows are the canonical maps. We therefore obtain the commutative diagram

$$\begin{tikzcd}
0 \arrow[r] & R_k \arrow[r] & H \arrow[r] & H_k \arrow[r] & Q_k \arrow[r] & 0 \\
0 \arrow[r] & R_{k+m} \arrow[r] \arrow[u] & H \arrow[r] \arrow[u, equal] & H_{k+m} \arrow[r] \arrow[u] & Q_{k+m} \arrow[r] \arrow[u, "\nu_m"] & 0,
\end{tikzcd}$$

whose rows are exact. For $k \geqslant k_0$, the last vertical arrow is zero by (4.1.7.20). Thus the image of H_{k+m} in H_k is contained in

$$\operatorname{Ker}(H_k \longrightarrow Q_k) = \operatorname{Im}(H \longrightarrow H_k).$$

Conversely, commutativity shows that it contains $\operatorname{Im}(H \to H_k)$, and hence it is equal to that image. The same is therefore true of the images in H_k of $H_{k'}$ for $k' \geqslant k+m$. This proves condition *(ML)* for the projective system $(H_k)_{k\geqslant 0}$.

Moreover, for every affine open subset U of X,

$$H^i(U,\mathscr{F}_k) = 0 \qquad (i > 0)$$

by (1.3.1), and, for $m > 0$, the map

$$H^0(U,\mathscr{F}_{k+m}) \longrightarrow H^0(U,\mathscr{F}_k)$$

is surjective (**I**, 1.3.9). We may therefore
apply (**0**, 13.3.1); the canonical homomorphism **III** | 129

$$H^n(\widehat{X},\widehat{\mathscr{F}}) \longrightarrow \varprojlim_k H^n(X,\mathscr{F}_k)$$

is bijective for every $n \geqslant 0$.

Since the projective system $(H/R_k)_{k\geqslant 0}$ is strict, we may pass to the projective limit in the exact sequences

$$0 \longrightarrow H/R_k \longrightarrow H_k \longrightarrow Q_k \longrightarrow 0 \tag{4.1.7.22}$$

by (**0**, 13.2.2). Since $\nu_m(Q_{k+m}) = 0$, we have

$$\varprojlim_k Q_k = 0,$$

and hence a topological isomorphism

$$\varprojlim_k (H/R_k) \simeq \varprojlim_k H_k.$$

But the filtration (R_k) of H is $\mathfrak{J}$-good, and therefore defines on H the $\mathfrak{J}$-preadic topology. Thus $\varprojlim_k(\mathrm{H}/\mathrm{R}_k)$ is the separated completion of H for this topology. This completes the proof of (4.1.7).

□

(4.1.8). We can now complete the proof of (4.1.5). For every affine open subset V of Y,

$$\Gamma\big(V, \widehat{\mathrm{R}^n f_*(\mathscr{F})}\big)$$

is the separated completion of $\Gamma(V, \mathrm{R}^n f_*(\mathscr{F}))$ for the $\mathfrak{J}$-preadic topology, if $\mathscr{J}|V = \widetilde{\mathfrak{J}}$, because $\mathrm{R}^n f_*(\mathscr{F})$ is a coherent $\mathscr{O}_Y$-module (**I**, 10.8.4). Furthermore,

$$\Gamma\left(V, \varprojlim_k \mathrm{R}^n f_*(\mathscr{F}_k)\right) = \varprojlim_k \Gamma\big(V, \mathrm{R}^n f_*(\mathscr{F}_k)\big)$$

by (**0**, 3.2.6). It follows from (4.1.7) and (1.4.11) that ϕ_n is a topological isomorphism. Likewise, again by (1.4.11), (4.1.7) shows that the homomorphism $\psi_{n,V}$ of (4.1.3.5) is an isomorphism. By the definition of $\mathrm{R}^n \widehat{f}_*(\widehat{\mathscr{F}})$, it follows that ψ_n is an isomorphism.

Corollary (4.1.9). — *Under the hypotheses of* (4.1.4)*, for every affine open subset V of Y, the canonical homomorphism*

$$\mathrm{H}^n\big(\widehat{\mathrm{X}} \cap f^{-1}(V), \widehat{\mathscr{F}}\big) \longrightarrow \Gamma\big(\widehat{\mathrm{Y}} \cap V, \mathrm{R}^n \widehat{f}_*(\widehat{\mathscr{F}})\big)$$

is bijective.

(4.1.10). *Remark.* Let $f : X \to Y$ be a morphism of finite type between Noetherian usual preschemes, and let $\mathscr{F}$ be a coherent $\mathscr{O}_X$-module whose support is proper over Y (**II**, 5.4.10). We then know (3.2.4) that $\mathrm{R}^n f_*(\mathscr{F})$ is a coherent $\mathscr{O}_Y$-module for every $n \geqslant 0$. Moreover, we may always suppose that

$$\mathscr{F} = u_*(\mathscr{G}), \qquad \mathscr{G} = u^*(\mathscr{F}),$$

where $\mathscr{G}$ is a coherent $\mathscr{O}_Z$-module, Z is a suitable closed subprescheme of X whose underlying space is $\mathrm{Supp}(\mathscr{F})$, and $u : Z \to X$ is the canonical injection (**I**, 9.3.5). If

$$\mathscr{G}_k = \mathscr{G} \otimes_{\mathscr{O}_Y} (\mathscr{O}_Y / \mathscr{J}^{k+1}),$$

then

$$\mathscr{G}_k = u^*(\mathscr{F}_k), \qquad \mathrm{R}^n f_*(\mathscr{F}_k) = \mathrm{R}^n (f \circ u)_*(\mathscr{G}_k)$$

and

$$\mathrm{R}^n f_*(\mathscr{F}) = \mathrm{R}^n (f \circ u)_*(\mathscr{G})$$

by (1.3.4); and, taking (**I**, 10.9.5) into account,

$$\mathrm{R}^n \widehat{f}_*(\widehat{\mathscr{F}}) = \mathrm{R}^n \widehat{(f \circ u)}_*(\widehat{\mathscr{G}}).$$

We may therefore apply (4.1.5) to $\mathscr{G}$ and to the proper morphism $f \circ u$. It follows that, under these hypotheses, the results of (4.1.5) remain valid for $\mathscr{F}$ and f.

4.2. Particular cases and variants The most useful form of the comparison theorem (4.1.5) is the following.

Proposition (4.2.1). — *Let Y be a locally Noetherian prescheme, let $f : X \to Y$ be a proper morphism, and let $\mathscr{F}$ be a coherent $\mathscr{O}_X$-module. Then, for every $y \in Y$ and every p,*

$$\left(\mathrm{R}^p f_*(\mathscr{F})\right)_y$$

is an $\mathscr{O}_y$-module of finite type and is therefore separated for the $\mathfrak{m}_y$-preadic topology. Moreover, there is a canonical topological isomorphism **III** | 130

$$\left(\widehat{\mathrm{R}^p f_*(\mathscr{F})}\right)_y \simeq \varprojlim_k \mathrm{H}^p\left(f^{-1}(y), \mathscr{F} \otimes_{\mathscr{O}_Y} (\mathscr{O}_y/\mathfrak{m}_y^k)\right). \tag{4.2.1.1}$$

Here the first term is the completion of $\left(\mathrm{R}^p f_*(\mathscr{F})\right)_y$ for the $\mathfrak{m}_y$-preadic topology. In the second term, for every $k \geqslant 0$, $f^{-1}(y)$ is regarded as the underlying space of the prescheme

$$X \times_Y \operatorname{Spec}(\mathscr{O}_y/\mathfrak{m}_y^k)$$

(**I**, 3.6.1).

Proof. Since $\mathscr{O}_y$ is a Noetherian local ring and $\left(\mathrm{R}^p f_*(\mathscr{F})\right)_y$ is an $\mathscr{O}_y$-module of finite type (3.2.1), the $\mathfrak{m}_y$-preadic topology on this module is separated (**0**, 7.3.5).

When Y is Noetherian and y is closed, the other assertions follow from (4.1.7), after replacing Y by an affine neighbourhood of y and taking $Y' = \{y\}$; here we use (G, II, 4.9.1).

In general, put

$$Y_1 = \operatorname{Spec}(\mathscr{O}_y), \qquad X_1 = X \times_Y Y_1, \qquad \mathscr{F}_1 = \mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{O}_{Y_1},$$

and let

$$f_1 = f \times 1_{Y_1} : X_1 \longrightarrow Y_1.$$

The prescheme Y_1 is Noetherian, the morphism f_1 is proper (**II**, 5.4.2, iii), and $\mathscr{F}_1$ is coherent (**0**, 5.3.11). Let y_1 be the unique closed point of Y_1. The proposition already proved applies to f_1, $\mathscr{F}_1$, and y_1. We have

$$\mathscr{O}_{y_1} = \mathscr{O}_y, \qquad f_1^{-1}(y_1) = f^{-1}(y)$$

(**I**, 3.6.5). Furthermore, the preschemes

$$X \times_Y \operatorname{Spec}(\mathscr{O}_y/\mathfrak{m}_y^k) \quad \text{and} \quad X_1 \times_{Y_1} \operatorname{Spec}(\mathscr{O}_y/\mathfrak{m}_y^k)$$

are canonically identified (**I**, 3.3.9), as are

$$\mathscr{F}_1 \otimes_{\mathscr{O}_{Y_1}} (\mathscr{O}_y/\mathfrak{m}_y^k) \quad \text{and} \quad \mathscr{F} \otimes_{\mathscr{O}_Y} (\mathscr{O}_y/\mathfrak{m}_y^k)$$

(**I**, 9.1.6). It remains only to observe that

$$\mathrm{R}^p f_{1*}(\mathscr{F}_1) \simeq \mathrm{R}^p f_*(\mathscr{F}) \otimes_{\mathscr{O}_Y} \mathscr{O}_{Y_1}.$$

This follows from (1.4.15), since the local morphism $\operatorname{Spec}(\mathscr{O}_y) \to Y$ is flat (**0**, 6.7.1), (**I**, 2.4.2). ☐

The following corollary uses the terminology of dimension theory (Chapter IV) and will not be applied before that chapter.

Corollary (4.2.2). — *Let Y be a locally Noetherian prescheme, let $f : X \to Y$ be a proper morphism, let $y \in Y$, and let r be the dimension of $f^{-1}(y)$. Then, for every coherent $\mathscr{O}_X$-module $\mathscr{F}$, the sheaves $\mathrm{R}^p f_*(\mathscr{F})$ vanish in a neighbourhood of y for every $p > r$.*

Proof. For every k, we have

$$\mathrm{H}^p\left(f^{-1}(y), \mathscr{F} \otimes_{\mathscr{O}_Y} (\mathscr{O}_y/\mathfrak{m}_y^k)\right) = 0$$

by (G, II, 4.15.2). It follows from (4.2.1) that the separated completion of $\left(\mathrm{R}^p f_*(\mathscr{F})\right)_y$ for the $\mathfrak{m}_y$-preadic topology is zero. Since this topology is separated, we also have

$$\left(\mathrm{R}^p f_*(\mathscr{F})\right)_y = 0.$$

The conclusion follows because $\mathrm{R}^p f_*(\mathscr{F})$ is coherent (**0**, 5.2.2). ☐

(4.2.3). The result (4.2.1) is used especially when $p = 0$. We obtain the following corollary.

Corollary (4.2.4). — *Under the hypotheses of (4.2.1), there is a canonical topological isomorphism*

$$\left(\widehat{f_*(\mathscr{F})}\right)_y \simeq \varprojlim_k \Gamma\left(f^{-1}(y), \mathscr{F}_y/\mathfrak{m}_y^k\mathscr{F}_y\right).$$

4.3. Zariski's connectedness theorem The results of this section and the next generalize well-known theorems of Zariski, and may all be deduced from (4.2.4). They are consequences of the following theorem.

Theorem (4.3.1). — (Connectedness theorem). *Let Y be a locally Noetherian prescheme and let $f : X \to Y$ be a proper morphism. Then*

$$\mathscr{A}(X) = f_*(\mathscr{O}_X)$$

is a coherent $\mathscr{O}_Y$-algebra.

*Let Y' be the finite Y-scheme such that $\mathscr{A}(Y') = \mathscr{A}(X)$; it is determined up to a Y-isomorphism (**II**, 1.3.1), (**II**, 6.1.3). If $f' = \mathscr{A}(e)$ is the Y-morphism $X \to Y'$ deduced from the identity isomorphism* **III** | 131

$$e : \mathscr{A}(Y') \simeq \mathscr{A}(X)$$

*(**II**, 1.2.7), then f' is proper, $f'_*(\mathscr{O}_X)$ is isomorphic to $\mathscr{O}_{Y'}$, and every fibre $f'^{-1}(y')$, $y' \in Y'$, is connected and nonempty.*

Proof. Let $g : Y' \to Y$ be the structural morphism. To prove that the homomorphism

$$\theta : \mathscr{O}_{Y'} \longrightarrow f'_*(\mathscr{O}_X)$$

entering into the definition of f' is bijective, it is enough, since Y' is affine over Y, to prove that

$$g_*(\theta) : g_*(\mathscr{O}_{Y'}) \longrightarrow g_*\left(f'_*(\mathscr{O}_X)\right) = f_*(\mathscr{O}_X)$$

is the identity (**II**, 1.4.2). This follows from the definitions, since $g_*(\mathscr{O}_{Y'}) = \mathscr{A}(Y')$ and $f_*(\mathscr{O}_X) = \mathscr{A}(X)$. The coherence of $\mathscr{A}(X)$ is a special case of the finiteness theorem (3.2.1). Since f is proper and g is separated, f' is proper (**II**, 5.4.3, i). It remains only to prove (4.3.2). □

Corollary (4.3.2). — *Under the hypotheses of (4.3.1), suppose in addition that $f_*(\mathscr{O}_X)$ is isomorphic to $\mathscr{O}_Y$. Then every fibre $f^{-1}(y)$ of f is connected and nonempty.*

Proof. The hypothesis that $f_*(\mathscr{O}_X)$ is isomorphic to $\mathscr{O}_Y$ already implies that f is dominant, hence surjective because f is a closed map. As in (4.2.1), we may reduce to the case where y is closed in Y. Since $f^{-1}(y)$ is a Noetherian space, it has finitely many connected components; these are also the connected components of the underlying space of the completion $\widehat{X}$ along $f^{-1}(y)$.

If Z_i, $1 \leqslant i \leqslant n$, are these connected components, then

$$\Gamma(\widehat{X}, \mathscr{O}_{\widehat{X}}) = \prod_{i=1}^{n} \Gamma(Z_i, \mathscr{O}_{\widehat{X}}),$$

and none of the rings on the right is zero, since the unit section is nonzero at every point of $\widehat{X}$. Applying (4.1.5) to $\mathscr{F} = \mathscr{O}_X$, whose completion along $f^{-1}(y)$ is $\mathscr{O}_{\widehat{X}}$, shows that $\Gamma(\widehat{X}, \mathscr{O}_{\widehat{X}})$ is isomorphic to the separated $\mathfrak{m}_y$-adic completion $\widehat{\mathscr{O}}_y$ of the local ring $\mathscr{O}_y$. It is therefore a local ring and cannot be a direct product of several nonzero rings. Thus $n = 1$. □

Corollary (4.3.3). — *Under the hypotheses of (4.3.1), for every $y \in Y$ the set of connected components of the fibre $f^{-1}(y)$ is in bijective correspondence with the finite set of points of the fibre $g^{-1}(y)$, where $g : Y' \to Y$ is the structural morphism; in other words, it corresponds to the set of maximal ideals of $\left(f_*(\mathscr{O}_X)\right)_y$.*

Proof. Since Y' is finite over Y, the space $g^{-1}(y)$ is finite and discrete (**II**, 6.1.7). As

$$f^{-1}(y) = f'^{-1}\left(g^{-1}(y)\right),$$

the assertion follows from this observation and (4.3.1). □

This gives a remarkable interpretation of the Y-prescheme Y' defined in (4.3.1). The factorization $f = g \circ f'$ of the proper morphism f is analogous to the factorization obtained by K. Stein for holomorphic maps of analytic spaces, and will henceforth be called the *Stein factorization* of f.

Remark (4.3.4). — Let k be an extension of the field $k(y)$. If

$$f^{-1}(y) \otimes_{k(y)} k = X \times_Y \operatorname{Spec}(k)$$

is connected, then $f^{-1}(y)$ is connected as well, since it is the image of the former under a projection morphism (I, 3.4.7). For a morphism $f : X \to Y$ of preschemes and a point $y \in Y$, we shall say that the fibre $f^{-1}(y)$ is *geometrically connected* if, for every extension k of $k(y)$, the prescheme $f^{-1}(y) \otimes_{k(y)} k = X \times_Y \operatorname{Spec}(k)$ is connected.

Under the hypotheses of (4.3.2), the conclusion can be strengthened: the fibres $f^{-1}(y)$ are geometrically connected. Indeed, for every extension k of $k(y)$ there exist a local Noetherian ring A and a local homomorphism III | 132

$$\varphi : \mathscr{O}_y \longrightarrow A$$

such that A is a flat $\mathscr{O}_y$-module and the residue field of A is $k(y)$-isomorphic to k (0, 10.3.1). Let $Y_1 = \operatorname{Spec}(A)$, and let $h : Y_1 \to Y$ be the local morphism corresponding to φ, taking the unique closed point y_1 of Y_1 to y (I, 2.4.1). Set

$$X_1 = X \times_Y Y_1, \qquad f_1 = f \times 1_{Y_1}.$$

The prescheme Y_1 is Noetherian, f_1 is proper (II, 5.4.2), and $f_1^{-1}(y_1)$ is a $k(y_1)$-prescheme isomorphic to $X \times_Y \operatorname{Spec}(k)$. It is therefore enough to prove that

$$f_{1*}(\mathscr{O}_{X_1}) = \mathscr{O}_{Y_1},$$

so that (4.3.2) may be applied to f_1. Now h is flat by (I, 2.4.2); hence, by (1.4.15) with $q = 0$,

$$f_{1*}(\mathscr{O}_{X_1}) = h^*\big(f_*(\mathscr{O}_X)\big) = h^*(\mathscr{O}_Y) = \mathscr{O}_{Y_1}.$$

In the general case of (4.3.1), the same argument shows, with the notation of that theorem, that

$$f_{1*}(\mathscr{O}_{X_1}) = h^*\big(g_*(\mathscr{O}_{Y'})\big),$$

and that the Stein factorization $f_1 = g_1 \circ f_1'$ of f_1 satisfies

$$g_1 = g \times 1_{Y_1}$$

(II, 1.5.2), the corresponding finite Y_1-scheme being $Y_1' = Y' \times_Y Y_1$. Taking the transitivity of fibres into account (I, 3.6.4), it follows from (4.3.3) that the number of connected components of $f_1^{-1}(y_1)$ is the number of elements of

$$g_1^{-1}(y_1) = g^{-1}(y) \otimes_{k(y)} k.$$

If k is chosen algebraically closed, this number is independent of the algebraically closed extension chosen and is equal to the *geometric number of points* of $g^{-1}(y)$ (I, 6.4.7), or equivalently to

$$\sum_i [k(y_i') : k(y)]_s,$$

where the y_i' range over the finite set $g^{-1}(y)$. This number is called the *geometric number of connected components* of $f^{-1}(y)$. The fields $k(y_i')$ are precisely the residue fields of the semilocal ring $\big(f_*(\mathscr{O}_X)\big)_y$.

Proposition (4.3.5). — *Let X and Y be locally Noetherian integral preschemes, and let $f : X \to Y$ be a proper dominant morphism. For every $y \in Y$, the number of connected components of $f^{-1}(y)$ is at most the number of maximal ideals of the integral closure $\mathscr{O}_y'$ of $\mathscr{O}_y$ in the field of rational functions* $\mathrm{R}(X)$.

Proof. For every open set U of Y,

$$\Gamma\big(U, f_*(\mathscr{O}_X)\big) = \Gamma\big(f^{-1}(U), \mathscr{O}_X\big)$$

is the intersection of the local rings $\mathscr{O}_x$ for $x \in f^{-1}(U)$ (I, 8.2.1.1). It follows at once that $\big(f_*(\mathscr{O}_X)\big)_y$ is a subring of $\mathrm{R}(X)$ containing $\mathscr{O}_y$. Since $f_*(\mathscr{O}_X)$ is a coherent $\mathscr{O}_Y$-module, $\big(f_*(\mathscr{O}_X)\big)_y$ is a finite $\mathscr{O}_y$-module, and hence is contained in $\mathscr{O}_y'$. Every maximal ideal of such a ring is the intersection of that ring with a maximal ideal of $\mathscr{O}_y'$ [SZ60, vol. I, pp. 257 and 259], proving the proposition. □

Definition (4.3.6). — An integral local ring is said to be *unibranch* if its integral closure is again a local ring. A point y of an integral prescheme Y is said to be *unibranch* if the local ring $\mathscr{O}_y$ is unibranch; this is in particular the case when Y is normal at y.

Let A be an integral local ring and let K be its field of fractions. The ring A is unibranch if and only if every subring A_1 of K that contains A and is a finite A-algebra is local. Indeed, let A' be the integral closure of A. By the first Cohen–Seidenberg theorem (Bourbaki, *Algèbre commutative*, Chapter V, §2, no. 1, Theorem 1), every maximal ideal of A_1 is the contraction to A_1 of a maximal ideal of A'; thus, if A' is local, so is A_1.

Conversely, A' is the inductive limit of the directed family of finite A-subalgebras A_α of A'. If each A_α is local, then for $A_\alpha \subset A_\beta$ the maximal ideal of A_α is the contraction of the maximal ideal of A_β, by the same argument; hence A' is local (**0**, 10.3.1.3). **III** | 133

Notice also that if the completion of a Noetherian local ring A is integral—a property expressed by saying that A is *analytically integral*—then A is unibranch. Let $\mathfrak{m}$ be the maximal ideal of A, let K be its field of fractions, and let K' be the field of fractions of $\widehat{A}$; then

$$K' = K \otimes_A \widehat{A}.$$

Let A'_F be a finite A-subalgebra of K. The subring B_F of K' generated by $\widehat{A}$ and A'_F is isomorphic to

$$A'_F \otimes_A \widehat{A};$$

it is a finite $\widehat{A}$-module and is the completion of A'_F for the $\mathfrak{m}$-adic topology (**0**, 7.3.3), (**0**, 7.3.6). Since A'_F is semilocal (Bourbaki, *Algèbre commutative*, Chapter IV, §2, no. 5, Corollary 3 to Proposition 9), while its completion is integral, A'_F can have only one maximal ideal $\mathfrak{m}'_F$, and $\mathfrak{m}'_F \cap A = \mathfrak{m}$. This proves the assertion.

Corollary (4.3.7). — *Under the hypotheses of (4.3.5), suppose that the algebraic closure of* $\mathrm{R}(Y)$ *in* $\mathrm{R}(X)$ *has separable degree n and that $y \in Y$ is unibranch. Then the fibre $f^{-1}(y)$ has at most n connected components. In particular, if the algebraic closure of* $\mathrm{R}(Y)$ *in* $\mathrm{R}(X)$ *is radicial over* $\mathrm{R}(Y)$*, then $f^{-1}(y)$ is connected.*

Proof. Let $\mathscr{O}'_y$ be the integral closure of $\mathscr{O}_y$, and let $\mathscr{O}''_y$ be the integral closure of $\mathscr{O}_y$ in $\mathrm{R}(X)$. The latter is also the integral closure of $\mathscr{O}'_y$ in $\mathrm{R}(X)$. If $\mathscr{O}'_y$ is local, then $\mathscr{O}''_y$ is a semilocal ring having at most n maximal ideals [SZ60, vol. I, p. 289, Theorem 22].

This corollary is essentially the form in which Zariski states his "connectedness theorem" for algebraic schemes. □

Remark (4.3.8). — If, in addition to the hypotheses of (4.3.7), Y is normal at y, then the fibre $f^{-1}(y)$ is geometrically connected: with the notation of (4.3.4), $g^{-1}(y)$ is a single point y', and $k(y')$ is radicial over $k(y)$.

Definition (4.3.9). — Let Y be a locally Noetherian prescheme. A morphism of finite type $f : X \to Y$ is said to be *universally open* if, for every irreducible locally Noetherian prescheme Y' and every dominant morphism $g : Y' \to Y$, every irreducible component of $X' = X \times_Y Y'$ dominates Y'.

If Y is irreducible, this says that if η and η' are the generic points of Y and Y', respectively, and if $f' = f \times 1_{Y'}$, every irreducible component of X' has its generic point in $f'^{-1}(\eta')$. Consequently, for every open set U of Y, the restricted morphism $f^{-1}(U) \to U$ is universally open.

Corollary (4.3.10). — *Let X and Y be locally Noetherian integral preschemes, and let $f : X \to Y$ be proper, dominant, and universally open. If the algebraic closure of* $\mathrm{R}(Y)$ *in* $\mathrm{R}(X)$ *is radicial over* $\mathrm{R}(Y)$*, then every fibre $f^{-1}(y)$, $y \in Y$, is geometrically connected.*

Proof. We may reduce to the case $Y = \mathrm{Spec}(B)$, where B is an integral Noetherian ring. By (**II**, 7.1.7), there exists an integrally closed Noetherian local ring A that dominates $\mathscr{O}_y$ and has $\mathrm{R}(Y)$ as its field of fractions. Put $Y' = \mathrm{Spec}(A)$, and let $h : Y' \to Y$ be the morphism corresponding to the canonical injection $B \to A$. It is birational, hence dominant; moreover, if y' is the unique closed point of Y', then $h(y') = y$.

Set

$$X' = X \times_Y Y', \qquad f' = f \times 1_{Y'}.$$

Let η, η', and ξ be the generic points of Y, Y', and X, respectively. Then $f(\xi) = \eta$ and $h^{-1}(\eta) = \{\eta'\}$; moreover $k(\eta) = k(\eta') = \mathrm{R}(Y)$. Thus $f'^{-1}(\eta')$ is isomorphic to $f^{-1}(\eta)$ (**I**, 3.6.4), and it has a single generic point, since ξ is the generic point of $f^{-1}(\eta)$ (**0**, 2.1.8). By universal openness, every irreducible component of X' has its generic point in $f'^{-1}(\eta')$. Hence X' is irreducible; its generic point ξ' is that of $f'^{-1}(\eta')$, and $k(\xi') = k(\xi)$.

Put $X'' = X'_{\mathrm{red}}$ and $f'' = f'_{\mathrm{red}}$. Then X'' is integral and Noetherian, f'' is proper (**II**, 5.4.6), and the underlying spaces of the fibres $f'^{-1}(y')$ and $f''^{-1}(y')$ are the same. Moreover, **III** | 134

$$\mathrm{R}(X'') = k(\xi') = \mathrm{R}(X).$$

Thus f'' satisfies the hypotheses of (4.3.8), and $f''^{-1}(y')$ is geometrically connected.

Let k now be any extension of $k(y)$. There exists an extension k_1 of $k(y)$ in which both $k(y')$ and k may be regarded as subextensions (Bourbaki, *Algèbre*, Chapter V, §4, Proposition 2). By the preceding paragraph,

$$f''^{-1}(y') \times_{Y'} \mathrm{Spec}(k_1)$$

is connected. It has the same associated reduced prescheme as $f'^{-1}(y') \times_{Y'} \mathrm{Spec}(k_1)$ (**I**, 5.1.8), so the latter is connected; it is isomorphic to $f^{-1}(y) \times_Y \mathrm{Spec}(k_1)$ (**I**, 3.6.4). Therefore $f^{-1}(y) \times_Y \mathrm{Spec}(k)$ is connected, and the observation at the beginning of (4.3.4) completes the proof. □

Remark (4.3.11). — *(i)* The preceding argument is due in substance to Zariski [Zar51], except that in his setting one may take for A the integral closure of $\mathscr{O}_y$, since this is a Noetherian ring for the local rings of classical algebraic geometry. Zariski also proves that if Y is the Chow variety of a projective space $\mathbf{P}^r_k$ over a field k, and X is the closed subset of $\mathbf{P}^r_k \times_k Y$ defining the Chow correspondence between $\mathbf{P}^r_k$ and Y, then the projection $X \to Y$ is universally open (*loc. cit.*, lemma on p. 82). It appears that this is the only formal property of "Chow coordinates" used in certain applications. In such a situation it is therefore useful to replace the language of specialization of cycles in projective space by that of fibres of a proper morphism, possibly assumed universally open or subject to analogous local regularity conditions.

(ii) In Chapter IV we shall see that a universally open morphism $f : X \to Y$ may equivalently be defined by requiring that, for every morphism $Z \to Y$, the base-changed morphism $f_{(Z)} : X_{(Z)} \to Z$ be open. One can also show that if f satisfies the hypotheses of (4.3.10), and if y is a specialization of y', then the geometric number of connected components of $f^{-1}(y)$ is at most that of $f^{-1}(y')$.

Corollary (4.3.12). — *Under the hypotheses of (4.3.5), suppose in addition that $\mathrm{R}(Y)$ is algebraically closed in $\mathrm{R}(X)$, and let y be a normal point of Y. Then $f^{-1}(y)$ is geometrically connected, and there exists an open neighbourhood U of y in Y such that*

$$f_*(\mathscr{O}_X|_{f^{-1}(U)}) \simeq \mathscr{O}_Y|_U.$$

In particular, if Y is normal and $\mathrm{R}(Y)$ is algebraically closed in $\mathrm{R}(X)$, then $f_*(\mathscr{O}_X) \simeq \mathscr{O}_Y$.

Proof. The assertion concerning $f^{-1}(y)$ is a special case of (4.3.8).

If **III** | 135

$$X \xrightarrow{f'} Y' \xrightarrow{g} Y$$

is the Stein factorization of f (4.3.3), it follows that $g^{-1}(y)$ consists of a single point y'. Moreover,

$$\mathscr{O}_y \subset \mathscr{O}_{y'} = \big(f_*(\mathscr{O}_X)\big)_y \subset \mathrm{R}(X).$$

Since $\mathscr{O}_{y'}$ is finite over $\mathscr{O}_y$, and hence *a fortiori* algebraic over $\mathrm{R}(Y)$ inside the relevant fraction field, the hypothesis forces it to lie in $\mathrm{R}(Y)$. Since y is normal, necessarily $\mathscr{O}_{y'} = \mathscr{O}_y$. Thus g is a local isomorphism at y' (**I**, 6.5.4), which proves the first part. The second assertion follows from the first: the additional hypothesis makes g bijective and a local isomorphism in a neighbourhood of every point of Y', hence an isomorphism. □

The fact that (4.3.7) is available for schemes yields, for example, the following application.

Proposition (4.3.13). — *Let A be a unibranch Noetherian local ring, let $\mathfrak{a}$ be an ideal of definition of A, let*

$$A_0 = A/\mathfrak{a}, \qquad S = \mathrm{gr}_{\mathfrak{a}}(A)$$

be the graded ring associated to the $\mathfrak{a}$-preadic filtration. Suppose that S is a graded A_0-algebra generated by S_1, where S_1 is a finite A_0-module. Then $\mathrm{Proj}(S)$ is a connected A_0-scheme.

Proof. Let $\mathfrak{m}$ be the maximal ideal of A. The scheme $Y = \operatorname{Spec}(A)$ is integral, and the point y corresponding to $\mathfrak{m}$ is its unique closed point. For some integer p,

$$\mathfrak{m}^p \subset \mathfrak{a} \subset \mathfrak{m},$$

so $V(\mathfrak{a}) = \{\mathfrak{m}\}$. Put

$$S' = \bigoplus_{n \geqslant 0} \mathfrak{a}^n \qquad \text{and} \qquad X = \operatorname{Proj}(S').$$

This is the Y-scheme obtained by blowing up the ideal $\mathfrak{a}$. It is integral, and the structural morphism $f : X \to Y$ is birational (**II**, 8.1.4) and projective. Therefore (4.3.7) applies and shows that $f^{-1}(y)$ is connected. But the underlying space of $f^{-1}(y)$ is that of

$$\operatorname{Proj}(S' \otimes_A A_0)$$

(**I**, 3.6.1), (**II**, 2.8.10); since $S' \otimes_A A_0 = S$ by definition, the proposition follows. □

4.4. Zariski's "main theorem"

Proposition (4.4.1). — *Let Y be a locally Noetherian prescheme and let $f : X \to Y$ be a proper morphism. Let X' be the set of points $x \in X$ that are isolated in their fibre $f^{-1}(f(x))$. Then X' is open in X. If*

$$f = g \circ f'$$

is the Stein factorization of f (4.3.3), the restriction of f' to X' is an isomorphism of X' onto the subprescheme induced on an open subset U of Y', and $X' = f'^{-1}(U)$.

Proof. Since $g^{-1}(f(x))$ is finite and discrete (4.3.3), (**II**, 6.1.7), the point x is isolated in $f^{-1}(f(x))$ if and only if it is isolated in $f'^{-1}(f'(x))$. We may therefore reduce to the case $f' = f$, so that $f_*(\mathscr{O}_X) = \mathscr{O}_Y$. If $x \in X'$, the fibre $f^{-1}(f(x))$, being connected by (4.3.2), must then consist of the single point x.

Since f is closed, for every open neighbourhood V of x in X, the closed set $f(X - V)$ does not contain $y = f(x)$. If U is its complement in Y, then $f^{-1}(U) \subset V$. Thus the inverse images under f of a fundamental system of open neighbourhoods of y form a fundamental system of open neighbourhoods of x. The equality $f_*(\mathscr{O}_X) = \mathscr{O}_Y$ and the definition of the direct image of a sheaf (**0**, 3.4.1), (4.2.1) now imply that, if $f = (\psi, \theta)$, the homomorphism

$$\theta_y^\# : \mathscr{O}_y \longrightarrow \mathscr{O}_x$$

is an isomorphism. Hence there are open neighbourhoods V of x and U of y such that the restriction of f is an isomorphism $V \simeq U$ (**I**, 6.5.4).

By the preceding paragraph we may moreover arrange that $f^{-1}(U) = V$. It follows immediately **III** | 136
that $V \subset X'$, which completes the proof. □

The following proposition was proved by Chevalley for algebraic schemes.

Proposition (4.4.2). — *Let Y be a locally Noetherian prescheme and let $f : X \to Y$ be a morphism. The following conditions are equivalent:*

a) *f is finite;*
b) *f is affine and proper;*
c) *f is proper and, for every $y \in Y$, the set $f^{-1}(y)$ is finite.*

Proof. Condition a) implies b) by (**II**, 6.1.2) and (**II**, 6.1.11). If f is proper and affine, then so is

$$f^{-1}(y) \longrightarrow \operatorname{Spec}(k(y))$$

(**II**, 1.6.2), (**II**, 5.4.2). The finiteness theorem (3.2.1), applied to the structural sheaf of $f^{-1}(y)$, shows that $f^{-1}(y) = \operatorname{Spec}(A)$ for a finite $k(y)$-algebra A. Thus $f^{-1}(y)$ is a finite set (**II**, 6.1.7), and b) implies c).

Finally, if c) holds, the fibre $f^{-1}(y)$ is an algebraic prescheme over $k(y)$ whose underlying set is finite, and is therefore discrete (**I**, 6.4.4). With the notation of (4.4.1), we have $X' = X$, so $f' : X \to Y'$ is an isomorphism. Since g is finite, c) implies a). □

Theorem (4.4.3). — (Zariski's "main theorem"). *Let Y be a Noetherian prescheme, let $f : X \to Y$ be a quasi-projective morphism, and let X' be the set of points $x \in X$ that are isolated in their fibre $f^{-1}(f(x))$. Then X' is open in X, and the subprescheme induced by X on X' is isomorphic to a subprescheme induced on an open subset of a Y-prescheme Y' finite over Y.*

Proof. There is a projective Y-prescheme Z such that X is Y-isomorphic to the subprescheme induced on an open subset of Z (**II**, 5.3.2), (**II**, 5.5.1). We are thus reduced to the case where f is projective, hence proper (**II**, 5.5.3), and the theorem follows immediately from (4.4.1). □

Remark (4.4.4). — If X is reduced (respectively, if X is irreducible and X' is nonempty), one may require in (4.4.3) that Y' be reduced (respectively, irreducible). Indeed, Y' may be replaced by the schematic closure $\overline{X'}$ of X' in Y' (**I**, 9.5.11), (**II**, 6.1.5). If X' is reduced, so is $\overline{X'}$ (**I**, 9.5.9); if X' is nonempty and irreducible, then $\overline{X'}$ is irreducible as well.

Corollary (4.4.5). — *Let Y be a locally Noetherian scheme, let $f : X \to Y$ be a morphism of finite type, and let x be a point of X isolated in its fibre $f^{-1}(f(x))$. Then there is an open neighbourhood of x in X which is isomorphic to an open subset of a Y-prescheme finite over Y.*

Proof. Set $y = f(x)$, let U be an affine open neighbourhood of y in Y, and let V be an affine open neighbourhood of x in X, contained in $f^{-1}(U)$. Since Y is separated, the inclusion $U \to Y$ is affine (**II**, 1.6.3); and since V is affine over U (*ibid.*), the restriction of f to V is an affine morphism $V \to Y$ (**II**, 1.6.2). A fortiori, this restriction is quasi-projective, since it is of finite type (**I**, 6.3.5), (**II**, 5.3.4). It remains only to apply (4.4.3) to this restriction. □

Corollary (4.4.5) may be stated in the language of commutative algebra as follows.

Corollary (4.4.6). — *Let A be a Noetherian ring, let B be an A-algebra of finite type, let $\mathfrak{q}$ be a prime ideal of B, and let $\mathfrak{p}$ be its inverse image in A. Suppose that $\mathfrak{q}$ is both maximal and minimal in the set of prime ideals of B whose inverse image is $\mathfrak{p}$. Then there exist an element $g \in B - \mathfrak{q}$, a finite A-algebra A', and an element $f' \in A'$ such that the A-algebras B_g and $A'_{f'}$ are isomorphic.*

Proof. Apply (4.4.5) to $Y = \operatorname{Spec}(A)$ and $X = \operatorname{Spec}(B)$. The hypothesis on $\mathfrak{q}$ says precisely that $\mathfrak{q}$ is isolated in its fibre (**I**, 1.1.7). □

The following consequence appears less general.

III | 137

Corollary (4.4.7). — *Let A be a Noetherian local ring, let B be an A-algebra of finite type, and let $\mathfrak{n}$ be a prime ideal of B whose inverse image in A is the maximal ideal $\mathfrak{m}$. Suppose that $\mathfrak{n}$ is maximal in B and minimal in the set of prime ideals of B whose inverse image is $\mathfrak{m}$ (which also means that $\mathfrak{m}B$ is $\mathfrak{n}$-primary). Then there exist a finite A-algebra A' and a maximal ideal $\mathfrak{m}'$ of A' (whose inverse image in A is $\mathfrak{m}$) such that $B_{\mathfrak{n}}$ is isomorphic, as an A-algebra, to $A'_{\mathfrak{m}'}$.*

The following special case of (4.4.7) is also sometimes called the "main theorem".

Corollary (4.4.8). — *Under the hypotheses of (4.4.7), suppose moreover that A and B are integral domains with the same field of fractions K. If A is integrally closed, then $A = B$.*

Proof. Remark (4.4.4) shows that, in applying (4.4.7), we may suppose that A' is an integral domain with field of fractions K. The hypothesis on A then gives $A' = A$, hence $B_{\mathfrak{n}} = A$. Since $A \subset B \subset B_{\mathfrak{n}}$, it follows that $A = B$. □

Statement (4.4.8) is the form in which Zariski gave his "main theorem" (extended here to arbitrary Noetherian integral local rings).

The preceding corollaries were local variants of (4.4.3), which is a global result. Here is another consequence of a global nature.

Corollary (4.4.9). — *Let Y be an integral locally Noetherian prescheme, and let $f : X \to Y$ be a separated morphism of finite type which is birational. Suppose moreover that Y is normal and that every fibre $f^{-1}(y)$, for $y \in Y$, is finite. Then f is an open immersion. If in addition f is closed (in particular, if f is proper), then f is an isomorphism.*

Proof. Let $x \in X$ and put $y = f(x)$. Since $f^{-1}(y)$ is a scheme algebraic over $k(y)$, the assumption that it is finite implies that it is discrete (**I**, 6.4.4). Moreover, $\mathscr{O}_y$ is integrally closed, and $\mathscr{O}_x$ and $\mathscr{O}_y$ have the same field of fractions (**I**, 7.1.5). We may therefore apply (4.4.8); if $f = (\psi, \theta)$, the homomorphism

$$\theta_y^\# : \mathscr{O}_y \longrightarrow \mathscr{O}_x$$

is bijective. It follows from (**I**, 6.5.4) that f is a local isomorphism. Since f is separated and X is integral, f is an open immersion (**I**, 8.2.8). The last assertion follows from the fact that f is dominant. □

Proposition (4.4.10). — *Let Y be a locally Noetherian prescheme, and let $f : X \to Y$ be a morphism locally of finite type. The set X' of points $x \in X$ which are isolated in their fibre $f^{-1}(f(x))$ is open in X.*

Proof. The question is local on X and Y, so we may suppose that X and Y are affine Noetherian and that f is of finite type. The morphism f is then affine and of finite type, hence quasi-projective (**II**, 5.3.4); it suffices to apply (4.4.3). □

III | 138

Corollary (4.4.11). — *Let Y be a locally Noetherian prescheme, and let $f : X \to Y$ be a proper morphism. The set U of points $y \in Y$ for which $f^{-1}(y)$ is discrete is open in Y, and the restricted morphism $f^{-1}(U) \to U$ is finite. In particular, every proper quasi-finite morphism $X \to Y$ is finite.*

Proof. The complement of U in Y is the image under f of $X - X'$, which is closed in X by (4.4.10); since f is a closed map, U is open. Furthermore, (**II**, 6.2.2) shows that $f^{-1}(y)$ is finite for every $y \in U$. Since the restricted morphism $f^{-1}(U) \to U$ is proper (**II**, 5.4.1), it is finite by (4.4.2). □

Remark (4.4.12). — *(i)* As announced in (**II**, 6.2.7), we shall show in Chapter V that if Y is locally Noetherian, every separated quasi-finite morphism $f : X \to Y$ is quasi-affine, hence quasi-projective. It will follow that the conclusion of the main theorem (4.4.3) remains valid when f is assumed only to be separated and of finite type. Indeed, (4.4.10) shows that X' is open in X; and since X is locally Noetherian, the restriction of f to X' is still of finite type (**I**, 6.3.5), hence quasi-finite by the definition of X', and clearly separated. We may therefore apply (4.4.3) to this restriction.

(ii) In Chapter IV we shall give a more elementary proof of (4.4.10), using dimension theory.

4.5. Completions of modules of homomorphisms

Proposition (4.5.1). — *Let A be a Noetherian ring, let $\mathfrak{J}$ be an ideal of A, let X be an A-prescheme of finite type, and let $\mathscr{F}$ and $\mathscr{G}$ be two coherent $\mathscr{O}_X$-modules whose supports have proper intersection over $Y = \operatorname{Spec}(A)$ (**II**, 5.4.10). Then, for every integer $n \geqslant 0$,*

$$\operatorname{Ext}^n_{\mathscr{O}_X}(X; \mathscr{F}, \mathscr{G})$$

is a finite A-module, and its separated completion for the $\mathfrak{J}$-preadic topology is canonically identified, with the notation of (4.1.7), with

$$\operatorname{Ext}^n_{\mathscr{O}_{\widehat{X}}}(\widehat{X}; \widehat{\mathscr{F}}, \widehat{\mathscr{G}}).$$

Proof. We know from (T, 4.2) that there is a biregular spectral sequence $\mathrm{E}(\mathscr{F}, \mathscr{G})$ whose abutment is

$$\operatorname{Ext}_{\mathscr{O}_X}(X; \mathscr{F}, \mathscr{G})$$

and whose E_2-terms are

$$\mathrm{E}_2^{pq} = \mathrm{H}^p\big(X, \mathscr{E}xt^q_{\mathscr{O}_X}(\mathscr{F}, \mathscr{G})\big).$$

The $\mathscr{O}_X$-module $\mathscr{E}xt^q_{\mathscr{O}_X}(\mathscr{F}, \mathscr{G})$ is coherent (**0**, 12.3.3); its support is contained in the intersection of the supports of $\mathscr{F}$ and $\mathscr{G}$ (T, 4.2.2), and is consequently proper over Y (**II**, 5.4.10). It follows from (3.2.4) that the E_2^{pq} are finite A-modules, and then from (**0**, 11.1.8) that the same is true of every term E_r^{pq} of the spectral sequence and of its abutment.

On the other hand, if $i : \widehat{X} \to X$ is the canonical morphism, then $\widehat{\mathscr{F}}$ and $\widehat{\mathscr{G}}$ are canonically identified with $i^*(\mathscr{F})$ and $i^*(\mathscr{G})$, and i is flat (**I**, 10.8.8), (**I**, 10.8.9). For every $q \geqslant 0$ there is therefore a canonical i-morphism

$$u_q : \mathscr{E}xt^q_{\mathscr{O}_X}(\mathscr{F}, \mathscr{G}) \longrightarrow \mathscr{E}xt^q_{\mathscr{O}_{\widehat{X}}}(\widehat{\mathscr{F}}, \widehat{\mathscr{G}})$$

(**0**, 12.3.4), and the corresponding $\mathscr{O}_{\widehat{X}}$-homomorphism

$$u_q^\# : i^*\big(\mathscr{E}xt^q_{\mathscr{O}_X}(\mathscr{F},\mathscr{G})\big) \longrightarrow \mathscr{E}xt^q_{\mathscr{O}_{\widehat{X}}}(\widehat{\mathscr{F}},\widehat{\mathscr{G}})$$

is an isomorphism (**0**, 12.3.5). In other words, (**I**, 10.8.8) identifies

$$\mathscr{E}xt^q_{\mathscr{O}_{\widehat{X}}}(\widehat{\mathscr{F}},\widehat{\mathscr{G}})$$

canonically with the completion of $\mathscr{E}xt^q_{\mathscr{O}_X}(\mathscr{F},\mathscr{G})$, in the notation of (4.1.7).

The comparison theorem (4.1.10) now shows, for every $p \geqslant 0$, that

$$\mathrm{H}^p\big(\widehat{X}, \mathscr{E}xt^q_{\mathscr{O}_{\widehat{X}}}(\widehat{\mathscr{F}},\widehat{\mathscr{G}})\big)$$

is canonically identified with the separated completion, for the $\mathfrak{J}$-preadic topology, of

$$\mathrm{H}^p\big(X, \mathscr{E}xt^q_{\mathscr{O}_X}(\mathscr{F},\mathscr{G})\big).$$

Let $\mathrm{E}(\widehat{\mathscr{F}},\widehat{\mathscr{G}})$ denote the biregular spectral sequence of (T, 4.2) associated with $\widehat{\mathscr{F}}$ and $\widehat{\mathscr{G}}$. If $\widehat{A}$ is the separated completion of A for the $\mathfrak{J}$-preadic topology, then, up to canonical isomorphism, **III** | 139

$$\mathrm{E}_2^{pq}(\widehat{\mathscr{F}},\widehat{\mathscr{G}}) = \mathrm{E}_2^{pq}(\mathscr{F},\mathscr{G}) \otimes_A \widehat{A}$$

(**0**, 7.3.3).

The flat morphism i defines a canonical homomorphism of spectral sequences

$$\varphi : \mathrm{E}(\mathscr{F},\mathscr{G}) \longrightarrow \mathrm{E}(\widehat{\mathscr{F}},\widehat{\mathscr{G}}) = \mathrm{E}(i^*(\mathscr{F}), i^*(\mathscr{G})).$$

On the E_2-terms and on the abutment, respectively, this is the homomorphism

$$\varphi_2^{pq} : \mathrm{H}^p\big(X, \mathscr{E}xt^q_{\mathscr{O}_X}(\mathscr{F},\mathscr{G})\big) \longrightarrow \mathrm{H}^p\big(\widehat{X}, \mathscr{E}xt^q_{\mathscr{O}_{\widehat{X}}}(\widehat{\mathscr{F}},\widehat{\mathscr{G}})\big)$$

and the homomorphism

$$\varphi^n : \mathrm{Ext}^n_{\mathscr{O}_X}(X; \mathscr{F},\mathscr{G}) \longrightarrow \mathrm{Ext}^n_{\mathscr{O}_{\widehat{X}}}(\widehat{X}; \widehat{\mathscr{F}},\widehat{\mathscr{G}}),$$

deduced from u_q and u_0, respectively, by functoriality (**0**, 12.3.4).

After tensoring with $\widehat{A}$, the φ_r^{pq} and φ^n give homomorphisms of $\widehat{A}$-modules

$$\psi_r^{pq} : \mathrm{E}_r^{pq}(\mathscr{F},\mathscr{G}) \otimes_A \widehat{A} \longrightarrow \mathrm{E}_r^{pq}(\widehat{\mathscr{F}},\widehat{\mathscr{G}})$$

and

$$\psi^n : \mathrm{Ext}^n_{\mathscr{O}_X}(X; \mathscr{F},\mathscr{G}) \otimes_A \widehat{A} \longrightarrow \mathrm{Ext}^n_{\mathscr{O}_{\widehat{X}}}(\widehat{X}; \widehat{\mathscr{F}},\widehat{\mathscr{G}}).$$

Since $\widehat{A}$ is a flat A-module (**0**, 7.3.3), the $\widehat{A}$-modules

$$\mathrm{E}_r^{pq}(\mathscr{F},\mathscr{G}) \otimes_A \widehat{A}$$

form a biregular spectral sequence with abutment

$$\mathrm{Ext}^n_{\mathscr{O}_X}(X; \mathscr{F},\mathscr{G}) \otimes_A \widehat{A},$$

and the ψ_r^{pq} and ψ^n form a morphism of spectral sequences. Since the ψ_2^{pq} are isomorphisms, the same is true of the ψ^n (**0**, 11.1.5). □

Corollary (4.5.2). — *Under the hypotheses of* (4.5.1), *suppose in addition that A is a Noetherian $\mathfrak{J}$-adic ring. Then, for every integer $n \geqslant 0$,*

$$\mathrm{Ext}^n_{\mathscr{O}_X}(X; \mathscr{F},\mathscr{G}) \simeq \mathrm{Ext}^n_{\mathscr{O}_{\widehat{X}}}(\widehat{X}; \widehat{\mathscr{F}},\widehat{\mathscr{G}})$$

canonically.

Proof. The finite A-module $\mathrm{Ext}^n_{\mathscr{O}_X}(X; \mathscr{F},\mathscr{G})$ is separated and complete for the $\mathfrak{J}$-preadic topology (**0**, 7.3.6). □

The special case $n = 0$ of (4.5.1) may be stated as follows.

Corollary (4.5.3). — *Under the hypotheses of (4.5.1), for every homomorphism $u : \mathscr{F} \to \mathscr{G}$ let $\widehat{u} : \widehat{\mathscr{F}} \to \widehat{\mathscr{G}}$ denote the completed homomorphism (**I**, 10.8.4). There is a canonical isomorphism*

(4.5.3.1) $$\big(\mathrm{Hom}_{\mathscr{O}_X}(\mathscr{F},\mathscr{G})\big)^{\wedge} \simeq \mathrm{Hom}_{\mathscr{O}_{\widehat{X}}}(\widehat{\mathscr{F}},\widehat{\mathscr{G}}),$$

where the left-hand side is the separated completion, for the $\mathfrak{J}$-preadic topology, of the A-module $\mathrm{Hom}_{\mathscr{O}_X}(\mathscr{F},\mathscr{G})$. This isomorphism is obtained by passing to separated completions in the homomorphism $u \mapsto \widehat{u}$.

4.6. Relations between formal morphisms and ordinary morphisms

Proposition (4.6.1). — *Let Y be a locally Noetherian prescheme, let $f : X \to Y$ be a proper morphism, let $\mathscr{F}$ be a coherent $\mathscr{O}_X$-module which is flat over Y, and let $y \in Y$. Suppose that, for some integer n,*

$$\mathrm{H}^n\big(f^{-1}(y), \mathscr{F} \otimes_{\mathscr{O}_Y} k(y)\big) = 0.$$

Then there is a neighbourhood U of y in Y such that

$$\mathrm{R}^n f_*(\mathscr{F})|U = 0,$$

and, for every integer $p \geqslant 0$, the canonical homomorphism

$$\big(\mathrm{R}^{n-1} f_*(\mathscr{F})\big)_y \longrightarrow \mathrm{H}^{n-1}\big(f^{-1}(y), \mathscr{F} \otimes_{\mathscr{O}_Y} (\mathscr{O}_y/\mathfrak{m}_y^{p+1})\big)$$

(4.2.1.1) *is surjective.*

Proof. The $\mathscr{O}_Y$-module $\mathrm{R}^n f_*(\mathscr{F})$ is coherent (3.2.1); hence the first assertion will follow once we prove

$$\big(\mathrm{R}^n f_*(\mathscr{F})\big)_y = 0$$

(**0**, 5.2.2). By (4.2.1), it is enough to prove that

$$\mathrm{H}^n\big(f^{-1}(y), \mathscr{F} \otimes_{\mathscr{O}_Y} (\mathscr{O}_y/\mathfrak{m}_y^{p+1})\big) = 0$$

for every p. This is true by hypothesis for $p = 0$; we proceed by induction on p.

Put

$$X_p = X \times_Y \mathrm{Spec}(\mathscr{O}_y/\mathfrak{m}_y^{p+1}).$$

Then X_{p-1} is a closed subprescheme of X_p with the same underlying space (**I**, 3.6.1). The induction hypothesis

$$\mathrm{H}^n\big(X_{p-1}, \mathscr{F} \otimes_{\mathscr{O}_Y} (\mathscr{O}_y/\mathfrak{m}_y^{p})\big) = 0$$

therefore gives

$$\mathrm{H}^n\big(X_p, \mathscr{F} \otimes_{\mathscr{O}_Y} (\mathscr{O}_y/\mathfrak{m}_y^{p})\big) = 0.$$

On the other hand, the exact sequence of $\mathscr{O}_{X_p}$-modules

$$0 \longrightarrow \mathfrak{m}_y^p\mathscr{F}/\mathfrak{m}_y^{p+1}\mathscr{F} \longrightarrow \mathscr{F}/\mathfrak{m}_y^{p+1}\mathscr{F} \longrightarrow \mathscr{F}/\mathfrak{m}_y^{p}\mathscr{F} \longrightarrow 0$$

gives the exact cohomology sequence

$$\mathrm{H}^n\big(X_p, \mathfrak{m}_y^p\mathscr{F}/\mathfrak{m}_y^{p+1}\mathscr{F}\big) \longrightarrow \mathrm{H}^n\big(X_p, \mathscr{F}/\mathfrak{m}_y^{p+1}\mathscr{F}\big) \longrightarrow \mathrm{H}^n\big(X_p, \mathscr{F}/\mathfrak{m}_y^{p}\mathscr{F}\big).$$

It is thus enough to show that

(4.6.1.1) $$\mathrm{H}^n\big(X_p, \mathfrak{m}_y^p\mathscr{F}/\mathfrak{m}_y^{p+1}\mathscr{F}\big) = 0.$$

Indeed, the middle term will then be a submodule of the last term, which is zero by the induction hypothesis.

The fibre **III | 140**

$$Z = f^{-1}(y) = X \times_Y \mathrm{Spec}(k(y))$$

is a closed subprescheme of X_p, and $\mathfrak{m}_y^p\mathscr{F}/\mathfrak{m}_y^{p+1}\mathscr{F}$ is annihilated by $\mathfrak{m}_y$. It may therefore be regarded as an $\mathscr{O}_Z$-module, and

$$\mathrm{H}^n\big(Z, \mathfrak{m}_y^p\mathscr{F}/\mathfrak{m}_y^{p+1}\mathscr{F}\big) = \mathrm{H}^n\big(X_p, \mathfrak{m}_y^p\mathscr{F}/\mathfrak{m}_y^{p+1}\mathscr{F}\big).$$

We shall now prove that the canonical $\mathscr{O}_Z$-homomorphism

(4.6.1.2) $$(\mathscr{F}/\mathfrak{m}_y\mathscr{F}) \otimes_{k(y)} (\mathfrak{m}_y^p/\mathfrak{m}_y^{p+1}) \longrightarrow \mathfrak{m}_y^p\mathscr{F}/\mathfrak{m}_y^{p+1}\mathscr{F}$$

is bijective. Once this is established, the fact that $\mathfrak{m}_y^p/\mathfrak{m}_y^{p+1}$ is a free $k(y)$-module gives

$$\begin{aligned} \mathrm{H}^n\left(\mathrm{Z}, \mathfrak{m}_y^p\mathscr{F}/\mathfrak{m}_y^{p+1}\mathscr{F}\right) &= \mathrm{H}^n\left(\mathrm{Z}, \mathscr{F}/\mathfrak{m}_y\mathscr{F}\right) \otimes_{k(y)} \left(\mathfrak{m}_y^p/\mathfrak{m}_y^{p+1}\right) \\ &= 0 \end{aligned}$$

(**0**, 12.2.3), since $\mathrm{H}^n(\mathrm{Z}, \mathscr{F}/\mathfrak{m}_y\mathscr{F}) = 0$ by hypothesis. This proves (4.6.1.1).

To finish the proof of the first assertion it remains only to show that (4.6.1.2) is bijective. The question is pointwise on X, and $\mathscr{F}_x$ is a flat $\mathscr{O}_y$-module by hypothesis for every $x \in f^{-1}(y)$. It is therefore enough to apply (**0**, 10.2.1), c), since $\mathscr{F}_x/\mathfrak{m}_y\mathscr{F}_x$ is flat over the field $k(y) = \mathscr{O}_y/\mathfrak{m}_y$.

For the second assertion of (4.6.1), we reduce at once, as in (4.2.1), to the case in which Y is affine and y is closed. The same argument shows, for every $k > 0$, that

$$\mathrm{H}^n\left(\mathrm{X}_{k+1}, \mathfrak{m}_y^k\mathscr{F}/\mathfrak{m}_y^{k+p+1}\mathscr{F}\right) = 0. \tag{4.6.1.3}$$

It follows from (4.2.1) that **III** | 141

$$\left(\mathrm{R}^n f_*(\mathfrak{m}_y^k\mathscr{F})\right)_y = 0. \tag{4.6.1.4}$$

The exact cohomology sequence now yields the exactness of

$$\left(\mathrm{R}^{n-1} f_*(\mathscr{F})\right)_y \longrightarrow \left(\mathrm{R}^{n-1} f_*(\mathscr{F}/\mathfrak{m}_y^p\mathscr{F})\right)_y \longrightarrow \left(\mathrm{R}^n f_*(\mathfrak{m}_y^p\mathscr{F})\right)_y = 0.$$

Since y is closed and Y is affine, we have (1.4.11)

$$\mathrm{R}^{n-1} f_*(\mathscr{F}/\mathfrak{m}_y^p\mathscr{F}) = \left(\mathrm{H}^{n-1}(\mathrm{X}, \mathscr{F}/\mathfrak{m}_y^p\mathscr{F})\right)^\sim = \left(\mathrm{H}^{n-1}(f^{-1}(y), \mathscr{F}/\mathfrak{m}_y^p\mathscr{F})\right)^\sim$$

(G, II, 4.9.1). The module

$$\mathrm{H}^{n-1}(f^{-1}(y), \mathscr{F}/\mathfrak{m}_y^p\mathscr{F})$$

is an $\mathscr{O}_y/\mathfrak{m}_y^p$-module, and hence

$$\left(\mathrm{R}^{n-1} f_*(\mathscr{F}/\mathfrak{m}_y^p\mathscr{F})\right)_y = \mathrm{H}^{n-1}(f^{-1}(y), \mathscr{F}/\mathfrak{m}_y^p\mathscr{F}).$$

This completes the proof. □

Corollary (4.6.2). — *Let Y be a locally Noetherian prescheme, let $f : X \to Y$ be a proper flat morphism, let $\mathscr{F}$ and $\mathscr{G}$ be two locally free $\mathscr{O}_X$-modules, and let y be a point of Y. Put*

$$\mathrm{X}_y = f^{-1}(y) = \mathrm{X} \times_\mathrm{Y} \operatorname{Spec}(k(y)), \qquad \mathscr{F}_y = \mathscr{F} \otimes_{\mathscr{O}_\mathrm{Y}} k(y), \qquad \mathscr{G}_y = \mathscr{G} \otimes_{\mathscr{O}_\mathrm{Y}} k(y),$$

and suppose that

$$\mathrm{H}^1\left(\mathrm{X}_y, \mathscr{H}om_{\mathscr{O}_{\mathrm{X}_y}}(\mathscr{F}_y, \mathscr{G}_y)\right) = 0. \tag{4.6.2.1}$$

Then, for every homomorphism $u_0 : \mathscr{F}_y \to \mathscr{G}_y$, there exist an open neighbourhood U of y in Y and a homomorphism

$$u : \mathscr{F}|_{f^{-1}(U)} \longrightarrow \mathscr{G}|_{f^{-1}(U)}$$

such that $u_0 = u \otimes 1$.

Proof. The hypothesis permits us to apply (4.6.1), with $n = 1$ and $p = 0$, to the coherent $\mathscr{O}_X$-module

$$\mathscr{H} = \mathscr{H}om_{\mathscr{O}_\mathrm{X}}(\mathscr{F}, \mathscr{G}).$$

Indeed, $\mathscr{H}$ is locally free and hence, a fortiori, flat over Y, while the $\mathscr{O}_{\mathrm{X}_y}$-module $\mathscr{H} \otimes_{\mathscr{O}_\mathrm{Y}} k(y)$ identifies with $\mathscr{H}om_{\mathscr{O}_{\mathrm{X}_y}}(\mathscr{F}_y, \mathscr{G}_y)$ (**0**, 6.2.2). We may suppose that $Y = \operatorname{Spec}(A)$ is affine. Then (1.4.11) gives

$$\mathrm{R}^0 f_*(\mathscr{H}) = \left(\operatorname{Hom}_{\mathscr{O}_\mathrm{X}}(\mathscr{F}, \mathscr{G})\right)^\sim,$$

and consequently

$$\left(\mathrm{R}^0 f_*(\mathscr{H})\right)_y = \operatorname{Hom}_{\mathscr{O}_\mathrm{X}}(\mathscr{F}, \mathscr{G}) \otimes_A \mathscr{O}_y.$$

By (4.6.1), the canonical homomorphism

$$\operatorname{Hom}_{\mathscr{O}_\mathrm{X}}(\mathscr{F}, \mathscr{G}) \otimes_A \mathscr{O}_y \longrightarrow \operatorname{Hom}_{\mathscr{O}_{\mathrm{X}_y}}(\mathscr{F}_y, \mathscr{G}_y)$$

is surjective. This proves the corollary, since every element of the module on the left may be written as $u \otimes (1/s)$, where $s \in A \setminus \mathfrak{m}_y$. □

Corollary (4.6.3). — *Under the hypotheses of (4.6.2), if u_0 is injective (respectively surjective, bijective), one may choose u to be injective (respectively surjective, bijective).*

Proof. We may restrict ourselves to the case $U = Y$. It is enough to prove that, if u_0 is injective (respectively surjective), then

$$\operatorname{Ker} u_x = 0 \quad (\text{respectively } \operatorname{Coker} u_x = 0)$$

for every $x \in f^{-1}(y)$. Indeed, $\operatorname{Ker} u$ and $\operatorname{Coker} u$ are coherent $\mathscr{O}_X$-modules (**0**, 5.3.4); hence there is a neighbourhood V of $f^{-1}(y)$ in X on which the restriction of $\operatorname{Ker} u$ (respectively $\operatorname{Coker} u$) is zero (**0**, 5.2.2). Since f is closed, there is an open neighbourhood $U' \subset U$ of y such that $f^{-1}(U') \subset V$, which proves the assertion after replacing U by U'.

By hypothesis, **III** | 142

$$u_x \otimes 1 : \mathscr{F}_x \otimes_{\mathscr{O}_y} k(y) \longrightarrow \mathscr{G}_x \otimes_{\mathscr{O}_y} k(y)$$

is injective (respectively surjective), $\mathscr{F}_x$ and $\mathscr{G}_x$ are finite free $\mathscr{O}_x$-modules, and $\mathscr{O}_x$ is flat over $\mathscr{O}_y$. If $u_x \otimes 1$ is injective, the injectivity of u_x follows from (**0**, 10.2.4). If $u_x \otimes 1$ is surjective, then, a fortiori, the induced homomorphism

$$\mathscr{F}_x / \mathfrak{m}_x \mathscr{F}_x \longrightarrow \mathscr{G}_x / \mathfrak{m}_x \mathscr{G}_x$$

is surjective. Since $\mathscr{G}_x$ is a finite $\mathscr{O}_x$-module and $\mathscr{O}_x$ is a local ring with maximal ideal $\mathfrak{m}_x$, the conclusion follows from Nakayama's lemma (Bourbaki, *Algèbre*, chap. VIII, §6, no. 3, cor. 4 to prop. 6). □

Corollary (4.6.4). — *Let Y be a locally Noetherian prescheme, let $f : X \to Y$ be a proper flat morphism, let y be a point of Y, and put $X_y = X \times_Y \operatorname{Spec}(k(y))$. Let $\mathscr{E}_0$ be a locally free $\mathscr{O}_{X_y}$-module such that*

(4.6.4.1) $$\mathrm{H}^1\big(X_y, \mathscr{H}om_{\mathscr{O}_{X_y}}(\mathscr{E}_0, \mathscr{E}_0)\big) = 0.$$

Let $\mathscr{F}$ and $\mathscr{G}$ be two locally free $\mathscr{O}_X$-modules such that $\mathscr{F}_y$ and $\mathscr{G}_y$, with the notation of (4.6.2), are isomorphic to $\mathscr{E}_0$. Then there is an open neighbourhood U of y such that $\mathscr{F}|_{f^{-1}(U)}$ and $\mathscr{G}|_{f^{-1}(U)}$ are isomorphic.

Corollary (4.6.5). — *Under the hypotheses of (4.6.4) on f, X, and Y, suppose that*

$$\mathrm{H}^1(X_y, \mathscr{O}_{X_y}) = 0.$$

If $\mathscr{F}$ and $\mathscr{G}$ are two invertible $\mathscr{O}_X$-modules such that $\mathscr{F}_y$ and $\mathscr{G}_y$ are isomorphic, then there is an open neighbourhood U of y such that $\mathscr{F}|_{f^{-1}(U)}$ and $\mathscr{G}|_{f^{-1}(U)}$ are isomorphic.

Proof. It is enough to apply (4.6.4) to the modules $\mathscr{F}^{-1} \otimes \mathscr{G}$ and $\mathscr{O}_X$. □

Remarks (4.6.6). —
(i) Using (4.6.5), we shall establish in Chapter V the classification of invertible sheaves on a projective bundle announced in (**II**, 4.2.7).
(ii) The result of (4.6.1) will appear in §7 as a consequence of more general propositions.

Proposition (4.6.7). — *Let Z be a locally Noetherian prescheme, and let X and Y be two Z-preschemes whose structural morphisms*

$$g : X \longrightarrow Z, \qquad h : Y \longrightarrow Z$$

are proper. Let $f : X \to Y$ be a Z-morphism, let z be a point of Z, and put

$$f_z = f \times_Z 1 : X \times_Z \operatorname{Spec}(k(z)) \longrightarrow Y \times_Z \operatorname{Spec}(k(z)).$$

(i) If f_z is finite (respectively a closed immersion), there is an open neighbourhood U of z such that the morphism

$$g^{-1}(U) \longrightarrow h^{-1}(U)$$

induced by f is finite (respectively a closed immersion).

(ii) Suppose in addition that g is flat. If f_z is an isomorphism, there is an open neighbourhood U of z such that the morphism $g^{-1}(U) \to h^{-1}(U)$ induced by f is an isomorphism.

Proof. In either case it is enough to prove that, for every $y \in h^{-1}(z)$, there is a neighbourhood V_y of y such that the restriction

$$f^{-1}(V_y) \longrightarrow V_y$$

of f is finite (respectively a closed immersion, an isomorphism). Indeed, if V is the union of the V_y, then $f^{-1}(V) \to V$ is finite (respectively a closed immersion, an isomorphism) (**II**, 6.1.1), (**I**, 4.2.4). Since h is closed, there is an open neighbourhood U of z such that $h^{-1}(U) \subset V$, and the proposition follows.

(i) First note that f is proper (**II**, 5.4.3). If f_z is finite, the required neighbourhood V_y, for each $y \in h^{-1}(z)$, exists by (4.4.11).

To treat the case in which f_z is a closed immersion, we may therefore already suppose that f is finite. Thus $X = \operatorname{Spec}(\mathscr{B})$, where $\mathscr{B}$ is a coherent $\mathscr{O}_Y$-algebra, and f corresponds (**II**, 1.2.7) to the canonical homomorphism **III | 143**

$$u : \mathscr{O}_Y \longrightarrow \mathscr{B}.$$

If, for every $y \in h^{-1}(z)$, the homomorphism $u_y : \mathscr{O}_y \to \mathscr{B}_y$ is surjective, then u is surjective on some neighbourhood V_y of y, since $\operatorname{Coker} u$ is coherent (**0**, 5.3.4), (**0**, 5.2.2). Now the finite morphism f_z corresponds to

$$v = u \otimes 1 : \mathscr{O}_Y \otimes_{\mathscr{O}_Z} k(z) \longrightarrow \mathscr{B} \otimes_{\mathscr{O}_Z} k(z),$$

and the hypothesis that f_z is a closed immersion implies that

$$u_y \otimes 1 : \mathscr{O}_y \otimes_{\mathscr{O}_z} k(z) \longrightarrow \mathscr{B}_y \otimes_{\mathscr{O}_z} k(z)$$

is surjective. Since $\mathscr{B}_y$ is a finite $\mathscr{O}_y$-module and $\mathscr{O}_y$ is a local Noetherian ring, the conclusion follows, as in (4.6.3), from Nakayama's lemma.

(ii) The same reasoning shows that it is now enough to prove that u_y is bijective, knowing that $u_y \otimes 1$ is bijective. The required injectivity follows from the lemma below; surjectivity follows from the preceding argument. □

Lemma (4.6.7.1). — *Let A and B be local Noetherian rings, let $\rho : A \to B$ be a local homomorphism, and let $u : N \to M$ be a homomorphism of B-modules. Suppose that M is flat over A, that N is a finite B-module, and that*

$$u \otimes 1 : N \otimes_A k \longrightarrow M \otimes_A k,$$

where k is the residue field of A, is injective. Then N is flat over A and u is injective.

Proof. To prove the first assertion, we must show that, for every pair of finite A-modules P, Q and every injective A-homomorphism $v : P \to Q$, the homomorphism

$$1_N \otimes v : N \otimes_A P \longrightarrow N \otimes_A Q$$

is injective. Consider the commutative diagram

$$\begin{tikzcd} N \otimes_A P \arrow[r, "1_N\otimes v"] \arrow[d, "u\otimes 1_P"'] & N \otimes_A Q \arrow[d, "u\otimes 1_Q"] \\ M \otimes_A P \arrow[r, "1_M\otimes v"'] & M \otimes_A Q. \end{tikzcd}$$

Since $1_M \otimes v$ is injective by the flatness of M, it is enough to prove that $u \otimes 1_P$ is injective.

Let $\mathfrak{m}$ be the maximal ideal of A. The $\mathfrak{m}$-adic filtration on the A-module $N \otimes_A P$ is also its $\mathfrak{m}B$-adic filtration as a B-module. The topology defined by this filtration is separated: B is Noetherian, $\mathfrak{m}B$ is contained in the radical of B, and $N \otimes_A P$ is a finite B-module, since N is finite over B and P is finite over A (**0**, 7.3.5). It is therefore enough to prove that

$$\operatorname{gr}(u \otimes 1_P) : \operatorname{gr}_\bullet(N \otimes_A P) \longrightarrow \operatorname{gr}_\bullet(M \otimes_A P)$$

is injective, where the associated graded modules are taken with respect to the $\mathfrak{m}$-adic filtrations (Bourbaki, *Algèbre commutative*, chap. III, § 2, no. 8, cor. 1 to th. 1).

Since M is flat over A, the homomorphisms

$$M \otimes_A (\mathfrak{m}^n P) \longrightarrow \mathfrak{m}^n (M \otimes_A P)$$

are bijective. Consequently the canonical homomorphism

$$\phi_M : \mathrm{gr}_0(M) \otimes_A \mathrm{gr}_\bullet(P) \longrightarrow \mathrm{gr}_\bullet(M \otimes_A P)$$

is bijective.

We have the commutative diagram **III** | 144

$$\begin{tikzcd} \mathrm{gr}_0(N) \otimes_A \mathrm{gr}_\bullet(P) \arrow[r, "\mathrm{gr}_0(u)\otimes 1"] \arrow[d, "\phi_N"'] & \mathrm{gr}_0(M) \otimes_A \mathrm{gr}_\bullet(P) \arrow[d, "\phi_M"] \\ \mathrm{gr}_\bullet(N \otimes_A P) \arrow[r, "\mathrm{gr}(u\otimes 1)"'] & \mathrm{gr}_\bullet(M \otimes_A P). \end{tikzcd}$$

Here ϕ_M is bijective and ϕ_N is surjective. Moreover, $\mathrm{gr}_0(u)$ is injective by hypothesis, and

$$\mathrm{gr}_0(N) \otimes_A \mathrm{gr}_\bullet(P) = \mathrm{gr}_0(N) \otimes_k \mathrm{gr}_\bullet(P),$$
$$\mathrm{gr}_0(M) \otimes_A \mathrm{gr}_\bullet(P) = \mathrm{gr}_0(M) \otimes_k \mathrm{gr}_\bullet(P).$$

Thus $\mathrm{gr}_0(u) \otimes 1$ is also injective. It follows from the diagram that $\mathrm{gr}(u \otimes 1_P)$ is injective, proving the first assertion. The second follows from the same argument by taking $P = A$. $\square$

Proposition (4.6.8). — *Let Z be a locally Noetherian prescheme, and let X and Y be two Z-preschemes whose structural morphisms $g : X \to Z$ and $h : Y \to Z$ are proper. Let Z' be a closed subset of Z, put*

$$X' = g^{-1}(Z'), \qquad Y' = h^{-1}(Z'),$$

and denote by

$$\widehat{X} = X_{/X'}, \qquad \widehat{Y} = Y_{/Y'}, \qquad \widehat{Z} = Z_{/Z'}$$

the formal completions along these closed subsets. Let $f : X \to Y$ be a Z-morphism and let $\widehat{f} : \widehat{X} \to \widehat{Y}$ be its extension to the formal completions. In order that $\widehat{f}$ be an isomorphism (respectively a closed immersion), it is necessary and sufficient that there exist an open neighbourhood U of Z' such that the morphism

$$g^{-1}(U) \longrightarrow h^{-1}(U)$$

induced by f is an isomorphism (respectively a closed immersion).

Proof. The sufficiency of the condition is immediate (**I**, 10.14.7). To prove its necessity, it is enough, by the same reasoning as in (4.6.7), to show that for every $y \in Y'$ there is an open neighbourhood V_y of y such that $f^{-1}(V_y) \to V_y$ is an isomorphism (respectively a closed immersion). We are thus reduced to the case

$$Y = Z = \mathrm{Spec}(A),$$

where A is Noetherian.

By hypothesis (**I**, 10.9.1), (**I**, 10.14.2), the fibre $f^{-1}(y)$ consists of a single point for every $y \in Y'$. Since f is proper (**II**, 5.4.3), (4.4.11) gives an open neighbourhood U of y for which $f^{-1}(U) \to U$ is finite. We may therefore suppose that f is finite, so that

$$X = \mathrm{Spec}(B),$$

where B is a finite A-algebra.

If $Y' = V(\mathfrak{J})$, then

$$\widehat{Y} = \mathrm{Spf}(\widehat{A}), \qquad \widehat{X} = \mathrm{Spf}(\widehat{B}),$$

where $\widehat{A}$ is the separated completion of A for the $\mathfrak{J}$-adic topology, and $\widehat{B}$ is the separated completion of B for the $\mathfrak{J}B$-adic topology, or, equivalently, the separated completion of the A-module B for the $\mathfrak{J}$-adic topology. Furthermore, $\widehat{f}$ corresponds to the continuous extension

$$\widehat{\phi} : \widehat{A} \longrightarrow \widehat{B}$$

of the canonical ring homomorphism $\phi : A \to B$, and the hypothesis is that $\widehat{\phi}$ is surjective (respectively bijective) (**I**, 10.14.2). But $\widehat{\phi}$ is also the continuous extension of ϕ regarded as a homomorphism of A-modules. It follows from (**I**, 10.8.14) that there is an open neighbourhood U of Y' such that the restriction to U of the homomorphism of $\mathscr{O}_Y$-modules

$$\widetilde{\phi} : \widetilde{A} \longrightarrow \widetilde{B}$$

is surjective (respectively bijective), which completes the proof. □

4.7. An ampleness criterion

Theorem (4.7.1). — *Let Y be a locally Noetherian prescheme, let $f : X \to Y$ be a proper morphism, let $\mathscr{L}$ be an invertible $\mathscr{O}_X$-module, and let y be a point of Y. Put*

$$X_y = X \times_Y \operatorname{Spec}(k(y)) = f^{-1}(y),$$

and let $g : X_y \to X$ be the canonical morphism. If

$$\mathscr{L}_y = g^*(\mathscr{L}) = \mathscr{L} \otimes_{\mathscr{O}_Y} k(y)$$

is ample on X_y, then there is an open neighbourhood U of y in Y such that $\mathscr{L}|_{f^{-1}(U)}$ is ample for the restriction of f to $f^{-1}(U)$.

Proof. **III | 145**
I) Put

$$Y' = \operatorname{Spec}(\mathscr{O}_y), \qquad X' = X \times_Y Y', \qquad \mathscr{L}' = \mathscr{L} \otimes_{\mathscr{O}_Y} \mathscr{O}_y.$$

We first prove that $\mathscr{L}'$ is ample for $f' = f_{(Y')}$. We have the commutative diagram

$$\begin{tikzcd} X & X' \arrow[l] \arrow[d, "f'"] & X_y \arrow[l] \arrow[d, "f_y"] \\ Y \arrow[from=u, "f"'] & Y' \arrow[l] & \operatorname{Spec}(k(y)) \arrow[l] \end{tikzcd}$$

Since f' is proper (**II**, 5.4.2), (iii), and $\mathscr{O}_y$ is Noetherian, (**II**, 4.6.6) shows that we may reduce to the case

$$Y = Y' = \operatorname{Spec}(\mathscr{O}_y), \qquad X = X',$$

assume that $\mathscr{L}_y$ is ample for f_y, and prove that $\mathscr{L}$ is ample for f. We apply the criterion (2.6.1), c), and prove that for every coherent $\mathscr{O}_X$-module $\mathscr{F}$ there is an integer N such that

$$\mathrm{H}^1(X, \mathscr{F}(n)) = 0 \quad \text{for all } n \geqslant N, \qquad \mathscr{F}(n) = \mathscr{F} \otimes \mathscr{L}^{\otimes n}.$$

The point y is closed in Y and corresponds to the maximal ideal $\mathfrak{m}$ of $\mathscr{O}_y$. Hence X_y is the closed subprescheme of X defined by the coherent ideal

$$\mathscr{J} = f^*(\widetilde{\mathfrak{m}})\mathscr{O}_X = \mathfrak{m}\mathscr{O}_X$$

(**I**, 4.4.5), and g is its canonical injection. Consider the graded $k(y)$-algebra

$$S = \operatorname{gr}(\mathscr{O}_y) = \bigoplus_{j \geqslant 0} \mathfrak{m}^j / \mathfrak{m}^{j+1}.$$

It is of finite type because $\mathscr{O}_y$ is Noetherian. The $\mathscr{O}_X$-algebra

$$\mathscr{S} = f^*(\widetilde{S})$$

is quasi-coherent and of finite type, and is annihilated by $\mathscr{J}$. Thus, if $\mathscr{S}_y = g^*(\mathscr{S})$, then $\mathscr{S}_y$ is a quasi-coherent $\mathscr{O}_{X_y}$-algebra of finite type and

$$\mathscr{S} = g_*(\mathscr{S}_y).$$

Put

$$\mathscr{M}_j = \mathfrak{m}^j \mathscr{F} / \mathfrak{m}^{j+1} \mathscr{F}, \qquad \mathscr{M} = \bigoplus_{j \geqslant 0} \mathscr{M}_j = \operatorname{gr}(\mathscr{F}).$$

Since $\mathscr{F}$ is coherent, $\mathscr{M}$ is a quasi-coherent $\mathscr{S}$-module of finite type (**0**, 10.1.1); it too is annihilated by $\mathscr{J}$. Consequently, if

$$\mathscr{M}'_j = g^*(\mathscr{M}_j), \qquad \mathscr{M}' = g^*(\mathscr{M}) = \bigoplus_{j \geqslant 0} \mathscr{M}'_j,$$

then $\mathscr{M}'$ is a graded quasi-coherent $\mathscr{S}_y$-module of finite type and $\mathscr{M} = g_*(\mathscr{M}')$. Moreover, on putting

$$\mathscr{M}'_j(n) = \mathscr{M}'_j \otimes \mathscr{L}_y^{\otimes n},$$

we have $\mathscr{M}'_j(n) = g^*(\mathscr{M}_j(n))$.

The morphism f_y is proper (**II**, 5.4.2), (iii), and $\mathscr{L}_y$ is ample; hence f_y is projective (**II**, 5.5.4), (**II**, 4.6.11). We may therefore apply (2.4.1), (ii), to $\operatorname{Spec}(k(y))$, f_y, $\mathscr{S}_y$, $\mathscr{L}_y$, and $\mathscr{M}'$. There is an integer N such that, for $n \geqslant N$,

$$\mathrm{H}^q(X_y, \mathscr{M}'_j(n)) = 0$$

for every $q > 0$ and every j. It follows that

$$\mathrm{H}^q(X, \mathscr{M}_j(n)) = 0$$

for every $q > 0$ and every j (G, II, 4.9.1).

Now put

$$\mathscr{F}(n)_j = \mathscr{F}(n)/\mathfrak{m}^{j+1}\mathscr{F}(n).$$

For $j \geqslant 1$ we have

$$\mathscr{F}(n)_{j-1} = \mathscr{F}(n)_j/\mathscr{M}_j(n), \qquad \mathscr{F}(n)_0 = \mathscr{M}_0(n).$$

Thus $\mathrm{H}^1(X, \mathscr{F}(n)_0) = 0$, and the exact cohomology sequence gives, for every $j \geqslant 1$,

$$\mathrm{H}^1(X, \mathscr{F}(n)_j) = \mathrm{H}^1(X, \mathscr{F}(n)_{j-1}).$$

Hence $\mathrm{H}^1(X, \mathscr{F}(n)_j) = 0$ for every $j \geqslant 0$. By (4.2.1), it follows that

$$\mathrm{H}^1(X, \mathscr{F}(n)) = 0,$$

which proves the assertion.

II) Return to the notation at the beginning of the proof. We may suppose that $Y = \operatorname{Spec}(A)$ is affine. **III** | 146
Since f' is of finite type and $\mathscr{L}'$ is ample for f', there is an integer $m > 0$ such that $\mathscr{L}'^{\otimes m}$ is very ample for f' (**II**, 4.6.11). Replacing $\mathscr{L}$ by $\mathscr{L}^{\otimes m}$, it is enough to consider the case in which $\mathscr{L}'$ is very ample for f' and to prove that $\mathscr{L}|_{f^{-1}(U)}$ is very ample for the restriction of f.

Since f' is proper, there is, for a suitable integer $r > 0$, a closed Y'-immersion

$$j : X' \longrightarrow P = \mathbf{P}^r_{Y'}$$

such that $\mathscr{L}' \simeq j^*(\mathscr{O}_P(1))$ (**II**, 5.5.4), (ii). This closed immersion corresponds canonically to a surjective $\mathscr{O}_{X'}$-homomorphism

$$u : \mathscr{O}^{r+1}_{X'} \longrightarrow \mathscr{L}'$$

(**II**, 4.2.3), or equivalently (**0**, 5.1.1) to $r+1$ sections s'_i $(0 \leqslant i \leqslant r)$ of $\mathscr{L}'$ over X' which generate this $\mathscr{O}_{X'}$-module.

By definition these are also sections of $f'_*(\mathscr{L}')$ over Y', and

$$f'_*(\mathscr{L}') = f_*(\mathscr{L}) \otimes_{\mathscr{O}_Y} \mathscr{O}_{Y'}$$

(**0**, 5.4.10). Since Y is affine and $\mathscr{O}_y$ is the local ring of A at the prime ideal $\mathfrak{j}_y$, each s'_i has the form

$$s'_i = s''_i/t_i,$$

where s''_i is a section of $f_*(\mathscr{L})$ over Y and $t_i \in A \setminus \mathfrak{j}_y$. It follows that there are an open neighbourhood V of y in Y and sections s_i of $f_*(\mathscr{L})|_V$ such that $s'_i = s_i/1$ (the space Y' is contained in V; see (**I**, 2.4.2)).

The sections s_i are sections of $\mathscr{L}$ over $f^{-1}(V)$ and therefore define a homomorphism

$$v : \left(\mathscr{O}_X|_{f^{-1}(V)}\right)^{r+1} \longrightarrow \mathscr{L}|_{f^{-1}(V)}.$$

By construction it is surjective at every point of $f^{-1}(y)$. Since $\operatorname{Coker}(v)$ is coherent (**0**, 5.3.4), its support is closed (**0**, 5.2.2); hence there is an open neighbourhood $W \subset f^{-1}(V)$ of $f^{-1}(y)$ on which v is surjective. Because f is closed, after shrinking around y we may choose an open neighbourhood $U \subset V$ with $f^{-1}(U) \subset W$. The conclusion now follows from (**II**, 4.2.3). $\square$

4.8. Finite morphisms of formal preschemes

Proposition (4.8.1). — *Let $\mathfrak{Y}$ be a locally Noetherian formal prescheme, $\mathscr{K}$ an ideal of definition of $\mathfrak{Y}$, and $f : \mathfrak{X} \to \mathfrak{Y}$ a morphism of formal preschemes. The following conditions are equivalent:*

a) *$\mathfrak{X}$ is locally Noetherian, f is an adic morphism (**I**, 10.12.1), and, if $\mathscr{J} = f^*(\mathscr{K})\mathscr{O}_{\mathfrak{X}}$, the morphism*
$$f_0 : (\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{J}) \longrightarrow (\mathfrak{Y}, \mathscr{O}_{\mathfrak{Y}}/\mathscr{K})$$
induced by f is finite.

b) *$\mathfrak{X}$ is locally Noetherian and is the inductive limit of an adic inductive (Y_n)-system (X_n) such that the morphism $X_0 \to Y_0$ is finite.*

c) *Every point of $\mathfrak{Y}$ has a Noetherian formal affine open neighbourhood V such that $f^{-1}(V)$ is a formal affine open and $\Gamma(f^{-1}(V), \mathscr{O}_{\mathfrak{X}})$ is a $\Gamma(V, \mathscr{O}_{\mathfrak{Y}})$-module of finite type.*

Proof. It is immediate from (**I**, 10.12.3) that *a)* implies *b)*. To see that *b)* implies *c)*, we may suppose that
$$\mathfrak{Y} = \mathrm{Spf}(B), \qquad \mathfrak{X} = \mathrm{Spf}(A),$$
where B is an adic Noetherian ring and $\mathfrak{K}$ is an ideal of definition of B. By hypothesis, X_0 is an affine scheme whose ring A_0 is a $B/\mathfrak{K}$-module of finite type (**II**, 6.1.3). By (**I**, 5.1.9), each X_n is an affine scheme; if A_n denotes its ring, condition *b)* implies that, for $m \leqslant n$,
$$A_m \simeq A_n/\mathfrak{K}^{m+1}A_n.$$
It follows that $\mathfrak{X} \simeq \mathrm{Spf}(A)$, where $A = \varprojlim A_n$, and the conclusion follows from (**0**, 7.2.9).

Finally, to prove that *c)* implies *a)*, we may again restrict to the case
$$\mathfrak{Y} = \mathrm{Spf}(B), \qquad \mathfrak{X} = \mathrm{Spf}(A),$$
where A is a finite B-algebra. Since $A/\mathfrak{K}A$ is then a finite $B/\mathfrak{K}$-algebra, (**I**, 10.10.9) shows that the conditions in *a)* are satisfied. □

Definition (4.8.2). — When the equivalent conditions *a)*, *b)*, and *c)* of (4.8.1) are satisfied, the morphism f is said to be *finite*; one also says that $\mathfrak{X}$ is a *finite formal $\mathfrak{Y}$-prescheme*, or a formal prescheme *finite over* $\mathfrak{Y}$.

Proposition (4.8.3). — (i) *A closed immersion of locally Noetherian formal preschemes is a finite morphism.*

(ii) *The composite of two finite morphisms of locally Noetherian formal preschemes is a finite morphism.*

(iii) *Let $\mathfrak{X}$, $\mathfrak{Y}$, and $\mathfrak{S}$ be locally Noetherian formal preschemes, $f : \mathfrak{X} \to \mathfrak{S}$ a finite morphism, and $g : \mathfrak{Y} \to \mathfrak{S}$ a morphism. Then the projection*
$$\mathfrak{X} \times_{\mathfrak{S}} \mathfrak{Y} \longrightarrow \mathfrak{Y}$$
is finite.

(iv) *Let $\mathfrak{S}$ be a locally Noetherian formal prescheme, and let $\mathfrak{X}'$ and $\mathfrak{Y}'$ be locally Noetherian formal preschemes such that $\mathfrak{X}' \times_{\mathfrak{S}} \mathfrak{Y}'$ is locally Noetherian. If $\mathfrak{X}$ and $\mathfrak{Y}$ are locally Noetherian formal $\mathfrak{S}$-preschemes and*
$$f : \mathfrak{X} \longrightarrow \mathfrak{X}', \qquad g : \mathfrak{Y} \longrightarrow \mathfrak{Y}'$$
are finite $\mathfrak{S}$-morphisms, then $f \times_{\mathfrak{S}} g$ is finite.

(v) *Let*
$$f : \mathfrak{X} \longrightarrow \mathfrak{Y}, \qquad g : \mathfrak{Y} \longrightarrow \mathfrak{Z}$$
be morphisms of locally Noetherian formal preschemes such that g is of finite type and separated. If $g \circ f$ is finite, then f is finite.

Proof. Assertion *(i)* is immediate. Using criterion *a)* of (4.8.1), the other assertions reduce at once to the corresponding propositions for morphisms of ordinary preschemes (**II**, 6.1.5). We leave the details to the reader, following the model of (**I**, 10.13.5). □

Corollary (4.8.4). — *Under the hypotheses of (**I**, 10.9.9), if f is a finite morphism, then so is its extension $\widehat{f}$ to the completions.*

Corollary (4.8.5). — *Let $\mathfrak{X}$ be a formal prescheme finite over $\mathfrak{Y}$, and let $f : \mathfrak{X} \to \mathfrak{Y}$ be the structural morphism. For every open subset $U \subset \mathfrak{Y}$, the formal prescheme $f^{-1}(U)$ is finite over U.*

Proposition (4.8.6). — *If $f : \mathfrak{X} \to \mathfrak{Y}$ is a finite morphism of locally Noetherian formal preschemes, then $f_*(\mathscr{O}_\mathfrak{X})$ is a coherent $\mathscr{O}_\mathfrak{Y}$-algebra.*

Proof. We may regard f as the inductive limit of an inductive system (f_n) of morphisms $f_n : X_n \to Y_n$. Let us show that the f_n are finite and that $f_*(\mathscr{O}_\mathfrak{X})$ is isomorphic to the projective limit of the $(f_n)_*(\mathscr{O}_{X_n})$; this will prove the assertion (**I**, 10.10.5). It is enough to restrict to the case

$$\mathfrak{Y} = \operatorname{Spf}(B), \qquad \mathfrak{X} = \operatorname{Spf}(A),$$

and to observe that, if $\mathfrak{R}$ is an ideal of definition of B and A is a B-module of finite type, then $A/\mathfrak{R}^{n+1}A$ is a module of finite type over $B/\mathfrak{R}^{n+1}B$, and A is the projective limit of the $A/\mathfrak{R}^{n+1}A$. □

Conversely:

Proposition (4.8.7). — *Let $\mathfrak{Y}$ be a locally Noetherian formal prescheme and $\mathscr{A}$ a coherent $\mathscr{O}_\mathfrak{Y}$-algebra. There exists a formal prescheme $\mathfrak{X}$ finite over $\mathfrak{Y}$, unique up to a unique $\mathfrak{Y}$-isomorphism, such that*

$$f_*(\mathscr{O}_\mathfrak{X}) = \mathscr{A},$$

where $f : \mathfrak{X} \to \mathfrak{Y}$ is the structural morphism.

Proof. Let $\mathscr{K}$ be an ideal of definition of $\mathfrak{Y}$, and set **III** | 148

$$Y_n = (\mathfrak{Y}, \mathscr{O}_\mathfrak{Y}/\mathscr{K}^{n+1}), \qquad \mathscr{A}_n = \mathscr{A}/\mathscr{K}^{n+1}\mathscr{A}.$$

Clearly $\mathscr{A}_n$ is a finite $\mathscr{O}_{Y_n}$-algebra, and hence defines a finite Y_n-prescheme

$$X_n = \operatorname{Spec}(\mathscr{A}_n)$$

(**II**, 6.1.3). For $m \leqslant n$, the canonical surjective homomorphism

$$h_{mn} : \mathscr{A}_n \longrightarrow \mathscr{A}_m$$

defines a morphism $u_{mn} : X_m \to X_n$ for which the diagram

$$\begin{tikzcd} X_n \arrow[d, "f_n"'] & X_m \arrow[l, "u_{mn}"'] \arrow[d, "f_m"] \\ Y_n & Y_m \arrow[l] \end{tikzcd}$$

is commutative, where f_n denotes the structural morphism; it also identifies X_m with $X_n \times_{Y_n} Y_m$, as follows at once from (**II**, 1.4.6). The formal prescheme $\mathfrak{X}$ obtained as the inductive limit of the inductive system (X_n) is therefore locally Noetherian, and its structural morphism

$$f : \mathfrak{X} \longrightarrow \mathfrak{Y},$$

the inductive limit of the system (f_n), is finite (4.8.1) (**I**, 10.12.3.1). Moreover, the proof of (4.8.6) shows that $f_*(\mathscr{O}_\mathfrak{X})$ is the projective limit of the $\mathscr{A}_n$, and is therefore equal to $\mathscr{A}$ (**I**, 10.10.6). The uniqueness assertion follows from the more general result below. □

Proposition (4.8.8). — *Let $\mathfrak{Y}$ be a locally Noetherian formal prescheme, and let $\mathfrak{X}$ and $\mathfrak{X}'$ be formal $\mathfrak{Y}$-preschemes finite over $\mathfrak{Y}$, with structural morphisms*

$$f : \mathfrak{X} \longrightarrow \mathfrak{Y}, \qquad f' : \mathfrak{X}' \longrightarrow \mathfrak{Y}.$$

There is a canonical bijection

$$\operatorname{Hom}_\mathfrak{Y}(\mathfrak{X}, \mathfrak{X}') \xrightarrow{\sim} \operatorname{Hom}_{\mathscr{O}_\mathfrak{Y}}(f'_*(\mathscr{O}_{\mathfrak{X}'}), f_*(\mathscr{O}_\mathfrak{X}))^3.$$

[3] The latter expression denotes the set of homomorphisms of $\mathscr{O}_\mathfrak{Y}$-algebras $f'_*(\mathscr{O}_{\mathfrak{X}'}) \to f_*(\mathscr{O}_\mathfrak{X})$.

Proof. The map $h \mapsto \mathscr{A}(h)$ is defined as in (**II**, 1.1.2). To prove that it is bijective, we reduce at once to the case in which $\mathfrak{Y} = \mathrm{Spf}(B)$ is a Noetherian formal affine prescheme. Then

$$\mathfrak{X} = \mathrm{Spf}(A), \qquad \mathfrak{X}' = \mathrm{Spf}(A'),$$

where A and A' are finite B-algebras, and

$$f_*(\mathscr{O}_{\mathfrak{X}}) = A^{\Delta}, \qquad f'_*(\mathscr{O}_{\mathfrak{X}'}) = A'^{\Delta}.$$

The conclusion follows from the bijective correspondence between $\mathfrak{Y}$-morphisms $\mathfrak{X} \to \mathfrak{X}'$ and continuous B-algebra homomorphisms $A' \to A$ (**I**, 10.2.2), together with the bijective correspondence between homomorphisms of B-modules $A' \to A$ and homomorphisms of $\mathscr{O}_{\mathfrak{Y}}$-modules $A'^{\Delta} \to A^{\Delta}$ (**I**, 10.10.2.3). ☐

Corollary (4.8.9). — *Under the canonical bijection of (4.8.8), closed immersions $\mathfrak{X} \to \mathfrak{X}'$ correspond to surjective homomorphisms of $\mathscr{O}_{\mathfrak{Y}}$-algebras*

$$f'_*(\mathscr{O}_{\mathfrak{X}'}) \longrightarrow f_*(\mathscr{O}_{\mathfrak{X}}).$$

Proof. The question is local on $\mathfrak{Y}$, and hence reduces to the definition of closed immersions of locally Noetherian formal preschemes (**I**, 10.14.2). ☐

Corollary (4.8.10). — *With the notation and hypotheses of (4.8.1), an adic morphism f is a closed immersion if and only if f_0 is a closed immersion of ordinary preschemes.*

Proof. This follows at once from (4.8.9) and the surjectivity criterion for a homomorphism of coherent $\mathscr{O}_{\mathfrak{Y}}$-modules (**I**, 10.11.5). ☐

Proposition (4.8.11). — *A morphism $f : \mathfrak{X} \to \mathfrak{Y}$ of locally Noetherian formal preschemes is finite if and only if it is proper and all its fibres $f^{-1}(y)$, for $y \in \mathfrak{Y}$, are finite.* **III** | 149

Proof. By the definitions (3.4.1) and (4.8.2), the assertion reduces immediately to the same assertion for f_0 (with the notation of (4.8.1)), which is precisely (4.4.2). ☐

§5. An existence theorem for coherent algebraic sheaves

5.1. Statement of the theorem

(5.1.1). Let A be an adic Noetherian ring and $\mathfrak{J}$ an ideal of definition of A, so that A is separated and complete for the $\mathfrak{J}$-adic topology. If $Y = \mathrm{Spec}(A)$, the affine formal prescheme $\mathrm{Spf}(A)$ is identified with the completion $\widehat{Y}$ of Y along the closed subset $Y' = \mathrm{V}(\mathfrak{J})$ (**I**, 10.10.1). Let X be an ordinary Y-prescheme of finite type, with structural morphism $f : X \to Y$. We denote by $\widehat{X}$ the completion of X along the closed subset $X' = f^{-1}(Y')$, or equivalently the formal $\widehat{Y}$-prescheme $X \times_Y \widehat{Y}$, and by $\widehat{f} : \widehat{X} \to \widehat{Y}$ the extension of f to the completions. Finally, for every coherent $\mathscr{O}_X$-module $\mathscr{F}$, we denote by $\widehat{\mathscr{F}}$ its completion $\mathscr{F}_{/X'}$, which is a coherent $\mathscr{O}_{\widehat{X}}$-module.

Proposition (5.1.2). — *With the hypotheses and notation of (5.1.1), let $\mathscr{F}$ be a coherent $\mathscr{O}_X$-module whose support is proper over Y (**II**, 5.4.10). The canonical homomorphisms (4.1.4)*

$$\rho_i : \mathrm{H}^i(X, \mathscr{F}) \longrightarrow \mathrm{H}^i(\widehat{X}, \widehat{\mathscr{F}})$$

are isomorphisms.

Proof. The A-module $\mathrm{H}^i(X, \mathscr{F})$ is of finite type (3.2.4), and is therefore identical with its separated completion for the $\mathfrak{J}$-preadic topology (**0**, 7.3.6). The proposition is consequently a special case of (4.1.10). ☐

Recall that the canonical isomorphisms ρ_i commute with the connecting homomorphisms associated with every exact sequence

$$0 \longrightarrow \mathscr{F}' \longrightarrow \mathscr{F} \longrightarrow \mathscr{F}'' \longrightarrow 0$$

of coherent $\mathscr{O}_X$-modules (**0**, 12.1.6) (**I**, 10.8.9).

Corollary (5.1.3). — *Let $\mathscr{F}$ and $\mathscr{G}$ be coherent $\mathscr{O}_X$-modules such that the intersection of their supports is proper over Y. The canonical homomorphism*

$$\operatorname{Hom}_{\mathscr{O}_X}(\mathscr{F},\mathscr{G}) \longrightarrow \operatorname{Hom}_{\mathscr{O}_{\widehat{X}}}(\widehat{\mathscr{F}},\widehat{\mathscr{G}}) \tag{5.1.3.1}$$

which sends a homomorphism $u : \mathscr{F} \to \mathscr{G}$ to its completion $\widehat{u} : \widehat{\mathscr{F}} \to \widehat{\mathscr{G}}$, is an isomorphism. Moreover, when f is closed, $\widehat{u}$ is injective (respectively, surjective) if and only if u is injective (respectively, surjective).

Proof. The first assertion is a special case of (4.5.3); it also follows from the fact that the source of (5.1.3.1) is an A-module of finite type and is therefore identical with its separated completion. For the second assertion, note that, by (**I**, 10.8.14), $\widehat{u}$ is injective (respectively, surjective) if and only if there is a neighbourhood of X' in X on which u is injective (respectively, surjective). The conclusion therefore follows from the lemma below. □

III | 150

Lemma (5.1.3.1). — *Under the hypotheses of (5.1.1), suppose in addition that f is closed. Every neighbourhood of X' in X is then equal to X.*

Proof. We first reduce to the case $f(X) = Y$. Indeed, by hypothesis, $f(X)$ is a closed subset Z of Y. We may replace f by f_{red} (**I**, 6.3.4), and hence suppose that X and Y are reduced; we may then replace Y by the reduced closed subprescheme having Z as its underlying space (**I**, 5.2.2), since every ideal of A is closed and every quotient ring of A is therefore adic and Noetherian.

We then have $f(X') = Y'$. If V is an open neighbourhood of X' in X, the set $f(X - V)$ is closed in Y and does not meet Y'. This is impossible unless $X - V$ is empty, because $\mathfrak{J}$ is contained in the radical of A (**I**, 1.1.15) (**0**, 7.1.10). Thus $V = X$. □

If we restrict attention to coherent $\mathscr{O}_X$-modules whose support is proper over Y, (5.1.3) says, in categorical language, that the functor

$$\mathscr{F} \longmapsto \widehat{\mathscr{F}}$$

is fully faithful from the category of such $\mathscr{O}_X$-modules to the category of coherent $\mathscr{O}_{\widehat{X}}$-modules. It thus gives an equivalence of the former category with a full subcategory of the latter (**0**, 8.1.6). The existence theorem will show that, when X is proper over Y, this subcategory is in fact the category of all coherent $\mathscr{O}_{\widehat{X}}$-modules. More precisely:

Theorem (5.1.4). — *Let A be an adic Noetherian ring, let $Y = \operatorname{Spec}(A)$, let $\mathfrak{J}$ be an ideal of definition of A, and put $Y' = \mathrm{V}(\mathfrak{J})$. Let $f : X \to Y$ be a separated morphism of finite type and put $X' = f^{-1}(Y')$. Let*

$$\widehat{Y} = Y_{/Y'} = \operatorname{Spf}(A), \qquad \widehat{X} = X_{/X'}$$

be the completions of Y and X along Y' and X', and let $\widehat{f} : \widehat{X} \to \widehat{Y}$ be the extension of f to the completions. Then the functor

$$\mathscr{F} \longmapsto \mathscr{F}_{/X'} = \widehat{\mathscr{F}}$$

is an equivalence from the category of coherent $\mathscr{O}_X$-modules whose support is proper over $\operatorname{Spec}(A)$ *to the category of coherent $\mathscr{O}_{\widehat{X}}$-modules whose support is proper over* $\operatorname{Spf}(A)$.

In other words, in view of (5.1.3):

Corollary (5.1.5). — *An $\mathscr{O}_{\widehat{X}}$-module is isomorphic to the completion of a coherent $\mathscr{O}_X$-module whose support is proper over* $\operatorname{Spec}(A)$ *if and only if it is coherent and its support is proper over* $\operatorname{Spf}(A)$.

The most important case is the following:

Corollary (5.1.6). — *Suppose that X is proper over $Y = \operatorname{Spec}(A)$. Then the functor $\mathscr{F} \mapsto \widehat{\mathscr{F}}$ is an equivalence between the category of coherent $\mathscr{O}_X$-modules and the category of coherent $\mathscr{O}_{\widehat{X}}$-modules.*

(5.1.7). *Scholium.* Taking account of the characterization of coherent sheaves on formal preschemes (**I**, 10.11.3), we see that, under the conditions of (5.1.1), giving a coherent $\mathscr{O}_X$-module whose support is proper over $\operatorname{Spec}(A)$ is equivalent—if

$$Y_n = \operatorname{Spec}(A/\mathfrak{J}^{n+1}), \qquad X_n = X \times_Y Y_n$$

—to giving a projective system $(\mathscr{F}_n)$ of coherent $\mathscr{O}_{X_n}$-modules such that, for $m \leqslant n$,

$$\mathscr{F}_m = \mathscr{F}_n \otimes_{\mathscr{O}_{Y_n}} \mathscr{O}_{Y_m}, \qquad \text{or equivalently} \qquad \mathscr{F}_m = \mathscr{F}_n / \mathfrak{J}^{m+1} \mathscr{F}_n,$$

and such that the support of $\mathscr{F}_0$ is a subset of X_0 proper over Y_0. By (**I**, 10.11.4), homomorphisms of coherent $\mathscr{O}_X$-modules are interpreted similarly as homomorphisms of projective systems of coherent $\mathscr{O}_{X_n}$-modules.

In all known applications, A is in fact a local adic Noetherian ring. Thus the Y_n are spectra of local Artinian rings, and the results of this subsection and of the preceding ones reduce, to a large extent, algebraic geometry over a local adic Noetherian ring to algebraic geometry over local Artinian rings. **III** | 151

Corollary (5.1.8). — *Under the hypotheses of (5.1.4), the map*

$$Z \longmapsto \widehat{Z} = Z_{/(Z \cap X')}$$

is a bijection from the set of closed subpreschemes Z of X which are proper over Y onto the set of closed formal subpreschemes of $\widehat{X}$ which are proper over $\widehat{Y}$.

Proof. A closed formal subprescheme of $\widehat{X}$ has the form

$$\left(T, (\mathscr{O}_{\widehat{X}}/\mathscr{A})|_T\right),$$

where $\mathscr{A}$ is a coherent ideal of $\mathscr{O}_{\widehat{X}}$ (**I**, 10.14.2). If T is proper over $\widehat{Y}$, (5.1.4) shows that $\mathscr{O}_{\widehat{X}}/\mathscr{A}$ is isomorphic to an $\mathscr{O}_{\widehat{X}}$-module of the form $\widehat{\mathscr{F}}$, where $\mathscr{F}$ is a coherent $\mathscr{O}_X$-module whose support is proper over Y. Moreover, (5.1.3) shows that the canonical homomorphism

$$\mathscr{O}_{\widehat{X}} \longrightarrow \mathscr{O}_{\widehat{X}}/\mathscr{A}$$

has the form $\widehat{u}$, where $u : \mathscr{O}_X \to \mathscr{F}$ is a surjective homomorphism of $\mathscr{O}_X$-modules. Consequently $\mathscr{F} = \mathscr{O}_X/\mathscr{N}$ for a coherent ideal $\mathscr{N}$ of $\mathscr{O}_X$, and $\mathscr{A} = \widehat{\mathscr{N}}$ (**I**, 10.8.8). The conclusion now follows from (**I**, 10.14.7). □

5.2. Proof of the existence theorem: the projective and quasi-projective case

(5.2.1). Under the conditions of (5.1.4), we shall say provisionally that a coherent $\mathscr{O}_{\widehat{X}}$-module is *algebraizable* if it is isomorphic to the completion $\widehat{\mathscr{F}}$ of a coherent $\mathscr{O}_X$-module $\mathscr{F}$ whose support is proper over Y.

Lemma (5.2.2). — *Let $\mathscr{F}'$ and $\mathscr{G}'$ be algebraizable $\mathscr{O}_{\widehat{X}}$-modules. For every homomorphism $u : \mathscr{F}' \to \mathscr{G}'$, the modules* $\operatorname{Ker}(u)$, $\operatorname{Im}(u)$, *and* $\operatorname{Coker}(u)$ *are algebraizable.*

Proof. Write

$$\mathscr{F}' = \widehat{\mathscr{F}}, \qquad \mathscr{G}' = \widehat{\mathscr{G}},$$

where $\mathscr{F}$ and $\mathscr{G}$ are coherent $\mathscr{O}_X$-modules whose supports are proper over Y. By (5.1.3), $u = \widehat{v}$ for a homomorphism $v : \mathscr{F} \to \mathscr{G}$. Since completion is exact, $\operatorname{Ker}(\widehat{v}) \simeq \widehat{\operatorname{Ker}(v)}$; and because the support of $\operatorname{Ker}(v)$ is contained in that of $\mathscr{F}$, it follows that $\operatorname{Ker}(u)$ is algebraizable. The arguments for $\operatorname{Im}(u)$ and $\operatorname{Coker}(u)$ are the same. □

Proposition (5.2.3). — *Let A be an adic Noetherian ring, $\mathfrak{J}$ an ideal of definition of A, $\mathfrak{Y} = \operatorname{Spf}(A)$, and $f : \mathfrak{X} \to \mathfrak{Y}$ a proper morphism of formal preschemes. Put*

$$Y_k = \operatorname{Spec}(A/\mathfrak{J}^{k+1}), \qquad X_k = \mathfrak{X} \times_{\mathfrak{Y}} Y_k,$$

and, for every $\mathscr{O}_{\mathfrak{X}}$-module $\mathscr{F}$, put

$$\mathscr{F}_k = \mathscr{F} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{O}_{X_k} = \mathscr{F}/\mathfrak{J}^{k+1}\mathscr{F}.$$

Let $\mathscr{L}$ be an invertible $\mathscr{O}_{\mathfrak{X}}$-module, and suppose that $\mathscr{L}_0 = \mathscr{L}/\mathfrak{J}\mathscr{L}$ is an ample $\mathscr{O}_{X_0}$-module. For every $\mathscr{O}_{\mathfrak{X}}$-module $\mathscr{F}$ and every integer n, set

$$\mathscr{F}(n) = \mathscr{F} \otimes \mathscr{L}^{\otimes n}.$$

Then, for every coherent $\mathscr{O}_{\mathfrak{X}}$-module $\mathscr{F}$, there is an integer n_0 such that, for every $n \geqslant n_0$:

(i) *the canonical homomorphism*

$$\mathrm{H}^0(\mathfrak{X}, \mathscr{F}(n)) \longrightarrow \mathrm{H}^0(\mathfrak{X}, \mathscr{F}_k(n))$$

is surjective for every $k \geqslant 0$*;*

(ii) $\mathrm{H}^q(\mathfrak{X}, \mathscr{F}(n)) = 0$ *for every* $q > 0$*.*

Proof. The underlying spaces of $\mathfrak{X}$ and X_0 are the same. The sheaves

$$\mathscr{M}_k = \mathfrak{J}^k\mathscr{F}/\mathfrak{J}^{k+1}\mathscr{F},$$

being annihilated by $\mathfrak{J}$, may be regarded as coherent $\mathscr{O}_{X_0}$-modules (**0**, 5.3.10). Moreover, if

$$\mathscr{M}_k(n) = \mathscr{M}_k \otimes_{\mathscr{O}_{X_0}} \mathscr{L}_0^{\otimes n},$$

then

$$\mathscr{M}_k(n) = \mathfrak{J}^k\mathscr{F}(n)/\mathfrak{J}^{k+1}\mathscr{F}(n).$$

Since $\mathscr{L}_0$ is ample for $f_0 : X_0 \to Y_0$ and f_0 is proper, f_0 is projective (**II**, 5.5.4). Let **III | 152**

$$S = \bigoplus_{k\geqslant 0} \mathfrak{J}^k/\mathfrak{J}^{k+1}$$

be the graded A-algebra associated with the $\mathfrak{J}$-adic filtration of A. It is of finite type because A is Noetherian. Put

$$\mathscr{S}' = f_0^*(\widetilde{S}), \qquad \mathscr{M} = \bigoplus_{k\geqslant 0} \mathscr{M}_k.$$

Then $\mathscr{S}'$ is a quasi-coherent $\mathscr{O}_{X_0}$-algebra of finite type, and $\mathscr{M}$ is a quasi-coherent graded $\mathscr{S}'$-module of finite type, since $\mathscr{F}_0$ is coherent and generates $\mathscr{M}$ as an $\mathscr{S}'$-module. Theorem (2.4.1), *(ii)*, therefore gives an integer n_0 such that, for $n \geqslant n_0$ and every k,

(5.2.3.1) $$\mathrm{H}^q(X_0, \mathscr{M}_k(n)) = 0 \qquad (q > 0).$$

Regarded now as an $\mathscr{O}_{\mathfrak{X}}$-module, $\mathscr{M}_k(n)$ consequently also satisfies

$$\mathrm{H}^q(\mathfrak{X}, \mathscr{M}_k(n)) = 0 \qquad (q > 0,\ n \geqslant n_0).$$

Apply the exact cohomology sequence to

$$0 \longrightarrow \frac{\mathfrak{J}^k\mathscr{F}(n)}{\mathfrak{J}^{k+1}\mathscr{F}(n)} \longrightarrow \frac{\mathfrak{J}^h\mathscr{F}(n)}{\mathfrak{J}^{k+1}\mathscr{F}(n)} \longrightarrow \frac{\mathfrak{J}^h\mathscr{F}(n)}{\mathfrak{J}^{k}\mathscr{F}(n)} \longrightarrow 0.$$

For $0 \leqslant h < k$, $n \geqslant n_0$, and $q > 0$, induction on $k - h$ gives

(5.2.3.2) $$\mathrm{H}^q\left(\mathfrak{X}, \frac{\mathfrak{J}^h\mathscr{F}(n)}{\mathfrak{J}^k\mathscr{F}(n)}\right) = 0,$$

and in particular, for $h = 0$,

(5.2.3.3) $$\mathrm{H}^q(\mathfrak{X}, \mathscr{F}_k(n)) = 0 \qquad (n \geqslant n_0,\ k \geqslant 0,\ q > 0).$$

Another part of the exact cohomology sequence, with $h = 0$, gives

(5.2.3.4) $$\mathrm{H}^0(\mathfrak{X}, \mathscr{F}_{k+1}(n)) \longrightarrow \mathrm{H}^0(\mathfrak{X}, \mathscr{F}_k(n)) \longrightarrow \mathrm{H}^1\left(\mathfrak{X}, \frac{\mathfrak{J}^k\mathscr{F}(n)}{\mathfrak{J}^{k+1}\mathscr{F}(n)}\right) = 0.$$

It follows that, for $h \leqslant k$, the canonical map

(5.2.3.5) $$\mathrm{H}^0(\mathfrak{X}, \mathscr{F}_k(n)) \longrightarrow \mathrm{H}^0(\mathfrak{X}, \mathscr{F}_h(n))$$

is surjective. Thus, for every q, the projective system

$$\left(\mathrm{H}^q(\mathfrak{X}, \mathscr{F}_k(n))\right)_{k\geqslant 0}$$

satisfies condition (ML) when $n \geqslant n_0$.

Furthermore, every formal affine open U of $\mathfrak{X}$ is an affine open in each X_k (**I**, 10.5.2). Hence $\mathrm{H}^q(U, \mathscr{F}_k(n)) = 0$ for $q > 0$ (**I**, 1.3.1), and

$$\mathrm{H}^0(U, \mathscr{F}_k(n)) \longrightarrow \mathrm{H}^0(U, \mathscr{F}_h(n))$$

is surjective for $h \leqslant k$ (**I**, 1.3.9). The hypotheses of (**0**, 13.3.1) are therefore satisfied. For $n \geqslant n_0$ we obtain:

1° for every $q > 0$, the map

$$\mathrm{H}^q(\mathfrak{X}, \mathscr{F}(n)) \longrightarrow \varprojlim_k \mathrm{H}^q(\mathfrak{X}, \mathscr{F}_k(n))$$

is bijective; hence, by (5.2.3.3), $\mathrm{H}^q(\mathfrak{X}, \mathscr{F}(n)) = 0$;

2° the homomorphism

$$\mathrm{H}^0(\mathfrak{X}, \mathscr{F}(n)) \longrightarrow \varprojlim_k \mathrm{H}^0(\mathfrak{X}, \mathscr{F}_k(n))$$

is bijective. Since the homomorphisms (5.2.3.5) are surjective, so is each homomorphism

$$\varprojlim_k \mathrm{H}^0(\mathfrak{X}, \mathscr{F}_k(n)) \longrightarrow \mathrm{H}^0(\mathfrak{X}, \mathscr{F}_h(n)).$$

This proves both assertions. □

Corollary (5.2.4). — *Under the hypotheses of (5.2.3), for every coherent $\mathscr{O}_{\mathfrak{X}}$-module $\mathscr{F}$ there is an integer N such that, for $n \geqslant N$, $\mathscr{F}(n)$ is generated by its sections over $\mathfrak{X}$. Equivalently, $\mathscr{F}$ is isomorphic to a quotient of an $\mathscr{O}_{\mathfrak{X}}$-module of the form $(\mathscr{O}_{\mathfrak{X}}(-n))^k$.* **III** | 153

Proof. Since X_0 is Noetherian, the hypothesis on $\mathscr{L}_0$ and (**II**, 4.5.5) give an integer n_0 such that $\mathscr{F}_0(n)$ is generated by its sections over $\mathfrak{X}$ for $n \geqslant n_0$. We may take n_0 large enough that

$$\Gamma(\mathfrak{X}, \mathscr{F}(n)) \longrightarrow \Gamma(\mathfrak{X}, \mathscr{F}_0(n))$$

is also surjective for $n \geqslant n_0$ (5.2.3). There are therefore finitely many sections $s_i \in \Gamma(\mathfrak{X}, \mathscr{F}(n))$ whose images generate $\mathscr{F}_0(n)$ (**0**, 5.2.3). Since $\mathfrak{J}$ is contained in the maximal ideal of the local ring at every point of $\mathfrak{X}$, Nakayama's lemma applied to those local rings shows that the s_i generate $\mathscr{F}(n)$ (**0**, 5.1.1). □

(5.2.5). *Proof of the existence theorem: the projective case.* With the notation of (5.1.4), suppose that f is projective, so that there is an ample $\mathscr{O}_X$-module $\mathscr{L}$ (**I**, 5.5.4). By definition,

$$X_n = \widehat{X} \times_{\widehat{Y}} Y_n$$

is the closed subprescheme $X \times_Y Y_n = f^{-1}(Y_n)$ of X. If

$$\mathscr{L}' = \mathscr{L} \otimes_{\mathscr{O}_X} \mathscr{O}_{\widehat{X}}$$

is the completion of $\mathscr{L}$, then $\mathscr{L}'_0 = \mathscr{L}/\mathfrak{J}\mathscr{L}$, regarded as an $\mathscr{O}_{X_0}$-module; this module is ample (**II**, 4.6.13, (i *bis*)).

We may therefore apply (5.2.4) to $\mathscr{L}'$ and to any coherent $\mathscr{O}_{\widehat{X}}$-module $\mathscr{F}$. It follows that $\mathscr{F}$ is isomorphic to a quotient of

$$\mathscr{G} = \left(\mathscr{L}'^{\otimes(-n)}\right)^k$$

for suitable integers $n > 0$ and $k > 0$. The module $\mathscr{G}$ is the completion of $(\mathscr{L}^{\otimes(-n)})^k$ (**I**, 10.8.10), and is therefore algebraizable. Let $u : \mathscr{G} \to \mathscr{F}$ be the canonical surjection, and put $\mathscr{H} = \operatorname{Ker}(u)$; this is a coherent $\mathscr{O}_{\widehat{X}}$-module (**0**, 5.3.4). Applying the same argument to $\mathscr{H}$, we find an algebraizable $\mathscr{O}_{\widehat{X}}$-module $\mathscr{K}$ and a homomorphism $v : \mathscr{K} \to \mathscr{G}$ such that $\mathscr{H} = \operatorname{Im}(v)$. Thus $\mathscr{F} = \operatorname{Coker}(v)$, and $\mathscr{F}$ is algebraizable by (5.2.2).

(5.2.6). *Proof of the existence theorem: the quasi-projective case.* Retain the notation of (5.1.4), and now suppose that f is quasi-projective. There is a projective morphism $g : Z \to Y$ such that X is identified with the Y-prescheme induced on an open subset of Z (**II**, 5.3.2). If $Z' = g^{-1}(Y')$, then $X' = X \cap Z'$. Consequently the completion $\widehat{X} = X_{/X'}$ is identified with the formal prescheme induced by $\widehat{Z} = Z_{/Z'}$ on the open subset $X \cap Z'$ of $\widehat{Z}$ (**I**, 10.8.5).

Let $\mathscr{F}'$ be a coherent $\mathscr{O}_{\widehat{X}}$-module whose support T' is proper over $\widehat{Y}$. By definition, there is a closed subprescheme of X' with underlying space $T' \subset X'$ such that the restriction $T' \to Y'$ of f is proper. Hence T' is proper over Y, and is therefore closed in Z' (**II**, 5.4.10). It follows that $\mathscr{F}'$ is induced on $\widehat{X}$ by the $\mathscr{O}_{\widehat{Z}}$-module $\mathscr{G}'$ obtained by gluing $\mathscr{F}'$, on the open $\widehat{X}$, with the zero sheaf on the open $\widehat{Z} - T'$; the two sheaves agree on their intersection $\widehat{X} - T'$.

The module $\mathscr{G}'$ is coherent. By (5.2.5), there is a coherent $\mathscr{O}_Z$-module $\mathscr{G}$ such that $\mathscr{G}' = \widehat{\mathscr{G}}$. Let T be the support of $\mathscr{G}$; then $T' = T \cap Z'$ (**I**, 10.8.12). If h is the restriction of g to the reduced closed subprescheme of Z having T as its underlying space, then

$$T' = h^{-1}(Y') = T \cap g^{-1}(Y').$$

Thus $X \cap T$ is an open subset of T containing T'.

Since h is proper (**II**, 5.4.2), and hence closed, (5.1.3.1) gives $X \cap T = T$. Thus $T \subset X$; and since T is closed in Z, it is proper over Y. If $\mathscr{F}$ is the sheaf induced on X by $\mathscr{G}$, its completion $\widehat{\mathscr{F}}$ is induced on $\widehat{X}$ by $\widehat{\mathscr{G}}$ (**I**, 10.8.4), and is therefore equal to $\mathscr{F}'$. This completes the proof. **III** | 154

5.3. Proof of the existence theorem: the general case

Lemma (5.3.1). — *Under the conditions of (5.1.4), let*

$$0 \longrightarrow \mathscr{H} \longrightarrow \mathscr{F} \longrightarrow \mathscr{G} \longrightarrow 0$$

be an exact sequence of coherent $\mathscr{O}_{\widehat{X}}$-modules. If $\mathscr{G}$ and $\mathscr{H}$ are algebraizable, then $\mathscr{F}$ is algebraizable.

Proof. Suppose that

$$\mathscr{G} = \widehat{\mathscr{B}}, \qquad \mathscr{H} = \widehat{\mathscr{C}},$$

where $\mathscr{B}$ and $\mathscr{C}$ are coherent $\mathscr{O}_X$-modules whose supports are proper over Y. The module $\mathscr{F}$ canonically defines an element of the A-module

$$\operatorname{Ext}^1_{\mathscr{O}_{\widehat{X}}}(\widehat{X}; \widehat{\mathscr{B}}, \widehat{\mathscr{C}})$$

(**0**, 12.3.2). The hypotheses imply that this A-module is canonically isomorphic to

$$\operatorname{Ext}^1_{\mathscr{O}_X}(X; \mathscr{B}, \mathscr{C})$$

(4.5.2). There is therefore an exact sequence

$$0 \longrightarrow \mathscr{C} \longrightarrow \mathscr{A} \longrightarrow \mathscr{B} \longrightarrow 0$$

of coherent $\mathscr{O}_X$-modules whose canonical class maps to the class corresponding to $\mathscr{F}$. By definition, taking account of (**I**, 10.8.8), (ii), this says that $\mathscr{F}$ is isomorphic to $\widehat{\mathscr{A}}$. The lemma follows, since $\operatorname{Supp}(\mathscr{A})$ is contained in $\operatorname{Supp}(\mathscr{B}) \cup \operatorname{Supp}(\mathscr{C})$ and is therefore proper over Y. □

Corollary (5.3.2). — *Under the conditions of (5.1.1), let $u : \mathscr{F} \to \mathscr{G}$ be a homomorphism of coherent $\mathscr{O}_{\widehat{X}}$-modules. If $\mathscr{G}$, $\operatorname{Ker}(u)$, and $\operatorname{Coker}(u)$ are algebraizable, then $\mathscr{F}$ is algebraizable.*

Proof. Lemma (5.2.2), applied to $\mathscr{G} \to \operatorname{Coker}(u)$, shows that $\operatorname{Im}(u)$ is algebraizable. It then suffices to apply Lemma (5.3.1) to the exact sequence

$$0 \longrightarrow \operatorname{Ker}(u) \longrightarrow \mathscr{F} \longrightarrow \operatorname{Im}(u) \longrightarrow 0.$$

□

Lemma (5.3.3). — *Under the conditions of (5.1.1), let $h : Z \to Y$ be a morphism of finite type, let $\widehat{Z}$ be the completion of Z along $Z' = h^{-1}(Y')$, let $g : Z \to X$ be a proper Y-morphism, and let $\widehat{g} : \widehat{Z} \to \widehat{X}$ be its extension to the completions. For every algebraizable $\mathscr{O}_{\widehat{Z}}$-module $\mathscr{F}'$, the module $\widehat{g}_*(\mathscr{F}')$ is an algebraizable $\mathscr{O}_{\widehat{X}}$-module.*

Proof. If $\mathscr{F}$ is a coherent $\mathscr{O}_Z$-module such that $\mathscr{F}' = \widehat{\mathscr{F}}$, the first comparison theorem (4.1.5) identifies $\widehat{g}_*(\widehat{\mathscr{F}})$ with the completion of $g_*(\mathscr{F})$. □

Lemma (5.3.4). — *Let X be an ordinary Noetherian scheme, let X' be a closed subset of X, let $f : Z \to X$ be a proper morphism, and put*

$$Z' = f^{-1}(X'), \qquad \widehat{X} = X_{/X'}, \qquad \widehat{Z} = Z_{/Z'}.$$

Let $\widehat{f} : \widehat{Z} \to \widehat{X}$ be the extension of f to the completions. Let $\mathscr{M}$ be a coherent ideal of $\mathscr{O}_X$ such that, if

$$U = X - \operatorname{Supp}(\mathscr{O}_X / \mathscr{M}),$$

the restriction $f^{-1}(U) \to U$ of f is an isomorphism. Then, for every coherent $\mathscr{O}_{\widehat{X}}$-module $\mathscr{F}$, there is an integer $n > 0$ such that the kernel and cokernel of the canonical homomorphism

$$\rho_{\mathscr{F}} : \mathscr{F} \longrightarrow \widehat{f}_*(\widehat{f}^*(\mathscr{F}))$$

(**0**, 4.4.3) *are annihilated by* $\widehat{\mathscr{M}}^n$.

Proof. We may restrict to the case $X = \mathrm{Spec}(B)$, where B is a Noetherian ring; then $X' = \mathrm{V}(\mathfrak{K})$ for an ideal $\mathfrak{K}$ of B. We first reduce to the case in which B is adic Noetherian and $\mathfrak{K}$ is an ideal of definition.

Let B_1 be the separated completion of B for the $\mathfrak{K}$-preadic topology. If $\mathfrak{K}_1 = \mathfrak{K}B_1$, then B_1 is an adic Noetherian ring and $\mathfrak{K}_1$ is an ideal of definition. Put $X_1 = \mathrm{Spec}(B_1)$, and let $h : X_1 \to X$ be the morphism corresponding to the canonical homomorphism $B \to B_1$. If $X'_1 = h^{-1}(X')$, then $X'_1 = \mathrm{V}(\mathfrak{K}_1)$. Finally put **III | 155**

$$Z_1 = Z \times_X X_1, \qquad f_1 : Z_1 \longrightarrow X_1.$$

The morphism f_1 is proper (**II**, 5.4.2). Denote by $\widehat{X}_1$ the completion of X_1 along X'_1, by

$$\widehat{Z}_1 = Z_1 \times_{X_1} \widehat{X}_1$$

the completion of Z_1 along $Z'_1 = f_1^{-1}(X'_1)$, and by $\widehat{f}_1$ the extension of f_1 to the completions.

The extension $\widehat{h} : \widehat{X}_1 \to \widehat{X}$ corresponds to the identity map of B_1 and is therefore an isomorphism (**I**, 10.9.1). The corresponding morphism $\widehat{Z}_1 \to \widehat{Z}$ is consequently also an isomorphism, and these isomorphisms identify $\widehat{f}_1$ with $\widehat{f}$. Moreover, $\mathscr{M}_1 = h^*(\mathscr{M})$ is a coherent ideal of $\mathscr{O}_{X_1}$ and

$$\mathrm{Supp}(\mathscr{O}_{X_1}/\mathscr{M}_1) = h^{-1}\big(\mathrm{Supp}(\mathscr{O}_X/\mathscr{M})\big)$$

(**I**, 9.1.13). Thus, if $U_1 = X_1 - \mathrm{Supp}(\mathscr{O}_{X_1}/\mathscr{M}_1)$, then $U_1 = h^{-1}(U)$, and the restriction $f_1^{-1}(U_1) \to U_1$ is an isomorphism (**I**, 3.2.7). Finally, $\widehat{\mathscr{M}}$ and $\widehat{\mathscr{M}_1}$ are identified by $\widehat{h}$ (**I**, 10.9.5). All the hypotheses of the lemma are therefore satisfied by X_1, X'_1, f_1, and $\mathscr{M}_1$; henceforth we may suppose that B is adic Noetherian and that $\mathfrak{K}$ is an ideal of definition.

We then have $\widehat{X} = \mathrm{Spf}(B)$ and $\mathscr{F} = N^\Delta$, where N is a finite-type B-module. Thus $\mathscr{F} = \widehat{\mathscr{G}}$, where $\mathscr{G}$ is the coherent $\mathscr{O}_X$-module $\widetilde{N}$ (**I**, 10.10.5), and

$$\widehat{f}^*(\mathscr{F}) = \widehat{f^*(\mathscr{G})}$$

(**I**, 10.9.5). By the first comparison theorem (4.1.5),

$$\widehat{f}_*\big(\widehat{f^*(\mathscr{G})}\big) \simeq f_*\big(\widehat{f^*(\mathscr{G})}\big),$$

and, by (5.1.3), the canonical homomorphism $\rho_{\mathscr{F}}$ is precisely $\widehat{\rho}_{\mathscr{G}}$.

The kernel $\mathscr{P}$ and cokernel $\mathscr{R}$ of

$$\rho_{\mathscr{G}} : \mathscr{G} \longrightarrow f_*\big(f^*(\mathscr{G})\big)$$

are coherent $\mathscr{O}_X$-modules, and their restrictions to U are zero. There is therefore an integer $n > 0$ such that

$$\mathscr{M}^n\mathscr{P} = \mathscr{M}^n\mathscr{R} = 0$$

(**I**, 9.3.4). It follows that

$$\widehat{\mathscr{M}}^n\widehat{\mathscr{P}} = \widehat{\mathscr{M}}^n\widehat{\mathscr{R}} = 0$$

(**I**, 10.8.8) (**I**, 10.8.10), which proves the lemma. □

(5.3.5). *End of the proof of the existence theorem.* Retain the hypotheses of (5.1.4). We use Noetherian induction (**0**, 2.2.2), assuming the theorem known for every closed subprescheme T of X whose underlying space is distinct from X; here $\widehat{T}$ denotes the completion of T along $T \cap X'$. We may suppose that X is nonempty.

Since f is separated and of finite type, Chow's lemma (**II**, 5.6.1) gives a Y-scheme Z and a Y-morphism $g : Z \to X$ such that the structural morphism $h : Z \to Y$ is quasi-projective, g is projective and surjective, and there is a nonempty open subset U of X for which $g^{-1}(U) \to U$ is an isomorphism. Let $\mathscr{M}$ be a coherent ideal of $\mathscr{O}_X$ defining a closed subprescheme with underlying space $X - U$ (**I**, 5.2.2), and let $\mathscr{F}$ be a coherent $\mathscr{O}_{\widehat{X}}$-module whose support E is proper over Y. Denote by $\widehat{Z}$ the completion of Z along $h^{-1}(Y')$, and by $\widehat{g} : \widehat{Z} \to \widehat{X}$ the extension of g to the completions.

The module $\widehat{g}^*(\mathscr{F})$ is a coherent $\mathscr{O}_{\widehat{Z}}$-module whose support is contained in $g^{-1}(E)$ and is therefore proper over Y, since g is projective and hence proper (**II**, 5.4.6). Since h is quasi-projective, $\widehat{g}^*(\mathscr{F})$ is algebraizable by (5.2.6). It follows from (5.3.3), since g is proper, that **III | 156**

$$\widehat{g}_*\big(\widehat{g}^*(\mathscr{F})\big)$$

is an algebraizable $\mathscr{O}_{\widehat{X}}$-module.

Apply (5.3.4) to $\mathscr{F}$ and g. The kernel $\mathscr{P}$ and cokernel $\mathscr{R}$ of

$$\rho_{\mathscr{F}} : \mathscr{F} \longrightarrow \widehat{g}_*\big(\widehat{g}^*(\mathscr{F})\big)$$

are annihilated by a power $\widehat{\mathscr{M}^n}$. Let T be the closed subprescheme of X defined by $\mathscr{M}^n$, whose underlying space is $X - U$, and let $j : T \to X$ be the canonical injection. Its extension $\widehat{j} : \widehat{T} \to \widehat{X}$ is the canonical injection (**I**, 10.14.7), and we may write

$$\mathscr{P} = \widehat{j}_*\big(\widehat{j}^*(\mathscr{P})\big), \qquad \mathscr{R} = \widehat{j}_*\big(\widehat{j}^*(\mathscr{R})\big).$$

Since U is nonempty, the induction hypothesis shows that $\widehat{j}^*(\mathscr{P})$ and $\widehat{j}^*(\mathscr{R})$ are algebraizable $\mathscr{O}_{\widehat{T}}$-modules. Lemma (5.3.3) then shows that $\mathscr{P}$ and $\mathscr{R}$ are algebraizable, and (5.3.2) finally proves that $\mathscr{F}$ is algebraizable.

5.4. Application: comparison between morphisms of ordinary preschemes and morphisms of formal preschemes. Algebraizable formal preschemes

Theorem (5.4.1). — *Let A be an adic Noetherian ring, let $\mathfrak{J}$ be an ideal of definition of A, and put*

$$S = \operatorname{Spec}(A), \qquad S' = \mathrm{V}(\mathfrak{J}).$$

Let $u : X \to S$ be a proper morphism and let $v : Y \to S$ be a separated morphism of finite type. Let $\widehat{S}$, $\widehat{X}$, and $\widehat{Y}$ be the completions of S, X, and Y along S', $u^{-1}(S')$, and $v^{-1}(S')$, respectively. For every S-morphism $f : X \to Y$, let $\widehat{f} : \widehat{X} \to \widehat{Y}$ be its extension to the completions. Then the map $f \mapsto \widehat{f}$ is a bijection

$$\operatorname{Hom}_S(X, Y) \xrightarrow{\sim} \operatorname{Hom}_{\widehat{S}}(\widehat{X}, \widehat{Y}).$$

Proof. We first prove injectivity. Suppose that $f, g : X \to Y$ are S-morphisms such that $\widehat{f} = \widehat{g}$. There is then an open neighbourhood V of $X' = u^{-1}(S')$ on which f and g coincide (**I**, 10.9.4). Since u is closed, (5.1.3.1) gives $V = X$, and hence $f = g$.

We now prove surjectivity. Let $h : \widehat{X} \to \widehat{Y}$ be an $\widehat{S}$-morphism. Put

$$Z = X \times_S Y,$$

and denote the canonical projections by $p : Z \to X$ and $q : Z \to Y$. The prescheme Z is of finite type over S (**I**, 6.3.4), and is therefore Noetherian. Let $\widehat{Z}$ be its completion along

$$Z' = p^{-1}\big(u^{-1}(S')\big).$$

The formal prescheme $\widehat{Z}$ is canonically identified with $\widehat{X} \times_{\widehat{S}} \widehat{Y}$, and its projections onto $\widehat{X}$ and $\widehat{Y}$ are identified with $\widehat{p}$ and $\widehat{q}$ (**I**, 10.9.7).

Since Y is separated over S, $\widehat{Y}$ is separated over $\widehat{S}$ (**I**, 10.15.7). The graph morphism

$$\Gamma_h = (1_{\widehat{X}}, h) : \widehat{X} \longrightarrow \widehat{Z}$$

is consequently a closed immersion (**I**, 10.15.4). Let $\mathfrak{T}$ be the closed formal subprescheme of $\widehat{Z}$ associated with this immersion, and let $j : \mathfrak{T} \to \widehat{Z}$ be the canonical injection. Thus

$$\Gamma_h = j \circ w,$$

where $w : \widehat{X} \to \mathfrak{T}$ is an isomorphism (**I**, 10.14.3) whose inverse is $\widehat{p} \circ j$. Moreover, $\mathfrak{T}$ is proper over $\widehat{S}$ because $\widehat{X}$ is. It follows from (5.1.8) that there is a closed subprescheme T of Z such that

$$\mathfrak{T} = \widehat{T} = T_{/(T \cap Z')},$$

and that $j = \widehat{i}$, where $i : T \to Z$ is the canonical injection (**I**, 10.14.7).

The morphism $p \circ i : T \to X$ is an isomorphism: its extension to the completions is the isomorphism $\widehat{p} \circ \widehat{i}$, and it suffices to apply (4.6.8), noting as above that S is the only neighbourhood of S' in S. Let $g : X \to T$ be the inverse of $p \circ i$, and put **III | 157**

$$f = q \circ i \circ g.$$

Then $f : X \to Y$ has graph $\Gamma_f = i \circ g$. Since $\widehat{g}$ is the inverse of $\widehat{p \circ i}$, we have

$$\widehat{\Gamma_f} = \widehat{i} \circ \widehat{g} = j \circ w = \Gamma_h.$$

But $\widehat{\Gamma_f} = \Gamma_{\widehat{f}}$ (**I**, 10.9.8); hence $h = \widehat{f}$, which completes the proof. □

In categorical language, the functor $X \mapsto \widehat{X}$ is therefore fully faithful (**0**, 8.1.6) from the category of preschemes proper over $\operatorname{Spec}(A)$ to the category of formal preschemes proper over $\operatorname{Spf}(A)$, for every adic Noetherian ring A. It consequently gives an equivalence between the first category and a full subcategory of the second. The objects of this subcategory will henceforth be called *algebraizable formal preschemes*. For such a formal prescheme $\mathfrak{X}$, there is an ordinary prescheme X, proper over $\operatorname{Spec}(A)$ and determined up to unique isomorphism, such that $\mathfrak{X} \simeq \widehat{X}$.

(5.4.2). *Scholium.* With the notation of (5.4.1), put

$$S_n = \operatorname{Spec}(A/\mathfrak{J}^{n+1}), \qquad X_n = X \times_S S_n, \qquad Y_n = Y \times_S S_n.$$

It follows from (5.4.1) and (**I**, 10.12.3) that giving an S-morphism $f : X \to Y$ is equivalent to giving an adic inductive (S_n)-system (**I**, 10.12.2) of S_n-morphisms $f_n : X_n \to Y_n$.

Remark (5.4.3). — Contrary to what the existence theorem (5.1.6) might suggest, there are formal preschemes proper over $\operatorname{Spf}(A)$ which are *not algebraizable*, just as there are compact analytic spaces which do not arise from complex algebraic varieties. We shall encounter such preschemes later in the "theory of moduli," which, when the base field is $\mathbb{C}$, deals precisely with infinitesimal variations of the complex structure of a complete algebraic variety; it is well known that such variations can give rise to analytic varieties which are not algebraic.

Proposition (5.4.4). — *Let A be an adic Noetherian ring, put $\mathfrak{S} = \operatorname{Spf}(A)$, and let*

$$g : \mathfrak{X} \longrightarrow \mathfrak{S}, \qquad h : \mathfrak{Y} \longrightarrow \mathfrak{S}$$

be two proper morphisms of formal preschemes. Let $f : \mathfrak{X} \to \mathfrak{Y}$ be an $\mathfrak{S}$-morphism. If f is finite and $\mathfrak{Y}$ is algebraizable, then $\mathfrak{X}$ is algebraizable.

Proof. The hypotheses on g and h already imply that f is proper (3.4.1); for f to be finite, it is enough that the fibre $f^{-1}(y)$ be finite for every $y \in \mathfrak{Y}$ (**0**, 4.8.11). By hypothesis,

$$\mathscr{B} = f_*(\mathscr{O}_{\mathfrak{X}})$$

is a coherent $\mathscr{O}_{\mathfrak{Y}}$-algebra (**0**, 4.8.6). Write $\mathfrak{Y} = \widehat{Y}$ and $h = \widehat{w}$, where $w : Y \to \operatorname{Spec}(A)$ is a proper morphism of ordinary preschemes. The existence theorem gives a coherent $\mathscr{O}_Y$-algebra $\mathscr{C}$ such that $\mathscr{B} = \widehat{\mathscr{C}}$. Put

$$X = \operatorname{Spec}(\mathscr{C}),$$

and let $u : X \to Y$ be the structural morphism. The definition of $\mathfrak{X}$ from $\mathscr{B}$ (**0**, 4.8.7) then shows that $\mathfrak{X}$ is canonically isomorphic to $\widehat{X}$ and that f is identified with $\widehat{u}$; it is enough to check this when Y is affine. □

Proposition (5.1.8) is a special case of (5.4.4).

Theorem (5.4.5). — *Let A be an adic Noetherian ring, let $\mathfrak{J}$ be an ideal of definition of A, put*

$$S = \operatorname{Spec}(A), \qquad \mathfrak{S} = \widehat{S} = \operatorname{Spf}(A),$$

and let $f : \mathfrak{X} \to \mathfrak{S}$ be a proper morphism of formal preschemes. Put

$$S_k = \operatorname{Spec}(A/\mathfrak{J}^{k+1}), \qquad X_k = \mathfrak{X} \times_{\mathfrak{S}} S_k,$$

and, for every $\mathscr{O}_{\mathfrak{X}}$-module $\mathscr{F}$, put

$$\mathscr{F}_k = \mathscr{F} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{O}_{X_k} = \mathscr{F}/\mathfrak{J}^{k+1}\mathscr{F}.$$

Let $\mathscr{L}$ be an invertible $\mathscr{O}_{\mathfrak{X}}$-module, and suppose that **III** | 158

$$\mathscr{L}_0 = \mathscr{L}/\mathfrak{J}\mathscr{L}$$

is an ample $\mathscr{O}_{X_0}$-module. Then $\mathfrak{X}$ is algebraizable. Moreover, if X is a proper S-prescheme such that $\mathfrak{X} \simeq \widehat{X}$, there is an ample $\mathscr{O}_X$-module $\mathscr{M}$ such that $\mathscr{L} \simeq \widehat{\mathscr{M}}$; in particular, X is projective over S.

Proof. Apply (5.2.3) with $\mathscr{F} = \mathscr{O}_{\mathfrak{X}}$. There is an integer n_0 such that, for $n \geqslant n_0$, the canonical homomorphism

$$\Gamma(\mathfrak{X}, \mathscr{L}^{\otimes n}) \longrightarrow \Gamma(X_0, \mathscr{L}_0^{\otimes n})$$

is surjective. Choose $n \geqslant n_0$ large enough that $\mathscr{L}_0^{\otimes n}$ is very ample for S_0 (**II**, 4.5.10). Since $f_0 : X_0 \to S_0$ is proper, $\Gamma(X_0, \mathscr{L}_0^{\otimes n})$ is a finite-type A-module (3.2.1). There is consequently a finite-type A-submodule

$$E \subset \Gamma(\mathfrak{X}, \mathscr{L}^{\otimes n})$$

whose image in $\Gamma(X_0, \mathscr{L}_0^{\otimes n})$ is the whole module.

For every $k \geqslant 0$, consider the homomorphism

$$u_k : E/\mathfrak{J}^{k+1}E \longrightarrow \Gamma(X_k, \mathscr{L}_k^{\otimes n})$$

induced by the canonical injection $E \to \Gamma(\mathfrak{X}, \mathscr{L}^{\otimes n})$. The module $(f_k)_*(\mathscr{L}_k^{\otimes n})$ is quasi-coherent, and

$$\Gamma\big(S_k, (f_k)_*(\mathscr{L}_k^{\otimes n})\big) = \Gamma(X_k, \mathscr{L}_k^{\otimes n}).$$

Thus u_k defines a homomorphism

$$\widetilde{u}_k : \widetilde{E/\mathfrak{J}^{k+1}E} \longrightarrow (f_k)_*(\mathscr{L}_k^{\otimes n}),$$

and hence, by adjunction, a homomorphism

$$\widetilde{u}_k^\sharp : f_k^*\big(\widetilde{E/\mathfrak{J}^{k+1}E}\big) \longrightarrow \mathscr{L}_k^{\otimes n}.$$

Put

$$\mathscr{G}_k = f_k^*\big(\widetilde{E/\mathfrak{J}^{k+1}E}\big).$$

We have $\mathscr{G}_0 = \mathscr{G}_k/\mathfrak{J}\mathscr{G}_k$ (**I**, 9.1.5), and

$$\widetilde{u}_0^\sharp : \mathscr{G}_0/\mathfrak{J}\mathscr{G}_0 \longrightarrow \mathscr{L}_0^{\otimes n}/\mathfrak{J}\mathscr{L}_0^{\otimes n}$$

is obtained from $\widetilde{u}_k^\sharp$ by passage to the quotients.

By the definition of E, $\widetilde{u}_0^\sharp$ is the canonical homomorphism

$$\sigma : f_0^*\big((f_0)_*(\mathscr{L}_0^{\otimes n})\big) \longrightarrow \mathscr{L}_0^{\otimes n}.$$

Since $\mathscr{L}_0^{\otimes n}$ is very ample, $\widetilde{u}_0^\sharp$ is surjective (**II**, 4.4.3). Nakayama's lemma then shows that every $\widetilde{u}_k^\sharp$ is surjective.

Each $\widetilde{u}_k^\sharp$ therefore defines (**II**, 4.2.2) an S_k-morphism

$$g_k : X_k \longrightarrow P_k = \mathbf{P}(E/\mathfrak{J}^{k+1}E).$$

For $h \leqslant k$,

$$P_h = P_k \times_{S_k} S_h$$

by (**II**, 4.1.3). The relations among the $\widetilde{u}_k^\sharp$ and (**II**, 4.2.10) show that (g_k) is an adic inductive (S_k)-system (**I**, 10.12.2). The g_k consequently define an $\mathfrak{S}$-morphism of formal preschemes

$$g : \mathfrak{X} \longrightarrow \mathfrak{P},$$

where $\mathfrak{P}$ is the inductive limit of the system (P_k), or equivalently the completion $\widehat{P}$ of $P = \mathbf{P}(E)$. The very ampleness of $\mathscr{L}_0^{\otimes n}$ implies that g_0 is a closed immersion (**II**, 4.4.3). Hence g is a closed immersion of formal preschemes (**0**, 4.8.10), and $\mathfrak{X}$ is algebraizable by (5.1.8).

The existence theorem (5.1.6) now shows that $\mathscr{L}$ is the completion $\widehat{\mathscr{M}}$ of an invertible $\mathscr{O}_X$-module $\mathscr{M}$. Moreover, $\mathscr{L}^{\otimes n}$ is the completion of $\mathscr{M}^{\otimes n}$ (**I**, 10.8.10), and the homomorphisms $\widetilde{u}_k^\sharp$ define a unique homomorphism

$$v : f^*(\widetilde{E}) \longrightarrow \mathscr{M}^{\otimes n}$$

(5.1.7). Since the $\widetilde{u}_k^\sharp$ are surjective, $\widehat{v}$ is surjective (**I**, 10.11.5), and therefore so is v (5.1.3). Let $r : X \to P$ be the morphism defined by v (**II**, 4.2.2). Its extension to the completions is g. Since g is a closed immersion, so is r, by (5.1.8) and (5.4.1). It follows that $\mathscr{M}^{\otimes n}$ is very ample (**II**, 4.4.6), and hence that $\mathscr{M}$ is ample (**II**, 4.5.10). □

Remark (5.4.6). — Let A be an adic Noetherian ring, put $\mathfrak{S} = \mathrm{Spf}(A)$, and let $f : \mathfrak{X} \to \mathfrak{S}$ be a proper morphism of formal preschemes. Let $\mathscr{N}$ be the coherent ideal of $\mathscr{O}_{\mathfrak{X}}$ such that, for every affine formal open subset U of $\mathfrak{X}$,

$$\Gamma(U, \mathscr{N})$$

is the nilradical of $\Gamma(U, \mathscr{O}_{\mathfrak{X}})$. The existence of this ideal follows readily from (**I**, 10.10.2) and from the fact that every ring homomorphism $B \to C$ sends the nilradical of B into that of C. Let $\mathfrak{X}'$ be the closed formal subprescheme of $\mathfrak{X}$ defined by $\mathscr{N}$ (**I**, 10.14.2). It would be interesting to know whether algebraizability of $\mathfrak{X}'$ implies algebraizability of $\mathfrak{X}$ itself.

One would doubtless arrive at a solution of this problem if one knew how to classify, for example by invariants of a cohomological nature, the *extensions* of a structural sheaf $\mathscr{O}_{\mathfrak{X}}$—for an ordinary or **III** | 159 a formal prescheme—by a square-zero ideal. Equivalently, these are the $\mathscr{O}_{\mathfrak{X}}$-algebras $\mathscr{A}$ such that $\mathscr{O}_{\mathfrak{X}} \simeq \mathscr{A} / \mathscr{J}$, where $\mathscr{J}$ is a square-zero ideal of $\mathscr{A}$.

5.5. A decomposition of certain preschemes

Proposition (5.5.1). — *Let A be an adic Noetherian ring, let $\mathfrak{J}$ be an ideal of definition of A, and put $Y = \mathrm{Spec}(A)$. Let $f : X \to Y$ be a separated morphism of finite type, and put*

$$Y_0 = \mathrm{Spec}(A/\mathfrak{J}), \qquad X_0 = X \times_Y Y_0 = f^{-1}(Y_0).$$

Let Z_0 be an open subset of X_0 which is proper over Y_0. Then there is an open and closed subset Z of X, proper over Y, such that

$$Z \cap X_0 = Z_0.$$

Proof. By hypothesis, there is an open subset T of X such that $T \cap X_0 = Z_0$. Let $\widehat{T}$ be the completion along Z_0 of the prescheme induced by X on T. The support of $\mathscr{O}_{\widehat{T}}$ is Z_0, which is proper over Y_0; hence $\widehat{T}$ is proper over $\widehat{Y} = \mathrm{Spf}(A)$ (3.4.1).

It follows from (5.1.8) that there is a closed subprescheme Z of T, proper over Y, such that, if $i : Z \to T$ is the canonical injection, then

$$\widehat{i} : \widehat{Z} \longrightarrow \widehat{T}$$

is an isomorphism; here $\widehat{Z}$ is the completion of Z along Z_0. By (4.6.8), there is an open neighbourhood V of Z_0 in T such that $i^{-1}(V) \to V$ is an isomorphism. But $i^{-1}(V)$ is a neighbourhood of Z_0 in Z, and is therefore equal to Z by (5.1.3.1). Thus Z is open in T, and hence in X. It is also closed in X, since Z is proper over Y and X is separated over Y. This proves the proposition. □

Corollary (5.5.2). — *If X_0 is proper over Y_0, then X is the union of two disjoint open subsets Z and Z' such that Z is proper over Y and contains X_0. Moreover, every closed subset P of X which is proper over Y is contained in Z.*

Proof. Apply (5.5.1) with $Z_0 = X_0$, and put $Z' = X - Z$. For the last assertion, $P \cap Z'$ is closed in P and is therefore proper over Y. If it were nonempty, $f(P \cap Z')$ would be a nonempty closed subset of Y, and hence would meet Y_0 (5.1.3.1). This contradicts $Z' \cap X_0 = \varnothing$, and proves that $P \subset Z$. □

§6. LOCAL AND GLOBAL TOR FUNCTORS; KÜNNETH FORMULA

6.1. Introduction **III** | 137

(6.1.1). Let $f : X \to Y$ be a morphism of preschemes, and let $\mathscr{F}$ be a quasi-coherent $\mathscr{O}_X$-module. In studying the higher direct images $\mathrm{R}^n f_*(\mathscr{F})$, one is led to consider the following general problem. Given a base-change morphism $g : Y' \to Y$, put

$$X' = X_{(Y')} = X \times_Y Y', \qquad \mathscr{F}' = \mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{O}_{Y'}, \qquad f' = f_{(Y')} : X' \longrightarrow Y'.$$

We seek information about the higher direct images $\mathrm{R}^n f'_*(\mathscr{F}')$, assuming that the $\mathrm{R}^n f_*(\mathscr{F})$ are known. One sees readily (cf. for example (7.7.2)) that this reduces to studying the variation of

$$\mathrm{R}^n f_*(\mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{G})$$

as $\mathscr{G}$ ranges over the quasi-coherent $\mathscr{O}_Y$-modules; in other words, to studying the functor

$$\mathscr{G} \longmapsto \mathrm{R}^n f_*(\mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{G}).$$

If $\mathscr{F}$ is flat over Y, the functor $\mathscr{G} \mapsto \mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{G}$ is exact (**0**, 6.7.4), and consequently the composite functors

$$\mathscr{G} \longmapsto \mathrm{R}^n f_*(\mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{G})$$

again form a cohomological functor. This is no longer true in general. In order to apply cohomological methods, one is therefore led to replace $\mathscr{G} \mapsto \mathrm{R}^n f_*(\mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{G})$ by other functors which are always cohomological.

These functors, which generalize the Tor functors of module theory, are defined in Sections 6.3–6.7. There are in fact two such generalizations, one local and the other global, related by spectral sequences discussed in Section 6.7. As an application of those spectral sequences one obtains, under suitable hypotheses, a Künneth formula expressing

$$\mathrm{R}^n (f_1 \times f_2)_*(\mathscr{F}_1 \otimes_Y \mathscr{F}_2)$$

in terms of the higher direct images $\mathrm{R}^p(f_1)_*(\mathscr{F}_1)$ and $\mathrm{R}^q(f_2)_*(\mathscr{F}_2)$. Other spectral sequences (6.8) generalize the associativity spectral sequences for the Tor functor of modules; finally, the base-change problem also leads to spectral sequences (6.9).

(6.1.2). Moreover, one observes in (6.10) that the cohomological functors

$$\mathscr{G} \longmapsto \mathscr{T}_\bullet(\mathscr{G})$$

so defined are locally on Y of the form

$$\mathscr{G} \longmapsto \mathscr{H}_\bullet(\mathscr{L}_\bullet \otimes_Y \mathscr{G}),$$

where $\mathscr{L}_\bullet$ is a complex of locally free $\mathscr{O}_Y$-modules, defined up to homotopy, and $\mathscr{H}_\bullet$ denotes homology. It is therefore useful to set aside the particular situation which produced $\mathscr{T}_\bullet$ and to study, in general, functors of the preceding form, imposing when necessary appropriate finiteness **III** | 138
hypotheses on the $\mathscr{L}_i$ or on the $\mathscr{H}_i(\mathscr{L}_\bullet)$. This is the subject of Section 7, which can for the most part be read independently of Section 6.

The most important properties of these functors concern exactness of a component $\mathscr{T}_i$ of $\mathscr{T}_\bullet$. We shall give various criteria for establishing such properties. As an application, we shall obtain conditions under which, with the notation of (6.1.1), the functor

$$\mathscr{G} \longmapsto \mathrm{R}^n f_*(\mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{G})$$

is exact; we shall express this by saying that $\mathscr{F}$ is *cohomologically flat over Y in dimension n*. Another important property of the components $\mathscr{T}_i$ of

$$\mathscr{T}_\bullet(\mathscr{G}) = \mathscr{H}_\bullet(\mathscr{L}_\bullet \otimes_Y \mathscr{G})$$

is semicontinuity of the function

$$y \longmapsto \dim_{k(y)}\big(T_i(k(y))\big).$$

When $\mathscr{T}_i$ is exact, semicontinuity is replaced by continuity; by a theorem of Grauert the converse also holds when Y is reduced (7.8.4).

(6.1.3). In Sections 6 and 7 we systematically use hypercohomology, taking complexes of sheaves rather than sheaves as arguments throughout, although the necessity of this point of view will become apparent only in later chapters. The cohomological formalism developed here will moreover become more transparent in the chapter of this Treatise devoted to an algebra of cohomological functors of coherent sheaves, including the formalism of duality. This, however, will require developments beyond the scope of the present chapter.

(6.1.4). For brevity, let $K^\bullet$ and $K'^\bullet$ be two complexes in an abelian category C. We shall call a morphism of complexes

$$f : K^\bullet \longrightarrow K'^\bullet$$

a *homotopism* if there is a morphism $g : K'^\bullet \to K^\bullet$ such that both composites $f \circ g$ and $g \circ f$ are homotopic to the identity. By abuse of language, when such a homotopism exists we shall also say that $K^\bullet$ and $K'^\bullet$ are homotopic.

Suppose that the hypercohomology of a covariant additive functor $T : \mathsf{C} \to \mathsf{C}'$, with values in an abelian category C', can be defined relative to a complex of C (**0**, 11.4.3). It is then immediate that a homotopism $K^\bullet \to K'^\bullet$ canonically defines an isomorphism

$$\mathbf{R}^\bullet T(K^\bullet) \xrightarrow{\sim} \mathbf{R}^\bullet T(K'^\bullet)$$

on hypercohomology *(loc. cit.)*.

6.2. Hypercohomology of complexes of modules on a prescheme

(6.2.1). Let X be a prescheme, and let $\mathscr{K}^\bullet = (\mathscr{K}^i)_{i\in\mathbf{Z}}$ be a complex of $\mathscr{O}_X$-modules whose differential has degree $+1$. Recall that, for every morphism $f : X \to Y$ of preschemes, the $\mathscr{O}_Y$-modules of hypercohomology $\mathscr{H}^n(f, \mathscr{K}^\bullet)$, also denoted $\mathscr{H}^n_f(\mathscr{K}^\bullet)$ or $\mathrm{R}^n f_*(\mathscr{K}^\bullet)$, have been defined for every $n \in \mathbf{Z}$ (**0**, 12.4.1). The hypercohomology $\mathscr{H}^\bullet(f, \mathscr{K}^\bullet)$ is the common abutment of the two spectral functors $'\mathscr{E}(f, \mathscr{K}^\bullet)$ and $''\mathscr{E}(f, \mathscr{K}^\bullet)$ whose E_2-terms are

$$'\mathscr{E}_2^{pq} = \mathscr{H}^p\big(\mathscr{H}^q(f, \mathscr{K}^\bullet)\big), \tag{6.2.1.1}$$

and

$$''\mathscr{E}_2^{pq} = \mathscr{H}^p\big(f, \mathscr{H}^q(\mathscr{K}^\bullet)\big) = \mathrm{R}^p f_*\big(\mathscr{H}^q(\mathscr{K}^\bullet)\big). \tag{6.2.1.2}$$

Here $\mathscr{H}^q(f, \mathscr{K}^\bullet)$ is the complex whose component of degree i is **III** | 139

$$\mathscr{H}^q(f, \mathscr{K}^i) = \mathrm{R}^q f_*(\mathscr{K}^i)$$

(loc. cit.). Recall also that, when Y is reduced to a point, the corresponding hypercohomology is denoted $\mathbf{H}^\bullet(X, \mathscr{K}^\bullet)$; it consists of modules over $\Gamma(X, \mathscr{O}_X)$ and is independent of the one-point prescheme Y chosen. When $Y = X$ and $f = 1_X$,

$$\mathscr{H}^n(f, \mathscr{K}^\bullet) = \mathscr{H}^n(\mathscr{K}^\bullet),$$

the cohomology of the complex $\mathscr{K}^\bullet$. When $\mathscr{K}^i = 0$ except for $i = i_0$, one has

$$\mathscr{H}^n(f, \mathscr{K}^\bullet) = \mathrm{R}^{n-i_0} f_*(\mathscr{K}^{i_0}).$$

The spectral sequence $'\mathscr{E}(f, \mathscr{K}^\bullet)$ is always regular; both spectral sequences are biregular when $\mathscr{K}^\bullet$ is bounded below (**0**, 12.4.1). Every homotopism $h : \mathscr{K}^\bullet \to \mathscr{K}'^\bullet$ of complexes of $\mathscr{O}_X$-modules (6.1.4) induces an isomorphism

$$\mathscr{H}^\bullet(f, \mathscr{K}^\bullet) \xrightarrow{\sim} \mathscr{H}^\bullet(f, \mathscr{K}'^\bullet)$$

on hypercohomology. The same conclusion holds if one assumes only that

$$\mathscr{H}^\bullet(h) : \mathscr{H}^\bullet(\mathscr{K}^\bullet) \xrightarrow{\sim} \mathscr{H}^\bullet(\mathscr{K}'^\bullet)$$

is an isomorphism and that both complexes are bounded below. This follows immediately from (**0**, 11.1.5), applied to the spectral sequence (6.2.1.2) and its analogue for $\mathscr{K}'^\bullet$.

Finally, for every open covering $\mathfrak{U} = (U_\alpha)$ of X, the hypercohomology $\mathbf{H}^\bullet(\mathfrak{U}, \mathscr{K}^\bullet)$ has also been defined (**0**, 12.4.5) as the cohomology of the bicomplex $\mathrm{C}^\bullet(\mathfrak{U}, \mathscr{K}^\bullet)$, whose component of bidegree (i, j) is by definition $\mathrm{C}^i(\mathfrak{U}, \mathscr{K}^j)$. The modules $\mathbf{H}^n(\mathfrak{U}, \mathscr{K}^\bullet)$ are again modules over $\Gamma(X, \mathscr{O}_X)$.

Proposition (6.2.2). — *Let X be a scheme, and let $\mathfrak{U} = (U_\alpha)$ be a covering of X by affine open subsets. For every complex $\mathscr{K}^\bullet$ of quasi-coherent $\mathscr{O}_X$-modules, the hypercohomology modules*

$$\mathbf{H}^\bullet(X, \mathscr{K}^\bullet) \quad \textit{and} \quad \mathbf{H}^\bullet(\mathfrak{U}, \mathscr{K}^\bullet)$$

are canonically isomorphic.

Proof. Every finite intersection V of members of $\mathfrak{U}$ is affine (**I**, 5.5.6); hence $\mathrm{H}^q(V, \mathscr{K}^i) = 0$ for every i and every $q > 0$ (1.3.1). The proposition is therefore a special case of (**0**, 12.4.7). □

Proposition (6.2.3). — *Let $f : X \to Y$ be a quasi-compact separated morphism of preschemes. For every complex $\mathscr{K}^\bullet$ of quasi-coherent $\mathscr{O}_X$-modules, the $\mathscr{O}_Y$-modules $\mathscr{H}^n(f, \mathscr{K}^\bullet)$ are quasi-coherent.*

Proof. The modules

$$\mathscr{H}^q(f, \mathscr{K}^i) = \mathrm{R}^q f_*(\mathscr{K}^i)$$

are quasi-coherent $\mathscr{O}_Y$-modules (1.4.10). Hence so is $'\mathscr{E}_2^{pq}$: by (6.2.1.1), it is the quotient of the kernel of a homomorphism of quasi-coherent modules by the image of such a homomorphism (**I**, 4.1.1). For the same reason, all terms, cycles, and boundaries of the first spectral sequence are quasi-coherent. Regularity implies that $\mathrm{Z}_\infty('\mathscr{E}_2^{pq})$ equals one of the $\mathrm{Z}_k('\mathscr{E}_2^{pq})$ and is therefore quasi-coherent. Likewise,

$$\mathrm{B}_\infty('\mathscr{E}_2^{pq}) = \varinjlim_k \mathrm{B}_k('\mathscr{E}_2^{pq})$$

is quasi-coherent (**0**, 11.2.4), (**I**, 4.1.1); thus the ${}'\mathscr{E}_\infty^{pq}$ are quasi-coherent as well.

Since the spectral sequence is regular, the filtration $F^\bullet \mathscr{H}^n(f, \mathscr{K}^\bullet)$ is discrete and exhaustive. Equivalently, $\mathscr{H}^n(f, \mathscr{K}^\bullet)$ is the union of an increasing sequence $(\mathscr{G}_k)_{k\geqslant 0}$ of $\mathscr{O}_Y$-modules such that $\mathscr{G}_0 = 0$ and every quotient $\mathscr{G}_k/\mathscr{G}_{k-1}$ is one of the ${}'\mathscr{E}_\infty^{pq}$, and hence is quasi-coherent. It follows inductively that the $\mathscr{G}_k$ are quasi-coherent (1.4.17). Since

$$\mathscr{H}^n(f, \mathscr{K}^\bullet) = \varinjlim_k \mathscr{G}_k,$$

the proposition follows from (**I**, 4.1.1). □

Corollary (6.2.4). — *Under the hypotheses of (6.2.3), for every affine open subset V of Y, the canonical homomorphism* **III** | 140

(6.2.4.1) $$\mathbf{H}^n\big(f^{-1}(V), \mathscr{K}^\bullet\big) \longrightarrow \Gamma\big(V, \mathscr{H}^n(f, \mathscr{K}^\bullet)\big)$$

is bijective for every $n \in \mathbf{Z}$.

Proof. The proof is the same as that of (1.4.11), using (6.2.2): one replaces the sheaf there by $\mathscr{K}^\bullet$, uses the Cech bicomplex $f_*\mathrm{C}^\bullet(\mathfrak{U}, \mathscr{K}^\bullet)$, and replaces ordinary cohomology by $\mathscr{H}^\bullet(f, \mathscr{K}^\bullet)$. The latter is a quasi-coherent $\mathscr{O}_Y$-module by (6.2.3). □

Proposition (6.2.5). — *Let Y be a locally Noetherian prescheme, let $f : X \to Y$ be proper, and let $\mathscr{K}^\bullet$ be a complex of $\mathscr{O}_X$-modules such that the $\mathscr{O}_X$-modules $\mathscr{H}^q(\mathscr{K}^\bullet)$ are coherent. Then the $\mathscr{O}_Y$-modules $\mathscr{H}^n(f, \mathscr{K}^\bullet)$ are coherent.*

Proof. The question is local on Y, so we may suppose that Y is Noetherian and affine. By (6.2.4), it is enough to prove that the $\mathbf{H}^n(X, \mathscr{K}^\bullet)$ are finite-type modules over $\Gamma(Y, \mathscr{O}_Y)$ (3.2.1). By (6.2.2),

$$\mathbf{H}^\bullet(X, \mathscr{K}^\bullet) = \mathbf{H}^\bullet(\mathfrak{U}, \mathscr{K}^\bullet),$$

where $\mathfrak{U}$ may be taken finite, since X is quasi-compact. The cochains in each complex $\mathrm{C}^\bullet(\mathfrak{U}, \mathscr{K}^j)$ are alternating by definition. Hence there is an integer $r > 0$ such that

$$\mathrm{C}^i(\mathfrak{U}, \mathscr{K}^j) = 0 \qquad \text{for } i < 0 \text{ and } i > r.$$

It follows from (**0**, 11.3.3) that both spectral sequences of the bicomplex $\mathrm{C}^\bullet(\mathfrak{U}, \mathscr{K}^\bullet)$ are biregular.

Intersections of members of $\mathfrak{U}$ are affine open subsets (**I**, 5.5.6), so each functor

$$\mathscr{F} \longmapsto \mathrm{C}^i(\mathfrak{U}, \mathscr{F})$$

is exact in the category of quasi-coherent $\mathscr{O}_X$-modules. Consequently the E_2-terms of the second spectral sequence are

$${}''E_2^{pq} = \mathrm{H}^p\big(\mathrm{C}^\bullet(\mathfrak{U}, \mathscr{H}^q(\mathscr{K}^\bullet))\big) = \mathbf{H}^p\big(\mathfrak{U}, \mathscr{H}^q(\mathscr{K}^\bullet)\big) = \mathrm{H}^p\big(X, \mathscr{H}^q(\mathscr{K}^\bullet)\big)$$

(**0**, 11.3.2), (1.4.1). Since f is proper, these are finite-type $\Gamma(Y, \mathscr{O}_Y)$-modules (3.2.1). Biregularity now implies that the $\mathbf{H}^n(X, \mathscr{K}^\bullet)$ are finite-type $\Gamma(Y, \mathscr{O}_Y)$-modules (**0**, 11.1.8).

A fortiori, if $\mathscr{K}^\bullet$ is a complex of coherent $\mathscr{O}_X$-modules, then the $\mathscr{H}^n(f, \mathscr{K}^\bullet)$ are coherent under the hypotheses on Y and f in (6.2.5) (**0**, 5.3.4). □

(6.2.6). The hypercohomology $\mathscr{H}^\bullet(f, \mathscr{K}^\bullet)$ is a cohomological functor on the category of bounded-below complexes of $\mathscr{O}_X$-modules (**0**, 12.4.4). It is a cohomological functor on the category of all complexes of $\mathscr{O}_X$-modules when f is quasi-compact and the underlying space of X is locally Noetherian. Indeed, f_* then commutes with inductive limits *(G, II, 3.10.1)*—the question being local on Y—and (**0**, 11.5.2) applies.

Finally, if f is separated, $\mathscr{H}^\bullet(f, \mathscr{K}^\bullet)$ is a cohomological functor on the category of complexes of quasi-coherent $\mathscr{O}_X$-modules. This is immediate when Y is affine, for then X is a scheme and the canonical isomorphism (6.2.2) reduces the assertion to the fact that

$$\mathscr{K}^\bullet \longmapsto \mathbf{H}^\bullet(\mathfrak{U}, \mathscr{K}^\bullet)$$

is cohomological. This in turn is immediate because

$$\mathscr{K}^\bullet \longmapsto \mathrm{C}^\bullet(\mathfrak{U}, \mathscr{K}^\bullet)$$

is exact in this category (**I**, 1.3.7).

In general, for every affine open subset V of Y, $f^{-1}(V)$ is a scheme. To apply the preceding argument, it is enough to verify that, for an exact sequence **III** | 141

$$0 \longrightarrow \mathscr{K}'^{\bullet} \longrightarrow \mathscr{K}^{\bullet} \longrightarrow \mathscr{K}''^{\bullet} \longrightarrow 0$$

of complexes of quasi-coherent $\mathscr{O}_X$-modules, the connecting homomorphism

$$\partial : \mathscr{H}^n(f, \mathscr{K}''^{\bullet})|V \longrightarrow \mathscr{H}^{n+1}(f, \mathscr{K}'^{\bullet})|V$$

does not depend on the affine open covering $\mathfrak{U}$ of $f^{-1}(V)$ used to define it. If $\mathfrak{U}'$ is an affine open refinement of $\mathfrak{U}$, this follows from commutativity of the triangle of canonical isomorphisms

$$\begin{tikzcd}
\mathbf{H}^{\bullet}(\mathfrak{U}, \mathscr{K}^{\bullet}) \arrow[d, "\iota"] \arrow[dr, "\sim"] & \\
& \mathbf{H}^{\bullet}(f^{-1}(V), \mathscr{K}^{\bullet}) \\
\mathbf{H}^{\bullet}(\mathfrak{U}', \mathscr{K}^{\bullet}) \arrow[ur, "\sim"'] &
\end{tikzcd}$$

and of the diagram

$$\begin{tikzcd}
\mathbf{H}^n(\mathfrak{U}, \mathscr{K}''^{\bullet}) \arrow[r, "\partial"] \arrow[d, "\iota"] & \mathbf{H}^{n+1}(\mathfrak{U}, \mathscr{K}'^{\bullet}) \arrow[d, "\iota"] \\
\mathbf{H}^n(\mathfrak{U}', \mathscr{K}''^{\bullet}) \arrow[r, "\partial"'] & \mathbf{H}^{n+1}(\mathfrak{U}', \mathscr{K}'^{\bullet}).
\end{tikzcd}$$

Whenever one of the preceding conditions holds and $\mathscr{K}^{\bullet} \to \mathscr{K}'^{\bullet}$ is a homotopism (6.1.4), the resulting isomorphism

$$\mathscr{H}^{\bullet}(f, \mathscr{K}^{\bullet}) \xrightarrow{\sim} \mathscr{H}^{\bullet}(f, \mathscr{K}'^{\bullet})$$

is an isomorphism of ∂-functors (**0**, 11.4.4).

(6.2.7). Everything above applies naturally, with only a change of notation, to a complex $\mathscr{K}_{\bullet}$ of quasi-coherent $\mathscr{O}_X$-modules whose differential has degree -1: it is enough to consider the complex $\mathscr{K}^{\bullet} = (\mathscr{K}^i)$ defined by

$$\mathscr{K}^i = \mathscr{K}_{-i} \qquad (i \in \mathbf{Z}).$$

6.3. Hypertor of two complexes of modules

(6.3.1). Let A be a commutative ring, and let $P_{\bullet}$ and $Q_{\bullet}$ be two complexes of A-modules whose differentials have degree -1. Let $L_{\bullet\bullet}$ and $M_{\bullet\bullet}$ be projective Cartan–Eilenberg resolutions of $P_{\bullet}$ and $Q_{\bullet}$, respectively (**0**, 11.6.1). Taking the sum of the first degrees and the sum of the second degrees,

$$L_{\bullet\bullet} \otimes_A M_{\bullet\bullet}$$

is a bicomplex whose differentials have degree -1. Its homology

$$\mathrm{H}_{\bullet}(L_{\bullet\bullet} \otimes_A M_{\bullet\bullet})$$

does not depend on the chosen Cartan–Eilenberg resolutions and is, by definition, the hyperhomology of the bifunctor $P_{\bullet} \otimes_A Q_{\bullet}$ in $P_{\bullet}$ and $Q_{\bullet}$ (**0**, 11.6.5). We put

(6.3.1.1) $$\mathbf{Tor}_n^A(P_{\bullet}, Q_{\bullet}) = \mathrm{H}_n(L_{\bullet\bullet} \otimes_A M_{\bullet\bullet})$$

and call this A-module the *hypertor of index n* of the two complexes $P_{\bullet}$ and $Q_{\bullet}$. In the category of bounded-below complexes of A-modules, the modules $\mathbf{Tor}_n^A(P_{\bullet}, Q_{\bullet})$ form a homological bifunctor in $P_{\bullet}$ and $Q_{\bullet}$ (**0**, 11.6.5). Moreover: **III** | 142

Proposition (6.3.2). — *The bifunctor* $\mathbf{Tor}_{\bullet}^A(P_{\bullet}, Q_{\bullet})$ *is the common abutment of two bifunctorial spectral sequences* ${}'E(P_{\bullet}, Q_{\bullet})$ *and* ${}''E(P_{\bullet}, Q_{\bullet})$ *whose* E_2*-terms are*

(6.3.2.1) $${}'E^2_{pq} = \mathrm{H}_p\big(\mathrm{Tor}_q^A(P_{\bullet}, Q_{\bullet})\big),$$

and

(6.3.2.2) $${}''E^2_{pq} = \bigoplus_{q'+q''=q} \mathrm{Tor}_p^A\big(\mathrm{H}_{q'}(P_{\bullet}), \mathrm{H}_{q''}(Q_{\bullet})\big).$$

In (6.3.2.1), $\mathrm{Tor}_q^A(P_\bullet, Q_\bullet)$ denotes the bicomplex formed by the A-modules $\mathrm{Tor}_q^A(P_i, Q_j)$. The spectral sequence (6.3.2.2) is always regular. If $P_\bullet$ and $Q_\bullet$ are bounded below, or if A has finite cohomological dimension, then both spectral sequences (6.3.2.1) and (6.3.2.2) are biregular.

Proof. This follows from (**0**, 11.6.5). Indeed, if A has finite cohomological dimension n, every A-module has a projective resolution of length n *(M, VI, 2.1)*. □

Corollary (6.3.3). — *Let $P'_\bullet$ and $Q'_\bullet$ be complexes of A-modules, and let*

$$u : P_\bullet \longrightarrow P'_\bullet, \qquad v : Q_\bullet \longrightarrow Q'_\bullet$$

be homomorphisms of complexes. If the induced homomorphisms

$$\mathrm{H}_\bullet(u) : \mathrm{H}_\bullet(P_\bullet) \longrightarrow \mathrm{H}_\bullet(P'_\bullet), \qquad \mathrm{H}_\bullet(v) : \mathrm{H}_\bullet(Q_\bullet) \longrightarrow \mathrm{H}_\bullet(Q'_\bullet)$$

are bijective, then the homomorphism

$$\mathbf{Tor}_n^A(P_\bullet, Q_\bullet) \longrightarrow \mathbf{Tor}_n^A(P'_\bullet, Q'_\bullet)$$

induced by u and v is bijective.

Proof. The induced homomorphism

$$''E(P_\bullet, Q_\bullet) \longrightarrow'' E(P'_\bullet, Q'_\bullet)$$

is an isomorphism on the E_2-terms. The conclusion follows from regularity of these spectral sequences (6.3.2) and (**0**, 11.1.5). □

Proposition (6.3.4). — *Let $P_\bullet$ and $Q_\bullet$ be bounded-below complexes of A-modules. Let $L_{\bullet\bullet}$ and $M_{\bullet\bullet}$ be bicomplexes of flat A-modules such that, for every i, $L_{i,\bullet}$ is a resolution of P_i and $M_{i,\bullet}$ is a resolution of Q_i. Then there are canonical isomorphisms*

$$\begin{aligned} \mathbf{Tor}_n^A(P_\bullet, Q_\bullet) &\xrightarrow{\sim} \mathrm{H}_n(L_{\bullet\bullet} \otimes_A Q_\bullet) \\ &\xrightarrow{\sim} \mathrm{H}_n(P_\bullet \otimes_A M_{\bullet\bullet}) \\ &\xrightarrow{\sim} \mathrm{H}_n(L_{\bullet\bullet} \otimes_A M_{\bullet\bullet}). \end{aligned} \tag{6.3.4.1}$$

Proof. This follows from (**0**, 11.6.5), parts (ii) and (iii), and from the definition of flat A-modules. □

Remarks (6.3.5). — *(i)* With the notation of (6.3.1), the bicomplexes $L_{\bullet\bullet} \otimes_A M_{\bullet\bullet}$ and $M_{\bullet\bullet} \otimes_A L_{\bullet\bullet}$ are canonically isomorphic. Hence there is a canonical isomorphism

$$\mathbf{Tor}_n^A(P_\bullet, Q_\bullet) \xrightarrow{\sim} \mathbf{Tor}_n^A(Q_\bullet, P_\bullet).$$

(ii) Let F and G be A-modules, and let $P_\bullet$ and $Q_\bullet$ be the complexes concentrated in degree 0 with values F and G, respectively. Projective resolutions $L_\bullet$ of F and $M_\bullet$ of G may be regarded, after adjoining zeros, as Cartan–Eilenberg resolutions of $P_\bullet$ and $Q_\bullet$. Thus in this case

$$\mathbf{Tor}_n^A(P_\bullet, Q_\bullet) = \mathrm{Tor}_n^A(F, G).$$

Proposition (6.3.6). — *Let $(P^\lambda_\bullet)$ and $(Q^\mu_\bullet)$ be two filtered inductive systems of complexes of A-modules. There is a canonical isomorphism*

$$\varinjlim_{\lambda,\mu} \mathbf{Tor}_n^A(P^\lambda_\bullet, Q^\mu_\bullet) \xrightarrow{\sim} \mathbf{Tor}_n^A\left(\varinjlim_\lambda P^\lambda_\bullet, \varinjlim_\mu Q^\mu_\bullet\right). \tag{6.3.6.1}$$

Proof. Put

$$P_\bullet = \varinjlim_\lambda P^\lambda_\bullet, \qquad Q_\bullet = \varinjlim_\mu Q^\mu_\bullet.$$

By functoriality, the modules $\mathbf{Tor}_n^A(P^\lambda_\bullet, Q^\mu_\bullet)$ form an inductive system, and the canonical maps to **III** | 143
$\mathbf{Tor}_n^A(P_\bullet, Q_\bullet)$ give the homomorphism (6.3.6.1). More generally, they give a canonical homomorphism of spectral sequences

$$\varinjlim_{\lambda,\mu}{}'' E(P^\lambda_\bullet, Q^\mu_\bullet) \longrightarrow'' E(P_\bullet, Q_\bullet),$$

whose homomorphism on abutments is (6.3.6.1).

The spectral sequence $''E(P_\bullet, Q_\bullet)$ is regular by (6.3.2). So is $\varinjlim''_{\lambda,\mu} E(P^\lambda_\bullet, Q^\mu_\bullet)$, as follows from the definitions (**0**, 11.1.7) and the proof of (**0**, 11.3.3). By (**0**, 11.1.5), it is therefore enough to prove that

$$\varinjlim_{\lambda,\mu}{}'' E(P^\lambda_\bullet, Q^\mu_\bullet) \longrightarrow'' E(P_\bullet, Q_\bullet) \tag{6.3.6.2}$$

is bijective on the E^2-terms.

Since homology commutes with inductive limits of complexes of modules, it remains only to prove that, for filtered inductive systems (F^λ) and (G^μ) of A-modules, the canonical homomorphism

$$\varinjlim_{\lambda,\mu} \operatorname{Tor}^A_n(F^\lambda, G^\mu) \longrightarrow \operatorname{Tor}^A_n\left(\varinjlim_\lambda F^\lambda, \varinjlim_\mu G^\mu\right)$$

is bijective.

For each F^λ, consider its canonical free resolution

$$L^\lambda_\bullet : \quad \cdots \longrightarrow L^\lambda_{i+1} \longrightarrow L^\lambda_i \longrightarrow \cdots \longrightarrow L^\lambda_1 \longrightarrow L^\lambda_0 \longrightarrow 0,$$

where L^λ_0 is the A-module of formal linear combinations of elements of F^λ, and L^λ_{i+1} is the A-module of formal linear combinations of elements of $\operatorname{Ker}(L^\lambda_i \to L^\lambda_{i-1})$. The $L^\lambda_\bullet$ form an inductive system of complexes. Put

$$F = \varinjlim_\lambda F^\lambda, \qquad L_i = \varinjlim_\lambda L^\lambda_i.$$

Since filtered inductive limits are exact, the L_i form a resolution $L_\bullet$ of F; moreover, each L_i is flat, being an inductive limit of free A-modules (**0**, 6.1.2).

Likewise, let $M^\mu_\bullet$ be the canonical free resolution of G^μ, and put

$$M_\bullet = \varinjlim_\mu M^\mu_\bullet, \qquad G = \varinjlim_\mu G^\mu.$$

Then $M_\bullet$ is a flat resolution of G. By (6.3.5) and (6.3.4),

$$\operatorname{Tor}^A_n(F, G) = \mathrm{H}_n(L_\bullet \otimes_A M_\bullet).$$

Since homology commutes with inductive limits of complexes of modules,

$$\mathrm{H}_n(L_\bullet \otimes_A M_\bullet) = \varinjlim_{\lambda,\mu} \mathrm{H}_n(L^\lambda_\bullet \otimes_A M^\mu_\bullet).$$

The last modules are $\operatorname{Tor}^A_n(F^\lambda, G^\mu)$, which proves (6.3.6.1).

If, in addition, there is an i_0 such that $P^\lambda_i = Q^\mu_i = 0$ for $i < i_0$, for all λ and μ, the same argument proves that the canonical homomorphism

$$\varinjlim_{\lambda,\mu}{}' E(P^\lambda_\bullet, Q^\mu_\bullet) \longrightarrow' E(P_\bullet, Q_\bullet) \tag{6.3.6.3}$$

is bijective. □

Proposition (6.3.7). — *Suppose that $P_\bullet$ and $Q_\bullet$ are bounded below. If $P_\bullet$ consists of flat A-modules, there is a canonical A-linear isomorphism of ∂-functors in $Q_\bullet$*

$$\mathbf{Tor}^A_n(P_\bullet, Q_\bullet) \xrightarrow{\sim} \mathrm{H}_n(P_\bullet \otimes_A Q_\bullet). \tag{6.3.7.1}$$

Proof. The spectral sequence (6.3.2.1) is biregular and degenerate, so existence of (6.3.7.1) follows from (**0**, 11.1.6). Computing hypertor from a projective Cartan–Eilenberg resolution of $P_\bullet$ as in (6.3.4) shows immediately that this isomorphism is an isomorphism of ∂-functors in $Q_\bullet$. □

(6.3.8). Let $\rho : A \longrightarrow A'$ be a homomorphism of rings. We shall define a functorial A-linear homomorphism of degree zero, canonically associated with ρ, **III | 144**

$$\rho_{P_\bullet, Q_\bullet} : \mathbf{Tor}^A_\bullet(P_\bullet, Q_\bullet) \longrightarrow \mathbf{Tor}^{A'}_\bullet(P_\bullet \otimes_A A', Q_\bullet \otimes_A A'). \tag{6.3.8.1}$$

For this purpose, let $L_{\bullet\bullet}$ be a projective Cartan–Eilenberg resolution of $P_\bullet$, and let $L'_{\bullet\bullet}$ be a projective Cartan–Eilenberg resolution of $P_\bullet \otimes_A A'$. We first show that there is an A'-linear homomorphism of complexes

$$L_{\bullet\bullet} \otimes_A A' \longrightarrow L'_{\bullet\bullet},$$

determined up to homotopy. Indeed, the construction of $L_{\bullet\bullet}$ is completely determined once one chooses, arbitrarily for each i, a projective resolution $(X^{\mathrm{B}}_{ij})_{j\geqslant 0}$ of $\mathrm{B}_i(P_\bullet)$ and a projective resolution $(X^{\mathrm{H}}_{ij})_{j\geqslant 0}$ of $\mathrm{H}_i(P_\bullet)$. These are respectively $\mathrm{B}^{\mathrm{I}}_i(L_{\bullet\bullet})$ and $\mathrm{H}^{\mathrm{I}}_i(L_{\bullet\bullet})$. One then obtains successively

$$\mathrm{Z}^{\mathrm{I}}_i(L_{\bullet\bullet}) = \mathrm{H}^{\mathrm{I}}_i(L_{\bullet\bullet}) \oplus \mathrm{B}^{\mathrm{I}}_i(L_{\bullet\bullet}), \qquad L_{i,\bullet} = \mathrm{Z}^{\mathrm{I}}_i(L_{\bullet\bullet}) \oplus \mathrm{B}^{\mathrm{I}}_{i-1}(L_{\bullet\bullet}).$$

Now $X^{\mathrm{B}}_{i,\bullet} \otimes_A A'$ is not in general a resolution of $\mathrm{B}_i(P_\bullet) \otimes_A A'$, but it is still a complex of projective A'-modules. Hence there is an A'-linear homomorphism

$$X^{\mathrm{B}}_{i,\bullet} \otimes_A A' \longrightarrow \mathrm{B}^{\mathrm{I}}_i(L'_{\bullet\bullet})$$

compatible with the augmentations and determined up to homotopy (M, V, 1.1). Likewise there is an A'-linear homomorphism

$$X^{\mathrm{H}}_{i,\bullet} \otimes_A A' \longrightarrow \mathrm{H}^{\mathrm{I}}_i(L'_{\bullet\bullet})$$

determined up to homotopy. By the construction just recalled, these maps give, for every i, an A'-linear homomorphism

$$L_{i,\bullet} \otimes_A A' \longrightarrow L'_{i,\bullet}.$$

For $i \in \mathbb{Z}$ these homomorphisms are compatible with the differentials $L_{i,\bullet} \longrightarrow L_{i-1,\bullet}$ and their analogues for $L'_{\bullet\bullet}$; together they therefore give the required homomorphism $L_{\bullet\bullet} \otimes_A A' \longrightarrow L'_{\bullet\bullet}$.

To define (6.3.8.1), take in the same way projective Cartan–Eilenberg resolutions $M_{\bullet\bullet}$ and $M'_{\bullet\bullet}$ of $Q_\bullet$ and $Q_\bullet \otimes_A A'$, respectively, and an A'-linear homomorphism $M_{\bullet\bullet} \otimes_A A' \longrightarrow M'_{\bullet\bullet}$. The resulting homomorphism

$$(L_{\bullet\bullet} \otimes_A A') \otimes_{A'} (M_{\bullet\bullet} \otimes_A A') \longrightarrow L'_{\bullet\bullet} \otimes_{A'} M'_{\bullet\bullet}$$

gives, by composition, an A-linear homomorphism of bicomplexes

$$L_{\bullet\bullet} \otimes_A M_{\bullet\bullet} \longrightarrow L'_{\bullet\bullet} \otimes_{A'} M'_{\bullet\bullet}.$$

Passing to homology yields (6.3.8.1); it is well defined because it is induced by a homomorphism of complexes determined up to homotopy.

If $\rho' : A' \longrightarrow A''$ is a second homomorphism of rings and $\rho'' = \rho' \circ \rho : A \longrightarrow A''$, then

$$\rho''_{P_\bullet,Q_\bullet} = \rho'_{P'_\bullet,Q'_\bullet} \circ \rho_{P_\bullet,Q_\bullet}, \qquad P'_\bullet = P_\bullet \otimes_A A', \quad Q'_\bullet = Q_\bullet \otimes_A A'.$$

The preceding homomorphism of bicomplexes also defines functorial homomorphisms of spectral sequences

$$'E^r_{pq}(P_\bullet, Q_\bullet) \longrightarrow' E^r_{pq}(P_\bullet \otimes_A A', Q_\bullet \otimes_A A')$$

and

$$''E^r_{pq}(P_\bullet, Q_\bullet) \longrightarrow'' E^r_{pq}(P_\bullet \otimes_A A', Q_\bullet \otimes_A A').$$

They are independent of the Cartan–Eilenberg resolutions chosen and satisfy the same transitivity property.

Proposition (6.3.9). — *Let $\rho : A \longrightarrow A'$ be a homomorphism of rings such that A' is flat as an A-module. There are canonical functorial isomorphisms*

$$\mathbf{Tor}^{A'}_\bullet(P_\bullet \otimes_A A', Q_\bullet \otimes_A A') \xrightarrow{\sim} \mathbf{Tor}^{A}_\bullet(P_\bullet, Q_\bullet) \otimes_A A', \tag{6.3.9.1}$$

$$\begin{cases} 'E(P_\bullet \otimes_A A', Q_\bullet \otimes_A A') \xrightarrow{\sim}' E(P_\bullet, Q_\bullet) \otimes_A A', \\ ''E(P_\bullet \otimes_A A', Q_\bullet \otimes_A A') \xrightarrow{\sim}'' E(P_\bullet, Q_\bullet) \otimes_A A'. \end{cases} \tag{6.3.9.2}$$

Proof. Since the functor $M \longmapsto M \otimes_A A'$ is exact, $L_{\bullet\bullet} \otimes_A A'$ and $M_{\bullet\bullet} \otimes_A A'$ are projective Cartan–Eilenberg resolutions of $P_\bullet \otimes_A A'$ and $Q_\bullet \otimes_A A'$, respectively. The assertion follows. □ **III** | 145

(6.3.10). Let $\rho : A \longrightarrow A'$ be a homomorphism of rings. For every complex $P'_\bullet$ of A'-modules, let $P'_{\bullet[\rho]}$ denote the same complex regarded as a complex of A-modules. The identity map $P'_{\bullet[\rho]} \longrightarrow P'_\bullet$ is the composite of the canonical maps

$$P'_{\bullet[\rho]} \longrightarrow P'_{\bullet[\rho]} \otimes_A A' \xrightarrow{\mu} P'_\bullet,$$

where μ is the A'-linear homomorphism $\mu(x \otimes a') = a'x$. If $Q'_\bullet$ is a second complex of A'-modules, there are therefore canonical functorial homomorphisms of degree zero

$$\begin{aligned} \mathbf{Tor}^A_\bullet(P'_{\bullet[\rho]}, Q'_{\bullet[\rho]}) &\longrightarrow \mathbf{Tor}^{A'}_\bullet(P'_{\bullet[\rho]} \otimes_A A', Q'_{\bullet[\rho]} \otimes_A A') \\ &\longrightarrow \mathbf{Tor}^{A'}_\bullet(P'_\bullet, Q'_\bullet). \end{aligned} \tag{6.3.10.1}$$

The first arrow is the A-linear homomorphism defined in (6.3.8); the second follows by functoriality from the A'-linear homomorphisms

$$P'_{\bullet[\rho]} \otimes_A A' \longrightarrow P'_\bullet, \qquad Q'_{\bullet[\rho]} \otimes_A A' \longrightarrow Q'_\bullet.$$

There are analogous homomorphisms for the spectral sequences of (6.3.2), together with the evident transitivity properties, whose formulation is left to the reader.

Proposition (6.3.11). — *Let $\rho : A \longrightarrow A'$ be a homomorphism of rings such that A' is flat as an A-module. For every complex $P'_\bullet$ of A'-modules and every bounded-below complex $Q_\bullet$ of A-modules, there is a canonical functorial isomorphism*

$$\mathbf{Tor}^A_\bullet(P'_{\bullet[\rho]}, Q_\bullet) \xrightarrow{\sim} \mathbf{Tor}^{A'}_\bullet(P'_\bullet, Q_\bullet \otimes_A A'). \tag{6.3.11.1}$$

Proof. If $M_{\bullet\bullet}$ is a projective Cartan–Eilenberg resolution of $Q_\bullet$, then $M_{\bullet\bullet} \otimes_A A'$ is a projective Cartan–Eilenberg resolution of $Q_\bullet \otimes_A A'$. Moreover, up to canonical isomorphism,

$$P'_{\bullet[\rho]} \otimes_A M_{\bullet\bullet} = P'_\bullet \otimes_{A'} (M_{\bullet\bullet} \otimes_A A').$$

The assertion follows from (6.3.4). □

Remark (6.3.12). — Let (A^λ) be a filtered inductive system of rings, and let $(P^\lambda_\bullet)$ and $(Q^\lambda_\bullet)$ be two inductive systems of complexes of A^λ-modules. There is a canonical isomorphism generalizing (6.3.6.1),

$$\varinjlim_\lambda \mathbf{Tor}^{A^\lambda}_\bullet(P^\lambda_\bullet, Q^\lambda_\bullet) \xrightarrow{\sim} \mathbf{Tor}^A_\bullet(P_\bullet, Q_\bullet), \tag{6.3.12.1}$$

where

$$A = \varinjlim_\lambda A^\lambda, \qquad P_\bullet = \varinjlim_\lambda P^\lambda_\bullet, \qquad Q_\bullet = \varinjlim_\lambda Q^\lambda_\bullet.$$

Once the homomorphisms

$$\mathbf{Tor}^{A^\lambda}_\bullet(P^\lambda_\bullet, Q^\lambda_\bullet) \longrightarrow \mathbf{Tor}^{A^\mu}_\bullet(P^\mu_\bullet, Q^\mu_\bullet) \qquad (\lambda \leqslant \mu)$$

have been defined by (6.3.10), the proof is the same as that of (6.3.6).

Proposition (6.3.13). — *Let S be a multiplicative subset of A, and let $P_\bullet$ and $Q_\bullet$ be complexes of A-modules on which multiplication by every element of S is bijective. Thus, if $A' = S^{-1}A$, both complexes consist of A'-modules. Then there is a canonical isomorphism*

$$\mathbf{Tor}^A_\bullet(P_\bullet, Q_\bullet) \xrightarrow{\sim} \mathbf{Tor}^{A'}_\bullet(P_\bullet, Q_\bullet).$$

Proof. The hypothesis implies that the canonical homomorphisms

$$P_\bullet \longrightarrow P_\bullet \otimes_A A', \qquad Q_\bullet \longrightarrow Q_\bullet \otimes_A A'$$

are bijective. Functoriality of hypertor also shows that each $s \in S$ acts bijectively on $\mathbf{Tor}^A_\bullet(P_\bullet, Q_\bullet)$; hence

$$\mathbf{Tor}^A_\bullet(P_\bullet, Q_\bullet) \longrightarrow \mathbf{Tor}^A_\bullet(P_\bullet, Q_\bullet) \otimes_A A'$$

is bijective. Since A' is flat over A, the assertion follows from (6.3.9). The same argument gives **III** | 146
canonical isomorphisms of the associated spectral sequences. □

6.4. Local hypertor functors of complexes of quasi-coherent modules: the affine scheme case

(6.4.1). Let S be an affine scheme with ring A, and let X and Y be affine S-schemes with rings B and C, respectively; thus B and C are A-algebras. Every complex $\mathscr{P}_\bullet$ of quasi-coherent $\mathscr{O}_X$-modules is of the form $\widetilde{P}_\bullet$ for a complex $P_\bullet$ of B-modules, and similarly every complex $\mathscr{Q}_\bullet$ of quasi-coherent $\mathscr{O}_Y$-modules is of the form $\widetilde{Q}_\bullet$ for a complex $Q_\bullet$ of C-modules ((**I**, 1.3.7) and (**I**, 1.3.8)).

Regarded as complexes of A-modules, $P_\bullet$ and $Q_\bullet$ have hypertor modules $\mathbf{Tor}_n^A(P_\bullet, Q_\bullet)$. By bifunctoriality, the A-algebras B and C act on this A-module; these actions make it a (B,C)-bimodule, equivalently a module over

$$B \otimes_A C = A(X \times_S Y).$$

We have thus defined a quasi-coherent $\mathscr{O}_{X\times_S Y}$-module

$$\mathscr{T}\!or_n^{\mathscr{O}_S}(\mathscr{P}_\bullet, \mathscr{Q}_\bullet) = \left(\mathbf{Tor}_n^A(P_\bullet, Q_\bullet)\right)^\sim. \tag{6.4.1.1}$$

It is called the *local hypertor of index n* of $\mathscr{P}_\bullet$ and $\mathscr{Q}_\bullet$, and is also denoted $\mathscr{T}\!or_n^S(\mathscr{P}_\bullet, \mathscr{Q}_\bullet)$.

Lemma (6.4.2). — *With the notation of (6.4.1), suppose that $A = R^{-1}A'$, where A' is a ring and R is a multiplicative subset of A'. Let $S' = \operatorname{Spec}(A')$. Then X and Y may be regarded as S'-schemes and $X \times_{S'} Y = X \times_S Y$ ((**I**, 1.6.2) and (3.2.4)); moreover,*

$$\mathscr{T}\!or_\bullet^{S'}(\mathscr{P}_\bullet, \mathscr{Q}_\bullet) = \mathscr{T}\!or_\bullet^{S}(\mathscr{P}_\bullet, \mathscr{Q}_\bullet).$$

Proof. This follows from (6.4.1.1) and (6.3.13). □

(6.4.3). With the notation and hypotheses of (6.4.1), let $\mathscr{F} = \widetilde{F}$ be a quasi-coherent $\mathscr{O}_X$-module and $\mathscr{G} = \widetilde{G}$ a quasi-coherent $\mathscr{O}_Y$-module. Regarding $\mathscr{F}$ and $\mathscr{G}$ as complexes concentrated in degree zero, we write $\mathscr{T}\!or_n^{\mathscr{O}_S}(\mathscr{F}, \mathscr{G})$, or $\mathscr{T}\!or_n^S(\mathscr{F}, \mathscr{G})$, for their local hypertor of index n. By (6.3.5)(ii),

$$\mathscr{T}\!or_n^{\mathscr{O}_S}(\mathscr{F}, \mathscr{G}) = \left(\operatorname{Tor}_n^A(F, G)\right)^\sim. \tag{6.4.3.1}$$

Return now to two arbitrary complexes of quasi-coherent modules $\mathscr{P}_\bullet$ and $\mathscr{Q}_\bullet$. Formulas (6.4.1.1) and (6.4.3.1), together with (6.3.2), show that $\mathscr{T}\!or_\bullet^S(\mathscr{P}_\bullet, \mathscr{Q}_\bullet)$ is the common abutment of two spectral sequences $'\mathscr{E}(\mathscr{P}_\bullet, \mathscr{Q}_\bullet)$ and $''\mathscr{E}(\mathscr{P}_\bullet, \mathscr{Q}_\bullet)$ whose E_2-terms are

$$'\mathscr{E}_{pq}^2 = \mathscr{H}_p\left(\mathscr{T}\!or_q^S(\mathscr{P}_\bullet, \mathscr{Q}_\bullet)\right) \tag{6.4.3.2}$$

and

$$''\mathscr{E}_{pq}^2 = \bigoplus_{q'+q''=q} \mathscr{T}\!or_p^S\left(\mathscr{H}_{q'}(\mathscr{P}_\bullet), \mathscr{H}_{q''}(\mathscr{Q}_\bullet)\right). \tag{6.4.3.3}$$

Here $\mathscr{T}\!or_q^S(\mathscr{P}_\bullet, \mathscr{Q}_\bullet)$ in (6.4.3.2) denotes the bicomplex of quasi-coherent $\mathscr{O}_{X\times_S Y}$-modules $\mathscr{T}\!or_q^S(\mathscr{P}_i, \mathscr{Q}_j)$.

(6.4.4). Let

$$X^{(1)} = \operatorname{Spec}(B^{(1)}), \qquad Y^{(1)} = \operatorname{Spec}(C^{(1)})$$

be two further affine schemes, where $B^{(1)}$ and $C^{(1)}$ are A-algebras, and let **III | 147**

$$u : X^{(1)} \longrightarrow X, \qquad v : Y^{(1)} \longrightarrow Y$$

be S-morphisms corresponding to the A-homomorphisms $\phi : B \longrightarrow B^{(1)}$ and $\psi : C \longrightarrow C^{(1)}$. Consider the complexes

$$u^*(\mathscr{P}_\bullet) = (P_\bullet \otimes_B B^{(1)})^\sim, \qquad v^*(\mathscr{Q}_\bullet) = (Q_\bullet \otimes_C C^{(1)})^\sim.$$

The canonical A-linear homomorphisms

$$P_\bullet \longrightarrow P_\bullet \otimes_B B^{(1)}, \qquad Q_\bullet \longrightarrow Q_\bullet \otimes_C C^{(1)}$$

give, by functoriality, an A-linear homomorphism

$$\mathbf{Tor}_\bullet^A(P_\bullet, Q_\bullet) \longrightarrow \mathbf{Tor}_\bullet^A(P_\bullet \otimes_B B^{(1)}, Q_\bullet \otimes_C C^{(1)}).$$

Again by functoriality, this is in fact a homomorphism of $(B \otimes_A C)$-modules. It therefore defines a $(u \times_S v)$-morphism

$$\theta : \mathscr{T}\!or_\bullet^S(\mathscr{P}_\bullet, \mathscr{Q}_\bullet) \longrightarrow \mathscr{T}\!or_\bullet^S(u^*\mathscr{P}_\bullet, v^*\mathscr{Q}_\bullet), \tag{6.4.4.1}$$

and hence a homomorphism of $\mathscr{O}_{X^{(1)}\times_S Y^{(1)}}$-modules

(6.4.4.2) $$\theta^\sharp : (u \times_S v)^* \mathscr{T}\!or_\bullet^S(\mathscr{P}_\bullet, \mathscr{Q}_\bullet) \longrightarrow \mathscr{T}\!or_\bullet^S(u^*\mathscr{P}_\bullet, v^*\mathscr{Q}_\bullet).$$

This is plainly a morphism of bi-∂-functors on the categories of bounded-below quasi-coherent modules. The homomorphism (6.4.4.2) need not be bijective; nevertheless:

Lemma (6.4.5). — *With the notation of (6.4.4), if u and v are open immersions, then (6.4.4.2) is bijective.*

Proof. Identify $X^{(1)}$ and $Y^{(1)}$ with open subsets of X and Y. They are unions of open subsets of the form $\mathrm{D}(f)$ and $\mathrm{D}(g)$, where $f \in B$ and $g \in C$; the schemes induced on $\mathrm{D}(\phi(f))$ and $\mathrm{D}(f)$, and likewise on $\mathrm{D}(\psi(g))$ and $\mathrm{D}(g)$, are isomorphic.

It is enough to prove the lemma when $X^{(1)} = \mathrm{D}(f)$ and $Y^{(1)} = \mathrm{D}(g)$. Indeed, once this is known, in the general case it suffices to show that the restriction of $\theta^\sharp$ to every $\mathrm{D}(f) \times_S \mathrm{D}(g)$ is an isomorphism. If

$$u_1 : \mathrm{D}(f) \longrightarrow X^{(1)}, \qquad v_1 : \mathrm{D}(g) \longrightarrow Y^{(1)}$$

are the canonical inclusions, this restriction is $(u_1 \times_S v_1)^*(\theta^\sharp)$. From (6.4.4) and (**0**, 4.4.8), it is immediate that composing it with the canonical homomorphism

(6.4.5.1) $$(u_1 \times_S v_1)^* \mathscr{T}\!or_\bullet^S(u^*\mathscr{P}_\bullet, v^*\mathscr{Q}_\bullet) \longrightarrow \mathscr{T}\!or_\bullet^S((u')^*\mathscr{P}_\bullet, (v')^*\mathscr{Q}_\bullet),$$

where $u' = u \circ u_1$ and $v' = v \circ v_1$, gives the canonical homomorphism

(6.4.5.2) $$(u' \times_S v')^* \mathscr{T}\!or_\bullet^S(\mathscr{P}_\bullet, \mathscr{Q}_\bullet) \longrightarrow \mathscr{T}\!or_\bullet^S((u')^*\mathscr{P}_\bullet, (v')^*\mathscr{Q}_\bullet).$$

If (6.4.5.1) and (6.4.5.2) are isomorphisms, then so is $(u_1 \times_S v_1)^*(\theta^\sharp)$.

Suppose therefore that $X^{(1)} = \mathrm{D}(f)$ and $Y^{(1)} = \mathrm{D}(g)$, so that $B^{(1)} = B_f$ and $C^{(1)} = C_g$. Then $u^*(\mathscr{P}_\bullet)$ and $v^*(\mathscr{Q}_\bullet)$ identify with $((P_\bullet)_f)^\sim$ and $((Q_\bullet)_g)^\sim$, respectively. Moreover, $X^{(1)} \times_S Y^{(1)}$ identifies with the open subscheme $\mathrm{D}(f \otimes g)$ of

$$X \times_S Y = \mathrm{Spec}(B \otimes_A C)$$

((**II**, 4.3.2.4)). It remains to prove that the homomorphism

(6.4.5.3) $$\big(\mathbf{Tor}_\bullet^A(P_\bullet, Q_\bullet)\big)_{f\otimes g} \longrightarrow \mathbf{Tor}_\bullet^A((P_\bullet)_f, (Q_\bullet)_g),$$

induced by the canonical homomorphisms $P_\bullet \longrightarrow (P_\bullet)_f$ and $Q_\bullet \longrightarrow (Q_\bullet)_g$, is bijective. **III** | 148

By (**0**, 1.6.1),

$$(P_\bullet)_f = \varinjlim_m P_\bullet^{(m)},$$

where every $P_\bullet^{(m)}$ is the same complex of B-modules as $P_\bullet$, and for $m \leqslant n$ the map $P_\bullet^{(m)} \longrightarrow P_\bullet^{(n)}$ is multiplication by f^{n-m}. The analogous statement holds for $Q_\bullet$, with g in place of f. The homomorphism

$$\mathbf{Tor}_\bullet^A(P_\bullet^{(m)}, Q_\bullet^{(m)}) \longrightarrow \mathbf{Tor}_\bullet^A(P_\bullet^{(n)}, Q_\bullet^{(n)})$$

corresponding to these transition maps is, by definition, multiplication by $(f \otimes g)^{n-m}$. The conclusion follows from (**0**, 1.6.1), applied to the left-hand side of (6.4.5.3), and from (6.3.6). □

(6.4.6). With the notation of (6.4.4), one defines in the same way canonical homomorphisms of spectral functors

(6.4.6.1) $$\begin{aligned} (u \times_S v)^*\,{}'\mathscr{E}(\mathscr{P}_\bullet, \mathscr{Q}_\bullet) &\longrightarrow {}'\mathscr{E}(u^*\mathscr{P}_\bullet, v^*\mathscr{Q}_\bullet), \\ (u \times_S v)^*\,{}''\mathscr{E}(\mathscr{P}_\bullet, \mathscr{Q}_\bullet) &\longrightarrow {}''\mathscr{E}(u^*\mathscr{P}_\bullet, v^*\mathscr{Q}_\bullet). \end{aligned}$$

The argument of (6.4.5) shows that when u and v are open immersions, these homomorphisms are bijective. Taking (6.3.6.2) and (6.3.6.3) into account, the argument proves that they are isomorphisms on the E^2-terms, while (6.4.5) proves that they are isomorphisms on the abutments. The assertion therefore follows from (**0**, 11.1.2) and (**0**, 11.2.4).

6.5. Local hypertor functors of complexes of quasi-coherent modules: the general case

(6.5.1). Let S now be an arbitrary scheme and let X and Y be two S-schemes. Let $\mathscr{P}_\bullet$ be a complex of quasi-coherent $\mathscr{O}_X$-modules and $\mathscr{Q}_\bullet$ a complex of quasi-coherent $\mathscr{O}_Y$-modules. Set $Z = X \times_S Y$. We shall define quasi-coherent $\mathscr{O}_Z$-modules

$$\mathscr{T}\!or_n^S(\mathscr{P}_\bullet, \mathscr{Q}_\bullet),$$

called the *local hypertors* of $\mathscr{P}_\bullet$ and $\mathscr{Q}_\bullet$, which reduce to those of (6.4) when S, X, and Y are affine.

When $\mathscr{P}_\bullet$ and $\mathscr{Q}_\bullet$ are concentrated in degree zero, with respective terms $\mathscr{F}$ and $\mathscr{G}$, we write $\mathscr{T}\!or_n^S(\mathscr{F}, \mathscr{G})$ instead of $\mathscr{T}\!or_n^S(\mathscr{P}_\bullet, \mathscr{Q}_\bullet)$.

(6.5.2). Suppose first that S is affine, and let (X_λ) and (Y_μ) be coverings of X and Y by affine open subsets. Then

$$Z_{\lambda\mu} = X_\lambda \times_S Y_\mu$$

form an affine open covering of Z. Put

$$\mathscr{P}_{\lambda,\bullet} = \mathscr{P}_\bullet | X_\lambda, \qquad \mathscr{Q}_{\mu,\bullet} = \mathscr{Q}_\bullet | Y_\mu.$$

For each pair (λ, μ) we thus have a quasi-coherent $\mathscr{O}_{Z_{\lambda\mu}}$-module

$$\mathscr{F}_{\lambda\mu} = \mathscr{T}\!or_n^S(\mathscr{P}_{\lambda,\bullet}, \mathscr{Q}_{\mu,\bullet}).$$

We must show that the $\mathscr{F}_{\lambda\mu}$ satisfy the gluing condition (**0**, 3.3.1). It is enough to verify that, for every affine open

$$U \subset X_\lambda \cap X_{\lambda'}, \qquad V \subset Y_\mu \cap Y_{\mu'},$$

the restrictions of $\mathscr{F}_{\lambda\mu}$ and $\mathscr{F}_{\lambda'\mu'}$ to $U \times_S V$ are canonically isomorphic. This follows at once from their canonical isomorphisms with

$$\mathscr{T}\!or_n^S(\mathscr{P}_\bullet | U, \mathscr{Q}_\bullet | V)$$

given by (6.4.5).

The definition and (6.4.5) also show that the resulting $\mathscr{O}_Z$-module is independent, up to a unique isomorphism compatible with the local identifications, of the chosen open coverings. We denote it by III | 149

$$\mathscr{T}\!or_n^S(\mathscr{P}_\bullet, \mathscr{Q}_\bullet).$$

Finally, for every open subset U of X and every open subset V of Y, its restriction to $U \times_S V$ is canonically isomorphic to

$$\mathscr{T}\!or_n^S(\mathscr{P}_\bullet | U, \mathscr{Q}_\bullet | V).$$

(6.5.3). Pass now to the general case, where S is arbitrary. Let (S_α) be a covering of S by affine open subsets, and let X_α and Y_α be the inverse images of S_α in X and Y. We must show that the sheaves

$$\mathscr{G}_\alpha = \mathscr{T}\!or_n^{S_\alpha}(\mathscr{P}_\bullet | X_\alpha, \mathscr{Q}_\bullet | Y_\alpha)$$

satisfy the gluing condition.

For every affine open subset $T \subset S_\alpha \cap S_\beta$, let U and V be its inverse images in X and Y. It is enough to define canonical isomorphisms between the restrictions of $\mathscr{G}_\alpha$ and $\mathscr{G}_\beta$ to $U \times_S V$ and

$$\mathscr{T}\!or_n^T(\mathscr{P}_\bullet | U, \mathscr{Q}_\bullet | V).$$

We may further restrict to the case in which $T = D(f_\alpha) = D(f_\beta)$, where f_α and f_β are sections of $\mathscr{O}_S$ over S_α and S_β, respectively. By (6.4.2),

$$\mathscr{T}\!or_n^T(\mathscr{P}_\bullet | U, \mathscr{Q}_\bullet | V)$$

is canonically isomorphic both to $\mathscr{T}\!or_n^{S_\alpha}(\mathscr{P}_\bullet | U, \mathscr{Q}_\bullet | V)$ and to $\mathscr{T}\!or_n^{S_\beta}(\mathscr{P}_\bullet | U, \mathscr{Q}_\bullet | V)$. Combining these isomorphisms with the local identifications of (6.5.2) completes the definition of the $\mathscr{O}_Z$-module

$$\mathscr{T}\!or_n^S(\mathscr{P}_\bullet, \mathscr{Q}_\bullet).$$

For every open subset U of X and every open subset V of Y, the restriction of this module to $U \times_S V$ is canonically isomorphic to

$$\mathscr{T}\!or_n^S(\mathscr{P}_\bullet | U, \mathscr{Q}_\bullet | V).$$

This construction plainly defines, on the categories of bounded-below complexes of quasi-coherent modules, a bi-∂-functor

$$\mathscr{T}\!or^S_\bullet(\mathscr{P}_\bullet,\mathscr{Q}_\bullet)$$

with values in $\mathscr{O}_Z$-modules. Indeed the assertion is local on X, Y, and S, by (6.4.5) and by the fact that (6.4.4.2) is a morphism of bi-∂-functors.

If $\mathscr{P}_\bullet$ and $\mathscr{Q}_\bullet$ are concentrated in degree zero, with respective terms $\mathscr{F}$ and $\mathscr{G}$, then

$$\mathscr{T}\!or^S_0(\mathscr{F},\mathscr{G}) = \mathscr{F}\otimes_S\mathscr{G},$$

the external tensor product defined in (**I**, 9.1.2); this follows from (6.4.1.1) and (**I**, 9.1.3).

(6.5.4). The preceding construction and (6.4.6) show that $\mathscr{T}\!or^S_\bullet(\mathscr{P}_\bullet,\mathscr{Q}_\bullet)$ is the common abutment of two spectral functors $'\mathscr{E}(\mathscr{P}_\bullet,\mathscr{Q}_\bullet)$ and $''\mathscr{E}(\mathscr{P}_\bullet,\mathscr{Q}_\bullet)$, whose E_2-terms are

$$'\mathscr{E}^2_{pq} = \mathscr{H}_p\big(\mathscr{T}\!or^S_q(\mathscr{P}_\bullet,\mathscr{Q}_\bullet)\big) \tag{6.5.4.1}$$

and

$$''\mathscr{E}^2_{pq} = \bigoplus_{q'+q''=q}\mathscr{T}\!or^S_p\big(\mathscr{H}_{q'}(\mathscr{P}_\bullet),\mathscr{H}_{q''}(\mathscr{Q}_\bullet)\big). \tag{6.5.4.2}$$

The spectral sequence (6.5.4.2) is always regular. Both spectral sequences are biregular when $\mathscr{P}_\bullet$ and $\mathscr{Q}_\bullet$ are bounded below. A further case in which they are biregular is described next.

(6.5.5). Let T be a topological space. A sheaf of rings $\mathscr{A}$ on T is said to have *cohomological dimension at most n* if the ring $\mathscr{A}_t$ has cohomological dimension at most n for every $t\in T$. In this case the ringed space $(T,\mathscr{A})$ is also said to have cohomological dimension at most n. A sheaf of rings, or a ringed space, has *finite cohomological dimension* if this holds for some integer n.

If the $\mathscr{A}_t$ are Noetherian commutative local rings, saying that they have cohomological dimension at most n means that they are regular and have Krull dimension at most n ((**0**, 17.3.1)). In the terminology of dimension theory to be introduced in Chapter IV, a locally Noetherian scheme T has cohomological dimension at most n exactly when it is regular ((**0**, 4.1.4)) and has dimension at most n. Equivalently, for every affine open subset U of T, the ring $\Gamma(U,\mathscr{O}_T)$ has cohomological dimension at most n ((**0**, 17.2.6)). **III** | 150

Consequently, if S is locally Noetherian and has finite cohomological dimension, then (6.3.2) shows that both $'\mathscr{E}(\mathscr{P}_\bullet,\mathscr{Q}_\bullet)$ and $''\mathscr{E}(\mathscr{P}_\bullet,\mathscr{Q}_\bullet)$ are biregular.

Finally, under the canonical isomorphism $X\times_S Y\xrightarrow{\sim} Y\times_S X$, $\mathscr{T}\!or^S_\bullet(\mathscr{P}_\bullet,\mathscr{Q}_\bullet)$ corresponds canonically to $\mathscr{T}\!or^S_\bullet(\mathscr{Q}_\bullet,\mathscr{P}_\bullet)$.

Proposition (6.5.6). — *Let $(\mathscr{P}_{\alpha\bullet})$ be a filtered direct system of complexes of quasi-coherent $\mathscr{O}_X$-modules. There is a canonical isomorphism*

$$\varinjlim_\alpha \mathscr{T}\!or^S_\bullet(\mathscr{P}_{\alpha\bullet},\mathscr{Q}_\bullet)\xrightarrow{\sim}\mathscr{T}\!or^S_\bullet\left(\varinjlim_\alpha \mathscr{P}_{\alpha\bullet},\mathscr{Q}_\bullet\right). \tag{6.5.6.1}$$

Proof. The question is local on S, X, and Y. We may therefore suppose that S, X, and Y are affine, in which case the proposition reduces to (6.3.6). □

(6.5.7). *Remarks.*

(i) Consider in particular the case $S=X=Y$, with $\mathscr{P}_\bullet$ and $\mathscr{Q}_\bullet$ two complexes of quasi-coherent $\mathscr{O}_S$-modules. Then the $\mathscr{T}\!or^S_n(\mathscr{P}_\bullet,\mathscr{Q}_\bullet)$ are quasi-coherent $\mathscr{O}_S$-modules. Moreover, for every point $z\in S$, (6.5.6) gives a canonical isomorphism

$$\big(\mathscr{T}\!or^S_n(\mathscr{P}_\bullet,\mathscr{Q}_\bullet)\big)_z\xrightarrow{\sim}\mathbf{Tor}^{\mathscr{O}_z}_n\big((\mathscr{P}_\bullet)_z,(\mathscr{Q}_\bullet)_z\big), \tag{6.5.7.1}$$

because the question is local and, by (6.4.1.1), reduces to the case of modules.

(ii) The definition of hypertor can be generalized to two complexes $\mathscr{P}_\bullet$, $\mathscr{Q}_\bullet$ of $\mathscr{O}_X$-modules on the same ringed space $(X,\mathscr{O}_X)$. For every open subset U of X, put

$$A(U)=\Gamma(U,\mathscr{O}_X),\qquad P_\bullet(U)=\Gamma(U,\mathscr{P}_\bullet),\qquad Q_\bullet(U)=\Gamma(U,\mathscr{Q}_\bullet).$$

The $A(U)$-modules

$$\mathbf{Tor}^{A(U)}_n\big(P_\bullet(U),Q_\bullet(U)\big)$$

then form a presheaf on X; denote the associated $\mathscr{O}_X$-module by $\mathscr{T}or_n^X(\mathscr{P}_\bullet, \mathscr{Q}_\bullet)$. When X is a prescheme, (6.3.12) shows that this module is canonically isomorphic to the hypertor defined above. We shall not pursue this generalization further.

Proposition (6.5.8). — *Let X and Y be two S-preschemes, and let $\mathscr{F}$ (respectively $\mathscr{G}$) be a quasi-coherent $\mathscr{O}_X$-module (respectively $\mathscr{O}_Y$-module). If $\mathscr{F}$ or $\mathscr{G}$ is S-flat, then*

$$\mathscr{T}or_n^S(\mathscr{F}, \mathscr{G}) = 0 \qquad (n \neq 0).$$

Proof. The question is local on X and Y, so we may suppose that X, Y, and S are affine, with respective rings B, C, and A, and write $\mathscr{F} = \widetilde{M}$ and $\mathscr{G} = \widetilde{N}$, where M is a B-module and N a C-module. Suppose, for example, that $\mathscr{F}$ is S-flat. This means that, for every $s \in S$, M_s is a flat A_s-module ((**0**, 6.7.1)); hence M is a flat A-module ((**0**, 6.3.3)). Thus $\mathrm{Tor}_n^A(M, N) = 0$ for $n > 0$ and every C-module N ((**0**, 6.1.1)), and the conclusion follows from (6.4.1.1). □

Corollary (6.5.9). — *Let X and Y be two S-preschemes, and let $\mathscr{P}_\bullet$ (respectively $\mathscr{Q}_\bullet$) be a bounded-below complex of quasi-coherent $\mathscr{O}_X$-modules (respectively $\mathscr{O}_Y$-modules). Suppose that every $\mathscr{P}_i$ is S-flat. Then there is a canonical isomorphism of ∂-functors in $\mathscr{Q}_\bullet$* **III** | 151

$$\mathscr{T}or_\bullet^S(\mathscr{P}_\bullet, \mathscr{Q}_\bullet) \xrightarrow{\sim} \mathscr{H}_\bullet(\mathscr{P}_\bullet \otimes_S \mathscr{Q}_\bullet). \tag{6.5.9.1}$$

Proof. When S, X, and Y are affine, this is precisely (6.3.7); the general case follows by the arguments of (6.5.2) and (6.5.3). □

(6.5.10). *Corollary.* Suppose that X is flat over S ((**0**, 6.7.1)), that $\mathscr{P}_\bullet$ and $\mathscr{Q}_\bullet$ are bounded below, and that every $\mathscr{P}_i$ is a locally free $\mathscr{O}_X$-module, not necessarily of finite type. Then the homomorphism (6.5.9.1) is bijective.

Indeed, the hypothesis of (6.5.9) is satisfied: flatness is, by definition, a pointwise property on X, and every direct sum of flat modules is flat ((**0**, 6.1.2)).

Proposition (6.5.11). — *Let X' and Y' be two S-preschemes, and let $f : X \to X'$ and $g : Y \to Y'$ be two affine S-morphisms. For a complex $\mathscr{P}_\bullet$ of quasi-coherent $\mathscr{O}_X$-modules and a complex $\mathscr{Q}_\bullet$ of quasi-coherent $\mathscr{O}_Y$-modules, there is a canonical functorial isomorphism*

$$(f \times_S g)_*\big(\mathscr{T}or_\bullet^S(\mathscr{P}_\bullet, \mathscr{Q}_\bullet)\big) \xrightarrow{\sim} \mathscr{T}or_\bullet^S(f_*\mathscr{P}_\bullet, g_*\mathscr{Q}_\bullet). \tag{6.5.11.1}$$

Proof. Since f and g are affine, $f_*\mathscr{P}_\bullet$ and $g_*\mathscr{Q}_\bullet$ are complexes of quasi-coherent modules ((**II**, 1.2.6)). If $Z' = X' \times_S Y'$, both sides of (6.5.11.1) are quasi-coherent $\mathscr{O}_{Z'}$-modules by (6.5.1). We readily reduce to the case in which S, X', and Y' are affine; then X and Y are affine as well, and the assertion follows immediately from (6.4.1.1) and (**I**, 1.6.3). □

(6.5.12). *Remark.* Let X' and Y' be two S-preschemes, with X' flat over S. Let X be a closed subprescheme of X', and let $i : X \to X'$ be the canonical immersion. Let $\mathscr{P}_\bullet$ (respectively $\mathscr{Q}_\bullet$) be a bounded-below complex of quasi-coherent $\mathscr{O}_X$-modules (respectively $\mathscr{O}_{Y'}$-modules). Finally, let $\mathscr{L}'_{\bullet\bullet}$ be a resolution of $i_*\mathscr{P}_\bullet$ consisting of locally free $\mathscr{O}_{X'}$-modules, such that every point of X' has an affine open neighborhood U for which $\mathscr{L}'_{j\bullet}|U$ is a free resolution of $i_*\mathscr{P}_j|U$, for every j. There is then a canonical isomorphism

$$(i \times_S 1)_*\big(\mathscr{T}or_\bullet^S(\mathscr{P}_\bullet, \mathscr{Q}_\bullet)\big) \xrightarrow{\sim} \mathscr{H}_\bullet(\mathscr{L}'_{\bullet\bullet} \otimes_S \mathscr{Q}_\bullet). \tag{6.5.12.1}$$

If S, X', and Y' are affine, and if $\mathscr{L}'_{j\bullet}$ is a free resolution of $i_*\mathscr{P}_j$ for every j, then (6.5.11) reduces us to the case $X' = X$, with X flat over S, and it is enough to apply (6.3.4). In general, (6.5.12.1) is defined locally, and it remains to verify that these local definitions give a global isomorphism.

For this, recall the definition of the first isomorphism (6.3.4.1). It comes from an isomorphism of spectral sequences ((**0**, 11.6.5) and (**0**, 11.5.3)), itself obtained from a morphism of bicomplexes

$$L_{\bullet\bullet} \longrightarrow L''_{\bullet\bullet},$$

where $L_{\bullet\bullet}$ is the given resolution of $P_\bullet$, and $L''_{\bullet\bullet}$ is a projective resolution of $P_\bullet$ in the category of bounded-below complexes of A-modules ((**0**, 11.5.2.2)). The assertion follows from the fact that (6.3.4.1) is independent of the chosen projective resolution $L''_{\bullet\bullet}$, since any two such resolutions are connected by a homotopy (M, V, 1.2). **III** | 152

Proposition (6.5.13). — *Let X and Y be two S-preschemes, and suppose that one of the following conditions holds:*

(i) X and $Z = X \times_S Y$ are locally Noetherian, and X is flat over S;
(ii) S and X are locally Noetherian, and Y is of finite type over S.

Let $\mathscr{P}_\bullet$ (respectively $\mathscr{Q}_\bullet$) be a bounded-below complex of quasi-coherent $\mathscr{O}_X$-modules (respectively $\mathscr{O}_Y$-modules). Suppose in addition that, for every n, $\mathscr{H}_n(\mathscr{P}_\bullet)$ (respectively $\mathscr{H}_n(\mathscr{Q}_\bullet)$) is an $\mathscr{O}_X$-module (respectively $\mathscr{O}_Y$-module) of finite type. Then

$$\mathscr{T}or_n^S(\mathscr{P}_\bullet, \mathscr{Q}_\bullet)$$

is a coherent $\mathscr{O}_Z$-module for every n.

Proof. Since $\mathscr{P}_\bullet$ and $\mathscr{Q}_\bullet$ are bounded below, the spectral sequence $''\mathscr{E}(\mathscr{P}_\bullet, \mathscr{Q}_\bullet)$ is biregular by (6.5.4). In either case (i) or (ii), Z is locally Noetherian, so (**0**, 11.1.8) reduces the assertion to the coherence of the terms $''\mathscr{E}^2_{pq}$. The finite-type hypothesis on the homology modules and formula (6.5.4.2) reduce the proposition to the special case in which $\mathscr{P}_\bullet$ and $\mathscr{Q}_\bullet$ are concentrated in degree zero, namely the following corollary. □

Corollary (6.5.14). — *Suppose that one of conditions* (i) *and* (ii) *of* (6.5.13) *holds, and let $\mathscr{F}$ (respectively $\mathscr{G}$) be a quasi-coherent $\mathscr{O}_X$-module (respectively $\mathscr{O}_Y$-module) of finite type. Then $\mathscr{T}or_n^S(\mathscr{F}, \mathscr{G})$ is a coherent $\mathscr{O}_Z$-module for every n.*

Proof. The question is local on X and Y, so we may suppose that S, X, and Y are affine.

(i) Under the hypotheses of (i), S, X, and Z are Noetherian. There is therefore a locally free resolution $\mathscr{L}_\bullet$ of $\mathscr{F}$ consisting of $\mathscr{O}_X$-modules of finite type ((**I**, 1.3.7)). Since X is flat over S, (6.3.4) gives

$$\mathscr{T}or_n^S(\mathscr{F}, \mathscr{G}) = \mathscr{H}_n(\mathscr{L}_\bullet \otimes_S \mathscr{G}).$$

The modules $\mathscr{L}_i \otimes_S \mathscr{G}$ are quasi-coherent $\mathscr{O}_Z$-modules of finite type ((**I**, 9.1.1)), hence are coherent. It follows that $\mathscr{H}_n(\mathscr{L}_\bullet \otimes_S \mathscr{G})$ is coherent ((**0**, 5.3.4)).

(ii) Now suppose that condition (ii) holds. Since $A(Y)$ is a quotient of a polynomial $A(S)$-algebra in finitely many indeterminates ((**I**, 6.3.3)), Y is a closed subprescheme of an affine S-scheme Y' that is flat and of finite type over S. The scheme Y' is Noetherian ((**I**, 6.3.7)), so there exists a locally free resolution $\mathscr{M}_\bullet$ of $j_*\mathscr{G}$ by $\mathscr{O}_{Y'}$-modules of finite type, where $j : Y \to Y'$ is the canonical immersion. By (6.5.12), $\mathscr{T}or_n^S(\mathscr{F}, \mathscr{G})$ is the inverse image under $1 \times j$ of the $\mathscr{O}_{Z'}$-module

$$\mathscr{H}_n(\mathscr{F} \otimes_S \mathscr{M}_\bullet), \qquad Z' = X \times_S Y'.$$

As in (i), the $\mathscr{F} \otimes_S \mathscr{M}_i$ are coherent $\mathscr{O}_{Z'}$-modules, and (**0**, 5.3.4) again gives the conclusion. □

(6.5.15). The theory developed above for two complexes $\mathscr{P}_\bullet, \mathscr{Q}_\bullet$ of quasi-coherent sheaves on two S-preschemes X and Y extends without difficulty to an arbitrary finite family of S-preschemes $X^{(i)}$ ($1 \leqslant i \leqslant m$), each equipped with a complex $\mathscr{P}_\bullet^{(i)}$ of quasi-coherent $\mathscr{O}_{X^{(i)}}$-modules. If

$$Z = X^{(1)} \times_S X^{(2)} \times_S \cdots \times_S X^{(m)},$$

one thereby defines a quasi-coherent $\mathscr{O}_Z$-module

$$\mathscr{T}or_q^S(\mathscr{P}_\bullet^{(1)}, \mathscr{P}_\bullet^{(2)}, \ldots, \mathscr{P}_\bullet^{(m)}).$$

We leave the development of the theory in this general case to the reader, and record only, for later reference, the E_2-term of the second, regular spectral sequence whose abutment is this hypertor: **III** | 153

(6.5.15.1) $$''\mathscr{E}^2_{pq} = \bigoplus_{q_1+q_2+\cdots+q_m=q} \mathscr{T}or_p^S(\mathscr{H}_{q_1}(\mathscr{P}_\bullet^{(1)}), \ldots, \mathscr{H}_{q_m}(\mathscr{P}_\bullet^{(m)})).$$

In (6.8) we shall study the associativity spectral sequences to which these hypertor functors of an arbitrary finite number of complexes give rise.

6.6. Global hypertor functors of complexes of quasi-coherent modules and Künneth spectral sequences: the affine-base case

(6.6.1). Let $S = \mathrm{Spec}(A)$ be an affine scheme, and let $X^{(i)}$ $(i = 1, 2)$ be two quasi-compact S-schemes. For $i = 1, 2$, let $\mathscr{P}_\bullet^{(i)}$ be a bounded-below complex of quasi-coherent $\mathscr{O}_{X^{(i)}}$-modules whose differential has degree -1. Choose a finite covering

$$\mathfrak{U}^{(i)} = (U_\alpha^{(i)})$$

of $X^{(i)}$ by affine open subsets. Put

$$X = X^{(1)} \times_S X^{(2)}.$$

This is a quasi-compact S-scheme ((**I**, 5.5.1) and (**I**, 6.6.4)), and $\mathfrak{U} = \mathfrak{U}^{(1)} \times_S \mathfrak{U}^{(2)}$ is the covering of X by the affine open subsets $U_\alpha^{(1)} \times_S U_\beta^{(2)}$.

For $p \leqslant 0$ and $q \in \mathbf{Z}$, the group of $(-p)$-alternating cochains

$$C^{-p}(\mathfrak{U}^{(i)}, \mathscr{P}_q^{(i)})$$

of the covering $\mathfrak{U}^{(i)}$ with coefficients in $\mathscr{P}_q^{(i)}$ (G, II, 5.1) is an A-module. For $p > 0$, put $C^p(\mathfrak{U}^{(i)}, \mathscr{P}_q^{(i)}) = 0$. This defines a bicomplex of A-modules

$$C^\bullet(\mathfrak{U}^{(i)}, \mathscr{P}_\bullet^{(i)})$$

whose two differentials have degree -1.

It follows from the definitions ((**0**, 12.1.2)) that the homology module

$$H_n\big(C^\bullet(\mathfrak{U}^{(i)}, \mathscr{P}_\bullet^{(i)})\big)$$

of this bicomplex, viewed in the usual way as a simple complex for the total degree, is the hypercohomology module

$$\mathrm{H}^{-n}\big(\mathfrak{U}^{(i)}, \mathscr{P}^{(i)\bullet}\big),$$

where $\mathscr{P}^{(i)\bullet}$ is the complex with differential of degree $+1$ whose component of degree q is $\mathscr{P}_{-q}^{(i)}$. By abuse of notation we write this as

$$\mathrm{H}^{-n}\big(\mathfrak{U}^{(i)}, \mathscr{P}_\bullet^{(i)}\big).$$

By (6.2.2), this module is canonically isomorphic to

$$\mathrm{H}^{-n}\big(X^{(i)}, \mathscr{P}^{(i)\bullet}\big),$$

also written $\mathrm{H}^{-n}(X^{(i)}, \mathscr{P}_\bullet^{(i)})$. It is therefore independent of the chosen finite covering $\mathfrak{U}^{(i)}$.

(6.6.2). Apply the general theory of hyperhomology of functors with respect to bicomplexes ((**0**, 11.7.4)) to the two bicomplexes of A-modules

$$L_{\bullet\bullet}^{(i)} = C^\bullet(\mathfrak{U}^{(i)}, \mathscr{P}_\bullet^{(i)}) \qquad (i = 1, 2)$$

and to the covariant bifunctor $L_{\bullet\bullet}^{(1)} \otimes_A L_{\bullet\bullet}^{(2)}$. Because the cochains are alternating and the coverings $\mathfrak{U}^{(i)}$ are finite, the modules

$$C^{-p}(\mathfrak{U}^{(i)}, \mathscr{P}_q^{(i)})$$

are nonzero for only finitely many values of p, independently of q. In particular, both degrees of each $L_{\bullet\bullet}^{(i)}$ are bounded below.

Denote by

$$\mathbf{Tor}_n^A(L_{\bullet\bullet}^{(1)}, L_{\bullet\bullet}^{(2)})$$

or by

$$\mathbf{Tor}_n^S(\mathfrak{U}^{(1)}, \mathfrak{U}^{(2)}; \mathscr{P}_\bullet^{(1)}, \mathscr{P}_\bullet^{(2)})$$

the n-th hyperhomology module of $L_{\bullet\bullet}^{(1)} \otimes_A L_{\bullet\bullet}^{(2)}$. We call it the hypertor of index n of $\mathscr{P}_\bullet^{(1)}$ and $\mathscr{P}_\bullet^{(2)}$ relative to the coverings $\mathfrak{U}^{(1)}$ and $\mathfrak{U}^{(2)}$. When these complexes are concentrated in degree zero, with terms $\mathscr{F}^{(1)}$ and $\mathscr{F}^{(2)}$, write

$$\mathbf{Tor}_n^S(\mathfrak{U}^{(1)}, \mathfrak{U}^{(2)}; \mathscr{F}^{(1)}, \mathscr{F}^{(2)})$$

for their hypertor. Following the general conventions, the same notation

$$\mathbf{Tor}_n^S(\mathfrak{U}^{(1)},\mathfrak{U}^{(2)};\mathscr{P}_\bullet^{(1)},\mathscr{P}_\bullet^{(2)})$$

also denotes the bicomplex whose component of bidegree (j,k) is

$$\mathbf{Tor}_n^S(\mathfrak{U}^{(1)},\mathfrak{U}^{(2)};\mathscr{P}_j^{(1)},\mathscr{P}_k^{(2)}).$$

The construction $L_{\bullet\bullet}^{(i)}$ is exact in $\mathscr{P}_\bullet^{(i)}$, since all intersections of members of $\mathfrak{U}^{(i)}$ are affine ((**I**, 5.5.6) and (**I**, 1.3.11)). Consequently **III** | 154

$$\mathbf{Tor}_\bullet^S(\mathfrak{U}^{(1)},\mathfrak{U}^{(2)};\mathscr{P}_\bullet^{(1)},\mathscr{P}_\bullet^{(2)})$$

is a covariant bi-∂-functor in $\mathscr{P}_\bullet^{(1)}$ and $\mathscr{P}_\bullet^{(2)}$, with values in the category of A-modules ((**0**, 11.7.3)). By (**0**, 11.7.2), it is the common abutment of six biregular spectral functors, denoted

$$^{(t)}E^S(\mathfrak{U}^{(1)},\mathfrak{U}^{(2)};\mathscr{P}_\bullet^{(1)},\mathscr{P}_\bullet^{(2)}),$$

or simply

$$^{(t)}E(\mathfrak{U}^{(1)},\mathfrak{U}^{(2)};\mathscr{P}_\bullet^{(1)},\mathscr{P}_\bullet^{(2)}),$$

where t is one of a,b,a',b',c,d. Their E_2-terms are

$$\begin{aligned}
^{(a)}E_{pq}^2 &= \bigoplus_{q_1+q_2=q} \operatorname{Tor}_p^A\big(H_{q_1}(L_{\bullet\bullet}^{(1)}),H_{q_2}(L_{\bullet\bullet}^{(2)})\big),\\
^{(b)}E_{pq}^2 &= H_p\big(\mathbf{Tor}_q^{A,\mathrm{II}}(L_{\bullet\bullet}^{(1)},L_{\bullet\bullet}^{(2)})\big),\\
^{(a')}E_{pq}^2 &= \bigoplus_{q_1+q_2=q} \operatorname{Tor}_p^A\big(H_{q_1}^{\mathrm{I}}(L_{\bullet\bullet}^{(1)}),H_{q_2}^{\mathrm{I}}(L_{\bullet\bullet}^{(2)})\big),\\
^{(b')}E_{pq}^2 &= H_p\big(\mathbf{Tor}_q^{A}(L_{\bullet\bullet}^{(1)},L_{\bullet\bullet}^{(2)})\big),\\
^{(c)}E_{pq}^2 &= \bigoplus_{q_1+q_2=q} \operatorname{Tor}_p^A\big(H_{q_1}^{\mathrm{II}}(L_{\bullet\bullet}^{(1)}),H_{q_2}^{\mathrm{II}}(L_{\bullet\bullet}^{(2)})\big),\\
^{(d)}E_{pq}^2 &= H_p\big(\mathbf{Tor}_q^{A,\mathrm{I}}(L_{\bullet\bullet}^{(1)},L_{\bullet\bullet}^{(2)})\big).
\end{aligned}$$

These notations agree with those of the general theory of hyperhomology. We now make the initial terms more explicit.

(6.6.3). *Spectral sequences* (a) *and* (a′)*.* By (6.6.1),

$$H_n(L_{\bullet\bullet}^{(i)}) = \mathrm{H}^{-n}(X^{(i)},\mathscr{P}_\bullet^{(i)}),$$

and hence

$$^{(a)}E_{pq}^2 = \bigoplus_{q_1+q_2=q} \operatorname{Tor}_p^A\big(\mathrm{H}^{-q_1}(X^{(1)},\mathscr{P}_\bullet^{(1)}),\mathrm{H}^{-q_2}(X^{(2)},\mathscr{P}_\bullet^{(2)})\big).$$

By definition, the component of degree k of the complex $H_n^{\mathrm{I}}(L_{\bullet\bullet}^{(i)})$ is

$$H_n\big(C^\bullet(\mathfrak{U}^{(i)},\mathscr{P}_k^{(i)})\big) = \mathrm{H}^{-n}(\mathfrak{U}^{(i)},\mathscr{P}_k^{(i)}).$$

By (1.4.1), this module is canonically isomorphic to $\mathrm{H}^{-n}(X^{(i)},\mathscr{P}_k^{(i)})$. Therefore

$$^{(a')}E_{pq}^2 = \bigoplus_{q_1+q_2=q} \operatorname{Tor}_p^A\big(\mathrm{H}^{-q_1}(X^{(1)},\mathscr{P}_\bullet^{(1)}),\mathrm{H}^{-q_2}(X^{(2)},\mathscr{P}_\bullet^{(2)})\big),$$

where each $\mathrm{H}^{-q_i}(X^{(i)},\mathscr{P}_\bullet^{(i)})$ in this last formula denotes the complex obtained by taking cohomology term by term.

(6.6.4). *Spectral sequences* (b) *and* (b′)*.* By definition,

$$\mathbf{Tor}_q^{A,\mathrm{II}}(L_{\bullet\bullet}^{(1)},L_{\bullet\bullet}^{(2)})$$

is a bicomplex whose component of bidegree (h,k) is

$$\operatorname{Tor}_q^A\big(C^{-h}(\mathfrak{U}^{(1)},\mathscr{P}_\bullet^{(1)}),C^{-k}(\mathfrak{U}^{(2)},\mathscr{P}_\bullet^{(2)})\big).$$

Let $\Phi^{(i)}$ be the index set of $\mathfrak{U}^{(i)}$. For $r \geqslant 0$, the complex $C^r(\mathfrak{U}^{(i)}, \mathscr{P}_\bullet^{(i)})$ is the direct sum of the complexes

$$\Gamma(U_\rho^{(i)}, \mathscr{P}_\bullet^{(i)}),$$

where $U_\rho^{(i)}$ is the intersection of the $U_\xi^{(i)}$ for $\xi \in \rho$, and ρ ranges over the appropriate elements of $\mathfrak{P}(\Phi^{(i)})$. Consequently

$$\operatorname{Tor}_q^A(C^{-h}(\mathfrak{U}^{(1)}, \mathscr{P}_\bullet^{(1)}), C^{-k}(\mathfrak{U}^{(2)}, \mathscr{P}_\bullet^{(2)}))$$

is the direct sum of the A-modules

$$\operatorname{Tor}_q^A(\Gamma(U_\sigma^{(1)}, \mathscr{P}_\bullet^{(1)}), \Gamma(U_\tau^{(2)}, \mathscr{P}_\bullet^{(2)})),$$

where σ and τ range over $\mathfrak{P}(\Phi^{(1)})$ and $\mathfrak{P}(\Phi^{(2)})$ with

$$\operatorname{Card}(\sigma) = -(h+1), \qquad \operatorname{Card}(\tau) = -(k+1),$$

respectively. Since $X^{(1)}$ and $X^{(2)}$ are schemes, the $U_\rho^{(i)}$ are affine. Thus (6.4.1.1) gives

$$\operatorname{Tor}_q^A(\Gamma(U_\sigma^{(1)}, \mathscr{P}_\bullet^{(1)}), \Gamma(U_\tau^{(2)}, \mathscr{P}_\bullet^{(2)})) = \Gamma\big(U_\sigma^{(1)} \times_S U_\tau^{(2)}, \mathscr{T}\!or_q^S(\mathscr{P}_\bullet^{(1)}, \mathscr{P}_\bullet^{(2)})\big).$$

It follows that ${}^{(b)}E_{pq}^2$ is the $(-p)$-th cohomology module of the complex **III** | 155

$$L^\bullet(\Phi^{(1)}, \Phi^{(2)}; \mathscr{S})$$

of bialternating cochains on $\Phi^{(1)}$ and $\Phi^{(2)}$ with values in the coefficient system

(6.6.4.1) $$\mathscr{S} : (\sigma, \tau) \longmapsto \Gamma\big(U_\sigma^{(1)} \times_S U_\tau^{(2)}, \mathscr{T}\!or_q^S(\mathscr{P}_\bullet^{(1)}, \mathscr{P}_\bullet^{(2)})\big)$$

((**0**, 11.8.4)). By (**0**, 11.8.5) and (**0**, 11.8.6), this complex has the same cohomology as the complex of all cochains

$$C^\bullet(\Phi^{(1)}, \Phi^{(2)}; \mathscr{S})$$

and as the complex

$$P^\bullet(\Phi^{(1)}, \Phi^{(2)}; \mathscr{S}),$$

whose elements are linear combinations of

$$\lambda(\sigma, \tau) \in \Gamma\big(U_\sigma^{(1)} \times_S U_\tau^{(2)}, \mathscr{T}\!or_q^S(\mathscr{P}_\bullet^{(1)}, \mathscr{P}_\bullet^{(2)})\big),$$

where

$$\sigma = (\alpha_0, \ldots, \alpha_h), \qquad \tau = (\beta_0, \ldots, \beta_h)$$

are sequences with the same number of terms. Now

$$U_\sigma^{(1)} \times_S U_\tau^{(2)} = (U_{\alpha_0}^{(1)} \times_S U_{\beta_0}^{(2)}) \cap \cdots \cap (U_{\alpha_h}^{(1)} \times_S U_{\beta_h}^{(2)})$$

by (**I**, 3.2.7). Let $\mathfrak{U}$ be the covering of $Z = X^{(1)} \times_S X^{(2)}$ by the affine open subsets $U_\alpha^{(1)} \times_S U_\beta^{(2)}$. Since Z is a scheme, (1.3.1) yields

(6.6.4.2) $${}^{(b)}E_{pq}^2 = \mathrm{H}^{-p}\big(Z, \mathscr{T}\!or_q^S(\mathscr{P}_\bullet^{(1)}, \mathscr{P}_\bullet^{(2)})\big).$$

Next,

$$\mathbf{Tor}_q^A(L_{\bullet\bullet}^{(1)}, L_{\bullet\bullet}^{(2)})$$

is a bicomplex whose component of bidegree (h,k) is the direct sum of the A-modules

$$\operatorname{Tor}_q^A(C^{-h_1}(\mathfrak{U}^{(1)}, \mathscr{P}_{k_1}^{(1)}), C^{-h_2}(\mathfrak{U}^{(2)}, \mathscr{P}_{k_2}^{(2)})),$$

where $h_1 + h_2 = h$ and $k_1 + k_2 = k$. Expanding the cochain modules as above shows that this component is also the direct sum of

$$\Gamma\big(U_\sigma^{(1)} \times_S U_\tau^{(2)}, \mathscr{T}\!or_q^S(\mathscr{P}_{-k_1}^{(1)}, \mathscr{P}_{-k_2}^{(2)})\big),$$

where $k_1 + k_2 = k$ and

$$\operatorname{Card}(\sigma) + \operatorname{Card}(\tau) = -h - 2.$$

The term ${}^{(b')}E^2_{pq}$ is the $(-p)$-th cohomology module of a bicomplex $N^{\bullet\bullet} = (N^{hk})$. For fixed k, the simple complex $N^{\bullet k}$ consists of bialternating cochains on $\Phi^{(1)}$ and $\Phi^{(2)}$ with values in the coefficient system

$$\mathscr{S}_k : (\sigma,\tau) \longmapsto \Gamma\left(U^{(1)}_\sigma \times_S U^{(2)}_\tau, \bigoplus_{k_1+k_2=k} \mathscr{T}\!or^S_q(\mathscr{P}^{(1)}_{-k_1}, \mathscr{P}^{(2)}_{-k_2})\right).$$

These coefficient systems form a complex $\mathscr{S}^\bullet$, whose differential is induced by that of the simple complex associated to the bicomplex

$$\mathscr{T}\!or^S_q(\mathscr{P}^{(1)\bullet}, \mathscr{P}^{(2)\bullet}).$$

By (**0**, 11.8.9), $N^{\bullet\bullet}$ has the same cohomology as

$$C^\bullet(\Phi^{(1)}, \Phi^{(2)}; \mathscr{S}^\bullet),$$

and also the same cohomology as

$$P^\bullet(\Phi^{(1)}, \Phi^{(2)}; \mathscr{S}^\bullet),$$

whose elements of bidegree (h,k) are linear combinations of

$$\lambda(\sigma,\tau) \in \Gamma\left(U^{(1)}_\sigma \times_S U^{(2)}_\tau, \bigoplus_{k_1+k_2=k} \mathscr{T}\!or^S_q(\mathscr{P}^{(1)}_{k_1}, \mathscr{P}^{(2)}_{k_2})\right),$$

with $\sigma = (\alpha_0,\ldots,\alpha_h)$ and $\tau = (\beta_0,\ldots,\beta_h)$ having the same number of terms ((**0**, 11.8.10)). As above, ${}^{(b')}E^2_{pq}$ is therefore the $(-p)$-th cohomology module of

$$C^\bullet(\mathfrak{U}, \mathscr{Q}^\bullet),$$

where $\mathscr{Q}^\bullet$ is the simple complex associated to the bicomplex

$$\mathscr{T}\!or^S_q(\mathscr{P}^{(1)\bullet}, \mathscr{P}^{(2)\bullet})$$

of $\mathscr{O}_Z$-modules. With the conventions of (6.6.1), we obtain

$$ {}^{(b')}E^2_{pq} = \mathrm{H}^{-p}\big(Z, \mathscr{T}\!or^S_q(\mathscr{P}^{(1)}_\bullet, \mathscr{P}^{(2)}_\bullet)\big). \tag{6.6.4.3}$$

III | 156

(6.6.5). *Spectral sequences* (c) *and* (d). By definition, the component of degree h of the complex $H^{\mathrm{II}}_n(L^{(i)}_{\bullet\bullet})$ is the A-module

$$C^{-h}\big(\mathfrak{U}^{(i)}, \mathscr{H}_n(\mathscr{P}^{(i)}_\bullet)\big),$$

because the functor C^{-h} is exact. Hence, by the definition of the hypertor of two modules relative to two coverings ((6.6.2)),

$${}^{(c)}E^2_{pq} = \bigoplus_{q_1+q_2=q} \mathbf{Tor}^S_p\big(\mathfrak{U}^{(1)}, \mathfrak{U}^{(2)}; \mathscr{H}_{q_1}(\mathscr{P}^{(1)}_\bullet), \mathscr{H}_{q_2}(\mathscr{P}^{(2)}_\bullet)\big).$$

Finally, by definition,

$$\mathbf{Tor}^{A,\mathrm{I}}_q(L^{(1)}_{\bullet\bullet}, L^{(2)}_{\bullet\bullet})$$

is a bicomplex whose component of bidegree (h,k) is the A-module

$$\mathbf{Tor}^S_q\big(\mathfrak{U}^{(1)}, \mathfrak{U}^{(2)}; \mathscr{P}^{(1)}_h, \mathscr{P}^{(2)}_k\big).$$

Consequently

$${}^{(d)}E^2_{pq} = H_p\left(\mathbf{Tor}^S_q\big(\mathfrak{U}^{(1)}, \mathfrak{U}^{(2)}; \mathscr{P}^{(1)}_\bullet, \mathscr{P}^{(2)}_\bullet\big)\right).$$

(6.6.6). The theory of hyperhomology for functors of bicomplexes ((**0**, 11.7.3)) shows, as in (6.3.4), that for every *flat* Cartan–Eilenberg resolution $M^{(i)}_{\bullet\bullet}$ of $L^{(i)}_{\bullet\bullet}$ in the category of complexes of modules bounded below $(i = 1, 2)$, there are canonical isomorphisms of bi-∂-functors

(6.6.6.1).

$$\begin{aligned} \mathbf{Tor}^S_\bullet(\mathfrak{U}^{(1)},\mathfrak{U}^{(2)};\mathscr{P}^{(1)}_\bullet,\mathscr{P}^{(2)}_\bullet) &\xrightarrow{\sim} H_\bullet(M^{(1)}_{\bullet\bullet}\otimes_A M^{(2)}_{\bullet\bullet}) \\ &\xrightarrow{\sim} H_\bullet(M^{(1)}_{\bullet\bullet}\otimes_A L^{(2)}_{\bullet\bullet}) \\ &\xrightarrow{\sim} H_\bullet(L^{(1)}_{\bullet\bullet}\otimes_A M^{(2)}_{\bullet\bullet}). \end{aligned} \tag{6.6.6.1}$$

(6.6.7). We shall now show that the global hypertor defined in (6.6.2), and the six corresponding spectral sequences, do not depend, up to canonical isomorphisms, on the finite affine open coverings $\mathfrak{U}^{(i)}$ used to define them. It is enough to show that if $\mathfrak{V}^{(i)}$ are two other coverings of the same kind, with $\mathfrak{V}^{(i)}$ finer than $\mathfrak{U}^{(i)}$ for $i=1,2$, then there are canonical isomorphisms of spectral functors

(6.6.7, t).

$$^{(t)}E(\mathfrak{U}^{(1)},\mathfrak{U}^{(2)};\mathscr{P}^{(1)}_\bullet,\mathscr{P}^{(2)}_\bullet) \xrightarrow{\sim} {}^{(t)}E(\mathfrak{V}^{(1)},\mathfrak{V}^{(2)};\mathscr{P}^{(1)}_\bullet,\mathscr{P}^{(2)}_\bullet), \tag{6.6.7, t}$$

where t is one of a,b,a',b',c,d.

For $i=1,2$ there are homomorphisms of bicomplexes

$$C^\bullet(\mathfrak{U}^{(i)},\mathscr{P}^{(i)}_\bullet) \longrightarrow C^\bullet(\mathfrak{V}^{(i)},\mathscr{P}^{(i)}_\bullet)$$

that are well defined up to homotopy ((**G**, II.5.7.1)). It follows at once that the homomorphisms (6.6.7, t) are canonically defined and compatible with the boundary operators in their abutments ((**0**, 11.3.2)). Moreover, the calculation of the E_2-terms of the spectral sequences (a), (b), (a′), and (b′) shows that (6.6.7, t) is an isomorphism on their E_2-terms. Since these spectral sequences are biregular, it follows that (6.6.7, t) is an isomorphism for these spectral functors, and hence an isomorphism of bi-∂-functors on their common abutment ((**0**, 11.1.5)).

In particular, if $\mathscr{F}^{(i)}$ is a quasi-coherent $\mathscr{O}_{X^{(i)}}$-module $(i=1,2)$, the canonical homomorphism

$$\mathbf{Tor}^S_n(\mathfrak{U}^{(1)},\mathfrak{U}^{(2)};\mathscr{F}^{(1)},\mathscr{F}^{(2)}) \longrightarrow \mathbf{Tor}^S_n(\mathfrak{V}^{(1)},\mathfrak{V}^{(2)};\mathscr{F}^{(1)},\mathscr{F}^{(2)})$$

is bijective. In view of the calculation in (6.6.5), the homomorphism (6.6.7, t) is therefore also an isomorphism on E_2-terms for $t=c$ and $t=d$. As above, we conclude that it is an isomorphism of spectral sequences for these two values of t.

The isomorphisms (6.6.7, t) may be regarded as defining inductive systems of spectral functors on **III** | 157
the filtering set of pairs $(\mathfrak{U}^{(1)},\mathfrak{U}^{(2)})$ of finite affine open coverings of $X^{(1)}$ and $X^{(2)}$. We denote the inductive limit by

$$^{(t)}E(X^{(1)},X^{(2)};\mathscr{P}^{(1)}_\bullet,\mathscr{P}^{(2)}_\bullet) \quad\text{or}\quad {}^{(t)}E^S(X^{(1)},X^{(2)};\mathscr{P}^{(1)}_\bullet,\mathscr{P}^{(2)}_\bullet).$$

Its abutment is denoted

$$\mathbf{Tor}^S_\bullet(X^{(1)},X^{(2)};\mathscr{P}^{(1)}_\bullet,\mathscr{P}^{(2)}_\bullet)$$

and is called the *global hypertor* of the two complexes $\mathscr{P}^{(1)}_\bullet$ and $\mathscr{P}^{(2)}_\bullet$. If the two complexes are concentrated in degree zero, with terms $\mathscr{F}^{(1)}$ and $\mathscr{F}^{(2)}$, we write

$$\mathbf{Tor}^S_\bullet(X^{(1)},X^{(2)};\mathscr{F}^{(1)},\mathscr{F}^{(2)}).$$

In accordance with the general conventions,

$$\mathbf{Tor}^S_q(X^{(1)},X^{(2)};\mathscr{P}^{(1)}_\bullet,\mathscr{P}^{(2)}_\bullet)$$

will denote the bicomplex whose component of bidegree (h,k) is

$$\mathbf{Tor}^S_q(X^{(1)},X^{(2)};\mathscr{P}^{(1)}_h,\mathscr{P}^{(2)}_k).$$

(6.6.8). Under the hypotheses of (6.6.1), consider two S-morphisms

$$f_i : X^{(i)} \longrightarrow Y^{(i)},$$

where $Y^{(i)}=\operatorname{Spec}(B_i)$ is an affine S-scheme, so that B_i is an A-algebra $(i=1,2)$. This defines an A-homomorphism

$$B_i \longrightarrow \Gamma(X^{(i)},\mathscr{O}_{X^{(i)}})$$

((**I**, 2.2.4)), and consequently each $L_{\bullet\bullet}^{(i)}$ defined in (6.6.2) is a bicomplex of B_i-modules. Thus

$$L_{\bullet\bullet}^{(1)} \otimes_A L_{\bullet\bullet}^{(2)}$$

is a quadricomplex of $(B_1 \otimes_A B_2)$-modules, and its six hyperhomology spectral functors may be regarded as taking values in the category of spectral sequences of $(B_1 \otimes_A B_2)$-modules.

Put

$$Y = Y^{(1)} \times_S Y^{(2)} = \operatorname{Spec}(B_1 \otimes_A B_2).$$

We may then consider the quasi-coherent $\mathscr{O}_Y$-modules associated with these modules ((**I**, 1.3.4)). For $t = a, b, a', b', c, d$, write

$${}^{(t)}\mathscr{E}(f_1, f_2; \mathscr{P}_\bullet^{(1)}, \mathscr{P}_\bullet^{(2)})$$

for the six spectral sequences of $\mathscr{O}_Y$-modules

$$\left({}^{(t)}E(X^{(1)}, X^{(2)}; \mathscr{P}_\bullet^{(1)}, \mathscr{P}_\bullet^{(2)})\right)^{\sim},$$

and write

$$\mathfrak{Tor}_\bullet^S(f_1, f_2; \mathscr{P}_\bullet^{(1)}, \mathscr{P}_\bullet^{(2)})$$

for their common abutment

$$\left(\mathbf{Tor}_\bullet^S(X^{(1)}, X^{(2)}; \mathscr{P}_\bullet^{(1)}, \mathscr{P}_\bullet^{(2)})\right)^{\sim}.$$

When $\mathscr{P}_\bullet^{(i)}$ is concentrated in degree zero, with term $\mathscr{F}^{(i)}$ $(i = 1, 2)$, we write this abutment as

$$\mathfrak{Tor}_\bullet^S(f_1, f_2; \mathscr{F}^{(1)}, \mathscr{F}^{(2)}).$$

6.7. Global hypertor functors of complexes of quasi-coherent modules and Künneth spectral sequences: the general case

(6.7.1). We now generalize the definitions of (6.6.8) to the case where S is an arbitrary prescheme, $X^{(i)}$ and $Y^{(i)}$ are S-preschemes, and

$$f_i : X^{(i)} \longrightarrow Y^{(i)}$$

are separated and quasi-compact S-morphisms. For every pair of bounded-below complexes $\mathscr{P}_\bullet^{(i)}$ of quasi-coherent $\mathscr{O}_{X^{(i)}}$-modules $(i = 1, 2)$, the aim is to define a quasi-coherent $\mathscr{O}_Y$-module

$$\mathfrak{Tor}_n^S(f_1, f_2; \mathscr{P}_\bullet^{(1)}, \mathscr{P}_\bullet^{(2)})$$

for every n, together with six spectral functors, in such a way that these definitions reduce to those of (6.6.8) when S, $Y^{(1)}$, and $Y^{(2)}$ are affine; here $Y = Y^{(1)} \times_S Y^{(2)}$.

First suppose that $S = \operatorname{Spec}(A)$ is affine, while $Y^{(1)}$ and $Y^{(2)}$ are arbitrary. Let $W^{(i)}$ be an affine open subset of $Y^{(i)}$. Then $f_i^{-1}(W^{(i)})$ is a quasi-compact S-scheme, and

$$W = W^{(1)} \times_S W^{(2)}$$

is an affine open subset of Y. Let

$$f_i' : f_i^{-1}(W^{(i)}) \longrightarrow W^{(i)}$$

be the restriction of f_i, and let

$$\mathscr{P}_\bullet'^{(i)} = \mathscr{P}_\bullet^{(i)}\,|_{f_i^{-1}(W^{(i)})} \qquad (i = 1, 2).$$

By (6.6.8) we then have the spectral sequences of quasi-coherent $(\mathscr{O}_Y|W)$-modules

$${}^{(t)}\mathscr{E}(f_1', f_2'; \mathscr{P}_\bullet'^{(1)}, \mathscr{P}_\bullet'^{(2)}),$$

and it remains to verify that they satisfy the gluing conditions of (**0**, 3.3.1).

We are immediately reduced to the case in which

$$Y^{(i)} = \operatorname{Spec}(B_i), \qquad W^{(i)} = D(g_i), \qquad g_i \in B_i,$$

so that

$$W = D(g_1 \otimes g_2)$$

in $Y = \operatorname{Spec}(B_1 \otimes_A B_2)$ ((**II**, 4.3.2.1)). Put $X'^{(i)} = f_i^{-1}(W^{(i)})$. We must establish an isomorphism of spectral functors

(6.7.1.1).

$$ {}^{(t)}E\big(X'^{(1)}, X'^{(2)}; \mathscr{P}'^{(1)}_\bullet, \mathscr{P}'^{(2)}_\bullet\big) \xrightarrow{\sim} {}^{(t)}E\big(X^{(1)}, X^{(2)}; \mathscr{P}^{(1)}_\bullet, \mathscr{P}^{(2)}_\bullet\big) \otimes_B B_g, \tag{6.7.1.1}$$

where

$$B = B_1 \otimes_A B_2, \qquad g = g_1 \otimes g_2.$$

Choose finite affine open coverings $\mathfrak{U}^{(i)}$ of $X^{(i)}$, and let $\mathfrak{U}'^{(i)}$ be their traces on $X'^{(i)}$. The latter are **III** | 158
again coverings by affine open subsets ((**I**, 5.5.10)), and more precisely

$$C^\bullet\big(\mathfrak{U}'^{(i)}, \mathscr{P}'^{(i)}_\bullet\big) = C^\bullet\big(\mathfrak{U}^{(i)}, \mathscr{P}^{(i)}_\bullet\big) \otimes_{B_i} (B_i)_{g_i}.$$

Put

$$L^{(i)}_{\bullet\bullet} = C^\bullet\big(\mathfrak{U}^{(i)}, \mathscr{P}^{(i)}_\bullet\big), \qquad L'^{(i)}_{\bullet\bullet} = C^\bullet\big(\mathfrak{U}'^{(i)}, \mathscr{P}'^{(i)}_\bullet\big).$$

Then

$$L'^{(1)}_{\bullet\bullet} \otimes_A L'^{(2)}_{\bullet\bullet} = \big(L^{(1)}_{\bullet\bullet} \otimes_{B_1} (B_1)_{g_1}\big) \otimes_A \big(L^{(2)}_{\bullet\bullet} \otimes_{B_2} (B_2)_{g_2}\big).$$

Since

$$B_g = (B_1)_{g_1} \otimes_A (B_2)_{g_2}$$

up to canonical isomorphism, we likewise have, up to canonical isomorphism,

$$L'^{(1)}_{\bullet\bullet} \otimes_A L'^{(2)}_{\bullet\bullet} = \big(L^{(1)}_{\bullet\bullet} \otimes_A L^{(2)}_{\bullet\bullet}\big) \otimes_B B_g.$$

Let $M^{(i)}_{\bullet\bullet}$ be a projective Cartan–Eilenberg resolution of $L^{(i)}_{\bullet\bullet}$, chosen to consist of B_i-modules. Because $(B_i)_{g_i}$ is flat over B_i,

$$M'^{(i)}_{\bullet\bullet} = M^{(i)}_{\bullet\bullet} \otimes_{B_i} (B_i)_{g_i}$$

is a projective Cartan–Eilenberg resolution of $L'^{(i)}_{\bullet\bullet}$. Moreover,

$$M'^{(1)}_{\bullet\bullet} \otimes_A M'^{(2)}_{\bullet\bullet} = \big(M^{(1)}_{\bullet\bullet} \otimes_A M^{(2)}_{\bullet\bullet}\big) \otimes_B B_g.$$

The desired isomorphism (6.7.1.1) now follows immediately from the definitions of the hyperhomology of a bicomplex and from the exactness of $G \longmapsto G \otimes_B B_g$ on B-modules.

(6.7.2). Now suppose that S is arbitrary, and let

$$u_i : Y^{(i)} \longrightarrow S \qquad (i = 1, 2)$$

be the structural morphisms. Choose an affine open covering (S_α) of S, put

$$Y^{(i)}_\alpha = u_i^{-1}(S_\alpha), \qquad X^{(i)}_\alpha = f_i^{-1}(Y^{(i)}_\alpha),$$

and let

$$f_{i\alpha} : X^{(i)}_\alpha \longrightarrow Y^{(i)}_\alpha$$

be the restriction of f_i, which is separated and quasi-compact. The schemes

$$Y_\alpha = Y^{(1)}_\alpha \times_{S_\alpha} Y^{(2)}_\alpha$$

form an open covering of Y, and on every Y_α, (6.7.1) defines the spectral functors

$${}^{(t)}\mathscr{E}^{S_\alpha}\left(f_{1\alpha}, f_{2\alpha}; \mathscr{P}^{(1)}_\bullet | X^{(1)}_\alpha, \mathscr{P}^{(2)}_\bullet | X^{(2)}_\alpha\right).$$

It remains again to show that these functors satisfy the gluing conditions.

We reduce immediately to the following situation: $S = \operatorname{Spec}(A)$ is affine, $S' = D(h)$ with $h \in A$, and $u_i(Y^{(i)}) \subset S'$. We may moreover assume that $Y^{(i)} = \operatorname{Spec}(B_i)$ is affine. It is then enough to define canonical isomorphisms

(6.7.2.1).

$$ {}^{(t)}E^S\big(X^{(1)}, X^{(2)}; \mathscr{P}^{(1)}_\bullet, \mathscr{P}^{(2)}_\bullet\big) \xrightarrow{\sim} {}^{(t)}E^{S'}\big(X^{(1)}, X^{(2)}; \mathscr{P}^{(1)}_\bullet, \mathscr{P}^{(2)}_\bullet\big). \tag{6.7.2.1}$$

With the notation of (6.6.2), the $L^{(i)}_{\bullet\bullet}$ consist of A_h-modules, and hence, up to canonical isomorphism,

$$L^{(1)}_{\bullet\bullet} \otimes_{A_h} L^{(2)}_{\bullet\bullet} = L^{(1)}_{\bullet\bullet} \otimes_A L^{(2)}_{\bullet\bullet}.$$

Since a projective Cartan–Eilenberg resolution $M^{(i)}_{\bullet\bullet}$ of $L^{(i)}_{\bullet\bullet}$ may be chosen to consist of A_h-modules, the desired canonical isomorphism follows immediately.

Theorem (6.7.3). — *Let S be a prescheme, let $f_i : X^{(i)} \to Y^{(i)}$ be a separated and quasi-compact S-morphism of S-preschemes, and let $\mathscr{P}^{(i)}_\bullet$ be a bounded-below complex of quasi-coherent $\mathscr{O}_{X^{(i)}}$-modules $(i = 1, 2)$. Put*

$$Y = Y^{(1)} \times_S Y^{(2)}.$$

There exists a bi-∂-functor

$$\mathfrak{Tor}^S_\bullet(f_1, f_2; \mathscr{P}^{(1)}_\bullet, \mathscr{P}^{(2)}_\bullet)$$

with values in the category of quasi-coherent $\mathscr{O}_Y$-modules, such that if $V^{(i)}$ is an affine open subset of $Y^{(i)}$ $(i = 1, 2)$ and $V = V^{(1)} \times_S V^{(2)}$, then

$$\begin{aligned}\mathfrak{Tor}^S_\bullet(f_1, f_2; \mathscr{P}^{(1)}_\bullet, \mathscr{P}^{(2)}_\bullet)\,|_V \\ = \left(\mathbf{Tor}^S_\bullet\left(f_1^{-1}(V^{(1)}), f_2^{-1}(V^{(2)}); \mathscr{P}^{(1)}_\bullet|f_1^{-1}(V^{(1)}), \mathscr{P}^{(2)}_\bullet|f_2^{-1}(V^{(2)})\right)\right)^\sim.\end{aligned}$$

This bifunctor is the common abutment of six biregular spectral functors **III** | 159

$${}^{(t)}\mathscr{E}(f_1, f_2; \mathscr{P}^{(1)}_\bullet, \mathscr{P}^{(2)}_\bullet) \qquad (t = a, b, a', b', c, d),$$

whose E_2-terms are

$$\begin{aligned}
{}^{(a)}\mathscr{E}^2_{pq} &= \bigoplus_{q_1+q_2=q} \mathscr{T}\!or^S_p(\mathscr{H}^{-q_1}(f_1, \mathscr{P}^{(1)}_\bullet), \mathscr{H}^{-q_2}(f_2, \mathscr{P}^{(2)}_\bullet)),\\
{}^{(b)}\mathscr{E}^2_{pq} &= \mathscr{H}^{-p}(f_1 \times_S f_2, \mathfrak{Tor}^S_q(\mathscr{P}^{(1)}_\bullet, \mathscr{P}^{(2)}_\bullet)),\\
{}^{(a')}\mathscr{E}^2_{pq} &= \bigoplus_{q_1+q_2=q} \mathfrak{Tor}^S_p(\mathscr{H}^{-q_1}(f_1, \mathscr{P}^{(1)}_\bullet), \mathscr{H}^{-q_2}(f_2, \mathscr{P}^{(2)}_\bullet)),\\
{}^{(b')}\mathscr{E}^2_{pq} &= \mathscr{H}^{-p}(f_1 \times_S f_2, \mathscr{T}\!or^S_q(\mathscr{P}^{(1)}_\bullet, \mathscr{P}^{(2)}_\bullet)),\\
{}^{(c)}\mathscr{E}^2_{pq} &= \bigoplus_{q_1+q_2=q} \mathfrak{Tor}^S_p(f_1, f_2; \mathscr{H}_{q_1}(\mathscr{P}^{(1)}_\bullet), \mathscr{H}_{q_2}(\mathscr{P}^{(2)}_\bullet)),\\
{}^{(d)}\mathscr{E}^2_{pq} &= \mathscr{H}_p\left(\mathfrak{Tor}^S_q(f_1, f_2; \mathscr{P}^{(1)}_\bullet, \mathscr{P}^{(2)}_\bullet)\right).
\end{aligned}$$

The spectral sequences (a) *and* (b) *are called the* Künneth spectral sequences. *Notice that* (a) *and* (a′), *respectively* (b) *and* (b′), *are identical when $\mathscr{P}^{(1)}_\bullet$ and $\mathscr{P}^{(2)}_\bullet$ are concentrated in degree zero. In that case,* (c) *and* (d) *are degenerate and are therefore of no interest.*

Remark (6.7.4). — The global hypertors just defined include as special cases both the hypercohomology modules defined in (6.2.1) and the local hypertors defined in (6.5.3). Indeed, for every quasi-compact and separated morphism $f : X \to Y$ and every bounded-below complex $\mathscr{P}_\bullet$ of quasi-coherent $\mathscr{O}_X$-modules, there is a canonical isomorphism of ∂-functors in $\mathscr{P}_\bullet$:

(6.7.4.1).

$$\mathfrak{Tor}^Y_n(f, 1_Y; \mathscr{P}_\bullet, \mathscr{O}_Y) \xrightarrow{\sim} \mathscr{H}^{-n}(f, \mathscr{P}_\bullet) \qquad (n \in \mathbf{Z}). \tag{6.7.4.1}$$

The gluing methods of (6.7.2) immediately reduce the proof to the case in which Y is affine. By (6.2.2), both sides of (6.7.4.1) may then be computed using the same finite covering $\mathfrak{U}$ of X by affine open subsets and, for the first side, the covering of Y consisting of Y itself. With the notation of (6.6.2), the bicomplex $L^{(2)}_{\bullet\bullet}$ is then concentrated in bidegree $(0, 0)$, where it is equal to A, and the conclusion follows from (**0**, 11.7.5).

For a generalization, see (6.7.7). Notice, however, that if $\mathscr{O}_Y$ on the left side of (6.7.4.1) is replaced by an arbitrary quasi-coherent $\mathscr{O}_Y$-module $\mathscr{F}$, there is in general no longer an isomorphism with

$$\mathscr{H}^{-n}(f, \mathscr{P}_\bullet \otimes_{\mathscr{O}_Y} \mathscr{F}),$$

although the bicomplex $L^{(1)}_{\bullet\bullet} \otimes_A L^{(2)}_{\bullet\bullet}$ occurring in the preceding calculation still identifies with

$$C^\bullet(\mathfrak{U}, \mathscr{P}_\bullet \otimes_Y \mathscr{F}).$$

On the other hand, there is a canonical isomorphism of bi-∂-functors

(6.7.4.2).

$$\mathfrak{Tor}^S_n(1_{X^{(1)}}, 1_{X^{(2)}}; \mathscr{P}^{(1)}_\bullet, \mathscr{P}^{(2)}_\bullet) \xrightarrow{\sim} \mathscr{T}\!or^S_n(\mathscr{P}^{(1)}_\bullet, \mathscr{P}^{(2)}_\bullet). \tag{6.7.4.2}$$

Indeed, (6.7.1) and (6.7.2) reduce us again to the case in which S and the $X^{(i)}$ are affine. In computing the first side of (6.7.4.2), we may then take $\mathfrak{U}^{(i)}$ to consist of the single member $X^{(i)}$.

With the notation of (6.6.2), $L^{(i)}_{\bullet\bullet}$ then reduces to **III** | 160

$$\Gamma(X^{(i)}, \mathscr{P}^{(i)}_\bullet),$$

regarded as a bicomplex whose components of first degree different from zero vanish. The equality of the two sides of (6.7.4.2) follows from (6.4.1.1) and (6.3.1).

Proposition (6.7.5). — *Let*

$$u : \mathscr{P}^{(1)}_\bullet \longrightarrow \mathscr{Q}^{(1)}_\bullet$$

be a homomorphism of bounded-below complexes of quasi-coherent $\mathscr{O}_{X^{(1)}}$-modules such that the induced homomorphism

$$\mathscr{H}_\bullet(u) : \mathscr{H}_\bullet(\mathscr{P}^{(1)}_\bullet) \longrightarrow \mathscr{H}_\bullet(\mathscr{Q}^{(1)}_\bullet)$$

is an isomorphism. Then the homomorphisms

$$^{(t)}\mathscr{E}(f_1, f_2; \mathscr{P}^{(1)}_\bullet, \mathscr{P}^{(2)}_\bullet) \longrightarrow {}^{(t)}\mathscr{E}(f_1, f_2; \mathscr{Q}^{(1)}_\bullet, \mathscr{P}^{(2)}_\bullet)$$

induced by u are isomorphisms for $t = a, b, c$.

Proof. For the spectral sequence (c), the assertion follows from biregularity and from the fact that, by hypothesis, the homomorphism under consideration is an isomorphism on E_2-terms ((**0**, 11.1.5)). This already shows that

$$\mathfrak{Tor}^S_n(f_1, f_2; \mathscr{P}^{(1)}_\bullet, \mathscr{P}^{(2)}_\bullet) \longrightarrow \mathfrak{Tor}^S_n(f_1, f_2; \mathscr{Q}^{(1)}_\bullet, \mathscr{P}^{(2)}_\bullet)$$

is an isomorphism. Applying (6.7.4.1) and (6.7.4.2), we first see that the homomorphisms

$$\mathscr{H}^{-n}(f_1, \mathscr{P}^{(1)}_\bullet) \longrightarrow \mathscr{H}^{-n}(f_1, \mathscr{Q}^{(1)}_\bullet)$$

and

$$\mathscr{T}\!or^S_n(\mathscr{P}^{(1)}_\bullet, \mathscr{P}^{(2)}_\bullet) \longrightarrow \mathscr{T}\!or^S_n(\mathscr{Q}^{(1)}_\bullet, \mathscr{P}^{(2)}_\bullet)$$

induced by u are isomorphisms. The assertion for (a) and (b) now follows from the biregularity of these spectral sequences ((6.7.3)) and the bijectivity of the induced homomorphisms on E_2-terms ((**0**, 11.1.5)).

Notice also that if $u : \mathscr{P}^{(1)}_\bullet \to \mathscr{Q}^{(1)}_\bullet$ is a homotopy equivalence, then it induces canonical isomorphisms

$$^{(t)}\mathscr{E}(f_1, f_2; \mathscr{P}^{(1)}_\bullet, \mathscr{P}^{(2)}_\bullet) \xrightarrow{\sim} {}^{(t)}\mathscr{E}(f_1, f_2; \mathscr{Q}^{(1)}_\bullet, \mathscr{P}^{(2)}_\bullet)$$

for all six spectral sequences. Indeed, when S and the $Y^{(i)}$ are affine, u induces a homotopy equivalence of bicomplexes

$$C^\bullet(\mathfrak{U}^{(1)}, \mathscr{P}^{(1)}_\bullet) \longrightarrow C^\bullet(\mathfrak{U}^{(1)}, \mathscr{Q}^{(1)}_\bullet),$$

and the assertion follows from the general theory of hyperhomology ((**0**, 11.3.2)). The passage to the general case is made by gluing, using the fact that a homotopy equivalence of complexes induces one between projective Cartan–Eilenberg resolutions of those complexes (M, XVII, 1.2). □

Proposition (6.7.6). — *Suppose that either $\mathscr{P}^{(1)}_\bullet$ or $\mathscr{P}^{(2)}_\bullet$ consists of S-flat modules, both complexes being bounded below. There is then a canonical isomorphism of bi-∂-functors*

(6.7.6.1).

$$\mathfrak{Tor}^S_n(f_1, f_2; \mathscr{P}^{(1)}_\bullet, \mathscr{P}^{(2)}_\bullet) \xrightarrow{\sim} \mathscr{H}^{-n}(f_1 \times_S f_2, \mathscr{P}^{(1)}_\bullet \otimes_S \mathscr{P}^{(2)}_\bullet). \tag{6.7.6.1}$$

Proof. First suppose that S, $Y^{(1)}$, and $Y^{(2)}$ are affine, so that we are in the situation of (6.6.2), whose notation we retain. Suppose, for example, that $\mathscr{P}_\bullet^{(1)}$ consists of S-flat modules. Using (6.6.6), the hypertor is the homology of

$$L_{\bullet\bullet}^{(1)} \otimes_A M_{\bullet\bullet\bullet}^{(2)},$$

where $M_{\bullet\bullet\bullet}^{(2)}$ is a projective Cartan–Eilenberg resolution of $L_{\bullet\bullet}^{(2)}$ in the sense of (**0**, 11.7.1). On the other hand, the modules $L_{ij}^{(1)}$ are flat over A by the hypothesis ((**I**, 1.4.15.1)). It follows from (**0**, 11.7.5) that there is a canonical isomorphism

(6.7.6.2).

$$\mathbf{Tor}_\bullet^S(\mathfrak{U}^{(1)},\mathfrak{U}^{(2)};\mathscr{P}_\bullet^{(1)},\mathscr{P}_\bullet^{(2)}) \xrightarrow{\sim} H_\bullet(L_{\bullet\bullet}^{(1)} \otimes_A L_{\bullet\bullet}^{(2)}). \tag{6.7.6.2}$$

There is also a natural homomorphism of bicomplexes

$$L_{\bullet\bullet}^{(1)} \otimes_A L_{\bullet\bullet}^{(2)} \longrightarrow C^\bullet(\mathfrak{U},\mathscr{Q}_\bullet),$$

where $\mathfrak{U}$ is the covering of

$$Z = X^{(1)} \times_S X^{(2)}$$

by the affine open subsets $U_\alpha^{(1)} \times_S U_\beta^{(2)}$, and

$$\mathscr{Q}_\bullet = \mathscr{P}_\bullet^{(1)} \otimes_S \mathscr{P}_\bullet^{(2)}$$

is regarded as the simple complex for the total degree.

The substance of this homomorphism was already given in the calculation of spectral sequence (b′) in (6.6.4), with $q = 0$. Retaining the notation used there, one need only observe that there is, first, a natural homomorphism from $N^{\bullet k}$ to **III | 161**

$$C^\bullet(\Phi^{(1)},\Phi^{(2)};\mathscr{S}_k)$$

((**0**, 11.8.5)); second, a natural homomorphism from the latter complex to

$$P^\bullet(\Phi^{(1)},\Phi^{(2)};\mathscr{S}_k)$$

((**0**, 11.8.6)); and finally, a natural homomorphism from this last cochain complex to its subcomplex of alternating cochains ((**0**, 11.8.7)). The resulting homomorphism of bicomplexes induces an isomorphism in homology, as was seen in (6.6.4). Composing with (6.7.6.2) therefore gives an isomorphism

(6.7.6.3).

$$\mathbf{Tor}_n^S(\mathfrak{U}^{(1)},\mathfrak{U}^{(2)};\mathscr{P}_\bullet^{(1)},\mathscr{P}_\bullet^{(2)}) \xrightarrow{\sim} \mathrm{H}^{-n}(\mathfrak{U},\mathscr{P}_\bullet^{(1)} \otimes_S \mathscr{P}_\bullet^{(2)}). \tag{6.7.6.3}$$

It remains to prove that the isomorphism just defined is independent of the chosen open coverings. The right side of (6.7.6.3) is canonically isomorphic, by (6.2.2), to

$$\mathrm{H}^{-n}(X^{(1)} \times_S X^{(2)},\mathscr{P}_\bullet^{(1)} \otimes_S \mathscr{P}_\bullet^{(2)}).$$

For the left side, use (6.6.7) and note, with the notation used there, that the following diagram commutes up to homotopy:

$$\begin{tikzcd} C^\bullet(\mathfrak{U}^{(1)},\mathscr{P}_\bullet^{(1)}) \otimes_A C^\bullet(\mathfrak{U}^{(2)},\mathscr{P}_\bullet^{(2)}) \arrow[r] \arrow[d] & C^\bullet(\mathfrak{U},\mathscr{Q}_\bullet) \arrow[d] \\ C^\bullet(\mathfrak{V}^{(1)},\mathscr{P}_\bullet^{(1)}) \otimes_A C^\bullet(\mathfrak{V}^{(2)},\mathscr{P}_\bullet^{(2)}) \arrow[r] & C^\bullet(\mathfrak{V},\mathscr{Q}_\bullet). \end{tikzcd}$$

The horizontal arrows are those defined above. Finally, one passes to the general case by gluing, exactly as in (6.7.1) and (6.7.2); the details are left to the reader. □

Proposition (6.7.7). — *Suppose that* $\mathscr{P}_\bullet^{(1)}$ *and* $\mathscr{P}_\bullet^{(2)}$ *are bounded below, and that either all the modules*

$$\mathscr{H}^{-n}(f_1, \mathscr{P}_\bullet^{(1)})$$

or all the modules

$$\mathscr{H}^{-n}(f_2, \mathscr{P}_\bullet^{(2)})$$

are S-flat. There is then a canonical isomorphism of bi-∂-functors, for $n \in \mathbf{Z}$,

(6.7.7.1).

$$\mathfrak{Tor}_n^S(f_1, f_2; \mathscr{P}_\bullet^{(1)}, \mathscr{P}_\bullet^{(2)}) \xrightarrow{\sim} \bigoplus_{q_1+q_2=n} \mathscr{H}^{-q_1}(f_1, \mathscr{P}_\bullet^{(1)}) \otimes_S \mathscr{H}^{-q_2}(f_2, \mathscr{P}_\bullet^{(2)}). \tag{6.7.7.1}$$

Proof. By (6.5.8), spectral sequence (a) of (6.7.3) degenerates. The assertion therefore follows immediately from (**0**, 11.1.6), since that spectral sequence is biregular ((6.7.3)). □

Theorem (6.7.8). — *Suppose that the following conditions hold:*

1° *The complexes* $\mathscr{P}_\bullet^{(1)}$ *and* $\mathscr{P}_\bullet^{(2)}$ *are bounded below.*
2° *Either* $\mathscr{P}_\bullet^{(1)}$ *or* $\mathscr{P}_\bullet^{(2)}$ *consists of S-flat modules.*

III | 162

3° *Either all the modules* $\mathscr{H}^{-n}(f_1, \mathscr{P}_\bullet^{(1)})$ *or all the modules* $\mathscr{H}^{-n}(f_2, \mathscr{P}_\bullet^{(2)})$ *are S-flat.*

There is then a canonical isomorphism of bi-∂-functors, for $n \in \mathbf{Z}$,

(6.7.8.1).

$$\mathscr{H}^n(f_1 \times_S f_2, \mathscr{P}_\bullet^{(1)} \otimes_S \mathscr{P}_\bullet^{(2)}) \xrightarrow{\sim} \bigoplus_{n_1+n_2=n} \mathscr{H}^{n_1}(f_1, \mathscr{P}_\bullet^{(1)}) \otimes_S \mathscr{H}^{n_2}(f_2, \mathscr{P}_\bullet^{(2)}). \tag{6.7.8.1}$$

This is the Künneth formula.

Proof. The formula follows from (6.7.6) and (6.7.7).

When S, $Y^{(1)}$, and $Y^{(2)}$ are affine, the inverse of (6.7.8.1) is obtained, with the notation of (6.7.6), from the homomorphism of bicomplexes

$$C^\bullet(\mathfrak{U}^{(1)}, \mathscr{P}_\bullet^{(1)}) \otimes_A C^\bullet(\mathfrak{U}^{(2)}, \mathscr{P}_\bullet^{(2)}) \longrightarrow C^\bullet(\mathfrak{U}, \mathscr{Q}_\bullet)$$

by the procedure defined in (G, I, 2.7), as follows from (G, I, 5.5). □

Proposition (6.7.9). — *Suppose that the following three conditions hold:*

1° *The schemes* S, $Y^{(1)}$, *and* $Y^{(2)}$ *are locally noetherian;* f_1 *and* f_2 *are proper; and either* $Y^{(1)}$ *or* $Y^{(2)}$ *is of finite type over* S.
2° *The complexes* $\mathscr{P}_\bullet^{(1)}$ *and* $\mathscr{P}_\bullet^{(2)}$ *are bounded below.*
3° *For every* $n \in \mathbf{Z}$, *the module* $\mathscr{H}_n(\mathscr{P}_\bullet^{(i)})$ *is coherent, for* $i = 1, 2$.

Then

$$\mathfrak{Tor}_n^S(f_1, f_2; \mathscr{P}_\bullet^{(1)}, \mathscr{P}_\bullet^{(2)})$$

is a coherent $\mathscr{O}_Y$*-module, where* $Y = Y^{(1)} \times_S Y^{(2)}$.

Proof. It follows from (6.5.13) that the local hypertor modules

$$\mathscr{T}\!or_n^S(\mathscr{P}_\bullet^{(1)}, \mathscr{P}_\bullet^{(2)})$$

are coherent $\mathscr{O}_X$-modules, where $X = X^{(1)} \times_S X^{(2)}$. Indeed, each $X^{(i)}$ is locally noetherian, and one of them is, by hypothesis, of finite type over S ((**I**, 6.3.4) and (**I**, 6.3.8)); hence X is locally noetherian.

Since Y is locally noetherian and $f_1 \times_S f_2$ is proper ((**II**, 5.4.2)), it follows from (6.2.5) that the terms ${}^{(b)}\mathscr{E}_{pq}^2$ of (6.7.3) are coherent $\mathscr{O}_Y$-modules. All the spectral sequences of (6.7.3) are biregular by hypothesis 2°, so the conclusion follows from (**0**, 11.1.8). □

(6.7.10). Let $Y'^{(i)}$ be two S-preschemes and let

$$v_i : Y'^{(i)} \longrightarrow Y^{(i)} \qquad (i = 1, 2)$$

be two S-morphisms. Write

$$v = v_1 \times_S v_2 : Y' \longrightarrow Y, \qquad Y' = Y'^{(1)} \times_S Y'^{(2)}.$$

For $i = 1, 2$, let $X'^{(i)}$ be an S-prescheme, and let

$$u_i : X'^{(i)} \longrightarrow X^{(i)}, \qquad f'_i : X'^{(i)} \longrightarrow Y'^{(i)}$$

be S-morphisms such that the diagrams

(6.7.10.1).

$$\begin{tikzcd} X'^{(i)} \arrow[r, "u_i"] \arrow[d, "f'_i"'] & X^{(i)} \arrow[d, "f_i"] \\ Y'^{(i)} \arrow[r, "v_i"'] & Y^{(i)} \end{tikzcd} \tag{6.7.10.1}$$

commute, the morphisms f'_i being separated and quasi-compact. There are then canonical $\mathscr{O}_{Y'}$-linear homomorphisms of spectral functors

(6.7.10.2).

$$v^{*\,(t)}\mathscr{E}(f_1, f_2; \mathscr{P}_\bullet^{(1)}, \mathscr{P}_\bullet^{(2)}) \longrightarrow {}^{(t)}\mathscr{E}(f'_1, f'_2; u_1^*(\mathscr{P}_\bullet^{(1)}), u_2^*(\mathscr{P}_\bullet^{(2)})) \tag{6.7.10.2}$$

for $t = a, a', b, b', c, d$.

To define them, first suppose that

$$S = \operatorname{Spec}(A), \qquad Y^{(i)} = \operatorname{Spec}(B_i), \qquad Y'^{(i)} = \operatorname{Spec}(B'_i)$$

are affine. The schemes $X^{(i)}$ and $X'^{(i)}$ are then quasi-compact. To compute

$${}^{(t)}\mathscr{E}(f_1, f_2; \mathscr{P}_\bullet^{(1)}, \mathscr{P}_\bullet^{(2)}),$$

choose, as in (6.6.1), finite affine open coverings $\mathfrak{U}^{(i)}$ of $X^{(i)}$. To compute

$${}^{(t)}\mathscr{E}(f'_1, f'_2; u_1^*(\mathscr{P}_\bullet^{(1)}), u_2^*(\mathscr{P}_\bullet^{(2)})),$$

choose finite affine open coverings $\mathfrak{U}'^{(i)}$ of $X'^{(i)}$, respectively finer than the inverse-image coverings $u_i^{-1}(\mathfrak{U}^{(i)})$.

The bicomplex **III | 163**

$$C^\bullet(\mathfrak{U}^{(i)}, \mathscr{P}_\bullet^{(i)}) = L_{\bullet\bullet}^{(i)}$$

may canonically be regarded as a sub-bicomplex of

$$C^\bullet(u_i^{-1}(\mathfrak{U}^{(i)}), u_i^*(\mathscr{P}_\bullet^{(i)}))$$

((0, 4.4.3.2)). A simplicial map (G, II, 5.7) from $\mathfrak{U}'^{(i)}$ to $u_i^{-1}(\mathfrak{U}^{(i)})$ defines a homomorphism of bicomplexes

$$C^\bullet(u_i^{-1}(\mathfrak{U}^{(i)}), u_i^*(\mathscr{P}_\bullet^{(i)})) \longrightarrow C^\bullet(\mathfrak{U}'^{(i)}, u_i^*(\mathscr{P}_\bullet^{(i)})).$$

By composition one obtains a homomorphism

$$L_{\bullet\bullet}^{(i)} \longrightarrow L'^{(i)}_{\bullet\bullet} = C^\bullet(\mathfrak{U}'^{(i)}, u_i^*(\mathscr{P}_\bullet^{(i)})).$$

Changing the simplicial map replaces this homomorphism by a homotopic one (G, II, 5.7.1). Thus one obtains a well-defined homomorphism of spectral functors

(6.7.10.3).

$${}^{(t)}\mathscr{E}(\mathfrak{U}^{(1)}, \mathfrak{U}^{(2)}; \mathscr{P}_\bullet^{(1)}, \mathscr{P}_\bullet^{(2)}) \longrightarrow {}^{(t)}\mathscr{E}(\mathfrak{U}'^{(1)}, \mathfrak{U}'^{(2)}; u_1^*(\mathscr{P}_\bullet^{(1)}), u_2^*(\mathscr{P}_\bullet^{(2)})). \tag{6.7.10.3}$$

Suppose that $\mathfrak{V}^{(i)}$ is a finite affine open covering of $X^{(i)}$ finer than $\mathfrak{U}^{(i)}$, and that $\mathfrak{V}'^{(i)}$ is a finite affine open covering of $X'^{(i)}$ finer than both $\mathfrak{U}'^{(i)}$ and $u_i^{-1}(\mathfrak{V}^{(i)})$. One verifies immediately that the diagram

$$\begin{tikzcd} C^\bullet(\mathfrak{U}^{(i)}, \mathscr{P}_\bullet^{(i)}) \arrow[r] \arrow[d] & C^\bullet(\mathfrak{V}^{(i)}, \mathscr{P}_\bullet^{(i)}) \arrow[d] \\ C^\bullet\big(\mathfrak{U}'^{(i)}, u_i^*(\mathscr{P}_\bullet^{(i)})\big) \arrow[r] & C^\bullet\big(\mathfrak{V}'^{(i)}, u_i^*(\mathscr{P}_\bullet^{(i)})\big) \end{tikzcd}$$

commutes. Consequently, (6.7.10.3) is essentially independent of the coverings used. We have therefore defined a homomorphism of A-modules

(6.7.10.4).

$$^{(t)}E\big(X^{(1)}, X^{(2)}; \mathscr{P}_\bullet^{(1)}, \mathscr{P}_\bullet^{(2)}\big) \longrightarrow {}^{(t)}E\big(X'^{(1)}, X'^{(2)}; u_1^*(\mathscr{P}_\bullet^{(1)}), u_2^*(\mathscr{P}_\bullet^{(2)})\big). \tag{6.7.10.4}$$

By the definition of the $u_i^*(\mathscr{P}_\bullet^{(i)})$ and the commutativity of (6.7.10.1), this is also a homomorphism of $(B_1 \otimes_A B_2)$-modules. Since the right-hand side of (6.7.10.4) consists of $(B_1' \otimes_A B_2')$-modules, it canonically induces a homomorphism of $(B_1' \otimes_A B_2')$-modules

(6.7.10.5).

$$\begin{aligned} ^{(t)}E\big(X^{(1)}, X^{(2)}; \mathscr{P}_\bullet^{(1)}, \mathscr{P}_\bullet^{(2)}\big) \otimes_{B_1 \otimes_A B_2} (B_1' \otimes_A B_2') \quad \longrightarrow \quad & {}^{(t)}E\big(X'^{(1)}, X'^{(2)}; \\ & u_1^*(\mathscr{P}_\bullet^{(1)}), u_2^*(\mathscr{P}_\bullet^{(2)})\big). \end{aligned} \tag{6.7.10.5}$$

In view of (I, 1.6.5), this is precisely (6.7.10.2) in the affine case.

It remains to pass to the general case by the gluing procedures of (6.7.1) and (6.7.2). The second passage is immediate. For the first, take, as in (6.7.1), elements $g_i \in B_i$ and their images $g_i' \in B_i'$, and set

$$g = g_1 \otimes g_2 \in B = B_1 \otimes_A B_2, \qquad g' = g_1' \otimes g_2' \in B' = B_1' \otimes_A B_2'.$$

Everything then reduces to the canonical isomorphism **III** | 164

$$(M \otimes_B B')_{g'} \xrightarrow{\sim} M_g \otimes_{B_g} B'_{g'}$$

((0, 1.5.4)). The details are left to the reader.

(6.7.11). The theory of global hypertor developed above for two S-morphisms $X^{(i)} \to Y^{(i)}$ and two bounded-below complexes $\mathscr{P}_\bullet^{(i)}$ of quasi-coherent modules extends immediately to the following general situation. Let S be a prescheme, let $(Y^{(i)})_{i \in I}$ be a finite family of S-preschemes, let

$$f_i : X^{(i)} \longrightarrow Y^{(i)} \qquad (i \in I)$$

be a finite family of separated and quasi-compact S-morphisms, and for each i let $\mathscr{P}_\bullet^{(i)}$ be a bounded-below complex of quasi-coherent $\mathscr{O}_{X^{(i)}}$-modules. If Y is the product of the S-preschemes $Y^{(i)}$, then for every $n \in \mathbf{Z}$ one defines a quasi-coherent $\mathscr{O}_Y$-module

$$\mathfrak{Tor}_n^S\big((f_i)_{i \in I}; (\mathscr{P}_\bullet^{(i)})_{i \in I}\big).$$

These modules form a covariant ∂-functor in each complex $\mathscr{P}_\bullet^{(i)}$; moreover, this functor is the common abutment of six spectral functors

$$^{(t)}\mathscr{E}\big((f_i)_{i \in I}; (\mathscr{P}_\bullet^{(i)})_{i \in I}\big).$$

We leave to the reader the repetition, in this general case, of the definitions and arguments given above for $I = \{1, 2\}$.

When I has a single element, this construction recovers the hypercohomology $\mathscr{H}^\bullet(f, \mathscr{P}_\bullet)$ defined in (6.2.7), as already noted in (6.7.4). When I is the interval $1 \leqslant i \leqslant m$ in $\mathbf{N}$, we write

$$\mathfrak{Tor}_n^S(f_1, \ldots, f_m; \mathscr{P}_\bullet^{(1)}, \ldots, \mathscr{P}_\bullet^{(m)})$$

for

$$\mathfrak{Tor}_n^S\big((f_i)_{i \in I}; (\mathscr{P}_\bullet^{(i)})_{i \in I}\big).$$

Proposition (6.7.12). — *With the notation of (6.7.11), let J be a subset of I such that, for $i \in I - J$,*

$$X^{(i)} = Y^{(i)} = S,$$

the morphism f_i is the identity, and $\mathscr{P}_\bullet^{(i)}$ is the complex concentrated in degree 0 *with value $\mathscr{O}_S$. There is then a canonical isomorphism of ∂-functors*

(6.7.12.1).

$$\mathfrak{Tor}_n^S\big((f_i)_{i\in I};(\mathscr{P}_\bullet^{(i)})_{i\in I}\big) \xrightarrow{\sim} \mathfrak{Tor}_n^S\big((f_i)_{i\in J};(\mathscr{P}_\bullet^{(i)})_{i\in J}\big). \tag{6.7.12.1}$$

Proof. It is enough to define this isomorphism when S and the $Y^{(i)}$ are affine, since the gluing is carried out as usual. For $i \in I - J$, take $\mathfrak{U}^{(i)}$ to be the covering consisting of the single set S. Then

$$L_{\bullet\bullet}^{(i)} = C^\bullet(\mathfrak{U}^{(i)}, \mathscr{P}_\bullet^{(i)})$$

has only one nonzero term, in bidegree $(0,0)$, equal to

$$\Gamma(S, \mathscr{O}_S) = A(S).$$

The isomorphism (6.7.12.1) is therefore immediate. □

Remark (6.7.13). — With the notation of (6.7.3), consider the canonical S-isomorphism

$$Y^{(1)} \times_S Y^{(2)} \longrightarrow Y^{(2)} \times_S Y^{(1)}$$

of (**I**, 3.3.5). Under this isomorphism, the image of

$$\mathfrak{Tor}_n^S(f_1, f_2; \mathscr{P}_\bullet^{(1)}, \mathscr{P}_\bullet^{(2)})$$

is

$$\mathfrak{Tor}_n^S(f_2, f_1; \mathscr{P}_\bullet^{(2)}, \mathscr{P}_\bullet^{(1)}).$$

This is a local assertion, so it reduces to the case considered in (6.6.2). If $M_{\bullet\bullet\bullet}^{(i)}$ is a projective Cartan–Eilenberg resolution of $L_{\bullet\bullet}^{(i)}$ for $i = 1, 2$, the isomorphism in question interchanges

$$M_{\bullet\bullet\bullet}^{(1)} \otimes_A M_{\bullet\bullet\bullet}^{(2)} \qquad \text{and} \qquad M_{\bullet\bullet\bullet}^{(2)} \otimes_A M_{\bullet\bullet\bullet}^{(1)}.$$

The assertion follows by taking the homology of the simple complexes associated with these tricomplexes.

6.8. The associativity spectral sequences of global hypertor

(6.8.1). Retain the hypotheses and notation of (6.7.11); in particular, the complexes $\mathscr{P}_\bullet^{(i)}$ are bounded below. Let $(I_j)_{j\in J}$ be a partition of the index set I. We seek an "associativity" relation between

$$\mathfrak{Tor}_n^S\big((f_i)_{i\in I};(\mathscr{P}_\bullet^{(i)})_{i\in I}\big)$$

and the "partial" hypertors

$$\mathscr{T}_{\bullet j} = \mathfrak{Tor}_\bullet^S\big((f_i)_{i\in I_j};(\mathscr{P}_\bullet^{(i)})_{i\in I_j}\big).$$

III | 165

To simplify the notation, we shall restrict attention to the case where I is the interval $1 \leqslant i \leqslant m$ and the partition consists of the two intervals

$$\{1, 2, \ldots, r\} \qquad \text{and} \qquad \{r+1, \ldots, m\}.$$

Proposition (6.8.2). — *There is a canonical biregular spectral functor, called the* associativity spectral functor, *denoted*

$${}^{(e)}\mathscr{E}^S(f_1, \ldots, f_m; \mathscr{P}_\bullet^{(1)}, \ldots, \mathscr{P}_\bullet^{(m)}),$$

or simply ${}^{(e)}\mathscr{E}$ with the same arguments, whose abutment is

$$\mathfrak{Tor}_\bullet^S(f_1, \ldots, f_m; \mathscr{P}_\bullet^{(1)}, \ldots, \mathscr{P}_\bullet^{(m)})$$

and whose E_2-term is

$$^{(e)}\mathscr{E}^2_{pq} = \bigoplus_{q_1+q_2=q} \mathscr{T}\!or^S_p\Big(\mathfrak{Tor}^S_{q_1}(f_1,\ldots,f_r;\mathscr{P}^{(1)}_\bullet,\ldots,\mathscr{P}^{(r)}_\bullet),\\ \mathfrak{Tor}^S_{q_2}(f_{r+1},\ldots,f_m;\mathscr{P}^{(r+1)}_\bullet,\ldots,\mathscr{P}^{(m)}_\bullet)\Big).$$

Proof. Here Y is canonically identified with $Z^{(1)} \times_S Z^{(2)}$, where

$$Z^{(1)} = Y^{(1)} \times_S \cdots \times_S Y^{(r)} \quad \text{and} \quad Z^{(2)} = Y^{(r+1)} \times_S \cdots \times_S Y^{(m)}.$$

It is enough to treat the case in which S and all the $Y^{(i)}$ are affine. The passage from this case to the general one uses the methods of (6.7.1) and (6.7.2); the details are left to the reader. Thus it is enough to prove the following affine statement. □

Corollary (6.8.3). — *Let A be a ring, let $S = \operatorname{Spec}(A)$, and let $X^{(i)}$, $1 \leqslant i \leqslant m$, be quasi-compact S-schemes. For each i, let $\mathscr{P}^{(i)}_\bullet$ be a bounded-below complex of quasi-coherent $\mathscr{O}_{X^{(i)}}$-modules. There is a canonical biregular spectral functor with abutment*

$$\mathbf{Tor}^S_\bullet(X^{(1)},\ldots,X^{(m)};\mathscr{P}^{(1)}_\bullet,\ldots,\mathscr{P}^{(m)}_\bullet)$$

and E_2-term

$$^{(e)}E^2_{pq} = \bigoplus_{q_1+q_2=q} \operatorname{Tor}^A_p\Big(\mathbf{Tor}^S_{q_1}(X^{(1)},\ldots,X^{(r)};\mathscr{P}^{(1)}_\bullet,\ldots,\mathscr{P}^{(r)}_\bullet),\\ \mathbf{Tor}^S_{q_2}(X^{(r+1)},\ldots,X^{(m)};\mathscr{P}^{(r+1)}_\bullet,\ldots,\mathscr{P}^{(m)}_\bullet)\Big).$$

Proof. Following the definition of (6.6.2), choose for each i a finite affine open covering $\mathfrak{U}^{(i)}$ of $X^{(i)}$, form the bicomplex

$$L^{(i)}_{\bullet\bullet} = C^\bullet(\mathfrak{U}^{(i)},\mathscr{P}^{(i)}_\bullet),$$

and choose a projective Cartan–Eilenberg resolution $M^{(i)}_{\bullet\bullet\bullet}$ of this bicomplex in the sense of (**0**, 11.7.1). The hypertor in question is the homology of the tensor product

$$M_{\bullet\bullet\bullet} = \bigotimes_{i=1}^m M^{(i)}_{\bullet\bullet\bullet}.$$

Regard $M_{\bullet\bullet\bullet}$ as a simple complex $N_\bullet$, the tensor product of the two simple complexes

$$N'_\bullet = \bigotimes_{i=1}^r M^{(i)}_{\bullet\bullet\bullet}, \qquad N''_\bullet = \bigotimes_{i=r+1}^m M^{(i)}_{\bullet\bullet\bullet},$$

where $N'_\bullet$ and $N''_\bullet$ are graded by the sums of the total degrees of the $M^{(i)}_{\bullet\bullet\bullet}$.

The A-modules forming $N'_\bullet$ and $N''_\bullet$ are projective. Hence (6.5.9) gives

$$H_\bullet(M_{\bullet\bullet\bullet}) = \mathbf{Tor}^A_\bullet(N'_\bullet,N''_\bullet).$$

The required spectral sequence is therefore precisely (6.3.2.2) applied to $N'_\bullet$ and $N''_\bullet$, using the preceding interpretation of their homology modules for the two partial products

$$X^{(1)} \times_S \cdots \times_S X^{(r)} \quad \text{and} \quad X^{(r+1)} \times_S \cdots \times_S X^{(m)}.$$

Finally, the regularity assertions follow from (6.3.2). Indeed, since the $\mathscr{P}^{(i)}_\bullet$ are bounded below, so are the $M^{(i)}_{\bullet\bullet\bullet}$, and therefore so are $N'_\bullet$ and $N''_\bullet$. □

6.9. The base change spectral sequences of global hypertor

(6.9.1). Retain the hypotheses and notation of (6.7.11); in particular, the complexes $\mathscr{P}_\bullet^{(i)}$ are bounded below. Let $g : S' \to S$ be a morphism of preschemes, and set

$$Y'^{(i)} = Y^{(i)}_{(S')}, \qquad X'^{(i)} = X^{(i)}_{(S')}, \qquad \mathscr{P}'^{(i)}_\bullet = \mathscr{P}^{(i)}_\bullet \otimes_{\mathscr{O}_S} \mathscr{O}_{S'}.$$

Thus $\mathscr{P}'^{(i)}_\bullet$ is a complex of quasi-coherent $\mathscr{O}_{X'^{(i)}}$-modules. Let

$$f'_i = (f_i)_{(S')} : X'^{(i)} \longrightarrow Y'^{(i)};$$

this morphism is separated and quasi-compact ((**I**, 5.5.1) and (6.6.4)).

We shall study the relation between the quasi-coherent $\mathscr{O}_{Y'}$-modules

$$\mathfrak{Tor}_n^{S'}\big((f'_i)_{i\in I}; (\mathscr{P}'^{(i)}_\bullet)_{i\in I}\big)$$

and

$$\mathfrak{Tor}_n^{S}\big((f_i)_{i\in I}; (\mathscr{P}^{(i)}_\bullet)_{i\in I}\big) \otimes_{\mathscr{O}_S} \mathscr{O}_{S'},$$

where

$$Y' = Y \times_S S' = Y_{(S')}.$$

The following particularly simple case reduces to (**I**, 1.4.15) when I has a single element and $\mathscr{P}_\bullet$ consists of a single module.

Proposition (6.9.2). — *If $g : S' \to S$ is flat, there is a canonical isomorphism of ∂-functors in the complexes $\mathscr{P}^{(i)}_\bullet$:*

(6.9.2.1).

$$\mathfrak{Tor}_n^{S}\big((f_i)_{i\in I}; (\mathscr{P}^{(i)}_\bullet)_{i\in I}\big) \otimes_{\mathscr{O}_S} \mathscr{O}_{S'} \xrightarrow{\sim} \mathfrak{Tor}_n^{S'}\big((f'_i)_{i\in I}; (\mathscr{P}'^{(i)}_\bullet)_{i\in I}\big). \tag{6.9.2.1}$$

Proof. It is enough to consider the case where S, S', and all the $Y^{(i)}$ are affine; the gluing is carried out by the methods of (6.7.1) and (6.7.2). Write

$$S = \operatorname{Spec}(A), \qquad S' = \operatorname{Spec}(A'),$$

and choose for each i a finite affine open covering $\mathfrak{U}^{(i)}$ of $X^{(i)}$. If $u_i : X'^{(i)} \to X^{(i)}$ is the canonical projection, then

$$\mathfrak{U}'^{(i)} = u_i^{-1}(\mathfrak{U}^{(i)})$$

is a finite affine open covering of $X'^{(i)}$ ((**II**, 1.5.5)), and

$$C^\bullet(\mathfrak{U}'^{(i)}, \mathscr{P}'^{(i)}_\bullet) = C^\bullet(\mathfrak{U}^{(i)}, \mathscr{P}^{(i)}_\bullet) \otimes_A A'.$$

Let $M^{(i)}_{\bullet\bullet\bullet}$ be a projective Cartan–Eilenberg resolution, in the sense of (**0**, 11.7.1), of

$$L^{(i)}_{\bullet\bullet} = C^\bullet(\mathfrak{U}^{(i)}, \mathscr{P}^{(i)}_\bullet)$$

by A-modules. Since A' is flat over A,

$$M^{(i)}_{\bullet\bullet\bullet} \otimes_A A'$$

is a projective Cartan–Eilenberg resolution, over A', of $L^{(i)}_{\bullet\bullet} \otimes_A A'$. The same flatness gives

$$H_\bullet\left(\bigotimes_{i=1}^m (M^{(i)}_{\bullet\bullet\bullet} \otimes_A A')\right) = H_\bullet\left(\bigotimes_{i=1}^m M^{(i)}_{\bullet\bullet\bullet}\right) \otimes_A A',$$

which proves (6.9.2.1). □

(6.9.2.2). When I consists of the single element 1, (6.9.2.1) also follows directly from (6.7.7). Indeed, take

$$Y_2 = X_2 = S', \qquad f_2 = 1_{S'},$$

and let $\mathscr{P}^{(2)}_\bullet$ be concentrated in degree 0 with value $\mathscr{O}_{S'}$. Then

$$\mathscr{H}^n(1_{S'}, \mathscr{O}_{S'})$$

vanishes for $n \neq 0$ and equals $\mathscr{O}_{S'}$ for $n = 0$ ((6.2.1)).

In the general case, replace $\mathscr{O}_{S'}$ by a bounded-below complex $\mathscr{Q}'_\bullet$ of quasi-coherent $\mathscr{O}_{S'}$-modules. Taking, for simplicity, $I = \{1, 2, \ldots, m\}$, one can then consider the ∂-functor

$$\mathfrak{Tor}^S_\bullet(f_1, \ldots, f_m, 1_{S'}; \mathscr{P}^{(1)}_\bullet, \ldots, \mathscr{P}^{(m)}_\bullet, \mathscr{Q}'_\bullet).$$

Proposition (6.9.3). — *There are three canonical biregular spectral functors, denoted*

$$^{(t)}\mathscr{E}(f_1, \ldots, f_m; \mathscr{P}^{(1)}_\bullet, \ldots, \mathscr{P}^{(m)}_\bullet, \mathscr{Q}'_\bullet), \qquad t = e, f, f',$$

with common abutment

$$\mathfrak{Tor}^S_\bullet(f_1, \ldots, f_m, 1_{S'}; \mathscr{P}^{(1)}_\bullet, \ldots, \mathscr{P}^{(m)}_\bullet, \mathscr{Q}'_\bullet),$$

and whose E_2-terms are respectively as follows.

III | 167

(6.9.3.1).

$$^{(e)}\mathscr{E}^2_{pq} = \bigoplus_{q'+q''=q} \mathscr{T}or^S_p\Big(\mathfrak{Tor}^S_{q'}(f_1, \ldots, f_m; \mathscr{P}^{(1)}_\bullet, \ldots, \mathscr{P}^{(m)}_\bullet), \mathscr{H}_{q''}(\mathscr{Q}'_\bullet)\Big). \tag{6.9.3.1}$$

(6.9.3.2).

$$^{(f)}\mathscr{E}^2_{pq} = \bigoplus_{q_1+\cdots+q_{m+1}=q} \mathscr{T}or^{S'}_p\Big(\mathfrak{Tor}^S_{q_1}(f_1, 1_{S'}; \mathscr{P}^{(1)}_\bullet, \mathscr{O}_{S'}), \ldots, \mathfrak{Tor}^S_{q_m}(f_m, 1_{S'}; \mathscr{P}^{(m)}_\bullet, \mathscr{O}_{S'}), \mathscr{H}_{q_{m+1}}(\mathscr{Q}'_\bullet)\Big). \tag{6.9.3.2}$$

(6.9.3.3).

$$^{(f')}\mathscr{E}^2_{pq} = \bigoplus_{q_1+\cdots+q_m=q} \mathfrak{Tor}^{S'}_p\Big(f'_1, \ldots, f'_m, 1_{S'}; \mathscr{T}or^S_{q_1}(\mathscr{P}^{(1)}_\bullet, \mathscr{O}_{S'}), \ldots, \mathscr{T}or^S_{q_m}(\mathscr{P}^{(m)}_\bullet, \mathscr{O}_{S'}), \mathscr{Q}'_\bullet\Big). \tag{6.9.3.3}$$

Proof. The sequence (e) is precisely the associativity sequence of (6.8.2), with $r = m$. To define the other two spectral sequences, it is again enough to treat the case in which S, S', and the $Y^{(i)}$ are affine. The passage to the general case uses the methods of (6.7.1) and (6.7.2) and is left to the reader. Thus it remains to prove the following affine statement. □

Corollary (6.9.4). — *Let A be a ring, let A' be an A-algebra, and put*

$$S = \operatorname{Spec}(A), \qquad S' = \operatorname{Spec}(A').$$

Let $X^{(i)}$, $1 \leqslant i \leqslant m$, be quasi-compact S-schemes, and for each i put

$$X'^{(i)} = X^{(i)}_{(S')};$$

this is a quasi-compact S'-scheme. For each i, let $\mathscr{P}^{(i)}_\bullet$ be a bounded-below complex of quasi-coherent $\mathscr{O}_{X^{(i)}}$-modules. Finally, let $Q'_\bullet$ be a bounded-below complex of A'-modules, and let $\widetilde{Q}'_\bullet$ be the associated complex.

There are three biregular spectral functors in the $\mathscr{P}^{(i)}_\bullet$ and in $Q'_\bullet$, with common abutment

$$\mathbf{Tor}^S_\bullet(X^{(1)}, \ldots, X^{(m)}, S'; \mathscr{P}^{(1)}_\bullet, \ldots, \mathscr{P}^{(m)}_\bullet, \widetilde{Q}'_\bullet),$$

and whose E_2-terms are respectively

$$^{(e)}E^2_{pq} = \bigoplus_{q'+q''=q} \operatorname{Tor}^A_p\Big(\mathbf{Tor}^S_{q'}(X^{(1)}, \ldots, X^{(m)}; \mathscr{P}^{(1)}_\bullet, \ldots, \mathscr{P}^{(m)}_\bullet), H_{q''}(Q'_\bullet)\Big),$$

$$^{(f)}E^2_{pq} = \bigoplus_{q_1+\cdots+q_{m+1}=q} \operatorname{Tor}^{A'}_p\Big(\mathbf{Tor}^S_{q_1}(X^{(1)}, S'; \mathscr{P}^{(1)}_\bullet, \mathscr{O}_{S'}), \ldots, \mathbf{Tor}^S_{q_m}(X^{(m)}, S'; \mathscr{P}^{(m)}_\bullet, \mathscr{O}_{S'}), H_{q_{m+1}}(Q'_\bullet)\Big),$$

and

$$
{}^{(f')}E^2_{pq} = \bigoplus_{q_1+\cdots+q_m=q} \mathbf{Tor}^{S'}_p \Big(X'^{(1)}, \ldots, X'^{(m)}, S';
$$
$$
\mathscr{T}\!or^S_{q_1}(\mathscr{P}^{(1)}_\bullet, \mathscr{O}_{S'}), \ldots, \mathscr{T}\!or^S_{q_m}(\mathscr{P}^{(m)}_\bullet, \mathscr{O}_{S'}), \widetilde{Q}'_\bullet\Big).
$$

Proof. We do not return to the first of these spectral functors, which was treated in (6.8.3) and is included here only for reference. To define the other two, choose for each i a finite affine open covering $\mathfrak{U}^{(i)}$ of $X^{(i)}$. If

$$u_i : X'^{(i)} \longrightarrow X^{(i)}$$

is the canonical projection, put

$$\mathfrak{U}'^{(i)} = u_i^{-1}(\mathfrak{U}^{(i)}).$$

By (6.6.6), the common abutment is obtained by choosing, for $1 \leqslant i \leqslant m$, a projective Cartan–Eilenberg resolution $M^{(i)}_{\bullet\bullet\bullet}$ of

$$L^{(i)}_{\bullet\bullet} = C^\bullet(\mathfrak{U}^{(i)}, \mathscr{P}^{(i)}_\bullet)$$

in the sense of (**0**, 11.7.1), and then taking the homology of the tricomplex

$$M_{\bullet\bullet\bullet} = M^{(1)}_{\bullet\bullet\bullet} \otimes_A \cdots \otimes_A M^{(m)}_{\bullet\bullet\bullet} \otimes_A Q'_\bullet,$$

where $Q'_\bullet$ is regarded as a tricomplex whose last two degrees are zero. Set

$$M'^{(i)}_{\bullet\bullet\bullet} = M^{(i)}_{\bullet\bullet\bullet} \otimes_A A'.$$

Since $Q'_\bullet$ is a complex of A'-modules, we may rewrite

$$M_{\bullet\bullet\bullet} = M'^{(1)}_{\bullet\bullet\bullet} \otimes_{A'} \cdots \otimes_{A'} M'^{(m)}_{\bullet\bullet\bullet} \otimes_{A'} Q'_\bullet.$$

Regard each $M'^{(i)}_{\bullet\bullet\bullet}$ as a simple complex for its total degree. Its terms are projective A'-modules; hence (6.3.7), extended to any finite number of complexes, identifies the homology of $M_{\bullet\bullet\bullet}$ with

$$\mathrm{Tor}^{A'}_\bullet(M'^{(1)}_{\bullet\bullet\bullet}, \ldots, M'^{(m)}_{\bullet\bullet\bullet}, Q'_\bullet).$$

By (6.5.15), this is the abutment of a spectral sequence having the required regularity properties and E_2-term

$$
E^2_{pq} = \bigoplus_{q_1+\cdots+q_{m+1}=q} \mathrm{Tor}^{A'}_p \Big(H_{q_1}(M'^{(1)}_{\bullet\bullet\bullet}), \ldots, H_{q_m}(M'^{(m)}_{\bullet\bullet\bullet}),
$$
$$
H_{q_{m+1}}(Q'_\bullet)\Big).
$$

III | 168

By the definition of global hypertors,

$$H_{q_i}(M'^{(i)}_{\bullet\bullet\bullet}) = \mathbf{Tor}^S_{q_i}(X^{(i)}, S'; \mathscr{P}^{(i)}_\bullet, \mathscr{O}_{S'}),$$

which gives the sequence (f).

On the other hand, regard $M'^{(i)}_{\bullet\bullet\bullet}$ as a bicomplex whose first degree is the sum of the first two degrees of the tricomplex and whose second degree is its third degree. Since its terms are projective A'-modules, the general theory of hyperhomology shows that the homology of

$$M'^{(1)}_{\bullet\bullet\bullet} \otimes_{A'} \cdots \otimes_{A'} M'^{(m)}_{\bullet\bullet\bullet} \otimes_{A'} Q'_\bullet$$

is canonically isomorphic to its hyperhomology ((**0**, 11.6.5)). It is therefore the abutment of a spectral sequence with E_2-term

$$
E^2_{pq} = \bigoplus_{q_1+\cdots+q_{m+1}=q} \mathrm{Tor}^{A'}_p \Big(H^{\mathrm{II}}_{q_1}(M'^{(1)}_{\bullet\bullet\bullet}), \ldots, H^{\mathrm{II}}_{q_m}(M'^{(m)}_{\bullet\bullet\bullet}),
$$
$$
H^{\mathrm{II}}_{q_{m+1}}(Q'_\bullet)\Big).
$$

The second degree of $Q'_\bullet$ is zero, so

$$H^{\mathrm{II}}_n(Q'_\bullet) = 0 \quad (n \neq 0), \qquad H^{\mathrm{II}}_0(Q'_\bullet) = Q'_\bullet,$$

and the preceding formula becomes

$$E^2_{pq} = \bigoplus_{q_1+\cdots+q_m=q} \operatorname{Tor}^{A'}_p\Big(H^{\mathrm{II}}_{q_1}(M'^{(1)}_{\bullet\bullet\bullet}),\ldots,\\ H^{\mathrm{II}}_{q_m}(M'^{(m)}_{\bullet\bullet\bullet}), Q'_\bullet\Big).$$

Moreover, by (6.3.4),

$$\begin{aligned} H^{\mathrm{II}}_{q_i}(M'^{(i)}_{\bullet\bullet\bullet}) &= H^{\mathrm{II}}_{q_i}(M^{(i)}_{\bullet\bullet\bullet}\otimes_A A') \\ &= \operatorname{Tor}^A_{q_i}(L^{(i)}_{\bullet\bullet}, A'). \end{aligned}$$

Now $L^{(i)}_{-j,k}$ is the direct sum of the modules $\Gamma(V,\mathscr{P}^{(i)}_k)$, where V runs through the affine intersections of $j+1$ members of $\mathfrak{U}^{(i)}$. If $V' = u_i^{-1}(V)$, then V' is affine in $X'^{(i)}$, and (6.4.1.1) gives

$$\Gamma\big(V', \mathscr{T}\!or^S_{q_i}(\mathscr{P}^{(i)}_k, \mathscr{O}_{S'})\big) = \operatorname{Tor}^A_{q_i}\big(\Gamma(V,\mathscr{P}^{(i)}_k), A'\big).$$

Consequently, the bicomplex $H^{\mathrm{II}}_{q_i}(M'^{(i)}_{\bullet\bullet\bullet})$ is

$$C^\bullet\big(\mathfrak{U}'^{(i)}, \mathscr{T}\!or^S_{q_i}(\mathscr{P}^{(i)}_\bullet, \mathscr{O}_{S'})\big).$$

This gives the asserted E_2-term of the sequence (f'). Its biregularity under the stated hypotheses follows in the usual way, since, when $\mathscr{P}^{(i)}_\bullet$ is bounded below, every degree of $M'^{(i)}_{\bullet\bullet\bullet}$ is bounded below. □

Remark (6.9.5). — As in (6.7.6), replacing the complexes $\mathscr{P}^{(i)}_\bullet$ and $\mathscr{Q}'_\bullet$ by respectively homotopic complexes does not change the spectral sequences (e), (f), and (f'), up to canonical isomorphism.

Moreover, for the sequence (f), homomorphisms of complexes

$$\mathscr{P}^{(i)}_\bullet \longrightarrow \mathscr{R}^{(i)}_\bullet, \qquad \mathscr{Q}'_\bullet \longrightarrow \mathscr{T}'_\bullet$$

which induce isomorphisms in homology

$$\mathscr{H}_\bullet(\mathscr{P}^{(i)}_\bullet) \xrightarrow{\sim} \mathscr{H}_\bullet(\mathscr{R}^{(i)}_\bullet), \qquad \mathscr{H}_\bullet(\mathscr{Q}'_\bullet) \xrightarrow{\sim} \mathscr{H}_\bullet(\mathscr{T}'_\bullet)$$

also induce an isomorphism of spectral sequences

$${}^{(f)}\mathscr{E}\big(f_1,\ldots,f_m;\mathscr{P}^{(1)}_\bullet,\ldots,\mathscr{P}^{(m)}_\bullet,\mathscr{Q}'_\bullet\big) \xrightarrow{\sim} {}^{(f)}\mathscr{E}\big(f_1,\ldots,f_m;\\ \mathscr{R}^{(1)}_\bullet,\ldots,\mathscr{R}^{(m)}_\bullet,\mathscr{T}'_\bullet\big).$$

The proof is the same as that of (6.7.6), taking into account the result of that section and the regularity of the sequence (f).

Corollary (6.9.6). — *Under the hypotheses of (6.9.1), suppose that:*

1° *the complexes $\mathscr{P}^{(i)}_\bullet$ consist of S-flat modules, and the $\mathscr{O}_Y$-modules*

$$\mathfrak{Tor}^S_n(f_1,\ldots,f_m;\mathscr{P}^{(1)}_\bullet,\ldots,\mathscr{P}^{(m)}_\bullet)$$

are S-flat;

2° *the complexes $\mathscr{P}^{(i)}_\bullet$ and $\mathscr{Q}'_\bullet$ are bounded below.*

Put **III | 169**

$$\mathscr{P}'^{(i)}_\bullet = \mathscr{P}^{(i)}_\bullet \otimes_{\mathscr{O}_S} \mathscr{O}_{S'}.$$

There are canonical functorial isomorphisms

(6.9.6.1).

$$\begin{aligned} &\mathfrak{Tor}^{S'}_n\big(f'_1,\ldots,f'_m,1_{S'};\mathscr{P}'^{(1)}_\bullet,\ldots,\mathscr{P}'^{(m)}_\bullet,\mathscr{Q}'_\bullet\big) \xrightarrow{\sim} \\ &\qquad \bigoplus_{n'+n''=n} \mathfrak{Tor}^S_{n'}(f_1,\ldots,f_m;\mathscr{P}^{(1)}_\bullet,\ldots,\mathscr{P}^{(m)}_\bullet)\otimes_{\mathscr{O}_S}\mathscr{H}_{n''}(\mathscr{Q}'_\bullet). \end{aligned} \tag{6.9.6.1}$$

In particular, when $\mathscr{Q}'_\bullet$ consists of a single term $\mathscr{F}'$ in degree 0, there are canonical functorial isomorphisms

(6.9.6.2).

$$\mathfrak{Tor}_n^{S'}(f'_1,\ldots,f'_m,1_{S'};\mathscr{P}'^{(1)}_\bullet,\ldots,\mathscr{P}'^{(m)}_\bullet,\mathscr{F}') \xrightarrow{\sim} \mathfrak{Tor}_n^{S}(f_1,\ldots,f_m;\mathscr{P}^{(1)}_\bullet,\ldots,\mathscr{P}^{(m)}_\bullet) \otimes_{\mathscr{O}_S} \mathscr{F}'. \tag{6.9.6.2}$$

More particularly, for $\mathscr{F}' = \mathscr{O}_{S'}$,

(6.9.6.3).

$$\mathfrak{Tor}_n^{S'}(f'_1,\ldots,f'_m;\mathscr{P}'^{(1)}_\bullet,\ldots,\mathscr{P}'^{(m)}_\bullet) \xrightarrow{\sim} \mathfrak{Tor}_n^{S}(f_1,\ldots,f_m;\mathscr{P}^{(1)}_\bullet,\ldots,\mathscr{P}^{(m)}_\bullet) \otimes_{\mathscr{O}_S} \mathscr{O}_{S'}. \tag{6.9.6.3}$$

Proof. The flatness of the terms of $\mathscr{P}^{(i)}_\bullet$ implies that

$$\mathscr{T}or^S_{q_i}(\mathscr{P}^{(i)}_\bullet,\mathscr{O}_{S'}) = 0 \qquad (q_i \neq 0)$$

by (6.5.8). Thus the sequence (f') degenerates. Hypothesis 2° also makes it biregular ((6.9.3)), so the edge homomorphism

$$\mathfrak{Tor}_n^{S}(f_1,\ldots,f_m,1_{S'};\mathscr{P}^{(1)}_\bullet,\ldots,\mathscr{P}^{(m)}_\bullet,\mathscr{Q}'_\bullet) \longrightarrow {}^{(f')}\mathscr{E}^2_{n0} = \mathfrak{Tor}_n^{S'}(f'_1,\ldots,f'_m,1_{S'};\mathscr{P}'^{(1)}_\bullet,\ldots,\mathscr{P}'^{(m)}_\bullet,\mathscr{Q}'_\bullet) \tag{6.9.6.4}$$

is bijective by (**0**, 11.1.6).

The flatness of the modules

$$\mathfrak{Tor}_n^{S}(f_1,\ldots,f_m;\mathscr{P}^{(1)}_\bullet,\ldots,\mathscr{P}^{(m)}_\bullet)$$

implies, by (6.5.8), that ${}^{(e)}\mathscr{E}^2_{pq} = 0$ for $p \neq 0$. Hence (e) also degenerates, and its biregularity makes the edge homomorphism

$$\mathfrak{Tor}_n^{S}(f_1,\ldots,f_m,1_{S'};\mathscr{P}^{(1)}_\bullet,\ldots,\mathscr{P}^{(m)}_\bullet,\mathscr{Q}'_\bullet) \longrightarrow {}^{(e)}\mathscr{E}^2_{0n} = \bigoplus_{n'+n''=n} \mathfrak{Tor}_{n'}^{S}(f_1,\ldots,f_m;\mathscr{P}^{(1)}_\bullet,\ldots,\mathscr{P}^{(m)}_\bullet) \otimes_{\mathscr{O}_S} \mathscr{H}_{n''}(\mathscr{Q}'_\bullet) \tag{6.9.6.5}$$

bijective. Combining these two edge isomorphisms gives (6.9.6.1). Formula (6.9.6.2) follows because $\mathscr{H}_q(\mathscr{Q}'_\bullet) = 0$ for $q \neq 0$ and $\mathscr{H}_0(\mathscr{Q}'_\bullet) = \mathscr{F}'$. Finally, taking $\mathscr{F}' = \mathscr{O}_{S'}$ in (6.9.6.2) and using (6.7.12) gives (6.9.6.3). □

Corollary (6.9.7). — *Under the hypotheses of (6.9.1), suppose that S and S' are affine, and choose an integer d_i for each $1 \leqslant i \leqslant m$. There is an integer N, depending only on S, the $X^{(i)}$, and the d_i, with the following property. For every integer n_0, the canonical isomorphisms (6.9.6.3) hold for $n \leqslant n_0$ and for every system of complexes $\mathscr{P}^{(i)}_\bullet$ satisfying:*

1° $\mathscr{P}^{(i)}_k = 0$ *for $k < d_i$;*

2° $\mathscr{P}^{(i)}_k$ *is S-flat for $k < n_0 + N$;*

3°

$$\mathfrak{Tor}_q^{S}(f_1,\ldots,f_m;\mathscr{P}^{(1)}_\bullet,\ldots,\mathscr{P}^{(m)}_\bullet)$$

is S-flat for $q < n_0 + N$.

Proof. Suppose that $\mathscr{P}^{(i)}_k$ is S-flat for $k < r$. Then

$$\mathscr{T}or^S_{q_i}(\mathscr{P}^{(i)}_k,\mathscr{O}_{S'}) = 0 \qquad (k < r,\ q_i \neq 0).$$

Consider

$$\mathfrak{Tor}_p^{S'}\Big(f'_1,\ldots,f'_m;\mathscr{T}or^S_{q_1}(\mathscr{P}^{(1)}_\bullet,\mathscr{O}_{S'}),\ldots, \mathscr{T}or^S_{q_m}(\mathscr{P}^{(m)}_\bullet,\mathscr{O}_{S'})\Big). \tag{6.9.7.1}$$

Compute (6.9.7.1) by the method of (6.6.2), using the inverse images of fixed finite affine open coverings $\mathfrak{U}^{(i)}$ of $X^{(i)}$. These coverings are independent of S' and of the complexes $\mathscr{P}_\bullet^{(i)}$. The terms $L_{jk}^{(i)}$ vanish for $j < -N_i$, where N_i depends only on $\mathfrak{U}^{(i)}$.

If some q_i is nonzero, the simple complex whose homology in degree p is (6.9.7.1) has zero terms in every degree

$$< r + \sum_{j \neq i} d_j - \sum_{\ell=1}^{m} N_\ell.$$

Consequently (6.9.7.1) vanishes for $p < r - N$, where

$$N = \max_i \left(\sum_{\ell=1}^{m} N_\ell - \sum_{j \neq i} d_j \right).$$

It follows that ${}^{(f')}\mathscr{E}^2_{pq} = 0$ for $q \neq 0$ and $p < r - N$. Since also ${}^{(f')}\mathscr{E}^2_{pq} = 0$ for $q < 0$, the edge homomorphism (6.9.6.4) is bijective for $n < r - N$ (M, XV, 5.6), when $\mathscr{Q}'_\bullet = \mathscr{O}_{S'}$.

Secondly, if

$$\mathfrak{Tor}_q^S(f_1, \ldots, f_m; \mathscr{P}_\bullet^{(1)}, \ldots, \mathscr{P}_\bullet^{(m)})$$

is S-flat for $q < r$, then ${}^{(e)}\mathscr{E}^2_{pq} = 0$ for $p \neq 0$ and $q < r$; moreover, ${}^{(e)}\mathscr{E}^2_{pq} = 0$ for $p < 0$. Thus the edge homomorphism (6.9.6.5) is bijective for $n < r$, which completes the proof. □

The case of (6.9.3) most important in applications is $m = 1$, with $\mathscr{Q}'_\bullet$ reduced to a single term $\mathscr{F}'$ in degree 0. We state it again for later reference.[4]

Proposition (6.9.8). — *Let S be a prescheme, let $g : S' \to S$ be a morphism, and let $f : X \to Y$ be a separated and quasi-compact S-morphism of S-preschemes. Let $\mathscr{P}_\bullet$ be a bounded-below complex of quasi-coherent $\mathscr{O}_X$-modules, and let $\mathscr{F}'$ be a quasi-coherent $\mathscr{O}_{S'}$-module. There are two biregular spectral functors in $\mathscr{P}_\bullet$ and $\mathscr{F}'$, with values in the category of quasi-coherent $\mathscr{O}_{Y_{(S')}}$-modules, having the same abutment*

$$\mathfrak{Tor}_\bullet^S(f, 1_{S'}; \mathscr{P}_\bullet, \mathscr{F}'),$$

and whose E_2-terms are

(6.9.8.1).

$$'\mathscr{E}^2_{pq} = \mathscr{T}\!or_p^S(\mathscr{H}^{-q}(f, \mathscr{P}_\bullet), \mathscr{F}') \tag{6.9.8.1}$$

and

(6.9.8.2).

$$''\mathscr{E}^2_{pq} = \mathscr{H}^{-p}(f', \mathscr{T}\!or_q^S(\mathscr{P}_\bullet, \mathscr{F}')), \tag{6.9.8.2}$$

where

$$f' = f_{(S')} : X_{(S')} \longrightarrow Y_{(S')}.$$

Proof. These spectral sequences may also be obtained, without starting from (6.9.3), from the sequences (a) and (b') of (6.7.3), by taking

$$X^{(1)} = X, \quad Y^{(1)} = Y, \quad X^{(2)} = Y^{(2)} = S', \quad f_1 = f, \quad f_2 = 1_{S'}.$$

When $S = S' = Y$ and Y is affine, one obtains two spectral sequences with E_2-terms

$$'\mathscr{E}^2_{pq} = \mathscr{T}\!or_p^Y(\mathscr{H}^{-q}(f, \mathscr{P}_\bullet), \mathscr{F}) \tag{6.9.8.3}$$

and

$$''\mathscr{E}^2_{pq} = \mathscr{H}^{-p}(f, \mathscr{T}\!or_q^Y(\mathscr{P}_\bullet, \mathscr{F})). \tag{6.9.8.4}$$

By (6.7.6), both abut to the hypercohomology

$$\mathscr{H}^\bullet(f, \mathscr{P}_\bullet \otimes_Y \mathscr{F})$$

[4] The case treated in (6.9.8), and in particular the spectral sequences (6.9.8.3) and (6.9.8.4), was pointed out to us by J.-P. Serre in 1957.

of f_* with respect to the complex $\mathscr{P}_\bullet \otimes_Y \mathscr{F}$ of $\mathscr{O}_X$-modules, for every quasi-coherent Y-flat $\mathscr{O}_Y$-module $\mathscr{F}$; if the terms of $\mathscr{P}_\bullet$ are Y-flat, $\mathscr{F}$ may be any quasi-coherent $\mathscr{O}_Y$-module. These spectral sequences are distinct from those of (6.2.1). □

Corollary (6.9.9). — *Under the hypotheses of (6.9.8), suppose that $\mathscr{P}_\bullet$ is bounded below, consists of S-flat modules, and that the $\mathscr{O}_Y$-modules $\mathscr{H}^n(f, \mathscr{P}_\bullet)$ are S-flat.*

Put **III | 171**

$$\mathscr{P}'_\bullet = \mathscr{P}_\bullet \otimes_{\mathscr{O}_S} \mathscr{O}_{S'}.$$

There are canonical functorial isomorphisms

(6.9.9.1).

$$\mathfrak{Tor}_n^{S'}(f', 1_{S'}; \mathscr{P}'_\bullet, \mathscr{F}') \xrightarrow{\sim} \mathscr{H}^{-n}(f, \mathscr{P}_\bullet) \otimes_{\mathscr{O}_S} \mathscr{F}'. \tag{6.9.9.1}$$

In particular, for $\mathscr{F}' = \mathscr{O}_{S'}$,

(6.9.9.2).

$$\mathscr{H}^n(f', \mathscr{P}'_\bullet) \xrightarrow{\sim} \mathscr{H}^n(f, \mathscr{P}_\bullet) \otimes_{\mathscr{O}_S} \mathscr{O}_{S'}. \tag{6.9.9.2}$$

This is the case $m = 1$ of (6.9.6).

Corollary (6.9.10). — *Let S be a prescheme, let $f : X \to Y$ be a separated and quasi-compact S-morphism of S-preschemes, and let $\mathscr{P}_\bullet$ be a bounded-below complex of quasi-coherent $\mathscr{O}_X$-modules that are flat over S. Suppose further that the $\mathscr{O}_Y$-modules $\mathscr{H}^n(f, \mathscr{P}_\bullet)$ are flat over S.*

For $s \in S$, write X_s and Y_s for the fibres

$$X \times_S \operatorname{Spec}(k(s)), \qquad Y \times_S \operatorname{Spec}(k(s)),$$

write

$$f_s : X_s \longrightarrow Y_s$$

for the morphism $f \times_S 1$, and put

$$\mathscr{P}^s_\bullet = \mathscr{P}_\bullet \otimes_{\mathscr{O}_S} k(s).$$

Then there are canonical functorial isomorphisms

(6.9.10.1).

$$\mathscr{H}^n(f_s, \mathscr{P}^s_\bullet) \xrightarrow{\sim} \mathscr{H}^n(f, \mathscr{P}_\bullet) \otimes_{\mathscr{O}_S} k(s). \tag{6.9.10.1}$$

Thus, under suitable flatness hypotheses, the formation of the derived functors $R^n f_*(\mathscr{F})$ "commutes with passage to the fibres." We shall obtain this result again by another method in §7.

6.10. Local structure of certain cohomological functors

Proposition (6.10.1). — *Let $S = \operatorname{Spec}(A)$ be an affine scheme, and let $Y^{(i)}$ $(1 \leqslant i \leqslant n)$ be a finite family of affine S-schemes, flat over S. For each i, let*

$$f_i : X^{(i)} \longrightarrow Y^{(i)}$$

be a separated and quasi-compact S-morphism, and let $\mathscr{P}^{(i)}_\bullet$ be a bounded-below complex of quasi-coherent $\mathscr{O}_{X^{(i)}}$-modules. Let Y be the product over S of the schemes $Y^{(i)}$.

There exists a complex $\mathscr{R}_\bullet$ of quasi-coherent $\mathscr{O}_Y$-modules, flat over S, with the following property. For every affine S-scheme S' and every bounded-below complex $\mathscr{Q}'_\bullet$ of quasi-coherent $\mathscr{O}_{S'}$-modules, there is an isomorphism

(6.10.1.1).

$$\mathbf{Tor}^S_\bullet(f_1, \ldots, f_n, 1_{S'}; \mathscr{P}^{(1)}_\bullet, \ldots, \mathscr{P}^{(n)}_\bullet, \mathscr{Q}'_\bullet) \xrightarrow{\sim} \mathscr{H}_\bullet(\mathscr{R}_\bullet \otimes_{\mathscr{O}_S} \mathscr{Q}'_\bullet), \tag{6.10.1.1}$$

which is an isomorphism of ∂-functors in $\mathscr{Q}'_\bullet$.

Moreover, for every S-morphism $u : S'' \to S'$ of affine S-schemes, the diagram

(6.10.1.2).

$$
\begin{tikzcd}
\begin{array}{c}\mathbf{Tor}^S_\bullet(f_1,\dots,f_n,1_{S'};\\ \mathscr{P}^{(1)}_\bullet,\dots,\mathscr{P}^{(n)}_\bullet,\mathscr{Q}'_\bullet)\end{array} \arrow[r, "\sim"] \arrow[d] & \mathscr{H}_\bullet(\mathscr{R}_\bullet \otimes_{\mathscr{O}_S} \mathscr{Q}'_\bullet) \arrow[d] \\
\begin{array}{c}\mathbf{Tor}^S_\bullet(f_1,\dots,f_n,1_{S''};\\ \mathscr{P}^{(1)}_\bullet,\dots,\mathscr{P}^{(n)}_\bullet,u^*(\mathscr{Q}'_\bullet))\end{array} \arrow[r, "\sim"] & \mathscr{H}_\bullet(\mathscr{R}_\bullet \otimes_{\mathscr{O}_S} u^*(\mathscr{Q}'_\bullet))
\end{tikzcd}
\tag{6.10.1.2}
$$

commutes. Here the vertical arrows are the canonical $(1_Y \times_S u)$-morphisms defined in (6.7.10).

Proof. Compute the hypertor by the method of (6.6.2), taking account of Remark (6.6.6). With the notation used there, each $L^{(i)}_{\bullet\bullet}$ is a bicomplex of A_i-modules, where A_i denotes the ring of $Y^{(i)}$. It therefore has a projective Cartan–Eilenberg resolution $M^{(i)}_{\bullet\bullet\bullet}$ (in the sense of (**0**, 11.7.1)) by projective A_i-modules. By (6.6.6), the left side of (6.10.1.1) is canonically isomorphic to **III | 172**

$$\mathrm{H}_\bullet(M_{\bullet\bullet\bullet} \otimes_A Q'_\bullet),$$

where

$$M_{\bullet\bullet\bullet} = M^{(1)}_{\bullet\bullet\bullet} \otimes_A M^{(2)}_{\bullet\bullet\bullet} \otimes_A \cdots \otimes_A M^{(n)}_{\bullet\bullet\bullet}$$

and $\mathscr{Q}'_\bullet = \widetilde{Q'_\bullet}$.

By hypothesis, the rings A_i are flat A-modules. Hence the $M^{(i)}_{\bullet\bullet\bullet}$ are tricomplexes of flat A-modules (**0**, 6.2.1), and so is $M_{\bullet\bullet\bullet}$. Furthermore, if B is the ring of Y, that is, the tensor product over A of the A_i, then $M_{\bullet\bullet\bullet}$ is a tricomplex of B-modules. Consequently the complex

$$\mathscr{R}_\bullet = \widetilde{M_{\bullet\bullet\bullet}},$$

where $M_{\bullet\bullet\bullet}$ is regarded as a simple complex, has the required properties, as follows immediately from (6.7.10). □

Corollary (6.10.2). — *In Proposition (6.10.1), the complex $\mathscr{R}_\bullet$ may be taken to be bounded below. If the $\mathscr{P}^{(i)}_\bullet$ are bounded above and the $Y^{(i)}$ have finite cohomological dimension, then $\mathscr{R}_\bullet$ may be taken to be bounded above.*

Proof. The first assertion follows because all three degrees of each $M^{(i)}_{\bullet\bullet\bullet}$ are bounded below. On the other hand, if the rings A_i have finite cohomological dimension, the third degree of each $M^{(i)}_{\bullet\bullet\bullet}$ assumes only finitely many values, and by its construction the same is true of its first degree (6.6.2). Its second degree is bounded above precisely when the degree of $\mathscr{P}^{(i)}_\bullet$ is bounded above (6.6.2), which proves the second assertion. □

Remarks (6.10.3). — (i) With the notation of (6.10.1),

$$\mathscr{H}_\bullet(\mathscr{R}_\bullet \otimes_S \mathscr{Q}'_\bullet) \simeq \mathbf{Tor}_\bullet(\mathscr{R}_\bullet, \mathscr{Q}'_\bullet),$$

because $\mathscr{R}_\bullet$ consists of $\mathscr{O}_Y$-modules that are flat over S (6.5.9). It is therefore (6.5.4) the abutment of a regular spectral sequence whose E^2-term is

(6.10.3.1).

$$E^2_{pq} = \bigoplus_{q'+q''=q} \mathscr{T}\!or^S_p\big(\mathscr{H}_{q'}(\mathscr{R}_\bullet), \mathscr{H}_{q''}(\mathscr{Q}'_\bullet)\big). \tag{6.10.3.1}$$

This is precisely the spectral sequence (e) for base change in (6.9.3).

(ii) Let $\mathscr{R}'_\bullet$ be another complex of quasi-coherent $\mathscr{O}_Y$-modules, flat over S, and let

$$g : \mathscr{R}'_\bullet \longrightarrow \mathscr{R}_\bullet$$

be a homomorphism of complexes for which

$$\mathscr{H}_\bullet(g) : \mathscr{H}_\bullet(\mathscr{R}'_\bullet) \longrightarrow \mathscr{H}_\bullet(\mathscr{R}_\bullet)$$

is an isomorphism. By (6.3.3) and (6.5.9), g induces an isomorphism of ∂-functors in $\mathscr{Q}'_\bullet$,

$$\mathscr{H}_\bullet(\mathscr{R}'_\bullet \otimes_S \mathscr{Q}'_\bullet) \xrightarrow{\sim} \mathscr{H}_\bullet(\mathscr{R}_\bullet \otimes_S \mathscr{Q}'_\bullet),$$

such that the diagram

$$\begin{tikzcd}
\mathscr{H}_\bullet(\mathscr{R}'_\bullet \otimes_S \mathscr{Q}'_\bullet) \arrow[r, "\sim"] \arrow[d] & \mathscr{H}_\bullet(\mathscr{R}_\bullet \otimes_S \mathscr{Q}'_\bullet) \arrow[d] \\
\mathscr{H}_\bullet(\mathscr{R}'_\bullet \otimes_S u^*(\mathscr{Q}'_\bullet)) \arrow[r, "\sim"] & \mathscr{H}_\bullet(\mathscr{R}_\bullet \otimes_S u^*(\mathscr{Q}'_\bullet))
\end{tikzcd}$$

commutes. Thus the properties in (6.10.1) do not determine the complex $\mathscr{R}_\bullet$ completely.

(iii) In the proof of (6.10.1), the $M^{(i)}_{\bullet\bullet\bullet}$ may be chosen to consist of free A_i-modules, as follows immediately by dualising the proof of (**0**, 11.5.2.1). The III | 173

$$M^{(i)}_{\bullet\bullet\bullet} \otimes_{A_i} B$$

then consist of free B-modules; since $M_{\bullet\bullet\bullet}$ is their tensor product over B, one may in addition require in (6.10.1) that $\mathscr{R}_\bullet$ be associated with a complex of free B-modules.

Moreover, by (M, XVII, 1.2), the tricomplex $M_{\bullet\bullet\bullet}$ depends functorially on each of the bicomplexes $L^{(i)}_{\bullet\bullet}$, hence on each $\mathscr{P}^{(i)}_\bullet$ once a finite covering of each $X^{(i)}$ has been fixed. Here "morphisms" of tricomplexes are understood as homomorphism classes modulo homotopy. Replacing a covering of $X^{(i)}$ by a finer one gives, for $L^{(i)}_{\bullet\bullet}$, homomorphisms defined up to homotopy by (6.6.8); thus, with the preceding convention on morphisms, $M_{\bullet\bullet\bullet}$ is a functor in each $\mathscr{P}^{(i)}_\bullet$.

We shall make this functorial dependence more precise, in particular the behaviour of $\mathscr{R}_\bullet$ with respect to short exact sequences

$$0 \longrightarrow \mathscr{P}'^{(i)}_\bullet \longrightarrow \mathscr{P}^{(i)}_\bullet \longrightarrow \mathscr{P}''^{(i)}_\bullet \longrightarrow 0,$$

in the chapter devoted to a general algebra of cohomological functors mentioned in (6.1.3).

Scholium (6.10.4). — The fact that $\mathscr{R}_\bullet$ consists of $\mathscr{O}_Y$-modules flat over S immediately implies that

$$\mathscr{H}_\bullet(\mathscr{R}_\bullet \otimes_S \mathscr{Q}'_\bullet)$$

is a homological functor in $\mathscr{Q}'_\bullet$; compare the argument of (7.7.1). As noted in (6.1.1), this property motivates the introduction of hypertor.

Put

$$X = X^{(1)} \times_S X^{(2)} \times_S \cdots \times_S X^{(n)}, \qquad f = f_1 \times_S f_2 \times_S \cdots \times_S f_n,$$
$$\mathscr{P}_\bullet = \mathscr{P}^{(1)}_\bullet \otimes_S \mathscr{P}^{(2)}_\bullet \otimes_S \cdots \otimes_S \mathscr{P}^{(n)}_\bullet,$$

and

$$X' = X \times_S S', \qquad Y' = Y \times_S S', \qquad f' = f \times_S 1_{S'}.$$

Problems of base change lead one to study the hypercohomology

$$\mathscr{H}^*_{f'}(\mathscr{P}_\bullet \otimes_S \mathscr{N}')$$

as a functor of the quasi-coherent $\mathscr{O}_{S'}$-module $\mathscr{N}'$, or equivalently the hypercohomology

$$\mathscr{H}^*_f(\mathscr{P}_\bullet \otimes_S \mathscr{N})$$

as a functor of the quasi-coherent $\mathscr{O}_S$-module $\mathscr{N}$. When the $\mathscr{P}^{(i)}_\bullet$, and therefore $\mathscr{P}_\bullet$, are flat over S, the preceding results and (6.7.6) show that this is indeed a cohomological functor in $\mathscr{N}$. This is no longer true when the flatness of the $\mathscr{P}^{(i)}_\bullet$ is not assumed, and the study of

$$\mathscr{H}^*_f(\mathscr{P}_\bullet \otimes_S \mathscr{N})$$

can then no longer be approached by the usual methods of homological algebra.

We shall chiefly use the case $n = 1$, $Y = S$, in which $\mathscr{P}_\bullet$ consists of $\mathscr{O}_X$-modules flat over Y. In this case we have the following theorem.

Theorem (6.10.5). — *Let $Y = \operatorname{Spec}(A)$ be an affine Noetherian scheme, let $f : X \to Y$ be a proper morphism, and let $\mathscr{P}_\bullet$ be a bounded-below complex of coherent $\mathscr{O}_X$-modules flat over Y. There exists a bounded-below complex $\mathscr{L}_\bullet$ of $\mathscr{O}_Y$-modules, whose terms have the form*

$$\mathscr{L}_i = \mathscr{O}_Y^{m_i},$$

and an isomorphism

(6.10.5.1).

$$\mathscr{H}^*(f, \mathscr{P}_\bullet \otimes_Y \mathscr{Q}_\bullet) \xrightarrow{\sim} \mathscr{H}_\bullet(\mathscr{L}_\bullet \otimes_Y \mathscr{Q}_\bullet) \tag{6.10.5.1}$$

of ∂-functors in the bounded-below complex $\mathscr{Q}_\bullet$ of quasi-coherent $\mathscr{O}_Y$-modules.

Moreover, for every morphism $u : Y' \to Y$, put

$$X' = X_{(Y')}, \qquad f' = f_{(Y')}, \qquad \mathscr{P}'_\bullet = \mathscr{P}_\bullet \otimes_Y \mathscr{O}_{Y'}, \qquad \mathscr{L}'_\bullet = u^*(\mathscr{L}_\bullet).$$

Then $\mathscr{L}'_\bullet$ is a complex of locally free $\mathscr{O}_{Y'}$-modules of finite type, and there is an isomorphism III | 174

(6.10.5.2).

$$\mathscr{H}^*(f', \mathscr{P}'_\bullet \otimes_{Y'} \mathscr{Q}'_\bullet) \xrightarrow{\sim} \mathscr{H}_\bullet(\mathscr{L}'_\bullet \otimes_{Y'} \mathscr{Q}'_\bullet) \tag{6.10.5.2}$$

of ∂-functors in the bounded-below complex $\mathscr{Q}'_\bullet$ of quasi-coherent $\mathscr{O}_{Y'}$-modules. These isomorphisms may be chosen so that the diagram

(6.10.5.3).

$$\begin{tikzcd} \mathscr{H}^*(f, \mathscr{P}_\bullet \otimes_Y \mathscr{Q}_\bullet) \arrow[r, "\sim"] \arrow[d] & \mathscr{H}_\bullet(\mathscr{L}_\bullet \otimes_Y \mathscr{Q}_\bullet) \arrow[d] \\ \mathscr{H}^*(f', \mathscr{P}'_\bullet \otimes_{Y'} u^*(\mathscr{Q}_\bullet)) \arrow[r, "\sim"] & \mathscr{H}_\bullet(\mathscr{L}'_\bullet \otimes_{Y'} u^*(\mathscr{Q}_\bullet)) \end{tikzcd} \tag{6.10.5.3}$$

commutes.

Proof. Proposition (6.10.1) first gives a bounded-below complex $\mathscr{R}_\bullet$ (6.10.2) of quasi-coherent $\mathscr{O}_Y$-modules that are free over Y (6.10.3) (iii), together with an isomorphism

(6.10.5.4).

$$\mathscr{H}^*(f, \mathscr{P}_\bullet \otimes_Y \mathscr{Q}_\bullet) \xrightarrow{\sim} \mathscr{H}_\bullet(\mathscr{R}_\bullet \otimes_Y \mathscr{Q}_\bullet) \tag{6.10.5.4}$$

of ∂-functors in $\mathscr{Q}_\bullet$. The terms of $\mathscr{R}_\bullet$ need not, *a priori*, be $\mathscr{O}_Y$-modules of finite type.

Apply (6.10.5.4) when $\mathscr{Q}_\bullet$ is the complex concentrated in one degree with sole term $\mathscr{O}_Y$. It follows that $\mathscr{H}_\bullet(\mathscr{R}_\bullet)$ is isomorphic to $\mathscr{H}^*(f, \mathscr{P}_\bullet)$ and hence consists of coherent $\mathscr{O}_Y$-modules (6.2.5). By (**0**, 11.9.2), there is therefore a bounded-below complex $\mathscr{L}_\bullet$ whose terms are associated with free A-modules of finite type, and a homomorphism

$$\mathscr{L}_\bullet \longrightarrow \mathscr{R}_\bullet$$

which induces an isomorphism

$$\mathscr{H}_\bullet(\mathscr{L}_\bullet) \xrightarrow{\sim} \mathscr{H}_\bullet(\mathscr{R}_\bullet).$$

Formula (6.10.5.1) now follows from (6.10.3) (ii).

The remaining assertions of (6.10.5) follow from (6.10.1) and (6.10.3) (ii) when Y' is affine. In the general case, cover Y' by affine open subsets (V_α). If (6.10.5.2) is formed over each V_α, its restrictions from V_α and V_β to an affine open subset

$$W \subset V_\alpha \cap V_\beta$$

both coincide with the isomorphism formed over W. This follows from the commutativity of (6.10.1.2), applied to the canonical inclusions $W \to V_\alpha$ and $W \to V_\beta$, and proves that the local isomorphisms glue. $\square$

Remark (6.10.6). — In the following chapters we shall apply (6.10.5) chiefly when $\mathscr{P}_\bullet$ is concentrated in one degree and its sole term is a coherent $\mathscr{O}_X$-module $\mathscr{F}$ flat over Y. Since

$$\mathscr{H}_n(\mathscr{L}_\bullet) = \mathscr{H}^{-n}(f, \mathscr{F}) = R^{-n} f_*(\mathscr{F}) \qquad (6.2.1),$$

the $\mathscr{H}_n(\mathscr{L}_\bullet)$ vanish for $n > 0$. We shall see later (7.7.12) (i) that $\mathscr{L}_\bullet$ may then be chosen to have terms only in degrees $\leqslant 0$, and hence only finitely many terms, provided the requirement that its terms be associated with free A-modules of finite type is replaced by the requirement that they be locally free of finite type.

The complex $\mathscr{L}_\bullet$ corresponding to such an $\mathscr{O}_X$-module $\mathscr{F}$ seems to have no special property apart from the preceding restriction on its degrees. One may therefore ask conversely whether, given a bounded-below complex $\mathscr{L}_\bullet$ whose terms are $\mathscr{O}_Y$-modules associated with projective A-modules of finite type and whose terms of degree > 0 vanish, there exist a Y-scheme X, projective and flat over Y, and a locally free $\mathscr{O}_X$-module $\mathscr{F}$ such that there is an isomorphism **III | 175**

$$\mathscr{H}^*(f, \mathscr{F} \otimes_Y \mathscr{Q}_\bullet) \xrightarrow{\sim} \mathscr{H}_\bullet(\mathscr{L}_\bullet \otimes_Y \mathscr{Q}_\bullet)$$

functorial in $\mathscr{Q}_\bullet$. Such a result would reduce the cohomological theory of coherent modules flat over Y on proper Y-schemes entirely to the theory, "up to homotopy," of complexes of projective A-modules of finite type over a Noetherian ring A.

§7. Base change for homological functors of sheaves of modules

7.1. Functors of A-modules

(7.1.1). Given a ring A, not necessarily commutative, denote by $\mathtt{Ab}_A$ the category of left A-modules, and simply by $\mathtt{Ab}$ the category of $\mathbf{Z}$-modules, which is the same as the category of commutative groups. Let

$$T : \mathtt{Ab}_A \longrightarrow \mathtt{Ab}$$

be an additive covariant functor, and let M be an (A, A)-bimodule. Then $T(M)$ is naturally endowed with the structure of a right A-module.

Indeed, for every $a \in A$, let $h_{a,M}$, or simply h_a, denote the endomorphism

$$x \longmapsto xa$$

of the left A-module M. By hypothesis, $T(h_a)$ is an endomorphism of the $\mathbf{Z}$-module $T(M)$. Since T is covariant and additive, for $a, b \in A$ one has

$$T(h_{ab}) = T(h_b \circ h_a) = T(h_b) \circ T(h_a)$$

and

$$T(h_{a+b}) = T(h_a + h_b) = T(h_a) + T(h_b).$$

Thus

$$(y, a) \longmapsto T(h_a)(y)$$

defines a right A-module scalar multiplication on $T(M)$. In particular, $T(A_s)$ is a right A-module.

(7.1.2). Suppose that A is commutative. It follows from (7.1.1) that, for every A-module M, the group $T(M)$ is naturally an A-module. Moreover, if $u : M \to N$ is an A-linear homomorphism, then, for every $a \in A$,

$$u \circ h_{a,M} = h_{a,N} \circ u,$$

and hence

$$T(u) \circ T(h_{a,M}) = T(h_{a,N}) \circ T(u).$$

Consequently $T(u) : T(M) \to T(N)$ is A-linear, and T may be regarded as an additive covariant functor from $\mathtt{Ab}_A$ to itself.

More precisely, this defines a canonical equivalence between the category of additive covariant functors

$$\mathtt{Ab}_A \longrightarrow \mathtt{Ab}$$

and the category of A-linear covariant functors

$$T : \mathtt{Ab}_A \longrightarrow \mathtt{Ab}_A,$$

that is, functors satisfying

$$T(h_{a,M}) = h_{a,T(M)} \qquad (a \in A).$$

The forgetful functor

$$I : \mathtt{Ab}_A \longrightarrow \mathtt{Ab},$$

which sends an A-module to its underlying **Z**-module, is exact and faithful. The two functors corresponding under the preceding equivalence therefore have the same exactness properties.

(7.1.3). Continue to suppose that A is commutative. Let B be an A-algebra, not necessarily commutative, and let

$$\rho : A \longrightarrow B$$

be the ring homomorphism defining the algebra structure. It defines an additive covariant functor **III** | 176

$$\rho_* : M \longmapsto M_{[\rho]}$$

from the category $\mathtt{Ab}_B$ of left B-modules to $\mathtt{Ab}_A$. By composition one obtains the additive covariant functor

$$T_{(B)} : \mathtt{Ab}_B \xrightarrow{\rho_*} \mathtt{Ab}_A \xrightarrow{T} \mathtt{Ab}.$$

For typographical reasons this functor will also be denoted $T^{(B)}$ or $T \otimes_A B$, and is said to be obtained from T by extension of scalars from A to B.

If B is commutative, $T_{(B)}$ may of course be regarded as a functor from $\mathtt{Ab}_B$ to itself (7.1.2). If B is commutative and C is a B-algebra, then

$$T_{(C)} = (T_{(B)})_{(C)}.$$

Extension of scalars is plainly functorial and additive in T. Furthermore, if T commutes with direct limits or direct sums, then so does $T_{(B)}$; and if T is left exact, right exact, or exact, respectively, the same is true of $T_{(B)}$. Indeed, ρ_* is exact and commutes with direct limits and direct sums.

(7.1.4). Suppose again that A is commutative, and let

$$T : \mathtt{Ab}_A \longrightarrow \mathtt{Ab}_A$$

be an additive covariant A-linear functor that commutes with direct limits. For every multiplicative subset S of A and every A-module M, there is a canonical functorial isomorphism of A-modules

(7.1.4.1).

(7.1.4.1) $$T(S^{-1}M) \xrightarrow{\sim} S^{-1}T(M).$$

First suppose that S is the set of powers f^n, $n \geqslant 0$, of an element $f \in A$. Then

$$M_f = \varinjlim M_n,$$

where (M_n, ϕ_{nm}) is the direct system of A-modules with $M_n = M$ and

$$\phi_{nm} : z \longmapsto f^{n-m}z \qquad (\mathbf{0}, 1.6.1).$$

Formula (7.1.4.1) follows in this case from the hypothesis on T. For arbitrary S, the module $S^{-1}M$ is the direct limit of the M_f, for $f \in S$ (**0**, 1.4.5), and the same argument applies.

The functoriality of (7.1.4.1) also shows that it is an isomorphism of $S^{-1}A$-modules. Thus, up to canonical isomorphism, one may write

(7.1.4.2).

(7.1.4.2) $$T_{(S^{-1}A)}(S^{-1}M) = S^{-1}T(M) = T(S^{-1}M).$$

If $S = A - \mathfrak{p}$ is the complement of a prime ideal $\mathfrak{p}$ of A, write $T_\mathfrak{p}$ instead of $T_{(A_\mathfrak{p})}$.

Proposition (7.1.5). — *Under the hypotheses of (7.1.4), suppose that $T_\mathfrak{m}$ is left exact, respectively right exact or exact, for every maximal ideal $\mathfrak{m}$ of A. Then T is left exact, respectively right exact or exact.*

Proof. If two submodules N and P of an A-module M satisfy

$$N_\mathfrak{m} = P_\mathfrak{m}$$

for every maximal ideal $\mathfrak{m}$ of A, then $N = P$ (Bourbaki, *Algèbre commutative*, chap. II, § 3, no. 3, th. 1). Applying this fact to the kernels and images in question proves the assertion. □

7.2. Characterisation of the tensor product functor

(7.2.1). Let A be a ring, not necessarily commutative; let M (respectively N) be a left (respectively right) A-module, and let P be a $\mathbf{Z}$-module. Recall that giving a $\mathbf{Z}$-homomorphism

$$v : N \otimes_A M \longrightarrow P$$

is equivalent to giving a $\mathbf{Z}$-bilinear map

$$u : N \times M \longrightarrow P$$

such that

$$u(ta, x) = u(t, ax) \qquad (a \in A,\ t \in N,\ x \in M),$$

the two maps being related by

$$v(t \otimes x) = u(t, x).$$

On the other hand, giving u is equivalent to giving a $\mathbf{Z}$-homomorphism **III** | 177

$$x \longmapsto f_x$$

from M to $\mathrm{Hom}_{\mathbf{Z}}(N, P)$ such that

$$f_{ax}(t) = f_x(ta) \qquad (a \in A,\ t \in N,\ x \in M),$$

the two maps being related by $u(t, x) = f_x(t)$.

(7.2.2). Let

$$T : \mathtt{Ab}_A \longrightarrow \mathtt{Ab}$$

be an additive covariant functor. For every left A-module M we shall define a canonical homomorphism of $\mathbf{Z}$-modules, functorial in M,

(7.2.2.1).

$$t_M : T(A_s) \otimes_A M \longrightarrow T(M). \tag{7.2.2.1}$$

By (7.2.1), it is enough to define a $\mathbf{Z}$-homomorphism

$$x \longmapsto t'_M(x)$$

from M to $\mathrm{Hom}_{\mathbf{Z}}(T(A_s), T(M))$ such that

$$t'_M(ax)(y) = t'_M(x)(ya) \qquad (a \in A,\ x \in M,\ y \in T(A_s)).$$

For this purpose, note that $\mathrm{Hom}_{\mathbf{Z}}(T(A_s), T(M))$ is canonically a left A-module, by virtue of the right A-module structure on $T(A_s)$, with scalar multiplication defined by

$$(a \cdot w)(y) = w(ya)$$

for $a \in A$, $w \in \mathrm{Hom}_{\mathbf{Z}}(T(A_s), T(M))$, and $y \in T(A_s)$. Define t'_M to be the composite of the two canonical homomorphisms

$$M \xrightarrow{\sim} \mathrm{Hom}_A(A_s, M) \xrightarrow{T} \mathrm{Hom}_{\mathbf{Z}}(T(A_s), T(M)).$$

The second arrow sends w to $T(w)$; the first is the canonical isomorphism of A-modules sending x to the map $\theta_x : A_s \to M$ defined by

$$\theta_x(\xi) = \xi x \qquad (\xi \in A,\ x \in M).$$

Since $\theta_{ax} = \theta_x \circ h_a$, one has

$$T(\theta_{ax}) = T(\theta_x) \circ T(h_a),$$

and consequently, for $y \in T(A_s)$,

$$T(\theta_{ax})(y) = T(\theta_x)\big(T(h_a)(y)\big) = T(\theta_x)(ya)$$

by the definition of the right A-module structure on $T(A_s)$. This proves the existence of t_M.

It is immediate that this homomorphism is functorial in M: for every homomorphism $w : M \to M'$ of left A-modules, the diagram

(7.2.2.2).

$$\begin{tikzcd} T(A_s)\otimes_A M \arrow[r, "t_M"] \arrow[d, "1\otimes w"'] & T(M) \arrow[d, "T(w)"] \\ T(A_s)\otimes_A M' \arrow[r, "t_{M'}"'] & T(M') \end{tikzcd} \tag{7.2.2.2}$$

is commutative. The functoriality of (7.2.2.1) also shows that, when A is commutative, t_M is a homomorphism of A-modules (7.1.2).

(7.2.3). When A is commutative, one can more generally define a canonical homomorphism of A-modules

(7.2.3.1).

$$T(N)\otimes_A M \longrightarrow T(N\otimes_A M). \tag{7.2.3.1}$$

for every A-module N: in the construction of (7.2.2), replace θ_x by the homomorphism of A-modules

$$N \longrightarrow N\otimes_A M, \qquad y \longmapsto y\otimes x.$$

It is immediate that this homomorphism is functorial in both M and N.

In particular, if B is an A-algebra, not necessarily commutative, there is a homomorphism, functorial in M, **III** | 178

(7.2.3.2).

$$(T(M))_{(B)} = T(M)\otimes_A B \longrightarrow T(M\otimes_A B) = T_{(B)}(M_{(B)}). \tag{7.2.3.2}$$

By the functoriality of (7.2.3.1) in M, this is a homomorphism of B-modules.

There is moreover a commutative diagram

(7.2.3.3).

$$\begin{tikzcd} T(A)\otimes_A M \arrow[r, "t_M"] \arrow[d] & T(M) \arrow[d] \\ T_{(B)}(B_s)\otimes_B M_{(B)} \arrow[r, "t_{M_{(B)}}"'] & T_{(B)}(M_{(B)}) \end{tikzcd} \tag{7.2.3.3}$$

The right vertical arrow is the composite

$$T(M) \longrightarrow T(M)\otimes_A B \longrightarrow T(M\otimes_A B) = T_{(B)}(M_{(B)})$$

of the canonical homomorphism and (7.2.3.2). The left vertical arrow in (7.2.3.3) is the homomorphism

$$T(A)\otimes_A M \longrightarrow T_{(B)}(B_s)\otimes_B (B\otimes_A M) = T_{(B)}(B_s)\otimes_A M,$$

where

$$T(A) \longrightarrow T_{(B)}(B_s) = T(B)$$

is $T(\rho)$, with ρ regarded as the homomorphism of A-modules $A\to B_{[\rho]}$.

Lemma (7.2.4). — *If T is an additive covariant functor from $\mathtt{Ab}_A$ to $\mathtt{Ab}$ that commutes with direct sums, then the canonical homomorphism t_L of (7.2.2.1) is an isomorphism for every free A-module L.*

Proof. Write

$$L = \bigoplus_{\alpha\in I} L_\alpha,$$

where every L_α is isomorphic to A_s. The definition of t_M in (7.2.2) shows that

$$t_L = \bigoplus_{\alpha\in I} t_{L_\alpha},$$

because

$$T : \mathrm{Hom}_A(A_s, L) \longrightarrow \mathrm{Hom}_{\mathbf{Z}}(T(A_s), T(L))$$

is the direct sum of the $\mathbf{Z}$-linear maps

$$T_\alpha : \mathrm{Hom}_A(A_s, L_\alpha) \longrightarrow \mathrm{Hom}_{\mathbf{Z}}(T(A_s), T(L_\alpha)),$$

by the hypothesis on T. It therefore remains only to prove the lemma for $L = A_s$; but then t_L is precisely the canonical isomorphism

$$T(A_s) \otimes_A A_s \xrightarrow{\sim} T(A_s),$$

valid for every right A-module. □

Proposition (7.2.5). — *Let T be an additive covariant functor from $\mathtt{Ab}_A$ to $\mathtt{Ab}$ that commutes with direct sums. The following conditions are equivalent:*

- *(a) T is right exact;*
- *(b) the canonical homomorphism t_M of (7.2.2.1) is an isomorphism for every left A-module M;*
- *(b′) T is semi-exact and t_M is surjective for every left A-module M;*
- *(c) T is isomorphic to a functor of M of the form $N \otimes_A M$, where N is a right A-module.*

Proof. It is clear that (b) implies (c), and that (c) implies (a). Let us prove that (a) implies (b). Put **III** | 179

$$T'(M) = T(A_s) \otimes_A M$$

for every left A-module M. There is an exact sequence

$$L' \longrightarrow L \longrightarrow M \longrightarrow 0,$$

where L and L' are free left A-modules. Since T and T' are right exact, there is a commutative diagram

$$\begin{tikzcd} T'(L') \arrow[r] \arrow[d, "t_{L'}"] & T'(L) \arrow[r] \arrow[d, "t_L"] & T'(M) \arrow[r] \arrow[d, "t_M"] & 0 \\ T(L') \arrow[r] & T(L) \arrow[r] & T(M) \arrow[r] & 0 \end{tikzcd}$$

whose rows are exact. By (7.2.4), t_L and $t_{L'}$ are isomorphisms; hence so is t_M, by the five lemma.

It is clear that (b) implies (b′). To show that (b′) implies (a), it is enough to prove the following lemma. □

Lemma (7.2.5.1). — *Let $\mathtt{K}$ and $\mathtt{K}'$ be abelian categories, let F and G be additive covariant functors from $\mathtt{K}$ to $\mathtt{K}'$, and let*

$$f : F \longrightarrow G$$

be a natural transformation (T, I, 1.2) *such that*

$$f_E : F(E) \longrightarrow G(E)$$

is an epimorphism for every object E of $\mathtt{K}$. If F is right exact and G is semi-exact, then G is right exact.

Proof. It is enough to show that, for every epimorphism $v : E' \to E$ in $\mathtt{K}$,

$$G(v) : G(E') \longrightarrow G(E)$$

is an epimorphism. There is a commutative diagram

$$\begin{tikzcd} F(E') \arrow[r, "F(v)"] \arrow[d, "f_{E'}"'] & F(E) \arrow[d, "f_E"] \\ G(E') \arrow[r, "G(v)"'] & G(E) \end{tikzcd}$$

Here $F(v)$, $f_{E'}$, and f_E are epimorphisms; consequently $G(v)$ is also an epimorphism. □

Remark (7.2.6). — For every right A-module N, put

$$T_N(M) = N \otimes_A M$$

for every left A-module M. Thus T_N is an additive covariant functor from $\mathtt{Ab}_A$ to $\mathtt{Ab}$, is right exact, and commutes with direct sums. If $T_N(A_s)$ is canonically identified with N, the corresponding homomorphism (7.2.2.1) is immediately seen to be the identity. It follows that the right A-module N in (7.2.5)(c) is determined up to unique isomorphism and is canonically isomorphic to $T(A_s)$.

Equivalently, the assignments

$$T \longmapsto T(A_s) \qquad \text{and} \qquad N \longmapsto T_N$$

define an equivalence *(T, I, 1.2)* between the category of right A-modules and the category of additive covariant functors

$$\mathtt{Ab}_A \longrightarrow \mathtt{Ab}$$

that are right exact and commute with direct sums.

Proposition (7.2.7). — *Let A be a left Artinian ring whose quotient by its radical $\mathfrak{m}$ is a field k, and let T be an additive covariant functor from $\mathtt{Ab}_A$ to $\mathtt{Ab}$ that commutes with direct sums. The conditions of (7.2.5) are then also equivalent to the following condition:*

(d) T is semi-exact and the homomorphism

$$T(\varepsilon) : T(A_s) \longrightarrow T(k)$$

induced by the canonical homomorphism $\varepsilon : A_s \to k$ is surjective.

Proof. It is clear that condition (b′) of (7.2.5) implies (d). We prove that (d) implies (b′). There is an integer n such that $\mathfrak{m}^n = 0$. For every A-module M, put **III** | 180

$$M_h = \mathfrak{m}^h M.$$

We shall prove, by descending induction on h, that t_{M_h} is surjective. The assertion is clear for $h = n$. If $h < n$, there is an exact sequence

$$0 \longrightarrow M_{h+1} \longrightarrow M_h \longrightarrow M_h/M_{h+1} \longrightarrow 0,$$

and the induction hypothesis says that $t_{M_{h+1}}$ is surjective. Moreover, M_h/M_{h+1} is annihilated by $\mathfrak{m}$, and is therefore an $(A/\mathfrak{m})$-module; in other words, it is a direct sum of A-modules isomorphic to k. Since T commutes with direct sums, it is therefore enough, in order to prove that $t_{M_h/M_{h+1}}$ is surjective, to prove that t_k is surjective. The diagram

$$\begin{tikzcd} T(A_s) \otimes_A A_s \arrow[r, "t_{A_s}"] \arrow[d, "1\otimes\varepsilon"'] & T(A_s) \arrow[d, "T(\varepsilon)"] \\ T(A_s) \otimes_A k \arrow[r, "t_k"'] & T(k) \end{tikzcd}$$

is commutative. Condition (d), together with (7.2.4), therefore shows that t_k is surjective.

To finish the proof, it remains to show that if

$$0 \longrightarrow M' \longrightarrow M \xrightarrow{v} M'' \longrightarrow 0$$

is an exact sequence of A-modules for which $t_{M'}$ and $t_{M''}$ are surjective, then t_M is surjective. There is a commutative diagram

$$\begin{tikzcd} T'(M') \arrow[r] \arrow[d, "t_{M'}"'] & T'(M) \arrow[r] \arrow[d, "t_M"'] & T'(M'') \arrow[r] \arrow[d, "t_{M''}"'] & 0 \arrow[d] \\ T(M') \arrow[r] & T(M) \arrow[r, "T(v)"'] & T(M'') \arrow[r] & \mathrm{Coker}(T(v)) \end{tikzcd}$$

whose two rows are exact, by the hypothesis that T is semi-exact. The induction hypothesis says that $t_{M'}$ and $t_{M''}$ are epimorphisms, while the last vertical arrow is a monomorphism. The five lemma *(M, I, 1.1)* therefore shows that t_M is an epimorphism. ☐

7.3. Exactness criteria for homological functors of modules

Proposition (7.3.1). — *Let A be a ring, not necessarily commutative, and let $T_\bullet$ be a covariant homological functor* (T, II, 2.1) *from $\mathtt{Ab}_A$ to $\mathtt{Ab}$ that commutes with direct sums. Let p be an integer such that T_p and T_{p-1} are defined. The following conditions are equivalent:*

(a) T_p is right exact;
(b) T_{p-1} is left exact;

III | 181

(c) for every left A-module M, the canonical functorial homomorphism (7.2.2.1)

(7.3.1.1)
$$T_p(A_s) \otimes_A M \longrightarrow T_p(M)$$

is an isomorphism;
(d) for every left A-module M, the homomorphism (7.3.1.1) *is an epimorphism;*
(e) T_p is isomorphic to a functor of the form

$$M \longmapsto N \otimes_A M,$$

where N is a right A-module.

If, in addition, the conditions of (7.2.7) *on A and $\mathfrak{m}$ are satisfied, the preceding conditions are also equivalent to*

(f) the canonical homomorphism

$$T_p(\varepsilon) : T_p(A_s) \longrightarrow T_p(k)$$

is an epimorphism.

Proof. By definition of a homological functor, T_i is semi-exact for every i for which it is defined; moreover, for every exact sequence

$$0 \longrightarrow M' \xrightarrow{u} M \xrightarrow{v} M'' \longrightarrow 0,$$

one has

$$\operatorname{Ker}\big(T_{i-1}(u)\big) = \operatorname{Coker}\big(T_i(v)\big).$$

It is therefore clear that (a) and (b) are equivalent, and the other assertions follow immediately from (7.2.5) and (7.2.7). ☐

Corollary (7.3.2). — *Let A be a commutative ring. With the notation of* (7.3.1)*, suppose that T_p is right exact. If $f \in A$ annihilates no nonzero element of an A-module M, then it annihilates no nonzero element of $T_{p-1}(M)$. In particular, if A is an integral domain, the A-module $T_{p-1}(A)$ is torsion-free.*

Proof. If h_f denotes the homothety $x \mapsto fx$ of M, the hypothesis says that h_f is injective. Condition (b) of (7.3.1) then shows that $T_{p-1}(h_f)$ is injective as well. ☐

Proposition (7.3.3). — *Let A be a ring, and let $T_\bullet$ be a covariant homological functor from $\mathtt{Ab}_A$ to $\mathtt{Ab}$ that commutes with direct sums. Let p be an integer such that T_{p-1}, T_p, and T_{p+1} are defined. The following conditions are equivalent:*

(a) T_p is exact;
(b) T_{p+1} and T_p are right exact;
(c) T_p and T_{p-1} are left exact;
(d) T_{p+1} is right exact and T_{p-1} is left exact;
(e) for every A-module M, the canonical homomorphisms

(7.3.3.1)
$$T_i(A_s) \otimes_A M \longrightarrow T_i(M)$$

are isomorphisms for $i = p$ and $i = p + 1$;
(e′) for every A-module M, the homomorphisms (7.3.3.1) *are epimorphisms for $i = p$ and $i = p + 1$;*
(f) for every A-module M, the homomorphism (7.3.3.1) *is an isomorphism for $i = p$, and $T_p(A_s)$ is flat as a right A-module;*
(f′) for every A-module M, the homomorphism (7.3.3.1) *is an epimorphism for $i = p$, and $T_p(A_s)$ is flat as a right A-module.*

Proof. The equivalence of (a), (b), (c), and (d) follows from the equivalence of conditions (a) and (b) of (7.3.1). The equivalence of (b), (e), and (e′) follows from the equivalence of (a), (c), and (d) in (7.3.1). Finally, to say that $T_p(A_s)$ is flat means that the functor

$$M \longmapsto T_p(A_s) \otimes_A M$$

is left exact; the equivalence of (a), (f), and (f′) again follows from the equivalence of (a), (c), and (d) in (7.3.1). □

III | 182

Corollary (7.3.4). — *Suppose that A is commutative, that T_p is exact, and that $T_p(A)$ is an A-module of finite presentation. Then the function*

$$x \longmapsto \operatorname{rank}_{k(x)}\big(T_p(k(x))\big)$$

is locally constant on $X = \operatorname{Spec}(A)$, and is therefore constant if $\operatorname{Spec}(A)$ is connected.

Proof. By condition (f) of (7.3.3), $T_p(A)$ is a flat A-module. It is consequently projective of finite type, so $\widetilde{T_p(A)}$ is a locally free $\mathscr{O}_X$-module (Bourbaki, *Algèbre commutative*, chap. II, § 5, no. 2, th. 1). Moreover,

$$T_p(k(x)) = T_p(A) \otimes_A k(x)$$

by condition (e) of (7.3.3), and the rank at x of the A-module $T_p(A)$ is locally constant *(loc. cit.)*. This proves the corollary. □

Proposition (7.3.5). — *Suppose that A is a left Artinian ring whose quotient by its radical $\mathfrak{m}$ is a field k. The conditions of (7.3.3) are also equivalent to each of the following:*

(g) the canonical homomorphism

$$T_i(\varepsilon) : T_i(A_s) \longrightarrow T_i(k)$$

is an epimorphism for $i = p$ and $i = p+1$;

(h) $T_p(\varepsilon)$ is an epimorphism and $T_p(A_s)$ is flat as a right A-module, or, equivalently, is a free right A-module (Bourbaki, Algèbre commutative, *chap. II, § 3, no. 2, cor. 2 of prop. 5).*

Suppose in addition that A is commutative and that the A-module $T_p(k)$ has finite length d. The preceding conditions are then also equivalent to each of the following:

(i) for every A-module M of finite length,

$$\operatorname{length}\big(T_p(M)\big) = d \operatorname{length}(M); \tag{7.3.5.1}$$

(j)

$$\operatorname{length}\big(T_p(A)\big) = d \operatorname{length}(A). \tag{7.3.5.2}$$

The equivalence of (g) and (h) with the conditions of (7.3.3) follows at once from (7.2.7). For the remaining assertions we shall use the following lemma.

Lemma (7.3.5.3). — *Let $\mathtt{K}$ and $\mathtt{K}'$ be abelian categories, and let*

$$F : \mathtt{K} \longrightarrow \mathtt{K}'$$

be an additive covariant functor. Suppose that F is semi-exact and that $F(S)$ has finite length in $\mathtt{K}'$ for every simple object S of $\mathtt{K}$. Then $F(E)$ has finite length in $\mathtt{K}'$ for every object E of finite length in $\mathtt{K}$. For every exact sequence

$$0 \longrightarrow E' \xrightarrow{u} E \xrightarrow{v} E'' \longrightarrow 0$$

of objects of finite length in $\mathtt{K}$, one has

$$\operatorname{length} F(E) \leqslant \operatorname{length} F(E') + \operatorname{length} F(E''), \tag{7.3.5.4}$$

and equality in (7.3.5.4) holds if and only if

$$0 \longrightarrow F(E') \longrightarrow F(E) \longrightarrow F(E'') \longrightarrow 0$$

is exact.

Proof. The sequence

$$F(E') \xrightarrow{F(u)} F(E) \xrightarrow{F(v)} F(E'')$$

is exact by hypothesis. If $F(E')$ and $F(E'')$ have finite length, so do $\mathrm{Im}(F(u))$ and $\mathrm{Im}(F(v))$. Since $\mathrm{Ker}(F(v)) = \mathrm{Im}(F(u))$, the object $F(E)$ has finite length, and

$$\begin{aligned} \text{length}\, F(E) &= \text{length}\, \mathrm{Im}(F(u)) + \text{length}\, \mathrm{Im}(F(v)) \\ &\leqslant \text{length}\, F(E') + \text{length}\, F(E''). \end{aligned} \tag{7.3.5.5}$$

Induction on the length of E proves the first assertion. Moreover, equality in (7.3.5.5) can hold only when **III** | 183

$$\text{length}\, \mathrm{Im}(F(u)) = \text{length}\, F(E')$$

and

$$\text{length}\, \mathrm{Im}(F(v)) = \text{length}\, F(E'').$$

The first equality is equivalent to $\text{length}\, \mathrm{Ker}(F(u)) = 0$, hence to $\mathrm{Ker}(F(u)) = 0$; the second is equivalent to $\text{length}\, \mathrm{Coker}(F(v)) = 0$, hence to $\mathrm{Coker}(F(v)) = 0$. This proves the last assertion. □

Now let M be an A-module of finite length, with A commutative. The quotients in a Jordan–Hölder series of M are necessarily isomorphic to the A-module k. Induction on the length of M, using (7.3.5.4), therefore gives

$$\text{length}\, T_p(M) \leqslant d\ \text{length}(M). \tag{7.3.5.6}$$

It also follows from (7.3.5.3) that if T_p is exact, then equality (7.3.5.1) holds. Thus condition (a) of (7.3.3) implies (i), and (i) plainly implies (j). It remains to prove the following lemma.

Lemma (7.3.5.7). — *The equality*

$$\text{length}\, T_p(A) = d\ \text{length}\, A$$

implies that $T_p(\varepsilon)$ is an epimorphism and that $T_p(A)$ is a flat A-module.

Proof. Starting from the exact sequence

$$0 \longrightarrow \mathfrak{m} \longrightarrow A \longrightarrow k \longrightarrow 0,$$

formulas (7.3.5.4) and (7.3.5.6) give

$$\begin{aligned} \text{length}\, T_p(A) &\leqslant \text{length}\, T_p(\mathfrak{m}) + \text{length}\, T_p(k) \\ &\leqslant d\big(\text{length}\, \mathfrak{m} + \text{length}\, k\big) = d\ \text{length}\, A. \end{aligned}$$

By (7.3.5.3), equality can hold only if

$$0 \longrightarrow T_p(\mathfrak{m}) \longrightarrow T_p(A) \longrightarrow T_p(k) \longrightarrow 0 \tag{7.3.5.8}$$

is exact. By (7.2.7) and (7.2.5), T_p is isomorphic to a functor

$$M \longmapsto N \otimes_A M.$$

The exactness of (7.3.5.8), together with the exact sequence of Tor, shows that

$$\mathrm{Tor}_1^A(N, k) = 0.$$

It follows that $N = T_p(A)$ is a flat A-module *(0, 10.1.3)*. □

Lemma (7.3.6). — *Let A be a ring, and let $T_\bullet$ be a covariant homological functor from $\mathtt{Ab}_A$ to $\mathtt{Ab}$ that commutes with direct sums. Suppose that T_p and T_{p+1} are defined and that T_p is left exact. Then T_{p+1} is exact if and only if $T_{p+1}(A_s)$ is flat as a right A-module.*

Proof. By (7.3.1), the canonical homomorphism

$$T_{p+1}(A_s) \otimes_A M \longrightarrow T_{p+1}(M)$$

is an isomorphism of functors. The assertion now follows from the definition of a flat A-module. □

Proposition (7.3.7). — *Let A be a ring, and let $T_\bullet$ be a covariant homological functor from $\mathtt{Ab}_A$ to $\mathtt{Ab}$ that commutes with direct sums. Suppose there is an i_0 such that T_i is exact for $i \leqslant i_0$. Then, for every integer $p > i_0$, the following conditions are equivalent:*

(a) T_q *is exact for* $q \leqslant p$;
(b) $T_q(A_s)$ *is flat as a right* A*-module for* $q \leqslant p$;
(c) for every A*-module* M*, the canonical homomorphism*

$$T_q(A_s) \otimes_A M \longrightarrow T_q(M)$$

is surjective for $q \leqslant p+1$.

Proof. The equivalence of (a) and (b) follows by induction on q from (7.3.6), since T_{i_0} is exact by hypothesis. The equivalence of (a) and (c) follows from the equivalence of conditions (a) and (e′) in (7.3.3). □

III | 184

(7.3.8). Let A be a commutative ring, let B be an A-algebra, not necessarily commutative, and let $T_\bullet$ be a covariant homological functor from $\mathtt{Ab}_A$ to $\mathtt{Ab}$. It follows from the definitions in (7.1.3) that the functor from $\mathtt{Ab}_B$ to $\mathtt{Ab}$ obtained by extension of scalars from A to B, denoted

$$T_\bullet^{(B)} = (T_i^{(B)}),$$

is again a homological functor.

Corollary (7.3.9). — *Suppose that* $T_\bullet$ *satisfies the general conditions of* (7.3.7) *and commutes with direct limits. Suppose further that* A *is an integral domain and that every* $T_n(A)$ *is an* A*-module of finite presentation. Then, for every integer* N*, there is an* $f \in A - \{0\}$ *such that*

$$T_p^{(A_f)} : \mathtt{Ab}_{A_f} \longrightarrow \mathtt{Ab}$$

is exact for $p \leqslant N$.

Proof. By hypothesis, T_i is exact for $i \leqslant i_0$, so $T_i(A)$ is flat for these values of i. By condition (b) of (7.3.7), it is enough to choose f such that

$$T_i^{(A_f)}(A_f) = T_i(A_f)$$

is a free A_f-module for $i_0 < i \leqslant N$. Now

$$T_i(A_f) = \big(T_i(A)\big)_f,$$

since T_i commutes with direct limits (7.1.4). If x is the generic point of $\operatorname{Spec}(A)$, then $\big(T_i(A)\big)_x$ is a finite-dimensional vector space over the fraction field of A. Since each $T_i(A)$ is of finite presentation, an f with the desired property exists (Bourbaki, *Algèbre commutative*, chap. II, § 5, no. 1, cor. of prop. 2).

If only finitely many indices i satisfy $T_i \neq 0$, one may choose $f \in A - \{0\}$ such that every $T_p^{(A_f)}$ is exact. □

Corollary (7.3.10). — *Suppose that* $T_\bullet$ *satisfies the general conditions of* (7.3.7) *and commutes with direct limits, that* A *is commutative and Noetherian, and that every* $T_n(A)$ *is an* A*-module of finite type. Then, for every integer* N*, there is a dense open subset* U *of* $\operatorname{Spec}(A)$ *such that, for every integer* $p \leqslant N$*, the function*

$$x \longmapsto \operatorname{rank}_{k(x)}\big(T_p(k(x))\big)$$

is constant on U.

Proof. Let $\mathfrak{p}$ be a minimal prime ideal of A. The ring $B = A/\mathfrak{p}$ is an integral domain, and $\operatorname{Spec}(B)$ is identified with an irreducible component of the topological space $\operatorname{Spec}(A)$. We prove by induction on $p \leqslant N$ that there is an $f_p \in B - \{0\}$ such that, if $B' = B_{f_p}$, then $T_i^{(B')}$ is exact and $T_i(B')$ is a B'-module of finite type for $i \leqslant p$.

The assertion holds for $p \leqslant i_0$ by hypothesis, with $f_p = 1$, so that $B' = B = A/\mathfrak{p}$. Indeed, T_p is then exact, and $T_p(B)$ is isomorphic to

$$T_p(A)/T_p(\mathfrak{p});$$

it is therefore an A-module, and *a fortiori* a B-module, of finite type.

For the induction step, let f_p be the canonical image in B of an element $g_p \in A$, and put $A' = A_{g_p}$. Then

$$B' = A'/\mathfrak{p}',$$

where $\mathfrak{p}'$ is the minimal prime ideal $\mathfrak{p}A_{g_p}$ of A'. Since

$$T_i(A_{g_p}) = \big(T_i(A)\big)_{g_p},$$

the $T_i(A')$ are A'-modules of finite type. Thus $T_\bullet^{(A')}$ satisfies the same hypotheses as $T_\bullet$, with i_0 replaced by p.

We may therefore reduce to the case $A' = A$ in which T_p is exact. The exact sequence

$$0 \longrightarrow \mathfrak{p} \longrightarrow A \longrightarrow A/\mathfrak{p} \longrightarrow 0$$

then gives an exact sequence

$$T_{p+1}(A) \longrightarrow T_{p+1}(A/\mathfrak{p}) \xrightarrow{\partial} T_p(\mathfrak{p}) \longrightarrow T_p(A).$$

Since T_p is exact, the last arrow is injective. Consequently $T_{p+1}(A/\mathfrak{p})$ is a quotient of $T_{p+1}(A)$, and is therefore of finite type.

The proof of (7.3.9) used the finite-type hypothesis on $T_i(A)$ only for $i \leqslant N$. We may therefore apply that corollary to the integral domain B, the functor $T_\bullet^{(B)}$, and $N = p+1$, which completes the induction. There is consequently an $f_N \in B - \{0\}$ such that $\operatorname{Spec}(B_{f_N})$ is an open subset V, dense in $\operatorname{Spec}(B)$, that meets no other irreducible component of $\operatorname{Spec}(A)$.

If the assertion has been proved for B_{f_N}, there is a dense open subset W of V on which the functions in the statement are constant, since III | 185

$$A_x = (B_{f_N})_x \qquad (x \in W).$$

Repeating the same argument for every irreducible component of $\operatorname{Spec}(A)$ proves the corollary. We may therefore reduce to the case where A is an integral domain. The argument of (7.3.9) then gives an $f \in A - \{0\}$ such that the $T_p(A_f)$ are free A_f-modules of finite type for $p \leqslant N$. The conclusion follows from (7.3.4). □

Proposition (7.3.11). — *Let A be a commutative local ring with residue field k, and let $T_\bullet$ be a covariant homological functor from $\mathtt{Ab}_A$ to $\mathtt{Ab}$ that commutes with direct sums. Suppose there is an i_0 such that T_i is exact for $i \leqslant i_0$, and that every $T_n(A)$ is an A-module of finite presentation. The equivalent conditions (a), (b), and (c) of (7.3.7) imply the following two conditions, and are equivalent to them when A is also reduced:*

(d) *for every $x \in \operatorname{Spec}(A)$,*

$$\operatorname{rank}_{k(x)} T_q(k(x)) = \operatorname{rank}_k T_q(k) \qquad (q \leqslant p);$$

(d′) *for every generic point x_j of an irreducible component of* $\operatorname{Spec}(A)$,

$$\operatorname{rank}_{k(x_j)} T_q(k(x_j)) = \operatorname{rank}_k T_q(k) \qquad (q \leqslant p).$$

Proof. Since $T_q(A)$ is an A-module of finite presentation, condition (b) of (7.3.7) is equivalent to saying that $T_q(A)$ is free for $q \leqslant p$ (Bourbaki, *Algèbre commutative*, chap. II, § 3, no. 2, cor. 2 of prop. 5). Condition (c) implies

$$T_q(k(x)) = T_q(A) \otimes_A k(x) \qquad (q \leqslant p).$$

Thus the equivalent conditions of (7.3.7) imply (d), and it is immediate that (d) implies (d′).

It remains to show that (d′) implies (a) when A is reduced. We argue by induction on $q \leqslant p$, since T_q is exact for $q \leqslant i_0$. Suppose that T_k is exact for $k \leqslant q < p$. We shall show that $T_{q+1}(A)$ is a free A-module. By the induction hypothesis, the canonical map

$$T_{q+1}(A) \otimes_A M \longrightarrow T_{q+1}(M)$$

is an isomorphism for every A-module M, by condition (c) of (7.3.7) and (7.3.3). Applying this to $M = k(x_j)$ and $M = k$, condition (d′) gives

$$\operatorname{rank}_{k(x_j)}\big(T_{q+1}(A) \otimes_A k(x_j)\big) = \operatorname{rank}_k T_{q+1}(k)$$

for every generic-point index j. It follows that $T_{q+1}(A)$ is free (Bourbaki, *Algèbre commutative*, chap. II, § 3, no. 2, prop. 7), which completes the proof. □

The preceding results will be considerably strengthened for the homological functors of the special type to be studied in (7.4): the resulting exactness criteria involve only a single one of the T_p.

7.4. Exactness criteria for the functors $H_\bullet(P_\bullet \otimes_A M)$

(7.4.1). Let A be a ring, not necessarily commutative, and let $P_\bullet$ be a complex of flat right A-modules. Since the functor

$$M \longmapsto P_k \otimes_A M$$

is then exact in $\mathtt{Ab}_A$ for every k, the ∂-functor

$$T_\bullet(M) = H_\bullet(P_\bullet \otimes_A M) \tag{7.4.1.1}$$

is a *homological functor* from $\mathtt{Ab}_A$ to $\mathtt{Ab}$; it is plainly A-linear when A is commutative (7.1.2), and it commutes with inductive limits. **III** | 186

If A is commutative, then, for every A-algebra B, the homological functor $T_\bullet^{(B)}$ (7.3.8) is, by definition, given by

$$T_i^{(B)}(N) = H_i(P_\bullet \otimes_A N_{[\rho]}), \tag{7.4.1.2}$$

where $\rho : A \to B$ is the homomorphism defining the A-algebra structure on B. Since one may also write

$$P_\bullet \otimes_A N_{[\rho]} = P_\bullet \otimes_A (B \otimes_B N)_{[\rho]} = (P_\bullet \otimes_A B) \otimes_B N,$$

it follows that

$$T_i^{(B)}(N) = H_i(P'_\bullet \otimes_B N) \tag{7.4.1.3}$$

for every B-module N, where $P'_\bullet$ is the complex $P_\bullet \otimes_A B$ of flat B-modules (**0**, 6.2.1).

Proposition (7.4.2). — *Under the general hypotheses of* (7.4.1)*, and for a given integer $p \in \mathbf{Z}$, the following conditions are equivalent:*

(a) T_p is left exact, or, equivalently, T_{p+1} is right exact;

(b)

$$Z'_p(P_\bullet) = \operatorname{Coker}(P_{p+1} \longrightarrow P_p)$$

is a flat right A-module;

(c) there exists a complex $P'_\bullet$ of flat right A-modules for which the differential

$$d'_{p+1} : P'_{p+1} \longrightarrow P'_p$$

is zero, together with an isomorphism of homological functors

$$H_\bullet(P_\bullet \otimes_A M) \simeq H_\bullet(P'_\bullet \otimes_A M).$$

Proof. By definition there is a sequence, exact and functorial in M,

$$0 \longrightarrow T_p(M) \longrightarrow Z'_p(P_\bullet) \otimes_A M \longrightarrow P_{p-1} \otimes_A M.$$

Indeed, by right exactness of the tensor product,

$$Z'_p(P_\bullet \otimes_A M) = \operatorname{Coker}(P_{p+1} \otimes_A M \longrightarrow P_p \otimes_A M) = Z'_p(P_\bullet) \otimes_A M.$$

For every homomorphism $f : M \to N$ one therefore has the commutative diagram

$$\begin{tikzcd}
0 \arrow[r] & T_p(M) \arrow[r] \arrow[d, "u"'] & Z'_p(P_\bullet) \otimes_A M \arrow[r] \arrow[d, "v"'] & P_{p-1} \otimes_A M \arrow[d, "w"'] \\
0 \arrow[r] & T_p(N) \arrow[r] & Z'_p(P_\bullet) \otimes_A N \arrow[r] & P_{p-1} \otimes_A N,
\end{tikzcd} \tag{7.4.2.1}$$

whose rows are exact. If f is a monomorphism, then so is w, because P_{p-1} is flat. If T_p is left exact, u is likewise a monomorphism, and it follows that v is a monomorphism. Thus $Z'_p(P_\bullet)$ is flat. Conversely, if $Z'_p(P_\bullet)$ is flat, then v is a monomorphism for every monomorphism $f : M \to N$, and diagram (7.4.2.1) shows that u is a monomorphism. Hence T_p, which is already half-exact, is left exact. This proves the equivalence of (a) and (b).

It is immediate that (c) implies (a). Indeed, if $d'_{p+1} : P'_{p+1} \to P'_p$ is zero and

$$0 \longrightarrow M' \longrightarrow M \longrightarrow M'' \longrightarrow 0$$

is an exact sequence of A-modules, then the boundary map in the exact sequence

$$H_{p+1}(P'_\bullet \otimes_A M'') \xrightarrow{\partial} H_p(P'_\bullet \otimes_A M') \longrightarrow H_p(P'_\bullet \otimes_A M)$$

is zero by definition *(M, IV, 1)*, so T_p is left exact. **III** | 187

Conversely, let us prove that (b) implies (c). Put

$$Z_{p+1}(P_\bullet) = \mathrm{Ker}(P_{p+1} \longrightarrow P_p).$$

There is an exact sequence

$$0 \longrightarrow Z_{p+1}(P_\bullet) \longrightarrow P_{p+1} \longrightarrow Z'_p(P_\bullet) \longrightarrow 0$$

in which P_{p+1} and $Z'_p(P_\bullet)$ are flat. Hence $Z_{p+1}(P_\bullet)$ is flat (**0**, 6.1.2). Define

$$P'_i = P_i \quad (i \neq p, p+1), \qquad P'_p = Z'_p(P_\bullet), \qquad P'_{p+1} = Z_{p+1}(P_\bullet).$$

For $i \neq p, p+1$, let $d'_i : P'_i \to P'_{i-1}$ be the differential of $P_\bullet$; let d'_p be the homomorphism

$$Z'_p(P_\bullet) \longrightarrow P_{p-1}$$

induced by d_p after passage to the quotient, and set $d'_{p+1} = 0$. From the flatness just established one has

$$\begin{aligned} Z'_i(P_\bullet \otimes_A M) &= Z'_i(P_\bullet) \otimes_A M, \\ Z_i(P_\bullet \otimes_A M) &= Z_i(P_\bullet) \otimes_A M, \\ B_i(P_\bullet \otimes_A M) &= B_i(P_\bullet) \otimes_A M, \end{aligned}$$

where

$$B_i(P_\bullet) = \mathrm{Im}(P_{i+1} \longrightarrow P_i).$$

One immediately obtains functorial isomorphisms

$$H_i(P_\bullet \otimes_A M) \simeq H_i(P'_\bullet \otimes_A M)$$

for every i. That these form an isomorphism of ∂-functors follows directly from the definition of ∂ *(M, IV, 1)*.

We also note that the conditions of (7.4.2) imply that $B_p(P_\bullet)$ is flat, since there is an exact sequence

$$0 \longrightarrow B_p(P_\bullet) \longrightarrow P_p \longrightarrow Z'_p(P_\bullet) \longrightarrow 0$$

in which P_p and $Z'_p(P_\bullet)$ are flat (**0**, 6.1.2). ☐

Corollary (7.4.3). — *Suppose that A is a regular Noetherian ring of dimension 1, in other words, a product of Dedekind rings (**0**, 17.1.3) and (**0**, 17.3.7); for example, A may be a principal ideal ring. Then T_p is left exact if and only if $T_p(A)$ is a flat A-module. The functor T_p is exact if and only if both $T_p(A)$ and $T_{p-1}(A)$ are flat A-modules.*

Proof. Recall that, for a module M over a Dedekind ring, being flat is equivalent to being torsion-free (**0**, 6.3.3) and (**0**, 6.3.4). Under the hypotheses of (7.4.3), every submodule of a flat A-module is therefore flat.

The second assertion follows from the first, since saying that T_p is exact amounts to saying that T_p and T_{p-1} are left exact. To prove the first assertion, observe that there is an exact sequence

$$0 \longrightarrow H_p(P_\bullet) \longrightarrow Z'_p(P_\bullet) \longrightarrow B_{p-1}(P_\bullet) \longrightarrow 0,$$

where $B_{p-1}(P_\bullet)$ is flat, being a submodule of the flat A-module P_{p-1}. Hence $H_p(P_\bullet)$ is flat if and only if $Z'_p(P_\bullet)$ is flat (**0**, 6.1.2). ☐

The most important applications of (7.4.2) are the following.

Proposition (7.4.4). — *Let A be a Noetherian ring and $P_\bullet$ a complex of flat A-modules. Suppose either that the P_i are of finite type, or that the $H_i(P_\bullet)$ are A-modules of finite type and there exists an i_0 such that $H_i(P_\bullet) = 0$ for $i < i_0$. Let $T_\bullet$ be the homological functor defined by (7.4.1.1). Then the set U of points $y \in \mathrm{Spec}(A)$ such that $(T_p)_y$ (7.1.4) is right exact, respectively left exact or exact, is open in $\mathrm{Spec}(A)$.*

Proof. Under the second hypothesis on $P_\bullet$, one may replace $P_\bullet$ by a complex $P'_\bullet$ of finite free A-modules such that the functor **III** | 188

$$H_\bullet(P'_\bullet \otimes_A M)$$

is isomorphic to $T_\bullet(M)$ as a ∂-functor (**0**, 11.9.3). Thus one may always reduce to the first hypothesis. In that case the modules $Z'_i(P_\bullet)$ are of finite type. Moreover, it is enough to prove the assertions concerning left exactness (cf. (7.4.2), (a)).

Let $x \in U$. Since $M \mapsto M_x$ is exact,

$$\big(Z'_p(P_\bullet)\big)_x = Z'_p\big((P_\bullet)_x\big).$$

Taking (7.4.1.3) into account, the hypothesis and (7.4.2), (b), show that $\big(Z'_p(P_\bullet)\big)_x$ is a flat A_x-module. It is therefore free, since it is of finite type and A_x is a Noetherian local ring (Bourbaki, *Algèbre commutative*, chap. II, § 3, no. 2, cor. 2 of prop. 5). It follows that there is an $f \in A$ for which $\big(Z'_p(P_\bullet)\big)_f$ is free over A_f (Bourbaki, *Algèbre commutative*, chap. II, § 5, no. 1, cor. of prop. 2). A fortiori, $\big(Z'_p(P_\bullet)\big)_y$ is free over A_y for every $y \in D(f)$, and (7.4.2), (b), completes the proof. □

Corollary (7.4.5). — *Under the hypotheses of (7.4.4), suppose in addition that A is an integral domain. Then the set U of $x \in \operatorname{Spec}(A)$ such that $(T_p)_x$ is exact is open and nonempty.*

Proof. It is enough to show that $(T_p)_x$ is exact at the generic point x of $\operatorname{Spec}(A)$. This is immediate, since A_x is a field and every additive functor on $\mathtt{Ab}_{A_x}$ is exact. □

Proposition (7.4.6). — *Under the general hypotheses of (7.4.4), conditions (a), (b), and (c) of (7.4.2) are also equivalent to:*

(d) there exists an A-module Q and a functorial isomorphism

(7.4.6.1) $$T_p(M) \simeq \operatorname{Hom}_A(Q, M).$$

Moreover, this property determines the A-module Q up to a unique isomorphism, and Q is of finite type.

Proof. The uniqueness of Q is a special case of the uniqueness of a representing object for a representable functor (**0**, 8.1.5). It is clear that the right-hand side of (7.4.6.1) is left exact.

Conversely, suppose that T_p is left exact. As in (7.4.4), one may first reduce to the case where the P_i are flat and of finite type, and hence, since A is Noetherian, projective of finite type (Bourbaki, *Algèbre commutative*, chap. II, § 5, no. 2, cor. of th. 1). The dual $\check{P}_i$ of P_i is then also a projective A-module of finite type, P_i is canonically isomorphic to the dual of $\check{P}_i$, and the canonical homomorphism

$$P_i \otimes_A M \longrightarrow \operatorname{Hom}_A(\check{P}_i, M)$$

is bijective (Bourbaki, *Algèbre*, chap. II, 3rd ed., § 4, no. 2, prop. 2).

By (7.4.2), (c), one may furthermore suppose that $d_{p+1} : P_{p+1} \to P_p$ is zero. There is then an exact sequence

$$0 \longrightarrow T_p(M) \xrightarrow{u} P_p \otimes_A M \xrightarrow{v} P_{p-1} \otimes_A M,$$

where $v = d_p \otimes 1$. Put $Q' = \operatorname{Ker}(d_p)$, so that

$$0 \longrightarrow Q' \longrightarrow P_p \xrightarrow{d_p} P_{p-1}$$

is exact. Transposition gives the exact sequence

$$\check{P}_{p-1} \xrightarrow{{}^t d_p} \check{P}_p \longrightarrow \check{Q}' \longrightarrow 0.$$

We claim that

$$Q = \check{Q}' = \operatorname{Coker}({}^t d_p)$$

has the required property. Indeed, there is an exact sequence

$$0 \longrightarrow \operatorname{Hom}_A(Q, M) \longrightarrow \operatorname{Hom}_A(\check{P}_p, M) \xrightarrow{v'} \operatorname{Hom}_A(\check{P}_{p-1}, M),$$

where $v' = \operatorname{Hom}_A({}^t d_p, 1)$. Under the canonical identifications **III** | 189

$$P_i \otimes_A M \simeq \operatorname{Hom}_A(\check{P}_i, M),$$

the homomorphism v' identifies with $v = d_p \otimes 1$. Thus one obtains the required functorial isomorphism

$$T_p(M) \simeq \operatorname{Hom}_A(Q, M).$$

Finally, Q is a quotient of $\check{P}_p$, and is therefore of finite type. □

Proposition (7.4.7). — *Suppose that the general hypotheses of (7.4.4) hold. For every A-module M of finite type:*

(i) the $T_i(M)$ are A-modules of finite type;

(ii) for every ideal $\mathfrak{m}$ of A, the canonical homomorphism

$$\widehat{T_i(M)} \longrightarrow \varprojlim_n T_i\big(M \otimes_A (A/\mathfrak{m}^{n+1})\big) \tag{7.4.7.1}$$

is bijective, where the left-hand side denotes the separated completion of $T_i(M)$ for the $\mathfrak{m}$-adic topology.

Proof. As in (7.4.4), one reduces first to the case where the P_i are of finite type. Since A is Noetherian, the submodules of the $P_i \otimes_A M$ are of finite type, which immediately proves (i). Assertion (ii) follows from the more general lemma below. □

Lemma (7.4.7.2). — *Let A be a Noetherian ring and $u : E \to F$ a homomorphism of finite-type A-modules. For every finite-type A-module M, put*

$$K(M) = \operatorname{Ker}(u \otimes 1_M), \qquad C(M) = \operatorname{Coker}(u \otimes 1_M).$$

Then, for every ideal $\mathfrak{m}$ of A, the canonical homomorphisms

$$\widehat{K(M)} \longrightarrow \varprojlim_n K(M_n), \qquad \widehat{C(M)} \longrightarrow \varprojlim_n C(M_n) \tag{7.4.7.3}$$

are bijective, where

$$M_n = M \otimes_A (A/\mathfrak{m}^{n+1}) = M/\mathfrak{m}^{n+1}M.$$

Proof. The modules $E \otimes_A M$ and $F \otimes_A M$ are of finite type, and the functor $M \mapsto \widehat{M}$ is exact on the category of finite-type A-modules (**0**, 7.3.3). Consequently, $\widehat{K(M)}$ and $\widehat{C(M)}$ are, respectively, the kernel and the cokernel of

$$\widehat{u \otimes 1} : \widehat{E \otimes_A M} \longrightarrow \widehat{F \otimes_A M}.$$

Left exactness of $\varprojlim$ therefore gives

$$\widehat{K(M)} = \varprojlim_n K(M_n).$$

On the other hand, right exactness of the tensor product gives

$$C(M_n) = C(M) \otimes_A (A/\mathfrak{m}^{n+1}),$$

and hence

$$\widehat{C(M)} = \varprojlim_n C(M_n)$$

by definition. □

Remark (7.4.8). — Taking (6.10.5) and (6.10.6) into account, one sees that, with an additional flatness hypothesis, (7.4.7) recovers the fact that (4.1.7.1) is an isomorphism, which is the essential content of the "first comparison theorem" for proper morphisms. Moreover, the statement applies not only to a coherent $\mathscr{O}_X$-module but to a *complex* of such modules. It would be interesting to obtain a statement that contains both (7.4.7) and (4.1.7.1) as special cases.

Notice also that, when the P_i are of finite type, the proof of (7.4.7) does not use their flatness. It would be worth examining whether the conclusion of (7.4.7) continues to hold when the P_i are assumed neither flat nor of finite type, but the $H_i(P_\bullet)$ are assumed to be of finite type for every i and zero for $i < i_0$. Can one then replace $P_\bullet$ by a complex $P'_\bullet$ of finite-type A-modules in such a way that the functors

$$H_\bullet(P_\bullet \otimes_A M) \quad \text{and} \quad H_\bullet(P'_\bullet \otimes_A M),$$

which are no longer homological, are still isomorphic?

7.5. The case of Noetherian local rings

(7.5.1). Let A be a Noetherian local ring and $\mathfrak{m}$ its maximal ideal. For every A-module M, denote by $\widehat{M}$ its separated completion for the $\mathfrak{m}$-adic topology, which is isomorphic to

$$\varprojlim_n (M \otimes_A (A/\mathfrak{m}^{n+1})) = \varprojlim_n (M/\mathfrak{m}^{n+1}M).$$

Let T be a covariant additive functor from $\mathtt{Ab}_A$ to $\mathtt{Ab}$. The canonical homomorphisms (7.2.3.1)

$$T(M) \otimes_A (A/\mathfrak{m}^{n+1}) \longrightarrow T(M \otimes_A (A/\mathfrak{m}^{n+1}))$$

plainly form a projective system of A-homomorphisms. On passing to the limit they therefore give an $\widehat{A}$-homomorphism, functorial in M,

$$\widehat{T(M)} \longrightarrow \varprojlim_n T(M_n), \tag{7.5.1.1}$$

where

$$M_n = M \otimes_A (A/\mathfrak{m}^{n+1}), \qquad A_n = A/\mathfrak{m}^{n+1}.$$

Proposition (7.5.2). — *Let A be a Noetherian local ring with maximal ideal $\mathfrak{m}$ and residue field $k = A/\mathfrak{m}$. Let T be a covariant additive functor from $\mathtt{Ab}_A$ to $\mathtt{Ab}$ that is half-exact and commutes with inductive limits. Suppose, moreover, that for every finite-type A-module M, the module $T(M)$ is of finite type and the canonical homomorphism (7.5.1.1) is an isomorphism. Then the following conditions are equivalent:*

- *(a) T is right exact;*
- *(b) for every n, the functor $N \mapsto T(N)$ is right exact in the category of finite-type A_n-modules; equivalently, T is right exact in the category of finite-length A-modules;*
- *(c) the canonical homomorphism*

  $$T(\varepsilon) : T(A) \longrightarrow T(k)$$

  is surjective;
- *(d) for every sufficiently large n, the canonical homomorphism*

  $$T(A_n) \longrightarrow T(k)$$

  is surjective.

Proof. It is clear that (a) implies (b). Let us prove the converse. Suppose that $u : M \to N$ is an epimorphism of A-modules; we must show that $T(u)$ is an epimorphism. Since T commutes with inductive limits and filtered inductive limits are exact in the category of modules, it is enough to consider the case where M and N are of finite type.

The modules $T(M)$ and $T(N)$ are then of finite type. Since A is Noetherian and local, it is enough to prove that

$$\widehat{T(u)} : \widehat{T(M)} \longrightarrow \widehat{T(N)}$$

is surjective (**0**, 7.3.5) and (**0**, 6.4.1). By hypothesis, $\widehat{T(M)}$ and $\widehat{T(N)}$ are, respectively,

$$\varprojlim_n T(M_n) \quad \text{and} \quad \varprojlim_n T(N_n).$$

Thus $\widehat{T(u)}$ is the inverse limit of the projective system of homomorphisms

$$T(u \otimes 1_{A_n}) : T(M_n) \longrightarrow T(N_n).$$

Condition (b) says precisely that these homomorphisms are surjective. Moreover, $T(M_n)$ is a finite-type A_n-module, and A_n is Artinian. It follows that $\widehat{T(u)}$ is surjective (**0**, 13.1.2) and (**0**, 13.2.2).

Clearly (a) implies (c), and (c) implies (d). Finally, (7.2.7) shows that (b) and (d) are equivalent, because T is half-exact in $\mathtt{Ab}_{A_n}$. This completes the proof. □

Corollary (7.5.3). — *Under the general hypotheses of (7.5.2), if $T(k) = 0$, then $T(M) = 0$ for every A-module M.*

Proof. Since k is the only simple A-module, (7.3.5.4) shows that $T(E) = 0$ for every finite-length A-module E. If M is of finite type, then **III** | 191

$$\widehat{T(M)} \simeq \varprojlim_n T(M_n).$$

Each M_n has finite length, so $\widehat{T(M)} = 0$. By hypothesis $T(M)$ is of finite type, and it embeds in $\widehat{T(M)}$ (**0**, 7.3.5); hence $T(M) = 0$. Finally, for an arbitrary A-module M, the module $T(M)$ is the inductive limit of the $T(N_\alpha)$, where the N_α run through the finite-type submodules of M. The proof is complete. □

Proposition (7.5.4). — *Let A be a Noetherian local ring with maximal ideal $\mathfrak{m}$ and residue field $k = A/\mathfrak{m}$. Let $T_\bullet$ be a homological functor from $\mathtt{Ab}_A$ to $\mathtt{Ab}$ that commutes with inductive limits. Suppose, moreover, that for every i and every finite-type A-module M, the module $T_i(M)$ is of finite type and the canonical homomorphism*

$$\widehat{T_i(M)} \longrightarrow \varprojlim_n T_i(M_n)$$

is bijective. For a given integer p, the following conditions are equivalent:

(a) *T_p is exact;*
(b) *T_p is right exact and $T_p(A)$ is a free A-module;*
(c) *the canonical homomorphisms*

$$T_{p+1}(A) \longrightarrow T_{p+1}(k), \qquad T_p(A) \longrightarrow T_p(k)$$

are surjective;

(d) *for every n, the canonical homomorphisms*

$$T_{p+1}(A_n) \longrightarrow T_{p+1}(k), \qquad T_p(A_n) \longrightarrow T_p(k)$$

are surjective;

(e) *for every n, the functor $N \mapsto T_p(N)$ is exact in the category of finite-type A_n-modules.*

Proof. By (7.3.3), condition (a) is equivalent to saying that T_{p+1} and T_p are right exact. Since $T_\bullet$ is a homological functor in $\mathtt{Ab}_{A_n}$, the same argument as in (7.3.1) shows that (e) is equivalent to saying that T_p and T_{p+1} are right exact on the category of finite-type A_n-modules. It follows from (7.5.2) that (a) and (e) are equivalent; the same proposition also gives the equivalence of (a), (c), and (d).

Finally, every finite-type flat module over the local ring A is free (Bourbaki, *Algèbre commutative*, chap. II, § 3, no. 2, cor. 2 of prop. 5). The equivalence of (a) and (b) therefore follows from (7.3.1) and (7.3.3). □

Corollary (7.5.5). — *Suppose that the general hypotheses of (7.5.4) hold.*

(i) *If $T_p(k) = 0$, then $T_p = 0$, the functor T_{p+1} is right exact, and T_{p-1} is left exact.*
(ii) *If $T_{p-1}(k) = T_{p+1}(k) = 0$, then T_p is exact, the canonical homomorphism*

$$T_p(A) \otimes_A M \longrightarrow T_p(M)$$

is bijective, and $T_p(A)$ is a free A-module.

Proof. Assertion (i) follows at once from (7.5.3), since T_p is half-exact; the last assertion follows from the definition of a homological functor. Taking (7.3.3) into account, (i) immediately gives the first two assertions of (ii), and the freeness of $T_p(A)$ follows from (7.5.4). □

Corollary (7.5.6). — *Suppose that the general hypotheses of (7.5.4) hold, and suppose in addition that A is a discrete valuation ring.*

(i) *The functor T_p is right exact if and only if $T_{p-1}(A)$ is a free A-module.*
(ii) *The functor T_p is exact if and only if $T_p(A)$ and $T_{p-1}(A)$ are free A-modules.*

III | 192

Proof. It is clear that (ii) implies (i) (cf. (7.3.3)). To prove (i), let f be a generator of the maximal ideal of A, that is, a uniformizer of A. A finite-type A-module M is free, equivalently flat, if and only if the homothety

$$h_f : M \longrightarrow M, \qquad x \longmapsto fx,$$

is injective, since in the present situation this amounts to saying that M is torsion-free (**0**, 6.3.4). The exact sequence

$$0 \longrightarrow A \xrightarrow{h_f} A \longrightarrow k \longrightarrow 0$$

gives the exact homology sequence

$$T_p(A) \longrightarrow T_p(k) \longrightarrow T_{p-1}(A) \xrightarrow{h_f} T_{p-1}(A).$$

Thus $T_{p-1}(A)$ is free if and only if $T_p(A) \to T_p(k)$ is surjective, and the conclusion follows from (7.5.2). ☐

Remark (7.5.7). — By (7.4.7), the general hypotheses of (7.4.4) imply that the homological functor $T_\bullet$ defined by (7.4.1.1) satisfies the general hypotheses of (7.5.4). In that case, (7.5.6) is therefore contained in (7.4.3).

7.6. Descent of exactness properties. Semicontinuity theorem and Grauert's exactness criterion

Proposition (7.6.1). — *Under the hypotheses of (7.4.1), let B be a commutative A-algebra. If T_p is right exact (respectively left exact, exact), then the same is true of $T_p^{(B)}$; the converse is true when B is a faithfully flat A-module.*

Proof. The first assertion is a special case of a trivial assertion of (7.1.3). Conversely, suppose first that B is a flat A-module. Then, for every A-module M,

$$H_\bullet(P_\bullet \otimes_A (M \otimes_A B)) = H_\bullet(P_\bullet \otimes_A M) \otimes_A B,$$

which may also be written, for every p,

$$T_p(M) \otimes_A B \simeq T_p^{(B)}(M_{(B)}) \tag{7.6.1.1}$$

up to canonical isomorphism. Suppose that $T_p^{(B)}$ is right exact (respectively left exact, exact). Since $M \mapsto M_{(B)}$ is an exact functor, the left-hand side of (7.6.1.1) is a right exact (respectively left exact, exact) functor of M. If B is now faithfully flat over A, it follows that T_p has the same exactness property (**0**, 6.4.1). ☐

Proposition (7.6.2). — *Under the hypotheses of (7.4.1), suppose in addition that A is a reduced Noetherian ring and that the P_i are finite-type A-modules. For T_p to be right exact (respectively left exact, exact), it is necessary and sufficient that $T_p^{(B)}$ have the same property for every A-algebra B that is a discrete valuation ring.*

Proof. By (7.3.1) and (7.3.3), we may restrict attention to right exactness, and only sufficiency has to be proved. By (7.4.2), it is enough to show that $Z'_{p-1}(P_\bullet)$ is a flat A-module. Since P_{p-1} is of finite type, $Z'_{p-1}(P_\bullet)$ is also of finite type; the criterion of (**0**, 10.2.8) therefore shows that it is enough for

$$Z'_{p-1}(P_\bullet) \otimes_A B$$

to be a flat B-module for every A-algebra B that is a discrete valuation ring. Since $P_\bullet$ is a complex of flat A-modules, we have

$$Z'_{p-1}(P_\bullet) \otimes_A B = Z'_{p-1}(P_\bullet \otimes_A B).$$

The complex $P_\bullet \otimes_A B$ consists of flat B-modules (**0**, 6.2.1), and for every B-module N we have **III** | 193

$$H_\bullet(P_\bullet \otimes_A N) = H_\bullet\big((P_\bullet \otimes_A B) \otimes_B N\big),$$

and hence

$$T_p^{(B)}(N) = H_p\big((P_\bullet \otimes_A B) \otimes_B N\big).$$

Applying (7.4.2) to $T_p^{(B)}$, we see that the hypothesis that $T_p^{(B)}$ is right exact is equivalent to $Z'_{p-1}(P_\bullet \otimes_A B)$ being a flat B-module.

The preceding criterion leads us to examine the case of discrete valuation rings more closely. ☐

Proposition (7.6.3). — *Under the hypotheses of (7.4.1), suppose that A is a regular Noetherian ring of dimension 1 (in other words, that A is Noetherian and, for every $x \in \operatorname{Spec}(A)$, the ring A_x is a field or a discrete valuation ring). Then, for every integer p and every A-module M, there is a canonical exact sequence, functorial in M,*

(7.6.3.1) $$0 \longrightarrow T_p(A) \otimes_A M \xrightarrow{t_M} T_p(M) \longrightarrow \operatorname{Tor}_1^A(T_{p-1}(A), M) \longrightarrow 0.$$

Proof. In what follows, to simplify the notation we omit the complex $P_\bullet$ from the usual homological notations $H_p(P_\bullet)$, $B_p(P_\bullet)$, $Z_p(P_\bullet)$, and $Z'_p(P_\bullet)$. We have the three exact sequences

$$0 \longrightarrow H_p \longrightarrow Z'_p \longrightarrow B_{p-1} \longrightarrow 0,$$
$$0 \longrightarrow B_{p-1} \longrightarrow Z_{p-1} \longrightarrow H_{p-1} \longrightarrow 0,$$
$$0 \longrightarrow Z_{p-1} \longrightarrow P_{p-1} \longrightarrow B_{p-2} \longrightarrow 0.$$

Since P_{p-1} and P_{p-2} are flat, so are their respective submodules B_{p-1}, Z_{p-1}, and B_{p-2}: for every $x \in \operatorname{Spec}(A)$, flat A_x-modules and torsion-free A_x-modules are the same. Tensoring with M therefore gives the exact sequences

(7.6.3.2) $$0 = \operatorname{Tor}_1^A(B_{p-1}, M) \longrightarrow H_p \otimes_A M \longrightarrow Z'_p \otimes_A M \xrightarrow{u} B_{p-1} \otimes_A M \longrightarrow 0,$$

(7.6.3.3) $$0 = \operatorname{Tor}_1^A(Z_{p-1}, M) \longrightarrow \operatorname{Tor}_1^A(H_{p-1}, M) \longrightarrow B_{p-1} \otimes_A M \xrightarrow{v} Z_{p-1} \otimes_A M,$$

and

(7.6.3.4) $$0 = \operatorname{Tor}_1^A(B_{p-2}, M) \longrightarrow Z_{p-1} \otimes_A M \xrightarrow{w} P_{p-1} \otimes_A M.$$

By definition,

$$T_p(M) = \operatorname{Ker}(d_p \otimes 1) / \operatorname{Im}(d_{p+1} \otimes 1).$$

It is therefore the kernel of the homomorphism

$$(P_p \otimes_A M) / \operatorname{Im}(d_{p+1} \otimes 1) \longrightarrow P_{p-1} \otimes_A M$$

induced by $d_p \otimes 1$. By the definition $Z'_p = P_p / B_p$, this homomorphism may also be written $Z'_p \otimes_A M \to P_{p-1} \otimes_A M$; it is the composite

$$Z'_p \otimes_A M \xrightarrow{u} B_{p-1} \otimes_A M \xrightarrow{v} Z_{p-1} \otimes_A M \xrightarrow{w} P_{p-1} \otimes_A M.$$

Since w is injective by (7.6.3.4), there is an exact sequence

$$0 \longrightarrow \operatorname{Ker} u \longrightarrow T_p(M) \longrightarrow \operatorname{Ker} v \longrightarrow 0.$$

In view of (7.6.3.2) and (7.6.3.3), and since $H_p = T_p(A)$ by definition, this is precisely (7.6.3.1). □

Remarks (7.6.4). — (i) The group $H_\bullet(P_\bullet \otimes_A M)$ is the homology of the bicomplex $P_\bullet \otimes_A M$, where M is regarded as a complex concentrated in degree 0. It is consequently (6.3.6)(6.3.2) the abutment of the regular spectral sequence whose E_2-term is

$$E^2_{pq} = \operatorname{Tor}_p^A(H_q(P_\bullet), M) = \operatorname{Tor}_p^A(T_q(A), M).$$

The hypothesis on A implies that $\operatorname{Tor}_p^A(E, F) = 0$ for $p \geqslant 2$ and arbitrary A-modules E, F (0, 17.2.2). **III** | 194
It is known (M, XV) that this implies the exactness of

$$0 \longrightarrow E^2_{0,q} \longrightarrow H_q(P_\bullet \otimes_A M) \longrightarrow E^2_{1,q-1} \longrightarrow 0,$$

which is precisely (7.6.3.1).

(ii) Taking (7.3.1) into account, the exact sequence (7.6.3.1) recovers (7.4.3) as a special case.

Corollary (7.6.5). — *Under the hypotheses of (7.4.1), suppose that A is a discrete valuation ring with field of fractions K and residue field k, and that the $T_i(A)$ are finite-type A-modules. Then*

(7.6.5.1) $$\operatorname{rank}_k T_p(k) \geqslant \operatorname{rank}_k(T_p(A) \otimes_A k) \geqslant \operatorname{rank}_A T_p(A) = \operatorname{rank}_K T_p(K).$$

Moreover, equality of the two extreme terms of this inequality holds if and only if T_p is exact, or, equivalently, if and only if $T_p(A)$ and $T_{p-1}(A)$ are free A-modules.

Proof. Set $M = k$ in the exact sequence (7.6.3.1). Since the terms are k-vector spaces, this gives

$$\mathrm{rank}_k T_p(k) = \mathrm{rank}_k\big(T_p(A) \otimes_A k\big) + \mathrm{rank}_k \mathrm{Tor}_1^A\big(T_{p-1}(A), k\big).$$

On the other hand, since $T_p(A)$ is a finite-type module over the local integral domain A, we have (Bourbaki, *Algèbre commutative*, chap. II, § 3, no. 2, cor. 1 of prop. 4)

$$\mathrm{rank}_k\big(T_p(A) \otimes_A k\big) \geqslant \mathrm{rank}_A T_p(A) = \mathrm{rank}_K\big(T_p(A) \otimes_A K\big), \tag{7.6.5.2}$$

and the two sides of (7.6.5.2) are equal if and only if $T_p(A)$ is a free A-module (*loc. cit.*, prop. 7). Since K is a flat A-module, we also have, by definition,

$$T_p(A) \otimes_A K = H_p(P_\bullet) \otimes_A K = H_p(P_\bullet \otimes_A K) = T_p(K).$$

This proves (7.6.5.1). It also shows that equality can hold only if, first, $T_p(A)$ is free, and, second,

$$\mathrm{Tor}_1^A\big(T_{p-1}(A), k\big) = 0,$$

the latter condition being equivalent to $T_{p-1}(A)$ being free (**0**, 10.1.3). Finally, for finite-type modules over A, flatness and freeness are equivalent (Bourbaki, *Algèbre commutative*, chap. II, § 3, no. 2, cor. 2 of prop. 5), and the result follows from (7.4.3). □

(7.6.6). The hypotheses remaining those of (7.4.1), for every $x \in \mathrm{Spec}(A)$ set

$$d_p(x) = d_p^T(x) = \mathrm{rank}_{k(x)} T_p(k(x)). \tag{7.6.6.1}$$

Lemma (7.6.7). — *Let $\varphi : A \to A'$ be a ring homomorphism, and let*

$$f = {}^a\varphi : \mathrm{Spec}(A') \longrightarrow \mathrm{Spec}(A)$$

be the corresponding map (**I**, 1.2.1)*. If $T'_\bullet = T_\bullet^{(A')}$* (7.1.3)*, then*

$$d_p^{T'} = d_p^T \circ f. \tag{7.6.7.1}$$

III | 195

Proof. For $x' \in \mathrm{Spec}(A')$, put $x = f(x')$. Then

$$\begin{aligned} H_\bullet(P_\bullet \otimes_A k(x')) &= H_\bullet\big((P_\bullet \otimes_A k(x)) \otimes_{k(x)} k(x')\big) \\ &= H_\bullet(P_\bullet \otimes_A k(x)) \otimes_{k(x)} k(x'), \end{aligned}$$

because $k(x')$ is flat over $k(x)$. This proves (7.6.7.1). □

Lemma (7.6.8). — *If A is Noetherian and $P_\bullet$ consists of finite-type A-modules, the function $x \mapsto d_p^T(x)$ on* $\mathrm{Spec}(A)$ *is constructible.*

Proof. For every irreducible closed subset Y of $X = \mathrm{Spec}(A)$, we must show that there is a nonempty open subset U of Y on which d_p is constant (**0**, 9.2.2). Write $Y = \mathrm{Spec}(A/\mathfrak{a})$, where $\mathfrak{a}$ is an ideal of A such that $A/\mathfrak{a}$ is reduced. By (7.6.7), we may reduce to the case $Y = X$ and A a Noetherian integral domain; the assertion then follows from (7.4.5). □

Theorem (7.6.9). — *Let A be a Noetherian ring, let $P_\bullet$ be a complex of finite-type flat A-modules, and let*

$$T_\bullet(M) = H_\bullet(P_\bullet \otimes_A M)$$

be the homological functor defined by $P_\bullet$. For $x \in \mathrm{Spec}(A)$, set

$$d_p(x) = \mathrm{rank}_{k(x)} T_p(k(x)).$$

Then:

- (i) *The function d_p is constructible and upper semicontinuous on* $\mathrm{Spec}(A)$.
- (ii) *If T_p is exact, d_p is continuous (and hence locally constant) on* $\mathrm{Spec}(A)$. *The converse is true when A is reduced.*

Proof. (i) Constructibility was proved in (7.6.8). To prove upper semicontinuity, it is therefore enough (**0**, 9.2.4) to show that if $x' \neq x$ is a generalization of x in $\operatorname{Spec}(A)$, then $d_p(x') \leqslant d_p(x)$. There is a discrete valuation ring B and a morphism

$$f : \operatorname{Spec}(B) \longrightarrow \operatorname{Spec}(A)$$

such that, if a is the closed point of $\operatorname{Spec}(B)$ and b its generic point, then $f(a) = x$ and $f(b) = x'$ (**II**, 7.1.9). By (7.6.7.1), we are reduced to proving $d_p(a) \geqslant d_p(b)$ on $\operatorname{Spec}(B)$, which is exactly (7.6.5.1).[5]

(ii) The first assertion was already proved in (7.3.4). For the converse, use the valuative criterion (7.6.2). In view of (7.6.7.1), we are reduced to the case in which A is a discrete valuation ring. Since $\operatorname{Spec}(A)$ then has only two points, the hypothesis that d_p is constant implies that T_p is exact, by (7.6.5). □

Corollary (7.6.10). — *Let A be a Noetherian ring, let $\mathfrak{p}_i$ $(1 \leqslant i \leqslant r)$ be its minimal prime ideals, and let k_i be the residue field of $A_{\mathfrak{p}_i}$.*

(i) For every $x \in \operatorname{Spec}(A)$, there is an index i such that

(7.6.10.1) $$d_p(x) \geqslant \operatorname{rank}_{k_i} T_p(k_i).$$

In particular, if A is an integral domain and K is its field of fractions, then

(7.6.10.2) $$d_p(x) \geqslant \operatorname{rank}_K T_p(K)$$

for every $x \in \operatorname{Spec}(A)$.

III | 196

(ii) Suppose in addition that A is local and reduced, and let k be its residue field. Then T_p is exact if and only if

(7.6.10.3) $$\operatorname{rank}_k T_p(k) = \operatorname{rank}_{k_i} T_p(k_i) \qquad (1 \leqslant i \leqslant r).$$

Proof. Assertion (i) is immediate: every neighbourhood of x contains one of the $\mathfrak{p}_i$, and it is enough to apply the definition of semicontinuity. If A is local, the only neighbourhood of the maximal ideal $\mathfrak{m}$ in $\operatorname{Spec}(A)$ is all of $\operatorname{Spec}(A)$; hence

$$d_p(x) \leqslant \operatorname{rank}_k T_p(k)$$

for every $x \in \operatorname{Spec}(A)$. Together with (i), this shows that (7.6.10.3) implies that d_p is constant on $\operatorname{Spec}(A)$, and hence that T_p is exact by (7.6.9, (ii)). The converse follows at once from the same result. □

Remarks (7.6.11). — One may ask whether (7.6.9, (i)) can be strengthened to the inequality

(7.6.11.1) $$\operatorname{rank}_{k(x)} T_p(k(x)) \geqslant \operatorname{rank}_{k(x)} \big(T_p(A) \otimes_A k(x)\big)$$

for every $x \in \operatorname{Spec}(A)$. This inequality does hold when A is a discrete valuation ring and x is its maximal ideal (7.6.5). Restrict now to the case in which A is a Noetherian local ring with maximal ideal $\mathfrak{m}$ and residue field k. The following conditions are equivalent:

a) For every complex $P_\bullet$ of finite-type flat A-modules,

(7.6.11.2) $$\operatorname{rank}_k T_p(k) \geqslant \operatorname{rank}_k \big(T_p(A) \otimes_A k\big) \qquad \text{for every integer } p.$$

b) For every finite-type A-module M,

(7.6.11.3) $$\operatorname{rank}_k(M \otimes_A k) \geqslant \operatorname{rank}_k(\check{M} \otimes_A k).$$

c) For every finite-type A-module N,

(7.6.11.4) $$\operatorname{rank}_k \operatorname{Tor}_1^A(N,k) \geqslant \operatorname{rank}_k \operatorname{Tor}_2^A(N,k).$$

[5] The principle of proving (i) by reduction to the case of a discrete valuation ring was communicated to us orally by Hironaka.

Equivalently, by dimension shifting (M, V, 7.2), one may require, for every $i \geqslant 1$,

(7.6.11.5) $$\operatorname{rank}_k \operatorname{Tor}_i^A(N,k) \geqslant \operatorname{rank}_k \operatorname{Tor}_{i+1}^A(N,k).$$

Here are brief indications of the proof. To see that a) implies b), consider an exact sequence

$$L_1 \xrightarrow{d} L_0 \longrightarrow M \longrightarrow 0,$$

where L_0 and L_1 are finite free, and apply a) to the complex

$$P_1 \xrightarrow{{}^t d} P_0, \qquad P_0 = \check{L}_1, \quad P_1 = \check{L}_0,$$

all its other terms being zero. Then

$$T_1(A) = \check{M}$$

and

$$T_1(k) = \operatorname{Hom}_A(M,k) = \operatorname{Hom}_k(M/\mathfrak{m}M,k).$$

Thus $T_1(k)$ is the dual of the vector space $M \otimes_A k$ and has the same rank. To prove that b) implies c), we first establish the following lemma.

Lemma (7.6.11.6). — *Given a complex of flat A-modules*

$$\cdots \longrightarrow 0 \longrightarrow P_1 \xrightarrow{d} P_0 \longrightarrow 0 \longrightarrow \cdots,$$

there is an exact sequence

(7.6.11.7) $$0 \longrightarrow \operatorname{Tor}_2^A(Z_0',k) \longrightarrow T_1(A) \otimes_A k \longrightarrow T_1(k) \longrightarrow \operatorname{Tor}_1^A(Z_0',k) \longrightarrow 0.$$

III | 197

Proof. From the exact sequence

$$0 \longrightarrow Z_1 \longrightarrow P_1 \longrightarrow B_0 \longrightarrow 0$$

we obtain

$$0 \longrightarrow \operatorname{Tor}_1^A(B_0,k) \longrightarrow Z_1 \otimes_A k \longrightarrow P_1 \otimes_A k \xrightarrow{u} B_0 \otimes_A k \longrightarrow 0.$$

The exact sequence

$$0 \longrightarrow B_0 \longrightarrow Z_0 \longrightarrow Z_0' \longrightarrow 0$$

and the flatness of $Z_0 = P_0$ give

$$\operatorname{Tor}_1^A(B_0,k) = \operatorname{Tor}_2^A(Z_0',k).$$

By definition, $Z_1 = T_1(A)$. Moreover, $T_1(k) = \operatorname{Ker}(d \otimes 1)$, and $d \otimes 1$ factors as

$$P_1 \otimes_A k \xrightarrow{u} B_0 \otimes_A k \xrightarrow{v} Z_0 \otimes_A k = P_0 \otimes_A k.$$

Thus $T_1(k) = u^{-1}(R)$, where $R = \operatorname{Ker} v$. Since u is surjective, $R = u(T_1(k))$; finally, $R = \operatorname{Tor}_1^A(Z_0',k)$ by the definition of v. This proves (7.6.11.7). □

To deduce c) from b), take an exact sequence

$$L_1 \xrightarrow{d} L_0 \longrightarrow N \longrightarrow 0$$

with L_0, L_1 finite free, and consider the functor T associated with the complex formed by L_1 and L_0. Since L_0 and L_1 are free, they identify with their biduals. If

$$M = \operatorname{Coker}({}^t d),$$

then

$$T_1(A) = \operatorname{Ker} d = \check{M}.$$

Furthermore,

$$M \otimes_A k = \operatorname{Coker}({}^t d \otimes 1_k)$$

has the same rank over k as $\operatorname{Ker}(d \otimes 1_k)$. Hypothesis b) therefore gives

$$\operatorname{rank}_k\big(T_1(A) \otimes_A k\big) \leqslant \operatorname{rank}_k T_1(k).$$

Since $Z_0' = N$, inequality (7.6.11.4) follows from the exact sequence (7.6.11.7).

Finally, to prove that c) implies a), apply (7.6.11.6) to the two-term complex

$$P_p \longrightarrow P_{p-1}.$$

Hypothesis c), applied to Z'_{p-1}, gives

$$\operatorname{rank}_k R \geqslant \operatorname{rank}_k S,$$

where

$$R = \operatorname{Ker}(P_p \otimes_A k \longrightarrow P_{p-1} \otimes_A k), \qquad S = Z_p \otimes_A k.$$

Factor $d_{p+1} : P_{p+1} \to P_p$ as

$$P_{p+1} \xrightarrow{v} Z_p \xrightarrow{j} P_p.$$

Then

$$\operatorname{Im}(d_{p+1} \otimes 1) = (j \otimes 1)\big(\operatorname{Im}(v \otimes 1)\big).$$

Since

$$T_p(A) \otimes_A k = (Z_p/B_p) \otimes_A k = (Z_p \otimes_A k)/\operatorname{Im}(v \otimes 1)$$

and

$$T_p(k) = R/\operatorname{Im}(d_{p+1} \otimes 1),$$

inequality (7.6.11.2) follows.

Now suppose that the local ring A is regular of dimension n. It is known [17] that the A-module $\operatorname{Tor}_i^A(k,k)$ is isomorphic to the exterior power

$$\bigwedge^i(\mathfrak{m}/\mathfrak{m}^2).$$

Thus (7.6.11.4) fails for $N = k$ as soon as $n \geqslant 4$. On the other hand, suppose that A is a local integral domain such that every finite-type reflexive A-module is free, as happens when A is a regular ring of dimension 2. Then (7.6.11.3) holds. Indeed, the dual $\check{M}$ of a finite-type A-module M is reflexive, hence free, and consequently

$$\operatorname{rank}_k(\check{M} \otimes_A k) = \operatorname{rank}_K(\check{M}) = \operatorname{rank}_K(M),$$

where K is the field of fractions of A. Every basis of $M \otimes_A k$ over k consists of the images of a system of generators of M (Bourbaki, *Algèbre commutative*, chap. II, § 3, no. 2, cor. 2 of prop. 4). Hence

$$\operatorname{rank}_K(M) \leqslant \operatorname{rank}_k(M \otimes_A k),$$

which proves the assertion.

7.7. Application to proper morphisms: I. The exchange property The next three paragraphs are, for the most part, translations into the language of morphisms of preschemes of the results of the preceding paragraphs.

(7.7.1). Let $f : X \to Y$ be a quasi-compact separated morphism of preschemes, and let $\mathscr{P}_\bullet$ be a complex of quasi-coherent $\mathscr{O}_X$-Modules whose differential has degree -1. Suppose in addition that the $\mathscr{O}_X$-Modules $\mathscr{P}_i$ are Y-flat (**0**, 6.7.1).

We shall consider the ∂-functor III | 198

$$\mathscr{M} \longmapsto \mathscr{T}_\bullet(\mathscr{M}),$$

also denoted $\mathscr{T}_\bullet(\mathscr{P}_\bullet, \mathscr{M})$, from the category of quasi-coherent $\mathscr{O}_Y$-Modules to itself (by (6.2.3)), defined by

$$\mathscr{T}_n(\mathscr{P}_\bullet, \mathscr{M}) = \mathscr{T}_n(\mathscr{M}) = \mathscr{H}^{-n}\big(f, \mathscr{P}^\bullet \otimes_{\mathscr{O}_Y} \mathscr{M}\big) \qquad (n \in \mathbf{Z}), \tag{7.7.1.1}$$

where $\mathscr{P}^\bullet$ is the complex whose term of degree j is $\mathscr{P}_{-j}$, so that its differential has degree $+1$. The functor $\mathscr{T}_\bullet$ thus defined is a *homological functor* in $\mathscr{M}$ (6.2.6).

(7.7.2). Let $g : Y' \to Y$ be a morphism, and set

$$X' = X_{(Y')} = X \times_Y Y', \qquad f' = f_{(Y')} : X' \longrightarrow Y'.$$

Thus f' is quasi-compact and separated. Put also

$$\mathscr{P}'_\bullet = \mathscr{P}_\bullet \otimes_{\mathscr{O}_Y} \mathscr{O}_{Y'}.$$

This is a complex of quasi-coherent $\mathscr{O}_{X'}$-Modules that are Y'-flat, by (**I**, 9.1.12) and (**0**, 6.2.1). With the same conventions on degrees, set

(7.7.2.1) $$\mathscr{T}_\bullet^{Y'}(\mathscr{M}') = \mathscr{H}^\bullet(f', \mathscr{P}'^\bullet \otimes_{\mathscr{O}_{Y'}} \mathscr{M}') = \mathscr{H}^\bullet(f', \mathscr{P}^\bullet \otimes_{\mathscr{O}_Y} \mathscr{M}').$$

This is a homological functor of the quasi-coherent $\mathscr{O}_{Y'}$-Module $\mathscr{M}'$. When Y' is an affine scheme with ring A', we write $\mathscr{T}_\bullet^{A'}$ in place of $\mathscr{T}_\bullet^{Y'}$. For every A'-module M',

$$\mathscr{T}_\bullet^{A'}(\widetilde{M'}) = \big(\Gamma(Y', \mathscr{T}_\bullet^{Y'}(\widetilde{M'}))\big)^\sim.$$

We set

$$T_\bullet^{A'}(M') = \Gamma(Y', \mathscr{T}_\bullet^{Y'}(\widetilde{M'}));$$

this is a homological functor from A'-modules to A'-modules.

If $Y = \operatorname{Spec}(A)$ is also affine, the functor $T_\bullet^{A'}$ on A'-modules is obtained from the homological functor $T_\bullet^A$ on A-modules by extension of scalars from A to A' (7.1.3). Indeed, let $g : Y' \to Y$ correspond to the ring homomorphism $A \to A'$, and let $g' : X' \to X$ be the corresponding morphism, which is affine (**II**, 1.6.2). If $\mathfrak{U}$ is an affine open covering of X, then $\mathfrak{U}' = g'^{-1}(\mathfrak{U})$ is an affine open covering of X'. By (6.2.2), it is enough to check

$$C^\bullet(\mathfrak{U}, \mathscr{P}_\bullet \otimes_{\mathscr{O}_Y} g_*(\mathscr{M}')) = C^\bullet(\mathfrak{U}', \mathscr{P}_\bullet \otimes_{\mathscr{O}_Y} \mathscr{M}').$$

Ultimately, if U is any affine open subset of X and $U' = g'^{-1}(U)$, this reduces to

$$\Gamma(U, \mathscr{P}_\bullet \otimes_{\mathscr{O}_Y} g_*(\mathscr{M}')) = \Gamma(U', \mathscr{P}_\bullet \otimes_{\mathscr{O}_Y} \mathscr{M}'),$$

which is immediate from (**I**, 1.3) and (3.2).

In particular, if U is an open subset of Y, then for every quasi-coherent $\mathscr{O}_Y$-Module $\mathscr{M}$,

(7.7.2.2) $$\mathscr{T}_\bullet^U(\mathscr{M}|U) = \mathscr{T}_\bullet(\mathscr{M})|U.$$

(7.7.3). For every quasi-coherent $\mathscr{O}_Y$-Module $\mathscr{M}$ there is a canonical homomorphism, functorial in $\mathscr{M}$,

(7.7.3.1) $$\mathscr{T}_p(\mathscr{O}_Y) \otimes_{\mathscr{O}_Y} \mathscr{M} \longrightarrow \mathscr{T}_p(\mathscr{M}).$$

Indeed, when Y is affine this homomorphism was defined in (7.2.2). The definition extends immediately to the general case: if U and V are affine open subsets of Y with $V \subset U$, the diagram **III** | 199

$$\begin{array}{ccc}
\begin{array}{c}(\mathscr{T}_p(\mathscr{O}_Y) \otimes_{\mathscr{O}_Y} \mathscr{M})|U \\ = \mathscr{T}_p^U(\mathscr{O}_Y|U) \otimes_{\mathscr{O}_Y|U} (\mathscr{M}|U)\end{array} & \longrightarrow & \begin{array}{c}\mathscr{T}_p^U(\mathscr{M}|U) \\ = \mathscr{T}_p(\mathscr{M})|U\end{array} \\
\Big\downarrow & & \Big\downarrow \\
\begin{array}{c}(\mathscr{T}_p(\mathscr{O}_Y) \otimes_{\mathscr{O}_Y} \mathscr{M})|V \\ = \mathscr{T}_p^V(\mathscr{O}_Y|V) \otimes_{\mathscr{O}_Y|V} (\mathscr{M}|V)\end{array} & \longrightarrow & \begin{array}{c}\mathscr{T}_p^V(\mathscr{M}|V) \\ = \mathscr{T}_p(\mathscr{M})|V\end{array}
\end{array}$$

commutes by (7.2.3.3).

For every morphism $g : Y' \to Y$ there is a canonical homomorphism

(7.7.3.2) $$\mathscr{T}_p(\mathscr{O}_Y) \otimes_{\mathscr{O}_Y} \mathscr{O}_{Y'} \longrightarrow \mathscr{T}_p^{Y'}(\mathscr{O}_{Y'}),$$

which is precisely the special case of (6.7.11.2), for the abutments, in which $S = Y$, $v_1 = f$, $v_2 = 1_Y$, and $\mathscr{P}_\bullet^{(2)}$ is concentrated in degree 0 with sole term $\mathscr{M}$.

When $Y = \operatorname{Spec}(A)$ and $Y' = \operatorname{Spec}(A')$ are affine, (7.7.3.2) is the homomorphism of sheaves corresponding to the canonical homomorphism of A'-modules defined in (7.2.2),

$$T_p^A(A) \otimes_A A' \longrightarrow T_p^{A'}(A') = T_p^A(A').$$

This follows immediately from (6.7.11), since in the situation at hand one may take $\mathfrak{U}'^{(i)} = u_i^{-1}(\mathfrak{U}^{(i)})$ there.

(7.7.4). Suppose that f is proper, that $Y = \mathrm{Spec}(A)$ is an affine Noetherian scheme, and that $\mathscr{P}_\bullet$ is a bounded-below complex of coherent, Y-flat $\mathscr{O}_X$-Modules. We saw in (6.10.5) that, up to isomorphism, one may write

$$\mathscr{T}_p(\mathscr{M}) = \mathscr{H}_p(\mathscr{L}_\bullet \otimes_{\mathscr{O}_Y} \mathscr{M}), \qquad \mathscr{L}_\bullet = \widetilde{L_\bullet},$$

where $L_\bullet$ is a bounded-below complex of finite-type free A-modules. Thus $\mathscr{T}_\bullet$ is of the kind studied in detail in (7.4) and (7.6). We shall now translate the results of that study.

Theorem (7.7.5). — *Let Y be a locally Noetherian prescheme, (U_α) a covering of Y by affine open subsets, $f : X \to Y$ a proper morphism, and $\mathscr{P}_\bullet$ a bounded-below complex of coherent, Y-flat $\mathscr{O}_X$-Modules. The homological functor $\mathscr{T}_\bullet(\mathscr{M})$ defined by* (7.7.1.1) *then has the following properties.*

I) (The semicontinuity property).[6] The function

(7.7.5.1) $$y \longmapsto d_p(y) = \mathrm{rank}_{k(y)}\, T_p^{k(y)}(k(y))$$

is upper semicontinuous.

II) (The exchange property). For a fixed integer p, the following conditions are equivalent: **III | 200**

- *a) $\mathscr{T}_p$ is right exact.*
- *a′) $\mathscr{T}_p(\mathscr{M})$ is isomorphic to a functor of the form $\mathscr{N} \otimes_{\mathscr{O}_Y} \mathscr{M}$, where necessarily*

$$\mathscr{N} \simeq \mathscr{T}_p(\mathscr{O}_Y) = \mathscr{H}^{-p}(f, \mathscr{P}^\bullet).$$

- *a″) The canonical functorial homomorphism* (7.7.3.1) *is an isomorphism.*
- *b) $\mathscr{T}_{p-1}$ is left exact.*
- *b′) There is an $\mathscr{O}_Y$-Module $\mathscr{Q}$, necessarily coherent and determined up to unique isomorphism, together with an isomorphism of functors*

(7.7.5.2) $$\mathscr{T}_{p-1}(\mathscr{M}) \xrightarrow{\sim} \mathscr{H}om_{\mathscr{O}_Y}(\mathscr{Q}, \mathscr{M}).$$

- *c) If A_α denotes the ring of the affine open subset U_α, then for every α the functor $T_p^{A_\alpha}$ on A_α-modules is right exact.*
- *d) For every morphism $g : Y' \to Y$, the canonical homomorphism*

(7.7.5.3) $$\mathscr{T}_p(\mathscr{O}_Y) \otimes_{\mathscr{O}_Y} \mathscr{O}_{Y'} \longrightarrow \mathscr{T}_p^{Y'}(\mathscr{O}_{Y'})$$

is an isomorphism.

Proof. The semicontinuity property is local on Y, and therefore follows from (7.7.4) and (7.6.9). It is clear that a″) implies a′), and that a′) implies a). When Y is affine, the equivalence of a), a″), b), and b′) was proved in (7.3.1) and (7.4.6), in view of (7.7.4).

To pass to the general case, first observe that a) is equivalent to c); this also proves that a) is local on Y. The same argument proves the locality of a″) and b). Condition c) plainly implies a), so it remains to prove the converse. It is enough to show that, for every affine open subset U of Y and every exact sequence

$$0 \longrightarrow \mathscr{F}' \longrightarrow \mathscr{F} \longrightarrow \mathscr{F}'' \longrightarrow 0$$

of quasi-coherent $(\mathscr{O}_Y|U)$-Modules, there is an exact sequence

$$0 \longrightarrow \mathscr{G}' \longrightarrow \mathscr{G} \longrightarrow \mathscr{G}'' \longrightarrow 0$$

of quasi-coherent $\mathscr{O}_Y$-Modules such that

$$\mathscr{F}' = \mathscr{G}'|U, \qquad \mathscr{F} = \mathscr{G}|U, \qquad \mathscr{F}'' = \mathscr{G}''|U.$$

This follows immediately from the hypothesis that Y is locally Noetherian and from (**I**, 9.4.2): extend $\mathscr{F}$ to a quasi-coherent $\mathscr{O}_Y$-Module $\mathscr{G}$, extend $\mathscr{F}'$ to a quasi-coherent submodule $\mathscr{G}'$ of $\mathscr{G}$, and take $\mathscr{G}'' = \mathscr{G}/\mathscr{G}'$.

[6] A special case of this theorem already occurs in note [3] of Chow–Igusa. The semicontinuity property was discovered, for analytic spaces and under rather special hypotheses, by Kodaira–Spencer, *On the variations of almost-complex structures*, in *Algebraic Geometry and Topology: A Symposium in Honor of S. Lefschetz*, Princeton Series no. 12, pp. 139–150, Princeton, 1957; the general version was proved by Grauert [5].

To prove the equivalence of b) and b′) in the general case, note first that, when Y is affine, $\mathscr{Q}$ is determined up to unique isomorphism. If U is an affine open subset of the affine scheme Y, it follows that there is a functorial isomorphism

$$\mathscr{T}^U_{p-1}(\mathscr{M}|U) \simeq \mathscr{H}om_{\mathscr{O}_Y|U}(\mathscr{Q}|U, \mathscr{M}|U).$$

For arbitrary Y and each affine open subset U, there is a coherent $(\mathscr{O}_Y|U)$-Module $\mathscr{Q}_U$ and a functorial isomorphism

$$\mathscr{T}^U_{p-1}(\mathscr{M}|U) \simeq \mathscr{H}om_{\mathscr{O}_Y|U}(\mathscr{Q}_U, \mathscr{M}|U).$$

The preceding observation shows that, whenever $V \subset U$ is affine, $\mathscr{Q}_U|V$ is canonically identified with $\mathscr{Q}_V$. Hence there exists a unique $\mathscr{O}_Y$-Module $\mathscr{Q}$ satisfying (7.7.5.2).

It remains to prove the equivalence of a) and d). Condition d) is local on Y, and we have just seen that the same is true of a); moreover, d) is also local on Y'. When $Y = \operatorname{Spec}(A)$ and $Y' = \operatorname{Spec}(A')$, the functor $T^{A'}_\bullet$ is obtained from $T^A_\bullet$ by extension of scalars to A'. It is then clear that a′) implies that (7.7.5.3) is an isomorphism.

Conversely, continue to suppose that $Y = \operatorname{Spec}(A)$ is affine and take for A' the A-algebra $A \oplus M$, **III** | 201
where M is an arbitrary A-module and multiplication is given by

$$(a_1, m_1)(a_2, m_2) = (a_1a_2, a_1m_2 + a_2m_1).$$

Then

$$T^{A'}_p(A') = T_p(A \oplus M) = T_p(A) \oplus T_p(M).$$

If (7.7.5.3) is bijective, the same is therefore true of the canonical homomorphism

$$T_p(A) \otimes_A M \longrightarrow T_p(M).$$

Thus d) implies a″), and the proof is complete. □

Theorem (7.7.6). — *Let Y be a locally Noetherian prescheme, let $f : X \to Y$ be proper, and let $\mathscr{F}$ be a coherent, Y-flat $\mathscr{O}_X$-Module. There is a coherent $\mathscr{O}_Y$-Module $\mathscr{Q}$, determined up to unique isomorphism, and an isomorphism of functors in the quasi-coherent $\mathscr{O}_Y$-Module $\mathscr{M}$,*

(7.7.6.1) $$f_*(\mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{M}) \xrightarrow{\sim} \mathscr{H}om_{\mathscr{O}_Y}(\mathscr{Q}, \mathscr{M}).$$

Consequently there is an isomorphism of functors

(7.7.6.2) $$\Gamma(X, \mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{M}) \xrightarrow{\sim} \operatorname{Hom}_{\mathscr{O}_Y}(\mathscr{Q}, \mathscr{M}).$$

Proof. The functor $\mathscr{M} \mapsto \mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{M}$ is exact (**0**, 6.7.4), while f_* is left exact. Hence

$$\mathscr{M} \longmapsto f_*(\mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{M})$$

is left exact. Apply the equivalence of b) and b′) in (7.7.5) with $p = 1$. □

Corollary (7.7.7). — *Let Y be a locally Noetherian prescheme, let $f : X \to Y$ be proper, let $\mathscr{F}$ and $\mathscr{F}'$ be coherent, Y-flat $\mathscr{O}_X$-Modules, and let $u : \mathscr{F} \to \mathscr{F}'$ be a homomorphism. Consider the two functors of the quasi-coherent $\mathscr{O}_Y$-Module $\mathscr{M}$,*

$$\begin{aligned} \mathscr{T}(\mathscr{M}) &= \operatorname{Ker}\left(f_*(\mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{M}) \longrightarrow f_*(\mathscr{F}' \otimes_{\mathscr{O}_Y} \mathscr{M})\right), \\ T(\mathscr{M}) &= \Gamma(Y, \mathscr{T}(\mathscr{M})) \\ &= \operatorname{Ker}\left(\Gamma(X, \mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{M}) \longrightarrow \Gamma(X, \mathscr{F}' \otimes_{\mathscr{O}_Y} \mathscr{M})\right). \end{aligned}$$

There is a coherent $\mathscr{O}_Y$-Module $\mathscr{R}$, determined up to unique isomorphism, and isomorphisms of functors

(7.7.7.1) $$\mathscr{T}(\mathscr{M}) \xrightarrow{\sim} \mathscr{H}om_{\mathscr{O}_Y}(\mathscr{R}, \mathscr{M}),$$

(7.7.7.2) $$T(\mathscr{M}) \xrightarrow{\sim} \operatorname{Hom}_{\mathscr{O}_Y}(\mathscr{R}, \mathscr{M}).$$

Proof. It is enough to prove (7.7.7.2). This proves (7.7.7.1) when Y is affine, and the passage to the general case proceeds as in the proof of the equivalence of b) and b′) in (7.7.5), using the uniqueness, up to unique isomorphism, of a representing object of a representable functor (**0**, 8.1.8).

By (7.7.6), there are coherent $\mathscr{O}_Y$-Modules $\mathscr{Q}$ and $\mathscr{Q}'$ and functorial isomorphisms

$$\Gamma(X, \mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{M}) \xrightarrow{\sim} \operatorname{Hom}_{\mathscr{O}_Y}(\mathscr{Q}, \mathscr{M}),$$

$$\Gamma(X, \mathscr{F}' \otimes_{\mathscr{O}_Y} \mathscr{M}) \xrightarrow{\sim} \mathrm{Hom}_{\mathscr{O}_Y}(\mathscr{Q}', \mathscr{M}).$$

The homomorphism $u : \mathscr{F} \to \mathscr{F}'$ canonically defines a morphism of functors between the two left-hand sides.

It corresponds to a unique homomorphism $v : \mathscr{Q}' \to \mathscr{Q}$ of $\mathscr{O}_Y$-Modules for which **III** | 202

$$\begin{array}{ccc} \Gamma(X, \mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{M}) & \longrightarrow & \Gamma(X, \mathscr{F}' \otimes_{\mathscr{O}_Y} \mathscr{M}) \\ \sim\downarrow & & \downarrow\sim \\ \mathrm{Hom}_{\mathscr{O}_Y}(\mathscr{Q}, \mathscr{M}) & \longrightarrow & \mathrm{Hom}_{\mathscr{O}_Y}(\mathscr{Q}', \mathscr{M}) \end{array}$$

commutes (**0**, 8.1.4). The contravariant functor

$$\mathscr{N} \longmapsto \mathrm{Hom}_{\mathscr{O}_Y}(\mathscr{N}, \mathscr{M})$$

is left exact in the category of $\mathscr{O}_Y$-Modules. Taking $\mathscr{R} = \mathrm{Coker}(v)$ therefore gives (7.7.7.2). □

Corollary (7.7.8). — *Under the hypotheses of (7.7.6) on X, Y, and f, let $\mathscr{F}$ and $\mathscr{G}$ be coherent $\mathscr{O}_X$-Modules satisfying:*

(i) *$\mathscr{F}$ is Y-flat;*

(ii) *$\mathscr{G}$ is isomorphic to the cokernel of a homomorphism $\mathscr{E}_1 \to \mathscr{E}_0$ between finite-type locally free $\mathscr{O}_X$-Modules.*

Consider the two functors of the quasi-coherent $\mathscr{O}_Y$-Module $\mathscr{M}$,

$$\begin{aligned} \mathscr{T}(\mathscr{M}) &= f_*\mathscr{H}om_{\mathscr{O}_X}(\mathscr{G}, \mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{M}), \\ T(\mathscr{M}) &= \Gamma(Y, \mathscr{T}(\mathscr{M})) \\ &= \mathrm{Hom}_{\mathscr{O}_X}(\mathscr{G}, \mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{M}). \end{aligned}$$

There is a coherent $\mathscr{O}_Y$-Module $\mathscr{N}$, determined up to unique isomorphism, and isomorphisms of functors

(7.7.8.1) $$\mathscr{T}(\mathscr{M}) \xrightarrow{\sim} \mathscr{H}om_{\mathscr{O}_Y}(\mathscr{N}, \mathscr{M}),$$

(7.7.8.2) $$T(\mathscr{M}) \xrightarrow{\sim} \mathrm{Hom}_{\mathscr{O}_Y}(\mathscr{N}, \mathscr{M}).$$

Proof. The functorial isomorphism (**0**, 5.4.2.1) gives, functorially in $\mathscr{M}$,

$$\begin{aligned} \mathscr{H}om_{\mathscr{O}_X}(\mathscr{E}_i, \mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{M}) &\simeq \mathscr{E}_i^\vee \otimes_{\mathscr{O}_X} (\mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{M}) \\ &\simeq (\mathscr{E}_i^\vee \otimes_{\mathscr{O}_X} \mathscr{F}) \otimes_{\mathscr{O}_Y} \mathscr{M} \\ &\simeq \mathscr{H}om_{\mathscr{O}_X}(\mathscr{E}_i, \mathscr{F}) \otimes_{\mathscr{O}_Y} \mathscr{M} \end{aligned}$$

for $i = 0, 1$. Put

$$\mathscr{F}_i = \mathscr{H}om_{\mathscr{O}_X}(\mathscr{E}_i, \mathscr{F}) \qquad (i = 0, 1).$$

These are coherent (**0**, 5.3.5) and Y-flat (**0**, 5.4.2). If $v : \mathscr{E}_1 \to \mathscr{E}_0$ is the given homomorphism, put

$$u = \mathscr{H}om(v, 1_{\mathscr{F}}) : \mathscr{F}_0 \longrightarrow \mathscr{F}_1.$$

Since

$$\mathscr{H} \longmapsto \mathscr{H}om_{\mathscr{O}_X}(\mathscr{H}, \mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{M})$$

is left exact, there are functorial isomorphisms

$$\begin{aligned} \mathscr{H}om_{\mathscr{O}_X}(\mathscr{G}, \mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{M}) &\simeq \mathrm{Ker}\left(\mathscr{H}om_{\mathscr{O}_X}(\mathscr{E}_0, \mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{M}) \longrightarrow \mathscr{H}om_{\mathscr{O}_X}(\mathscr{E}_1, \mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{M})\right) \\ &\simeq \mathrm{Ker}\left(\mathscr{F}_0 \otimes_{\mathscr{O}_Y} \mathscr{M} \longrightarrow \mathscr{F}_1 \otimes_{\mathscr{O}_Y} \mathscr{M}\right). \end{aligned}$$

As f_* is left exact, it follows that

$$f_*\mathscr{H}om_{\mathscr{O}_X}(\mathscr{G}, \mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{M}) \simeq \mathrm{Ker}\left(f_*(\mathscr{F}_0 \otimes_{\mathscr{O}_Y} \mathscr{M}) \longrightarrow f_*(\mathscr{F}_1 \otimes_{\mathscr{O}_Y} \mathscr{M})\right).$$

The assertion now follows from (7.7.7). □

III | 203

Remarks (7.7.9). — (i) In (7.7.6), (7.7.7), and (7.7.8), the formation of the $\mathscr{O}_Y$-Modules $\mathscr{Q}$, $\mathscr{R}$, and $\mathscr{N}$ commutes with base change. For example, retaining the notation of (7.7.2), in the situation of (7.7.6) one has, for every quasi-coherent $\mathscr{O}_{Y'}$-Module $\mathscr{M}'$,

$$f'_*(\mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{M}') \simeq \mathscr{H}om_{\mathscr{O}_{Y'}}(g^*(\mathscr{Q}), \mathscr{M}').$$

Indeed, by the observation in (7.7.2), it is enough to use

$$\mathrm{Hom}_{\mathscr{O}_Y}(\mathscr{Q}, g_*(\mathscr{M}')) = \mathrm{Hom}_{\mathscr{O}_{Y'}}(g^*(\mathscr{Q}), \mathscr{M}'),$$

which is (**0**, 4.4.3.1).

Likewise, if in (7.7.7) one replaces $Y, f, \mathscr{M}, \mathscr{F}, \mathscr{F}'$ by

$$Y', f', \mathscr{M}', \mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{O}_{X'}, \mathscr{F}' \otimes_{\mathscr{O}_X} \mathscr{O}_{X'},$$

then one must replace $\mathscr{R}$ by $g^*(\mathscr{R})$. Finally, in (7.7.8), if $X, Y, f, \mathscr{M}, \mathscr{F}$ are replaced by

$$X', Y', f', \mathscr{M}', \mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{O}_{X'},$$

and $\mathscr{G}$ by

$$\mathscr{G}' = \mathscr{G} \otimes_{\mathscr{O}_X} \mathscr{O}_{X'},$$

then $\mathscr{N}$ must be replaced by $g^*(\mathscr{N})$. This follows because there remains an exact sequence

$$\mathscr{E}'_1 \longrightarrow \mathscr{E}'_0 \longrightarrow \mathscr{G}' \longrightarrow 0, \qquad \mathscr{E}'_i = \mathscr{E}_i \otimes_{\mathscr{O}_X} \mathscr{O}_{X'},$$

and because, for $i = 0, 1$,

$$(\mathscr{E}'_i)^\vee \otimes_{\mathscr{O}_{X'}} (\mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{M}') = \mathscr{E}_i^\vee \otimes_{\mathscr{O}_X} (\mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{M}').$$

(ii) Condition (ii) in (7.7.8) is satisfied by every coherent $\mathscr{O}_X$-Module $\mathscr{G}$ whenever there exists a Y-ample invertible $\mathscr{O}_X$-Module; this holds, for example, when Y is affine and $f : X \to Y$ is projective. Indeed, by (**II**, 5.5.1) and (**II**, 2.7.10), there is a finite-type locally free $\mathscr{O}_X$-Module $\mathscr{E}_0$ with $\mathscr{G}$ isomorphic to a quotient of $\mathscr{E}_0$. Since $\mathscr{E}_0$ and $\mathscr{G}$ are coherent, so is the kernel $\mathscr{G}_1$ of $\mathscr{E}_0 \to \mathscr{G}$. Applying the same result to $\mathscr{G}_1$ gives an exact sequence

$$\mathscr{E}_1 \longrightarrow \mathscr{E}_0 \longrightarrow \mathscr{G} \longrightarrow 0$$

with $\mathscr{E}_0$ and $\mathscr{E}_1$ finite-type locally free.

(iii) We shall prove in Chapter V that the restrictive hypothesis (ii) of (7.7.8) is redundant.

Proposition (7.7.10). — (Local criteria for the exchange property). *Under the general hypotheses of (7.7.5), let $y \in Y$ and let p be an integer. The following conditions are equivalent:*

a) The functor $T_p^{\mathscr{O}_y}$ is right exact.
b) The canonical homomorphism

$$T_p^{\mathscr{O}_y}(\mathscr{O}_y) \longrightarrow T_p^{\mathscr{O}_y}(k(y))$$

is surjective.
c) For every integer n, the canonical homomorphism

$$T_p^{\mathscr{O}_y}(\mathscr{O}_y/\mathfrak{m}_y^{n+1}) \longrightarrow T_p^{\mathscr{O}_y}(k(y))$$

is surjective.

Moreover, the set of points $y \in Y$ satisfying these conditions is the largest open subset U of Y for which $\mathscr{T}_p^U$ is right exact.

Proof. In view of (7.7.4), the equivalence of a), b), and c) follows from (7.4.7) and (7.5.2). That the locus U on which $T_p^{\mathscr{O}_y}$ is right exact is open follows from (7.4.4). Conversely, if $\mathscr{T}_p^V$ is right exact, then $T_p^{\mathscr{O}_y}$ is right exact for every $y \in V$, by condition c) of (7.7.5) and (7.6.1). □

Corollary (7.7.11). — *If $\mathscr{T}_p$ is right exact (respectively left exact), then for every morphism $g : Y' \to Y$ the functor $\mathscr{T}_p^{Y'}$ is right exact (respectively left exact). The converse holds when g is faithfully flat.*

Proof. The first assertion follows immediately from (7.6.1) and from the fact that the question is local on Y and Y', by conditions c) and b) of (7.7.5). For the converse, it is enough, by (7.7.10), to show that $T_p^{\mathscr{O}_y}$ is right exact (respectively left exact) for every $y \in Y$. By hypothesis there is a point $y' \in Y'$ with $g(y') = y$, and $\mathscr{O}_{y'}$ is faithfully flat over $\mathscr{O}_y$. The conclusion follows from the hypothesis and (7.6.1). □ III | 204

Remarks (7.7.12). — (i) Under the hypotheses of (7.7.4), suppose in addition that $\mathscr{P}_\bullet$ is a finite complex. Since one may choose a finite affine open covering $\mathfrak{U}$ of X, it follows from (7.7.1) that the bicomplex

$$C^\bullet(\mathfrak{U}, \mathscr{P}^\bullet \otimes_{\mathscr{O}_Y} \mathscr{M})$$

is finite as well. More precisely, there is a finite set E of pairs, independent of $\mathscr{M}$, such that

$$C^h(\mathfrak{U}, \mathscr{P}^k \otimes_{\mathscr{O}_Y} \mathscr{M}) = 0 \qquad \text{for } (h,k) \notin E.$$

Consequently there is an integer i_1 such that

$$\mathscr{T}_i(\mathscr{M}) = 0 \qquad (i \geqslant i_1)$$

for every quasi-coherent $\mathscr{O}_Y$-Module $\mathscr{M}$. Thus $\mathscr{T}_i$ is trivially exact for these values of i, and (7.4.1) shows that $Z'_i(L_\bullet)$ is a flat finite-type A-module, hence a finite-type projective A-module since A is Noetherian.

Define a complex $L'_\bullet$ of A-modules by

$$L'_i = L_i \quad (i < i_1), \qquad L'_{i_1} = Z'_{i_1}(L_\bullet), \qquad L'_i = 0 \quad (i > i_1),$$

and put $\mathscr{L}'_\bullet = \widetilde{L'_\bullet}$. Plainly

$$\mathscr{H}_i(\mathscr{L}'_\bullet \otimes_{\mathscr{O}_Y} \mathscr{M}) = \mathscr{H}_i(\mathscr{L}_\bullet \otimes_{\mathscr{O}_Y} \mathscr{M})$$

for $i < i_1 - 1$ and for $i \geqslant i_1$, the two sides being zero in the latter range. Since

$$\operatorname{Im}(Z'_{i_1} \otimes_A M) = \operatorname{Im}(L_{i_1} \otimes_A M)$$

by definition, the same equality holds for $i = i_1 - 1$. Thus in (7.7.4) one may also take $\mathscr{L}_\bullet$ to be finite, provided only that its terms are locally free $\mathscr{O}_Y$-Modules associated to finite-type projective A-modules.

This applies in particular when $\mathscr{P}_\bullet$ has only one nonzero term $\mathscr{F}$, in degree 0. In that case

$$\mathscr{T}_n(\mathscr{M}) = R^{-n} f_*(\mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{M}),$$

and one may take $\mathscr{L}_i = 0$ for $i > 0$. In this case it is preferable to use cohomological notation, writing $\mathscr{T}^{-p}$ in place of $\mathscr{T}_p$.

(ii) If the terms $\mathscr{P}_i$ in (7.7.5) are no longer assumed Y-flat, the conclusions remain valid provided one defines

$$\mathscr{T}_p(\mathscr{M}) = \mathbf{Tor}_p^Y(f, 1_Y; \mathscr{P}_\bullet, \mathscr{M}). \tag{7.7.12.1}$$

Indeed,

$$\mathbf{Tor}_n^Y(f, 1_Y; \mathscr{P}_\bullet, \mathscr{O}_Y)$$

is then a coherent $\mathscr{O}_Y$-Module by (6.7.9). The proof of (6.10.5) applies without change, in view of (6.10.1), and also shows that, when $Y = \operatorname{Spec}(A)$ is affine,

$$\mathscr{T}_p(\mathscr{M}) = \mathscr{H}_p(\mathscr{L}_\bullet \otimes_{\mathscr{O}_Y} \mathscr{M}), \qquad \mathscr{L}_\bullet = \widetilde{L_\bullet},$$

where $L_\bullet$ is a complex of finite-type free A-modules. This proves the assertion.

7.8. Application to proper morphisms: II. Cohomological flatness criteria

Definition (7.8.1). — Let X and Y be two preschemes, let $f : X \to Y$ be a quasi-compact separated morphism, let $\mathscr{P}_\bullet$ be a complex of quasi-coherent, Y-flat $\mathscr{O}_X$-Modules, and let $\mathscr{T}_\bullet$ be the homological functor on quasi-coherent $\mathscr{O}_Y$-Modules defined by (7.7.1.1). Let y be a point of Y.

We say that $\mathscr{P}_\bullet$ is *homologically flat over Y at y, in dimension p* (or *cohomologically flat over Y at y, in dimension $-p$*) if there is an open neighbourhood U of y in Y such that **III | 205**

$$\mathscr{T}_p^U = \mathscr{T}_U^{-p}$$

is exact.

We say that $\mathscr{P}_\bullet$ is *homologically flat in dimension p over Y* (or *cohomologically flat in dimension $-p$ over Y*) if it is homologically flat over Y at every point $y \in Y$, in dimension p.

When $\mathscr{P}_\bullet$ is homologically flat over Y (respectively over Y at y) in *every* dimension p, we say simply that $\mathscr{P}_\bullet$ is *homologically flat over Y* (respectively over Y at y), or *cohomologically flat over Y* (respectively over Y at y).

(7.8.2). By definition, the notion of homological flatness over Y is *local on Y*.

If Y is locally Noetherian, or if Y is a scheme, then for $\mathscr{P}_\bullet$ to be homologically flat over Y in dimension p, it is necessary and sufficient that the functor $\mathscr{T}_p$ be exact. The proof for locally Noetherian Y was given in the course of the proof of (7.7.5); when Y is a scheme the argument is the same, based on (**I**, 9.4.2) applied to an affine open subset of a quasi-compact scheme.

Proposition (7.8.3). — *With the notation and hypotheses of (7.8.1), the following conditions are equivalent:*

a) *$\mathscr{P}_\bullet$ is homologically flat over Y at y, in dimension p.*
b) *There is an open neighbourhood U of y in Y such that $\mathscr{T}_p^U$ and $\mathscr{T}_{p+1}^U$ are right exact.*
c) *There is an open neighbourhood U of y in Y such that $\mathscr{T}_p^U$ and $\mathscr{T}_{p-1}^U$ are left exact.*
d) *There is an open neighbourhood U of y in Y such that $\mathscr{T}_{p+1}^U$ is right exact and $\mathscr{T}_{p-1}^U$ is left exact.*

Proof. In view of the interpretation of $\mathscr{T}_p$ when Y is affine, this is merely a translation of part of (7.3.3). □

Proposition (7.8.4). — *Let Y be a locally Noetherian prescheme, let $f : X \to Y$ be a proper morphism, let $\mathscr{P}_\bullet$ be a bounded-below complex of coherent, Y-flat $\mathscr{O}_X$-Modules, and let $\mathscr{T}_\bullet$ be the functor defined by (7.7.1.1). For every $y \in Y$, the following conditions are equivalent:*

a) *$\mathscr{P}_\bullet$ is homologically flat over Y at y, in dimension p.*
b) *The functor $\mathscr{T}_p^{\mathscr{O}_y}$ is exact.*
c) *There is an integer n_0 such that, for $n \geqslant n_0$,*

(7.8.4.1) $$\operatorname{length} \mathscr{T}_p^{\mathscr{O}_y}(\mathscr{O}_y/\mathfrak{m}_y^{n+1}) = \operatorname{length} \mathscr{T}_p^{\mathscr{O}_y}(k(y)) \cdot \operatorname{length}(\mathscr{O}_y/\mathfrak{m}_y^{n+1}).$$

Here all lengths are lengths of $\mathscr{O}_y$-modules.

d) *There is an open neighbourhood U of y such that*

$$\mathscr{H}^{-p}(f, \mathscr{P}^\bullet)|U$$

is isomorphic to an $(\mathscr{O}_Y|U)$-Module of the form $(\mathscr{O}_Y|U)^m$ and, for every quasi-coherent $(\mathscr{O}_Y|U)$-Module $\mathscr{M}$, the canonical homomorphism

(7.8.4.2) $$\mathscr{H}^{-p}(f, \mathscr{P}^\bullet)|U \otimes_{\mathscr{O}_Y|U} \mathscr{M} \longrightarrow \mathscr{H}^{-p}(f, (\mathscr{P}^\bullet|U) \otimes_{\mathscr{O}_Y|U} \mathscr{M})$$

is bijective.

When these conditions hold, one also has:

e) *There is a neighbourhood of y on which the function $z \mapsto d_p(z)$, defined in (7.7.5.1), is constant.*

*Moreover, if Y is reduced at y (**0**, 4.1.4), condition e) is equivalent to the other conditions.*

Proof. Indeed, condition b) is equivalent to saying that $\mathscr{T}_p^{\mathscr{O}_y}$ and $\mathscr{T}_{p+1}^{\mathscr{O}_y}$ are right exact (7.3.3). The equivalence of a) and b) then follows from (7.7.10) and (7.8.3). **III | 206**

Since $\mathscr{O}_y/\mathfrak{m}_y^{n+1}$ is Artinian, and

$$\mathscr{T}_p^{\mathscr{O}_y}(\mathscr{O}_y/\mathfrak{m}_y^{n+1}) \quad \text{and} \quad \mathscr{T}_p^{\mathscr{O}_y}(k(y))$$

are finite-type $(\mathscr{O}_y/\mathfrak{m}_y^{n+1})$-modules (7.7.4), hence have finite length, the equivalence of b) and c) follows again from (7.7.10) and (7.3.5.7).

That a) implies e), and that a) and e) are equivalent when $\mathscr{O}_y$ is reduced, follows from (7.6.9). Finally, a) implies that (7.8.4.2) is bijective, by the definition (7.8.1) and (7.7.5). It also implies that

$$\big(\mathscr{H}^{-p}(f,\mathscr{P}^\bullet)\big)_y$$

is a flat $\mathscr{O}_y$-module by condition (f) of (7.3.3), hence a free $\mathscr{O}_y$-module of finite type (**0**, 10.1.3), since it is of finite type by (7.7.4). As $\mathscr{H}^{-p}(f,\mathscr{P}^\bullet)$ is a coherent $\mathscr{O}_Y$-Module (7.7.4), it is locally free in a neighbourhood of y (**0**, 5.2.7). Conversely, d) plainly implies a), by the definition of the functor $\mathscr{T}_p^U$ (7.7.2.2). □

Proposition (7.8.5). — *Under the hypotheses of (7.8.4), the following conditions are equivalent:*

a) $\mathscr{P}_\bullet$ is homologically flat over Y in every dimension $i \leqslant p$.
b) For $i \leqslant p+1$, the functors $\mathscr{T}_i$ are right exact.
c) For $i \geqslant -p$, the $\mathscr{O}_Y$-Modules $\mathscr{H}^i(f,\mathscr{P}^\bullet)$ are locally free.

Proof. The equivalence of a) and b) is immediate from (7.8.3), and a) implies c) by (7.8.4).

Conversely, suppose that c) holds. Recall also that $\mathscr{L}_i = 0$ for $i < i_0$ (7.7.4), and hence $\mathscr{T}_i = 0$ for $i \leqslant i_0$. Every point $y \in Y$ therefore has an affine neighbourhood $U = \operatorname{Spec}(A)$ such that $T_i^A(A)$ is a free A-module for $i \leqslant p$. It follows from (7.3.7) that $\mathscr{T}_i^U = T_i^A$ is exact for $i \leqslant p$. □

We shall chiefly apply the criteria for cohomological flatness to the case where the complex $\mathscr{P}_\bullet$ is concentrated in a *single* coherent $\mathscr{O}_X$-Module $\mathscr{F}$, flat over Y, taken as $\mathscr{P}_0$. Recall that in this case

$$\mathscr{T}_p(\mathscr{M}) = R^{-p}f_*(\mathscr{F}\otimes_{\mathscr{O}_Y}\mathscr{M}).$$

Proposition (7.8.6). — *Let Y be a locally Noetherian prescheme, let $f : X \to Y$ be a proper flat morphism, and let y be a point of Y. Denote the fibre $f^{-1}(y) = X \otimes_Y k(y)$ by X_y. Suppose that*

$$\Gamma(X_y,\mathscr{O}_{X_y}) = R$$

is a separable $k(y)$-algebra (Bourbaki, Algèbre*, chap. VIII, § 7, no. 5), that is, a direct sum of finitely many finite-degree separable extensions of $k(y)$. Then $\mathscr{O}_X$ is cohomologically flat over Y at y, in dimension 0.*

Proof. By (7.8.4), we may restrict to the case where Y is the spectrum of the local ring $A = \mathscr{O}_y$. The flatness of f implies $\mathscr{T}_{-1} = 0$, so that T_0^A is already left exact and it remains only to prove that it is right exact. By condition c) of (7.7.10), we may even reduce to the case where $A = \mathscr{O}_y$ is Artinian.

Let k' be a finite extension of $k(y)$ which splits R, so that

$$R\otimes_{k(y)} k'$$

is a direct sum of finitely many fields isomorphic to k'. There is a local homomorphism from A to a local ring A' such that A' is a finite free A-algebra and its residue field is isomorphic to k' (**0**, 10.3.2). By (7.6.1), it is therefore enough to prove that $T_0^{A'}$ is right exact; in other words, we may suppose that R is a direct sum of m fields isomorphic to $k(y)$.

We shall use the following elementary lemma.

Lemma (7.8.6.1). — *Let Z be a locally ringed space. For Z to be connected, it is necessary and sufficient that the ring $\Gamma(Z,\mathscr{O}_Z)$ not be a product of two nonzero rings.* **III** | 207

Proof. It is clear that if Z is the union of two disjoint nonempty open subsets Z_1 and Z_2, then $\Gamma(Z,\mathscr{O}_Z)$ is isomorphic to the product of the two nonzero rings $\Gamma(Z_1,\mathscr{O}_Z)$ and $\Gamma(Z_2,\mathscr{O}_Z)$.

Conversely, to say that $\Gamma(Z,\mathscr{O}_Z)$ is such a product is equivalent to saying that it contains an idempotent s distinct from 0 and 1. For every $z \in Z$, the germ s_z is then an idempotent in the local ring $\mathscr{O}_z$, and hence equals 0 or 1. The set of z for which $s_z = 0$ is open. On the other hand, $s_z = 1$ implies, by definition, that $s(z) \neq 0$, and the set of z for which $s_z = 1$ is open as well (**0**, 5.5.2). The conclusion follows. □

It follows from the lemma that X_y has exactly m connected components X_i' and that

$$\Gamma(X_i',\mathscr{O}_{X_i'}) = k(y)$$

for every i. Since A is local and Artinian, its spectrum consists of one point, and consequently X and X_y have the same underlying space. Thus X has m connected components X_i such that

$$X'_i = X_i \otimes_Y k(y).$$

We are finally reduced to the case $R = k(y)$. By condition b) of (7.7.10), it remains to prove that the canonical homomorphism

$$\Gamma(X, \mathscr{O}_X) \longrightarrow \Gamma(X_y, \mathscr{O}_{X_y})$$

is surjective. This is immediate, since the composite

$$\Gamma(Y, \mathscr{O}_Y) = A \longrightarrow \Gamma(X, \mathscr{O}_X) \longrightarrow \Gamma(X_y, \mathscr{O}_{X_y}) = k(y)$$

is already surjective. □

Corollary (7.8.7). — *Under the hypotheses of (7.8.6), there is an open neighbourhood U of y such that:*

(i) $f_*(\mathscr{O}_X)|U$ is isomorphic to an $(\mathscr{O}_Y|U)$-Module of the form $(\mathscr{O}_Y|U)^m$;

(ii) for every $z \in U$, the canonical homomorphism

$$\big(f_*(\mathscr{O}_X)\big)_z \otimes_{\mathscr{O}_z} k(z) \longrightarrow \Gamma(X_z, \mathscr{O}_{X_z})$$

is bijective.

Proof. Assertion (i) follows from (7.8.6) and (7.8.4). Assertion (ii) follows from the exactness of $\mathscr{T}_0^U$, for a suitable choice of U, and from (7.7.5.3). □

Corollary (7.8.8). — *Suppose that the hypotheses of (7.8.6) hold and, in addition, that*

$$\Gamma(X_y, \mathscr{O}_{X_y}) = k(y).$$

Then there is an open neighbourhood U of y such that the canonical homomorphism

$$\mathscr{O}_Y|U \longrightarrow f_*(\mathscr{O}_X)|U$$

is bijective.

Proof. Indeed, it follows from assertion (ii) of (7.8.7) that the integer m occurring in assertion (i) of that corollary is necessarily equal to 1. □

Corollary (7.8.9). — *Under the hypotheses of (7.8.6), there are an open neighbourhood U of y, a coherent $\mathscr{O}_U$-Module $\mathscr{Q}$, determined up to unique isomorphism, and an isomorphism of functors in the quasi-coherent $\mathscr{O}_U$-Module $\mathscr{M}$,*

(7.8.9.1) $$R^1 f_*\big(f^*(\mathscr{M})\big) \simeq \mathscr{H}om_{\mathscr{O}_U}(\mathscr{Q}, \mathscr{M}).$$

Proof. The hypothesis implies that $\mathscr{T}_0^U$ is exact for a suitable U. It is therefore enough to apply the equivalence of conditions a) and b′) in (7.7.5), with $p = 0$ and with $\mathscr{P}_\bullet$ the complex concentrated in degree 0 with term $\mathscr{O}_X$. □

Remarks (7.8.10). — (i) Under the hypotheses of (7.8.6), consider the Stein factorisation of f (4.3.3),

$$X \xrightarrow{f'} Y' \xrightarrow{g} Y.$$

Here **III** | 208

$$Y' = \operatorname{Spec}\big(f_*(\mathscr{O}_X)\big).$$

The finite morphism g is such that

$$g_*(\mathscr{O}_{Y'}) = f_*(\mathscr{O}_X)$$

is locally free near y, and its fibre over y is the spectrum of a separable algebra over $k(y)$ (**II**, 1.5.1). We shall deduce in Chapter IV that there is an open neighbourhood U of y in Y such that, for the restriction $g^{-1}(U) \to U$ of g, *every* fibre $g^{-1}(z)$, $z \in U$, is the spectrum of a separable algebra over $k(z)$. This is what we shall call an *étale covering* of U. It will then follow from assertion (ii) of (7.8.7) that the hypothesis on the point y in (7.8.6) also holds at every point of a neighbourhood of y.

(ii) We shall see in Chapter V that, even if X is projective over Y (and even if it is also "simple" over Y, a property to be defined in Chapter IV), the $\mathscr{O}_U$-Module $\mathscr{Q}$ of (7.8.9) need not be locally free. In other words, under these hypotheses $\mathscr{O}_X$ need not be cohomologically flat in *dimension* 1 over

Y at y. In Chapter V we shall interpret $\mathscr{Q}$ as the sheaf of 1-differentials of the Picard scheme of X relative to Y, along the unit section.

III | 208

7.9. Application to proper morphisms: III. Invariance of the Euler–Poincaré characteristic and the Hilbert polynomial

(7.9.1). Let A be a ring and let M be a projective A-module of finite type. Recall (Bourbaki, *Alg. comm.*, chap. II, §5, no. 2) that this is equivalent to saying that the $\mathscr{O}_X$-Module $\widetilde{M}$ associated with M on $X = \operatorname{Spec}(A)$ is locally free of finite type. For every $\mathfrak{p} \in \operatorname{Spec}(A)$, the *rank of* M *at* $\mathfrak{p}$, denoted $\operatorname{rank}_{\mathfrak{p}}(M)$, is the rank of the free $A_{\mathfrak{p}}$-module $M_{\mathfrak{p}}$ (or, equivalently, the rank at $\mathfrak{p}$ of the locally free $\mathscr{O}_X$-Module $\widetilde{M}$). Thus

(7.9.1.1) $$\operatorname{rank}_{\mathfrak{p}} M = \operatorname{rank}_{\mathfrak{p}}(M_{\mathfrak{p}}) = \operatorname{rank}_{k(\mathfrak{p})}\big(M \otimes_A k(\mathfrak{p})\big).$$

Proposition (7.9.2). — *Let $P_\bullet$ be a finite complex of projective A-modules of finite type, and, for every A-module M, set*

$$T_\bullet(M) = H_\bullet(P_\bullet \otimes_A M).$$

Then, for every $\mathfrak{p} \in \operatorname{Spec}(A)$,

(7.9.2.1) $$\sum_i (-1)^i \operatorname{rank}_{k(\mathfrak{p})} T_i\big(k(\mathfrak{p})\big) = \sum_i (-1)^i \operatorname{rank}_{\mathfrak{p}}(P_i).$$

Proof. Indeed, $T_i(k(\mathfrak{p})) = H_i(P_\bullet \otimes_A k(\mathfrak{p}))$ by definition. In view of (7.9.1.1), formula (7.9.2.1) is simply the invariance of the Euler–Poincaré characteristic of a finite complex of finite-dimensional vector spaces upon passage to homology (**0**, 11.10.2). □

Corollary (7.9.3). — *The function*

$$\mathfrak{p} \longmapsto \sum_i (-1)^i \operatorname{rank}_{k(\mathfrak{p})} T_i\big(k(\mathfrak{p})\big)$$

is locally constant on $\operatorname{Spec}(A)$.

Theorem (7.9.4). — *Let Y be a locally Noetherian prescheme, let $f : X \to Y$ be a proper morphism, and let $\mathscr{P}_\bullet$ be a finite complex of coherent, Y-flat $\mathscr{O}_X$-Modules. If*

$$\mathscr{T}_\bullet(\mathscr{M}) = \mathscr{H}^{-\bullet}(f, \mathscr{P}^\bullet \otimes_{\mathscr{O}_Y} \mathscr{M}) \qquad \text{(cf. (7.7.1.1))},$$

then the function **III | 209**

(7.9.4.1) $$y \longmapsto \sum_i (-1)^i \operatorname{rank}_{k(y)} \mathscr{T}_i\big(k(y)\big)$$

is locally constant on Y.

Proof. We may restrict ourselves to the case where $Y = \operatorname{Spec}(A)$ is affine and A is Noetherian. Since the complex $\mathscr{P}_\bullet$ is finite, (7.7.12)(i) shows that

$$\mathscr{T}_p(\mathscr{M}) = \mathscr{H}_p(\mathscr{L}_\bullet \otimes_{\mathscr{O}_Y} \mathscr{M}),$$

where $\mathscr{L}_\bullet = \widetilde{L}_\bullet$ and $L_\bullet$ is a finite complex of projective A-modules of finite type. The theorem now follows from (7.9.3). □

(7.9.5). Under the hypotheses of (7.9.4), the function (7.9.4.1) is *constant* when Y is *connected*. When Y is connected and nonempty, its unique (integral) value is denoted

$$\operatorname{EP}(f, \mathscr{P}_\bullet), \qquad \operatorname{EP}(Y, \mathscr{P}_\bullet), \qquad \text{or simply} \qquad \operatorname{EP}(\mathscr{P}_\bullet)$$

when no confusion is possible; this integer is called the *Euler–Poincaré characteristic* of $\mathscr{P}_\bullet$ relative to f (or to Y). In general, we likewise write

$$\operatorname{EP}(f, \mathscr{P}_\bullet; y), \qquad \operatorname{EP}(Y, \mathscr{P}_\bullet; y), \qquad \operatorname{EP}(\mathscr{P}_\bullet; y)$$

for the right-hand side of (7.9.4.1).

(7.9.6). Under the hypotheses of (7.9.4) concerning X, Y, and f, let

$$0 \longrightarrow \mathscr{P}'_\bullet \xrightarrow{u} \mathscr{P}_\bullet \xrightarrow{v} \mathscr{P}''_\bullet \longrightarrow 0$$

be an exact sequence of finite complexes of coherent, Y-flat $\mathscr{O}_X$-Modules, where the homomorphisms u and v have even degrees $2d$ and $2d'$, respectively. Since $\mathscr{T}_\bullet$ is a homological functor (7.7.1), there is an exact homology sequence

$$\cdots \longrightarrow \mathscr{T}_i(\mathscr{P}'_\bullet, k(y)) \longrightarrow \mathscr{T}_{i+2d}(\mathscr{P}_\bullet, k(y)) \longrightarrow \mathscr{T}_{i+2d+2d'}(\mathscr{P}''_\bullet, k(y)) \longrightarrow \mathscr{T}_{i-1}(\mathscr{P}'_\bullet, k(y)) \longrightarrow \cdots,$$

which moreover has only finitely many terms. On writing that the Euler–Poincaré characteristic of this complex is zero (**0**, 11.10.1), we obtain at once

$$\mathrm{EP}(\mathscr{P}_\bullet; y) = \mathrm{EP}(\mathscr{P}'_\bullet; y) + \mathrm{EP}(\mathscr{P}''_\bullet; y) \tag{7.9.6.1}$$

for every $y \in Y$.

Suppose, for example, that $\mathscr{P}_\bullet = (\mathscr{P}_i)$ and that $\mathscr{P}_i = 0$ for $i < 0$. We then have the following exact sequence of complexes:

$$\begin{tikzcd}
\cdots \arrow[r] & 0 \arrow[r] \arrow[d] & 0 \arrow[r] \arrow[d] & 0 \arrow[r] \arrow[d] & 0 \arrow[r] & \cdots \\
\cdots \arrow[r] & 0 \arrow[r] \arrow[d] & 0 \arrow[r] \arrow[d] & \mathscr{P}_1 \arrow[r] \arrow[d] & \mathscr{P}_2 \arrow[r] & \cdots \\
\cdots \arrow[r] & 0 \arrow[r] \arrow[d] & \mathscr{P}_0 \arrow[r] \arrow[d] & \mathscr{P}_1 \arrow[r] \arrow[d] & \mathscr{P}_2 \arrow[r] & \cdots \\
\cdots \arrow[r] & 0 \arrow[r] \arrow[d] & \mathscr{P}_0 \arrow[r] \arrow[d] & 0 \arrow[r] \arrow[d] & 0 \arrow[r] & \cdots \\
\cdots \arrow[r] & 0 \arrow[r] & 0 \arrow[r] & 0 \arrow[r] & 0 \arrow[r] & \cdots
\end{tikzcd}$$

the nonzero vertical arrows being identity automorphisms. Applying (7.9.6.1) to this exact sequence and arguing by induction on the length of $\mathscr{P}_\bullet$ gives

$$\mathrm{EP}(\mathscr{P}_\bullet; y) = \sum_i (-1)^i \,\mathrm{EP}(\mathscr{P}_i; y). \tag{7.9.6.2}$$

Here, for each coherent $\mathscr{O}_X$-Module $\mathscr{F}$ that is flat over Y, the notation $\mathrm{EP}(\mathscr{F}; y)$ (or $\mathrm{EP}(f, \mathscr{F}; y)$, or III | 210
$\mathrm{EP}(Y, \mathscr{F}; y)$) means $\mathrm{EP}(\mathscr{Q}_\bullet; y)$ (with the corresponding relative notation) for the complex $\mathscr{Q}_\bullet$ whose only nonzero term is $\mathscr{F}$ in degree 0. Thus the study of Euler–Poincaré characteristics of complexes reduces to that of complexes with a single term.

Proposition (7.9.7). — *Under the hypotheses of (7.9.4), let Y' be a locally Noetherian prescheme, let $g : Y' \to Y$ be a morphism, put*

$$X' = X \times_Y Y', \qquad f' = f_{(Y')} : X' \longrightarrow Y',$$

and let

$$\mathscr{P}'_\bullet = \mathscr{P}_\bullet \otimes_{\mathscr{O}_Y} \mathscr{O}_{Y'}$$

be the resulting finite complex of $\mathscr{O}_{X'}$-Modules. Then $\mathscr{P}'_\bullet$ consists of coherent, Y'-flat $\mathscr{O}_{X'}$-Modules, and, for every $y' \in Y'$,

$$\mathrm{EP}(\mathscr{P}'_\bullet; y') = \mathrm{EP}(\mathscr{P}_\bullet; g(y')). \tag{7.9.7.1}$$

Proof. The $\mathscr{O}_{X'}$-Modules $\mathscr{P}'_i$, being inverse images of the $\mathscr{P}_i$ under the projection $X' \to X$, are coherent. They are Y'-flat by (**0**, 6.2.1) and (**I**, 4.14.5), the question being local on X, Y, and Y'. Finally, f' is proper by (**II**, 5.4.2), so the left-hand side of (7.9.7.1) is defined. Formula (7.9.7.1) now follows from (6.10.4.2), (7.7.2), and (7.6.7), after reducing, as one may always do, to the case where Y and Y' are affine. ☐

Proposition (7.9.8). — *Suppose that the hypotheses of (7.9.4) hold and, in addition, that there is an integer i_0 such that*

$$\mathscr{T}_i(k(y)) = 0 \qquad \text{for } i \neq i_0 \text{ and every } y \in Y.$$

Then

$$\mathscr{T}_{i_0}(\mathscr{O}_Y) = \mathscr{H}^{-i_0}(f, \mathscr{P}^\bullet)$$

is a locally free $\mathscr{O}_Y$-Module, and its rank at $y \in Y$ is

$$(-1)^{i_0}\,\mathrm{EP}(f, \mathscr{P}_\bullet; y).$$

Proof. First observe that the hypotheses of (7.4.4) are satisfied by the functors $\mathscr{T}_i^{\mathscr{O}_y}$, so that (7.4.7) applies to them. The hypothesis and (7.5.3) imply that $\mathscr{T}_i^{\mathscr{O}_y}$ is zero for $i \neq i_0$. Consequently $\mathscr{T}_{i_0}$ is exact by (7.3.3), and (7.8.4) shows that $\mathscr{H}^{-i_0}(f, \mathscr{P}^\bullet)$ is locally free. Its rank at $y \in Y$ is

$$\mathrm{rank}_{k(y)}\,\mathscr{T}_{i_0}(k(y)) = (-1)^{i_0}\,\mathrm{EP}(f, \mathscr{P}_\bullet; y),$$

by definition, since $\mathscr{T}_i(k(y)) = 0$ for $i \neq i_0$.[7] □

Corollary (7.9.9). — *Let Y be a locally Noetherian prescheme, let $f : X \to Y$ be a proper morphism, and let $\mathscr{F}$ be a coherent, Y-flat $\mathscr{O}_X$-Module. Suppose that there is an integer i_0 such that*

$$H^i\big(f^{-1}(y), \mathscr{F} \otimes_{\mathscr{O}_Y} k(y)\big) = 0$$

for every $i \neq i_0$ and every $y \in Y$. Then $R^{i_0} f_*(\mathscr{F})$ is a locally free $\mathscr{O}_Y$-Module, and its rank at y is $(-1)^{i_0}\,\mathrm{EP}(f, \mathscr{F}; y)$.

In particular:

Corollary (7.9.10). — *Under the preliminary hypotheses of (7.9.9) concerning X, Y, and $\mathscr{F}$, suppose that $R^i f_*(\mathscr{F}) = 0$ for every $i > 0$. Then $f_*(\mathscr{F})$ is a locally free $\mathscr{O}_Y$-Module, and its rank at y is $\mathrm{EP}(f, \mathscr{F}; y)$.*

Proof. In view of (7.9.9), it is enough to prove the following lemma. □

Lemma (7.9.10.1). — *Under the hypotheses of (7.9.10),*

$$H^i\big(f^{-1}(y), \mathscr{F} \otimes_{\mathscr{O}_Y} k(y)\big) = 0$$

for every $i > 0$ and every $y \in Y$.

Proof. We may restrict ourselves to the case where $Y = \mathrm{Spec}(A)$ is affine. With the notation of (7.9.4), and with $\mathscr{P}_\bullet$ reduced to its only nonzero term $\mathscr{F}$ in degree 0, the hypothesis gives $\mathscr{T}_p(\mathscr{O}_Y) = 0$ for $p < 0$. It follows from (7.3.7) that $\mathscr{T}_p$ is exact for $p < 0$, and the lemma then follows from the equivalence of conditions a) and d) in (7.7.5). □

III | 211

Proposition (7.9.11). — *Under the hypotheses of (7.9.4), let $\mathscr{L}$ be an invertible $\mathscr{O}_X$-Module that is very ample over Y, and, for every $n \in \mathbf{Z}$, put*

$$\mathscr{P}_\bullet(n) = \mathscr{P}_\bullet \otimes_{\mathscr{O}_X} \mathscr{L}^{\otimes n}.$$

Then, for every $y \in Y$, the function

$$n \longmapsto \mathrm{EP}(f, \mathscr{P}_\bullet(n); y) \tag{7.9.11.1}$$

is a polynomial with rational coefficients, and is the same for all points in any one connected component of Y.

Proof. It is clear that $\mathscr{P}_\bullet(n)$ is a complex of Y-flat $\mathscr{O}_X$-Modules. By (7.9.6.2), we may reduce to the case where $\mathscr{P}_\bullet$ has a single nonzero term $\mathscr{F} \neq 0$ in degree 0. Since the questions are local on Y, we may moreover suppose that Y is affine and that f is projective (**II**, 5.5.3). Put

$$X_y = f^{-1}(y), \qquad \mathscr{L}_y = \mathscr{L} \otimes_{\mathscr{O}_Y} k(y);$$

[7] The printed French proof omits the factor $(-1)^{i_0}$ in this displayed equality; it is required both by the definition and by the statement of the proposition.

then $\mathscr{L}_y$ is a very ample $\mathscr{O}_{X_y}$-Module (II, 4.4.10). By (7.7.2), for the functor $\mathscr{T}_\bullet$ associated with $\mathscr{P}_\bullet(n)$ we have

$$\mathscr{T}_i(k(y)) = H^{-i}(X_y, \mathscr{F}_y \otimes \mathscr{L}_y^{\otimes n}), \qquad \mathscr{F}_y = \mathscr{F} \otimes_{\mathscr{O}_Y} k(y).$$

Thus $\mathrm{EP}(f, \mathscr{F}(n); y)$ is precisely the Euler–Poincaré characteristic $\chi_{k(y)}(\mathscr{F}_y(n))$ defined in (2.5.1). It follows from (2.5.3) that (7.9.11.1) is a polynomial. For each fixed n, its value is constant on each connected component of Y by (7.9.4); this completes the proof. □

(7.9.12). The polynomial (7.9.11.1), with rational coefficients, will be denoted

$$\mathrm{PH}(f, \mathscr{P}_\bullet; y) \qquad \text{or} \qquad \mathrm{PH}(\mathscr{P}_\bullet; y),$$

and will be called the *Hilbert polynomial at y* relative to $\mathscr{P}_\bullet$, f, and $\mathscr{L}$ (or simply the *Hilbert polynomial at y* of $\mathscr{P}_\bullet$, or of f, when no confusion is possible). When Y is connected and nonempty, the reference to y is omitted from the notation and terminology. This invariant will play an essential role in Chapter V, in the theory of "moduli" of coherent quotient sheaves of a given coherent sheaf.

With the notation of (7.9.6) and (7.9.11), we have

$$\mathrm{PH}(\mathscr{P}_\bullet; y) = \mathrm{PH}(\mathscr{P}'_\bullet; y) + \mathrm{PH}(\mathscr{P}''_\bullet; y), \tag{7.9.12.1}$$

and in particular

$$\mathrm{PH}(\mathscr{P}_\bullet; y) = \sum_i (-1)^i \, \mathrm{PH}(\mathscr{P}_i; y). \tag{7.9.12.2}$$

These formulas follow immediately from (7.9.6.1) and (7.9.6.2). Likewise, with the notation and hypotheses of (7.9.7),

$$\mathrm{PH}(\mathscr{P}'_\bullet; y') = \mathrm{PH}(\mathscr{P}_\bullet; g(y')). \tag{7.9.12.3}$$

Formula (7.9.12.2) reduces the study of the Hilbert polynomials of a complex to that of the Hilbert polynomial of a single Y-flat $\mathscr{O}_X$-Module. Such polynomials have the following remarkable interpretation, independent of homological considerations.

Corollary (7.9.13). — *Let Y be a Noetherian prescheme, let $f : X \to Y$ be a proper morphism, let $\mathscr{L}$ be an invertible $\mathscr{O}_X$-Module that is very ample over Y, and let $\mathscr{F}$ be a coherent, Y-flat $\mathscr{O}_X$-Module. There is an integer n_0 such that, for $n \geqslant n_0$, $f_*(\mathscr{F}(n))$ is a locally free $\mathscr{O}_Y$-Module whose rank at $y \in Y$ is*

$$\mathrm{PH}(f, \mathscr{F}; y)(n).$$

Proof. Since f is projective (II, 5.5.3), there is an integer n_0 such that, for $n \geqslant n_0$, **III** | 212

$$R^i f_*(\mathscr{F}(n)) = 0 \qquad \text{for every } i > 0$$

by (2.2.1). The conclusion follows from (7.9.10). □

The following flatness criterion will be important in Chapter V, in the theory of "moduli" of coherent sheaves.

Proposition (7.9.14). — *Let Y be a locally Noetherian prescheme, let $f : X \to Y$ be a projective morphism, and let $\mathscr{L}$ be an invertible $\mathscr{O}_X$-Module that is ample for f. For every $\mathscr{O}_X$-Module $\mathscr{F}$ and every $n \in \mathbf{Z}$, put*

$$\mathscr{F}(n) = \mathscr{F} \otimes \mathscr{L}^{\otimes n}.$$

A coherent $\mathscr{O}_X$-Module $\mathscr{F}$ is Y-flat if and only if there is an integer n_0 such that, for every $n \geqslant n_0$, $f_*(\mathscr{F}(n))$ is a locally free $\mathscr{O}_Y$-Module.

Proof. The necessity of the condition is proved as in (7.9.13); the result of (2.2.1) applies to an ample sheaf because f is projective.

Conversely, we may reduce to the case where $Y = \mathrm{Spec}(A)$ is affine. By the hypothesis and (2.2.2)(i), the A-modules $\Gamma(X, \mathscr{F}(n))$ are projective and of finite type (Bourbaki, *Alg. comm.*, chap. II, §5, no. 2, th. 1). Let

$$S = \bigoplus_{n \geqslant 0} \Gamma(X, \mathscr{L}^{\otimes n})$$

be the associated graded ring. We know that X is canonically identified with $\mathrm{Proj}(S)$ by (**II**, 4.5.2)(b) and (5.4.4). Let

$$M = \bigoplus_{n \geqslant n_0} \Gamma(X, \mathscr{F}(n)).$$

After replacing $\mathscr{L}$, if necessary, by a power $\mathscr{L}^{\otimes d}$, we may suppose that S is generated by finitely many elements of degree 1 (2.3.5.1); it then follows from (**II**, 2.7.5) and (**II**, 2.7.2) that $\mathscr{F}$ is identified with $\mathscr{P}\!roj_0(M)$.

For every homogeneous element $g \in S$ of positive degree, we therefore have

$$\Gamma(X_g, \mathscr{F}) = M_{(g)}.$$

Now M, being a direct sum of projective A-modules, is a flat A-module. Hence M_g is flat by (**0**, 6.3.2), and so is $M_{(g)}$, which is a direct factor of M_g by (**0**, 6.1.2). We conclude from (**I**, 4.14.5) that $\mathscr{F}$ is Y-flat at every point of X_g. Since the open subsets X_g cover X, the proposition is proved. □

(II, 5.3.6) On line 16 of p. 100, replace (4.6.18) by (4.6.17).
(II, 6.2.7) On line 9 from the bottom of p. 116, replace chap. V by chap. IV.
(II, 6.6.5) On line 15 from the bottom of p. 132, replace chap. V by chap. IV.
(II, 7.4.12) On line 1 of p. 151, replace chap. V by chap. III.
(II, 8.1.4) On line 15 of p. 154, replace (III, 2.3.8) by (III, 2.3.7).
(II, 8.10.5) On line 17 from the bottom of p. 187, replace $g_{(j)x}$ by $g_{j(x)}$.
(0_{III}, 10.2.7) On line 1 of p. 20, replace u-adic by $\mathfrak{m}$-adic. On line 13 from the bottom of p. 20, replace k by k_i.
(0_{III}, 11.1.1) On line 18 of p. 23, replace $\mathrm{Im}(d_r^{p+r,q-r+1})$ by $\mathrm{Im}(d_r^{p-r,q+r-1})$.
(0_{III}, 11.8.6) On line 14 from the bottom of p. 45, replace the arrows $\to$ by $\rightsquigarrow$ (4 times).
(0_{III}, 12.3.4) On line 4 of p. 61, replace $\rightsquigarrow$ by $\to$.
(0_{III}, 13.2.4) On line 2 from the bottom of p. 67, replace $\varinjlim$ by $\varprojlim$ (2 times).
(III, 1.1.7) On line 15 of p. 85, replace A^r by $\bigwedge(A^r)$ (2 times).
(III, 1.2.4) On line 7 of p. 87, replace $\Gamma(U, \mathscr{F})$ by $\Gamma(U, \mathscr{O}_X)$ and replace $\mathscr{G}$ by $\mathscr{F}$. On line 8 of p. 87, replace $\mathrm{H}^p(\mathfrak{U}, \mathscr{G})$ by $\mathrm{H}^p(\mathfrak{U}, \mathscr{F})$.
(III, 2.5.3.1) On line 3 of p. 111, replace $n > 0$ by $n \geqslant 0$. On line 8 of p. 111, replace $-r \leqslant n \leqslant 0$ by $-r \leqslant n < 0$.
(III, 3.1.2) On line 13 of p. 116, replace $\mathscr{G}$ by $\mathscr{G} \in \mathbf{K}'$.
(III, 4.3.6) On line 7 of p. 133, replace $K' = K \otimes_A \widehat{A}$ by $K' \supset K \otimes_A \widehat{A}$. On line 16 of p. 133, replace $R(X)$ by $R(Y)$.
(III, 4.4.12) On line 10 of p. 138, replace chap. V by chap. IV.
(III, 4.6.6) On line 19 of p. 142, replace "chap. V" by "in a later section".

B) *Textual modifications*[8]

(**Err**$_{\mathrm{III}}$, 1) In (0_{I}, 5.1.3), on line 18 of p. 45, replace "direct sum" by "finite direct sum".
(**Err**$_{\mathrm{III}}$, 2) In (0_{I}, 5.4.3), on lines 8 to 4 from the bottom of p. 49, replace the text beginning "In the general case…" by the following:

In the general case where X is a ringed space such that $\mathscr{O}_x$ is a *local* ring for every $x \in X$, if $\mathscr{L}$ is an $\mathscr{O}_X$-Module *of finite type* for which there exists an $\mathscr{O}_X$-Module $\mathscr{F}$ such that $\mathscr{L} \otimes_{\mathscr{O}_X} \mathscr{F}$ is *isomorphic to* $\mathscr{O}_X$, the preceding argument shows that, for every $x \in X$, $\mathscr{L}_x$ is isomorphic to $\mathscr{O}_x$. It follows that $\mathscr{L}$ is then *invertible*. Indeed, for every $x \in X$, let U be an open neighborhood of x such that $\mathscr{L}|U$ is generated by n sections s_i ($1 \leqslant i \leqslant n$) over U (5.2.1). We may suppose, for example, that $s = s_1$ is such that $s_x \neq 0$; and since $\mathscr{L}_x$ is isomorphic to $\mathscr{O}_x$, for each i there exists a section t_i of $\mathscr{O}_X$ over an open neighborhood $V_i \subset U$ of x such that $(t_i)_x s_x = (s_i)_x$. Consequently there is an open neighborhood $V \subset \bigcap_{i=1}^n V_i$ of x such that $t_i s = s_i$ in V; in other words, $\mathscr{L}|V$ is generated by the *single* section $s|V$. Moreover, if z is a section over an open subset $W \subset V$ of the kernel of the homomorphism $\mathscr{O}_X|V \to \mathscr{L}|V$ defined by s (5.1.1), then z_y annihilates $\mathscr{L}_y$ for every $y \in W$, so $z_y = 0$ by hypothesis and hence $z = 0$, which completes the proof of our assertion. Finally, consideration of the tensor product $\mathscr{L}^{-1} \otimes \mathscr{L} \otimes \mathscr{F}$ immediately shows that $\mathscr{F}$ is isomorphic to $\mathscr{L}^{-1}$. **III** | 219

(**Err**$_{\mathrm{III}}$, 3) In (0_{I}, 7.2.4), one must impose the condition that the powers $\mathfrak{J}^n$ are *closed* ideals in the admissible ring A in order for the proposition to be correct. The proof given is incorrect, and the corrected statement follows from Bourbaki, *Top. gén.*, chap. III, 3rd ed., § 3, no. 5, cor. 1 of prop. 9. The $\mathfrak{J}^n$ must likewise be assumed *closed* in A in statements (0_{I}, 7.2.5) and (0_{I}, 7.2.6).
(**Err**$_{\mathrm{III}}$, 4) After proposition (I, 2.2.5), add: with the notation of (I, 2.2.5), if $\mathfrak{J}$ is an ideal of A, we denote by $\widetilde{\mathfrak{J}\mathscr{F}}$ the $\mathscr{O}_X$-submodule $\mathfrak{J}\widetilde{\mathscr{F}}$ defined in (0, 4.3.5).

[8] To facilitate the search for references, modifications belonging to the errata list inserted in chapter N will henceforth be designated by **Err**$_{\mathrm{N}}$ followed by a number.

(**Err**$_{\text{III}}$, 5) In (I, 3.4.5), on line 1 from the bottom of p. 112, replace "*a field K*" by "*an algebraically closed field K*". On line 1 of p. 113, replace "*extension*" by "*algebraically closed extension*". On lines 1 to 4 of p. 113, replace the text beginning "*K* will be called..." by the following:

For every point of X with values in a field K, K will be called the *field of values* of the corresponding point; and if x is the locality of this point, the latter is also said to be *localized at x*. This defines a map $X(K) \to X$ that associates to a point with values in K its locality.

On lines 7 and 16 of p. 113, delete "geometric"; on lines 10 and 13 of p. 113, delete "geometric". On lines 10 and 11 from the bottom of p. 115, delete "*geometric*".

(**Err**$_{\text{III}}$, 6) At the end of the proof of (I, 3.6.1), on line 12 from the bottom of p. 117, add: If we set $X' = X \times_Y \operatorname{Spec}(\mathscr{O}_y/\mathfrak{a}_y)$, then, for every point $x \in X'$, identified by p with a point of X, we have $\mathscr{O}_{X',x} = \mathscr{O}_{X,x}/\mathfrak{a}_y\mathscr{O}_{X,x}$. Since the question is local on X and Y, we may suppose that $X = \operatorname{Spec}(B)$ and $Y = \operatorname{Spec}(A)$; then $(B/\mathfrak{a}_yB)_x = B_x/\mathfrak{a}_yB_x$ by flatness (0, 1.3.2).

(**Err**$_{\text{III}}$, 7) In (I, 5.1.1), on line 3 from the bottom of p. 127, replace "quasi-coherent $\mathscr{O}_X$-Module" by "*quasi-coherent ideal of $\mathscr{B}$*".

(**Err**$_{\text{III}}$, 8) After (I, 5.1.10), on line 16 of p. 131, add:

Remark (5.1.11). — A slight adaptation of the argument used in (5.1.9) shows that the conclusion remains valid *without assuming a priori that X is a prescheme*, but

assuming only that $(X, \mathscr{O}_X)$ is a ringed space in local rings, that $\mathscr{J}$ is an ideal of $\mathscr{O}_X$ such that **III** | 220
$\mathscr{J}^n = 0$, that the ringed space $X_0 = (X, \mathscr{O}_X/\mathscr{J})$ is an affine scheme, and finally that the ideals $\mathscr{J}^k/\mathscr{J}^{k+1}$ are quasi-coherent $\mathscr{O}_{X_0}$-Modules. It suffices to use (1.8.1) (cf. (**Err**$_{\text{II}}$)) instead of (2.2.4) in the argument.

(**Err**$_{\text{III}}$, 9) In (I, 5.3.1), on line 11 of p. 132, after "or Δ_X", insert "or Δ_ϕ if $\phi : X \to S$ is the structural morphism".

(**Err**$_{\text{III}}$, 10) In (I, 5.3.9), the proof is insufficient, because it does not prove that $\Delta_X(X)$ is locally closed in $X \times_S X$. To obtain a correct proof, it suffices to use (4.2.4, *a*)): for every $x \in X$ and every affine neighborhood U of x in X, $U \times_S U$ is an affine neighborhood of $\Delta_X(x)$; taking (5.3.16) into account (whose proof uses only definition (5.3.1.1)), we are reduced to proving (5.3.9) when $S = \operatorname{Spec}(B)$ and $X = \operatorname{Spec}(A)$ are affine schemes. It is then clear from (5.3.1.1) that Δ_X corresponds to the canonical homomorphism $A \otimes_B A \to A$ that sends $x \otimes y$ to xy; since this homomorphism is surjective, Δ_X is then a closed immersion (4.2.3), which completes the proof.

(**Err**$_{\text{III}}$, 11) In (I, 7.1.15) and (I, 7.1.16), on lines 7 and 15 from the bottom of p. 158, delete "*geometric*".

(**Err**$_{\text{III}}$, 12) Replace (I, 7.4.7) by: We extend (by abuse of language) the definitions of (7.4.1) to the case where X is a *reduced* prescheme every point of which admits an open neighborhood having only a *finite* number of irreducible components. It then follows from (7.3.4) and (7.4.6) that, for a quasi-coherent $\mathscr{O}_X$-Module of finite type $\mathscr{F}$, to say that $\mathscr{F}$ is a *torsion sheaf* is equivalent to saying that $\operatorname{Supp}(\mathscr{F})$ *contains no irreducible component of X*.

(**Err**$_{\text{III}}$, 13) In (I, 10.11.7), on lines 17 to 23 of p. 205, the end of the proof beginning "It remains to prove..." is unnecessary by (10.11.6), since the sheaves in question are coherent by (0, 5.3.5).

(**Err**$_{\text{III}}$, 14) In (II, 1.7.8), after line 10 from the bottom of p. 16, add: when $\mathscr{E} = \mathscr{O}_S^n$, we also write $\mathbf{V}_S^n$ in place of $\mathbf{V}(\mathscr{E})$; if moreover $S = \operatorname{Spec}(A)$ is affine, we write $\mathbf{V}_A^n$ in place of $\mathbf{V}_S^n$; we have $\mathbf{V}_A^n = \operatorname{Spec}(A[T_1, \ldots, T_n])$, where the T_i are indeterminates.

(**Err**$_{\text{III}}$, 15) In (II, 1.7.10), on line 10 of p. 17, delete "*geometric*"; on lines 12 and 16–17 of p. 17, delete "geometric".

(**Err**$_{\text{III}}$, 16) In (II, 1.7.12), add: We set similarly:

$$\mathbf{V}(\mathscr{O}_S^n) = \mathbf{V}_S^n = S[T_1, \ldots, T_n].$$

(**Err**$_{\text{III}}$, 17) In (II, 4.2.6), on line 7 of p. 75, delete "*geometric*"; on line 8 of p. 75, delete "*geometric*".

(**Err**$_{\text{III}}$, 18) In (II, 4.6.13), on line 7 of p. 92, the argument must be made more precise, because with the notation of (4.4.10) one must prove here that the immersion Γ_f is *quasi-compact*, in order to apply (i bis). By (4.6.4), to prove that $\mathscr{L}$ is ample relative to f, we may restrict to the case where Y is affine. Observe also that in each of the hypotheses of (v), f is quasi-compact (I, 6.6.4). On the other hand, if g is separated, Γ_f is a closed immersion (I, 5.4.3), hence quasi-compact (I, 6.6.4). If, on the **III** | 221
contrary, X is locally Noetherian, then since Y is affine and f is quasi-compact, the underlying space

of X is quasi-compact, hence Noetherian; and (I, 6.6.4) may again be applied to prove that Γ_f is quasi-compact.

(**Err**$_{\text{III}}$, 19) The statement of (II, 5.2.2) is incorrect: conditions b), c), and c') are not local on Y when it is not known whether, for an open subset U of Y, a quasi-coherent $(\mathscr{O}_X|f^{-1}(U))$-Module is the restriction to $f^{-1}(U)$ of a quasi-coherent $\mathscr{O}_X$-Module. Thus, on line 16 of p. 98, replace "*Let $f : X \to Y$ be a separated quasi-compact morphism*" by: "*Let X and Y be two preschemes such that X is a scheme or the underlying space of X is locally Noetherian, and let $f : X \to Y$ be a quasi-compact morphism.*" In the proof, observe that the hypotheses imply that f is *separated* when X is assumed to be a scheme, by (I, 5.5.5 and 5.5.8); hence (I, 9.2.2) may be applied in both cases.

(**Err**$_{\text{III}}$, 20) In (II, 6.2.3), after line 18 from the bottom of p. 115, add:

A morphism $f : X \to Y$ is said to be quasi-finite at a point $x \in X$ if there exist an affine open neighborhood V of $y = f(x)$ and an affine open neighborhood U of x such that $f(U) \subset V$ and the morphism $U \to V$ induced by restricting f is quasi-finite. A morphism $f : X \to Y$ is said to be locally quasi-finite if it is quasi-finite at every point of X.

(**Err**$_{\text{III}}$, 21) In (II, 6.4.3), the proof is incorrect, since the elements of a finite-type A-submodule of K are not necessarily integral over A. Replace the last 9 lines of p. 121 by the following text: Since we may suppose that E is torsion-free, hence faithful, E is also a faithful $A[u]$-module (A being embedded in the ring of endomorphisms of E). Since E is an A-module of finite type, it follows that u is *integral* over A (Bourbaki, *Alg. comm.*, chap. V, § 1, no. 1, lemma 1). We immediately conclude that the eigenvalues of $u \otimes 1$ (in an algebraic closure of K) are elements *integral* over A, and consequently so are the $\sigma_i(u)$.

(**Err**$_{\text{III}}$, 22) In (0_{III}, 9.1.1), on line 18 from the bottom of p. 12, delete "open".

(**Err**$_{\text{III}}$, 23) In (0_{III}, 11.7.3), on line 10 of p. 43, after C'', add: such that for every projective object P of C' (resp. every projective object P' of C''), the functor $A' \rightsquigarrow T(P, A')$ (resp. $A \rightsquigarrow T(A, P')$) is exact in C' (resp. C).

(**Err**$_{\text{III}}$, 24) The statement of (0_{III}, 13.7.7) is inaccurate and must be modified as follows: on line 6 of p. 78, delete "and $(\mathrm{R}^{n+1}T(A_k))_{k\in\mathbf{Z}}$"; on line 7 of p. 78, replace "$\mathrm{R}'^{n}T(A)$ is an S-module of finite type" by "$\mathrm{R}'^{n}T(A)$ and $\mathrm{R}'^{n+1}T(A)$ are S-modules of finite type"; on lines 12–13 of p. 78, delete "and $p + q = n + 1$". In the proof, on line 23 of p. 78, delete "and for $n + 1$".

(**Err**$_{\text{III}}$, 25) In (III, 1.4.15), on line 6 from the bottom of p. 92, replace "*of finite type*" by "*quasi-compact*".

(**Err**$_{\text{III}}$, 26) In (III, 2.2.4), on line 1 of p. 102, replace "*the supports of $\mathscr{F}$ and $\mathscr{H}$ are proper over Y*" by "*the support of* $\mathrm{Im}(\mathscr{F} \to \mathscr{G})$ *is proper over Y*". In the proof, replace the text of lines 10 to 16, beginning "This being so…", by:

Set $\mathscr{G}_1 = \mathrm{Im}(\mathscr{F} \to \mathscr{G}) = \mathrm{Ker}(\mathscr{G} \to \mathscr{H})$, which is coherent. Since we have the exact sequence **III** | 222 $0 \to \mathscr{G}_1(n) \to \mathscr{G}(n) \to \mathscr{H}(n)$ and the functor f_* is left exact, the sequence $0 \to f_*(\mathscr{G}_1(n)) \to f_*(\mathscr{G}(n)) \to f_*(\mathscr{H}(n))$ is exact for every n; it therefore suffices to show that, for sufficiently large n, the sequence $f_*(\mathscr{F}(n)) \to f_*(\mathscr{G}_1(n)) \to 0$ is exact. In other words, we may restrict to the case where $\mathscr{H} = 0$ and the support of $\mathscr{G}$ is proper over Y, hence *closed in* Z (II, 5.4.10). Consequently $\mathscr{G}' = i_*(\mathscr{G})$ is a coherent $\mathscr{O}_Z$-Module such that $\mathscr{G}'|X = \mathscr{G}$. We know from (I, 9.4.3) that there exists a coherent $\mathscr{O}_Z$-Module $\mathscr{F}'$ such that $\mathscr{F}'|X = \mathscr{F}$. Moreover, since X is open in Z and $\mathrm{Supp}(\mathscr{G}) \subset X$ is closed in Z, it is immediate that one defines a surjective homomorphism $u' : \mathscr{F}' \to \mathscr{G}'$ of sheaves such that $u'|X$ is the given surjective homomorphism $u : \mathscr{F} \to \mathscr{G}$, by taking $u'|U = 0$ for every open subset U of Z not meeting $\mathrm{Supp}(\mathscr{G})$ and $u'|U = u|U$ for every open subset $U \subset X$. This being so, as at the beginning of the proof of (2.2.2), we see that we may reduce to the case where Y is affine; it is therefore enough to show that, for sufficiently large n, the homomorphism $\Gamma(u) : \Gamma(X, \mathscr{F}(n)) \to \Gamma(X, \mathscr{G}(n))$ is surjective. We have the commutative diagram

$$\begin{tikzcd}
\Gamma(Z, \mathscr{F}'(n)) \arrow[r, "\Gamma(u')"] \arrow[d, "v"'] & \Gamma(Z, \mathscr{G}'(n)) \arrow[d, "w"] \\
\Gamma(X, \mathscr{F}(n)) \arrow[r, "\Gamma(u)"'] & \Gamma(X, \mathscr{G}(n))
\end{tikzcd}$$

where v and w are the restriction homomorphisms. The definition of $\mathscr{G}'$ moreover shows that w is *bijective*; and by (2.2.3), $\Gamma(u')$ is *surjective* for sufficiently large n, so the same is true of $\Gamma(u)$.

($\mathbf{Err}_{\mathrm{III}}$, 27) In (III, 2.2.5), after line 7 from the bottom of p. 102, add:

(iii) Under the hypotheses of (2.2.4) concerning X, Y, f, and $\mathscr{L}$, it is immediate that if $\mathscr{H}$ is a coherent $\mathscr{O}_X$-Module whose support is *proper over* Y, an argument analogous to that of (2.2.4) shows that there exists an integer N such that, for $n \geqslant N$, $\mathrm{R}^i f_*(\mathscr{H}(n)) = 0$ for every $i > 0$. It follows from the exact cohomology sequence that if $u : \mathscr{F} \to \mathscr{G}$ is a homomorphism of coherent $\mathscr{O}_X$-Modules such that $\mathrm{Ker}(u)$ and $\mathrm{Coker}(u)$ have supports *proper over* Y, then there exists N such that for $n \geqslant N$, the corresponding homomorphism $\mathrm{R}^i f_*(\mathscr{F}(n)) \to \mathrm{R}^i f_*(\mathscr{G}(n))$ is *bijective* for every $i > 0$.

($\mathbf{Err}_{\mathrm{III}}$, 28) In (III, 4.4.9), on line 17 from the bottom of p. 137, replace "*Let Y be a locally Noetherian integral prescheme*" by "*Let X and Y be two locally Noetherian integral preschemes*"; on line 16 from the bottom of p. 137, replace "*of finite type*" by "*locally of finite type*". The proof is essentially unchanged, since $f^{-1}(y)$ is locally of finite type over $k(y)$ and is therefore still discrete.

($\mathbf{Err}_{\mathrm{III}}$, 29) In (I, 9.3.4), on line 19 from the bottom of p. 173, replace "*Noetherian*" by "*quasi-compact*"; on lines 18 and 19 from the bottom of p. 173, replace "*coherent*" by "*quasi-coherent of finite type*". In the proof, we reduce to the case where

$X = \mathrm{Spec}(A)$ and $\mathscr{F} = \widetilde{M}$, where M is an A-module of finite type, and $\mathscr{J} = \widetilde{\mathfrak{J}}$, where $\mathfrak{J}$ is an **III** | 223
ideal of finite type in A; the rest of the argument is then unchanged.

($\mathbf{Err}_{\mathrm{III}}$, 30) In (I, 9.3.5), replace lines 1 to 7 from the bottom of p. 173 by the following text:

Proposition (9.3.5). — Let X be a prescheme and $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-Module of finite type. Then there exist a closed subprescheme Y of X, whose underlying space is equal to $\mathrm{Supp}(\mathscr{F})$*, and a quasi-coherent $\mathscr{O}_Y$-Module of finite type $\mathscr{G}$ such that, if $j : Y \to X$ is the canonical injection, $\mathscr{F}$ is isomorphic to $j_*(\mathscr{G})$.*

It will suffice to show that the ideal $\mathscr{J}$ of $\mathscr{O}_X$, *annihilator of* $\mathscr{F}$, is *quasi-coherent*. We then take for Y the closed subprescheme of X defined by $\mathscr{J}$ (I, 4.1.2), and since $\mathscr{J}\mathscr{F} = 0$, $\mathscr{F}$ is an $(\mathscr{O}_X/\mathscr{J})$-Module and we answer the question by taking $\mathscr{G} = j^*(\mathscr{F})$. To see that $\mathscr{J}$ is quasi-coherent, we may (the question being local) restrict to the case where $X = \mathrm{Spec}(A)$ and $\mathscr{F} = \widetilde{M}$, where M is an A-module generated by finitely many elements x_i $(1 \leqslant i \leqslant r)$. The ideal $\mathscr{J}$ is then the intersection of the annihilators of the x_i. But the annihilator of x_i is the kernel of the homomorphism $\mathscr{O}_X \to \mathscr{F}$ corresponding to the homomorphism $s \mapsto sx_i$ from A to M; it is therefore indeed a quasi-coherent ideal (I, 4.1.1), and every finite intersection of such ideals is also a quasi-coherent ideal (I, 1.3.10).

CHAPTER IV

LOCAL STUDY OF SCHEMES AND MORPHISMS OF SCHEMES

Summary

[1]The order and content of §§ 11 to 21 are given only as an indication and may be modified before their publication.

The subjects treated in this Chapter call for the following remarks: **IV-1** | 223

a) Their common feature is that they concern *local* properties of preschemes or morphisms, i.e. properties considered at a point, at the points of a fibre, or in an unspecified neighbourhood of a point or a fibre. These properties are generally *topological*, *differential*, or *dimensional* in nature (i.e. involving the notions of *dimension* and *depth*), and are linked to properties of the *local rings* at the points under consideration. One typical problem is, for a given morphism $f : X \to Y$ and a point $x \in X$, to relate the properties of X at x to those of Y at $y = f(x)$ and of the fibre $X_y = f^{-1}(y)$ at x. Another is to determine the topological nature (for example, constructibility, or being open or closed) of the set of points $x \in X$ at which X has a given property, or for which the fibre $X_{f(x)}$ passing through x has a given property at x. Similarly, we shall be interested in the topological nature of the set of points $y \in Y$ such that X has a given property at all points of the fibre X_y, or such that this fibre has a given property.

b) The most important notions for the following chapters are that of a *flat morphism of finite presentation* and those of a *smooth morphism* and an *étale morphism*, which are special cases. Their detailed study, together with related questions, properly begins in § 11.

c) Sections 1 to 10 may be regarded as preliminary in nature and develop three types of techniques, used not only in the other sections of this chapter but, of course, also in the following chapters:

c 1) Sections 1 to 4 consider various aspects of the notion of *base change*, especially in relation to finiteness or flatness conditions; the technique of *descent* is initiated there in its most elementary aspects (questions of "effectivity" connected with this technique will be studied in Chapter V).

c 2) Sections 5 to 7 centre on what may be called *Noetherian techniques*: the preschemes considered are always assumed locally Noetherian, whereas, on the contrary, no finiteness condition is generally imposed on the *morphisms*. This is essentially because the notions of dimension and depth are manageable only for Noetherian local rings. Recall that § 7 constitutes a "fine" theory of Noetherian local rings, used relatively little in the remainder of the chapter.

c 3) Sections 8 to 10 provide, among other things, a means of *eliminating Noetherian hypotheses* on the preschemes studied, by replacing them with suitable *finiteness* hypotheses ("finite presentation") on the *morphisms* considered. The advantage of this replacement is that the latter hypotheses are *stable under base change*, whereas this is not the case for Noetherian hypotheses on preschemes. The technique permitting this passage rests, on the one hand, on the use of the notion of a *projective limit* of preschemes, by which a question may be reduced to the same question under *Noetherian* hypotheses, and, on the other hand, on the systematic use of *constructible sets*, which have the double advantage of being preserved by inverse image (under an arbitrary morphism)

and by direct image (under a morphism of finite presentation), and of having manageable topological properties in locally Noetherian preschemes. The same techniques often even permit reduction to more particular Noetherian rings, for example finitely generated **Z**-algebras, and it is here that the properties of "excellent" rings, studied in § 7, intervene decisively. Quite apart from the elimination of Noetherian hypotheses, the very elementary techniques of §§ 8 to 10 are in constant use in almost all applications. **IV-1** | 224

§1. Relative finiteness conditions. Constructible sets in preschemes

In this section, we will resume and complete the exposé of "finiteness conditions" for a morphism of preschemes $f : X \to Y$ given in (**I**, 6.3 and 6.6). There are essentially two notions of "finiteness" of a *global* nature on X, that of *quasi-compact* morphism (defined in (**I**, 6.6.1)) and that of a *quasi-separated* morphism; on the other hand, there are two notions of "finiteness" of a *local* nature on X, that of a morphism *locally of finite type* (defined in (**I**, 6.6.2)) and that of a morphism *locally of finite presentation*. By combining these local notions with the preceding global notions, we obtain the notion of a morphism *of finite type* (defined in (**I**, 6.3.1)) and of a morphism *of finite presentation*. For the convenience of the reader, we will give again in this section the principal properties stated in (**I**, 6.3 and 6.6), referring, of course, to those numbered passages in Chapter I for their proofs.

In n^{os}1.8 and 1.9, we complete, in the context of preschemes, and making use of the previous notions of finiteness, the results on constructible sets given in ($\mathbf{0}_{\text{III}}$, §9).

1.1. Quasi-compact morphisms

Definition (1.1.1). — We say that a morphism of preschemes $f : X \to Y$ is *quasi-compact* if the continuous map f from the topological space X to the topological space Y is quasi-compact (**0**, 9.1.1), in other words, if the inverse image $f^{-1}(U)$ of every quasi-compact open subset U of Y is quasi-compact (cf. (**I**, 6.6.1)).

If $\mathfrak{B}$ is a basis for the topology of Y consisting of affine open sets, then for f to be quasi-compact, it is necessary and sufficient that for all $V \in \mathfrak{B}$, $f^{-1}(V)$ is a *finite union of affine open sets*. For example, if Y is affine and X is quasi-compact, *every* morphism $f : X \to Y$ is quasi-compact (**I**, 6.6.1).

If $f : X \to Y$ is a quasi-compact morphism, then it is clear that for every open subset V of Y, the restriction of f to $f^{-1}(V)$ is a quasi-compact morphism $f^{-1}(V) \to V$. Conversely, if (U_α) is an open cover of Y and $f : X \to Y$ is a morphism such that the restrictions $f^{-1}(U_\alpha) \to U_\alpha$ are quasi-compact, then f is quasi-compact. As a result, if $f : X \to Y$ is an S-morphism of S-preschemes, and if there **IV-1** | 225
exists an open cover (S_λ) of S such that the restrictions $g^{-1}(S_\lambda) \to h^{-1}(S_\lambda)$ of f (where g and h are the structure morphisms) are quasi-compact, then f is quasi-compact.

Proposition (1.1.2). —

(i) *An immersion $X \to Y$ is quasi-compact if it is closed, or if the underlying space of Y is locally Noetherian or if the underlying space of X is Noetherian.*

(ii) *The composition of two quasi-compact morphisms is quasi-compact.*

(iii) *If $f : X \to Y$ is a quasi-compact S-morphism, the same is true of $f_{(S')} : X_{(S')} \to Y_{(S')}$ for every extension $g : S' \to S$ of the base prescheme.*

(iv) *If $f : X \to X'$ and $g : Y \to Y'$ are two quasi-compact S-morphisms,*
$$f \times_S g : X \times_S Y \longrightarrow X' \times_S Y'$$
is quasi-compact.

(v) *If the composition $g \circ f$ of two morphisms $f : X \to Y$, $g : Y \to Z$ is quasi-compact, and if either g is separated or the underlying space of X is locally Noetherian, then f is quasi-compact.*

(vi) *For a morphism f to be quasi-compact, it is necessary and sufficient that f_{red} be so.*

For the proof, see (**I**, 6.6.4). We note that the assertion (vi) is also a consequence of the following more general proposition:

Proposition (1.1.3). — *Let $f : X \to Y$, $g : Y \to Z$ be two morphisms. If $g \circ f$ is quasi-compact and f is surjective, then g is quasi-compact.*

Proof. Indeed, if V is a quasi-compact open subset of Z, $f^{-1}(g^{-1}(V))$ is quasi-compact by hypothesis, and we have $g^{-1}(V) = f(f^{-1}(g^{-1}(V)))$, since f is surjective; so $g^{-1}(V)$ is quasi-compact. □

Corollary (1.1.4). — *Let $f : X \to Y$, $g : Y' \to Y$ be two morphisms, $X' = X \times_Y Y'$, $f' = f_{(Y')} : X' \to Y'$; suppose g is quasi-compact and surjective* (*resp. surjective*)*. Then, for f to be quasi-compact* (*resp. dominant*)*, it suffices that f' be so.*

Proof. If $g' : X' \to X$ is the canonical projection, g' is a surjective morphism (**I**, 3.5.2), and we have $f \circ g' = g \circ f'$; if f' is quasi-compact (resp. dominant), the same is true of $g \circ f'$ since g is quasi-compact (1.1.2) (resp. surjective); as $f \circ g'$ is quasi-compact (resp. dominant) and g' is surjective, we deduce that f is quasi-compact (1.1.3) (resp. dominant). □

To abbreviate, we will call *maximal point* of a prescheme X every generic point of an irreducible **IV-1** | 226
component of X; if $X = \operatorname{Spec}(A)$ is affine, the maximal points of X are the *minimal prime ideals* of A.

Proposition (1.1.5). — *Let $f : X \to Y$ be a quasi-compact morphism. The following conditions are equivalent:*

a) *f is dominant;*

b) *for every maximal point y of Y, we have $f^{-1}(y) \neq \varnothing$;*

c) *for every maximal point y of Y, $f^{-1}(y)$ contains a maximal point of X.*

The equivalence of *a)* and *c)* was proved in (**I**, 6.6.5). It is clear that *c)* implies *b)*; on the other hand, if X' is an irreducible component of X meeting $f^{-1}(y)$, $f(X')$ is irreducible and contains y, so it is contained in the irreducible component $Y' = \overline{\{y\}}$ of Y (**0**, 2.1.6); if x is the generic point of X', we therefore necessarily have $f(x) = y$ (**0**, 2.1.5); so *b)* implies *c)*.

Proposition (1.1.6). — *Let $f' : X' \to Y$, $f'' : X'' \to Y$ be two morphisms, X the coproduct prescheme $X' \coprod X''$, $f : X \to Y$ the morphism equal to f' on X' and to f'' on X''. For f to be quasi-compact, it is necessary and sufficient that f' and f'' be so.*

This follows immediately from the definition.

1.2. Quasi-separated morphisms

Definition (1.2.1). — Let X, Y be two preschemes. We say that a morphism $f : X \to Y$ is *quasi-separated* (or that X is *quasi-separated over* Y) if the diagonal morphism $\Delta_f = (1_X, 1_X)_Y : X \to X \times_Y X$ is quasi-compact. We say that a prescheme X is *quasi-separated* if it is quasi-separated over $\operatorname{Spec}(\mathbf{Z})$.

By definition, every separated morphism is quasi-separated, Δ_f being a closed immersion (1.1.2, (i)); a *scheme* X is a quasi-separated prescheme, being separated over $\operatorname{Spec}(\mathbf{Z})$ (**I**, 5.4.1).

Proposition (1.2.2). —

(i) Every monomorphism of preschemes $f : X \to Y$ (in particular every immersion) is quasi-separated.
(ii) If $f : X \to Y$ and $g : Y \to Z$ are two quasi-separated morphisms, $g \circ f : X \to Z$ is quasi-separated.
(iii) Let X, Y be two S-preschemes, $f : X \to Y$ a quasi-separated S-morphism. Then, for every base change $g : S' \to S$, the morphism $f_{(S')} : X_{(S')} \to Y_{(S')}$ is quasi-separated.
(iv) If $f : X \to Y$, $f' : X' \to Y'$ are two quasi-separated S-morphisms, then

$$f \times_S f' : X \times_S X' \longrightarrow Y \times_S Y'$$

is quasi-separated.
(v) If $f : X \to Y$, $g : Y \to Z$ are two morphisms such that $g \circ f$ is quasi-separated, then f is quasi-separated.
(vi) If $f : X \to Y$ is a quasi-separated morphism, $f_{\mathrm{red}} : X_{\mathrm{red}} \to Y_{\mathrm{red}}$ is quasi-separated.

Proof. By virtue of (**I**, 5.5.12), it suffices to prove (i), (ii) and (iii).

The assertion (i) is trivial, every monomorphism being separated (**I**, 5.5.1). To prove (iii), we reduce immediately to the case where $Y = S$ (**I**, 3.3.11) and the assertion follows from the fact that $\Delta_{f_{(S')}} = (\Delta_f)_{(S')}$ (**I**, 5.3.4) and from (1.1.2, (iii)). To prove (ii), consider the projections p and q of $X \times_Y X$ over X; if $i = (p, q)_Z$, we know that the diagram

$$\begin{tikzcd} X \times_Y X \arrow[r, "i"] \arrow[d, "\pi"'] & X \times_Z X \arrow[d, "f \times_Z f"] \\ Y \arrow[r, "\Delta_g"'] & Y \times_Z Y \end{tikzcd}$$

(where π is the structure morphism) is commutative and identifies $X \times_Y X$ with the product, as **IV-1** | 227
$(Y \times_Z Y)$-preschemes, of Y and $X \times_Z X$ (**I**, 5.3.5). If g is quasi-separated, Δ_g is quasi-compact, and hence so is i (1.1.2, (iii)); if in addition f is quasi-separated, Δ_f is quasi-compact, and hence so is $i \circ \Delta_f$ (1.1.2, (ii)), which is equal to $\Delta_{g \circ f}$. □

Corollary (1.2.3). —

(i) Let X be a quasi-separated prescheme. Then every morphism $f : X \to Y$ is quasi-separated.
(ii) Let Y be a quasi-separated prescheme. For a morphism $f : X \to Y$ to be quasi-separated, it is necessary and sufficient that the prescheme X be quasi-separated.

This follows immediately from (1.2.2, (ii) and (v)) applied to X, Y and $\operatorname{Spec}(\mathbf{Z})$.

Proposition (1.2.4). — *Let $f : X \to Y$ be a morphism, $g : Y \to Z$ a quasi-separated morphism. If $g \circ f$ is quasi-compact, then so is f.*

Proof. We know that f is the composite morphism $X \xrightarrow{\Gamma_f} X \times_Z Y \xrightarrow{\mathrm{pr}_2} Y$ (**I**, 5.3.13); on the other hand, pr_2 is identified with $(g \circ f) \times_Z 1_Y$ (**I**, 3.3.4) and since $g \circ f$ is quasi-compact, so is pr_2 (1.1.2, (iv)). Finally, we have the commutative diagram

(1.2.4.1)
$$\begin{tikzcd} X \arrow[r, "\Gamma_f"] \arrow[d, "f"'] & X \times_Z Y \arrow[d, "f \times 1_Y"] \\ Y \arrow[r, "\Delta_g"'] & Y \times_Z Y \end{tikzcd}$$

which identifies X with the product, as $(Y \times_Z Y)$-preschemes, of Y and $X \times_Z Y$ (**I**, 5.3.7). As by hypothesis Δ_g is a quasi-compact morphism, so is Γ_f (1.1.2, (iii)); the conclusion then follows from (1.1.2, (ii)). □

Proposition (1.2.5). — *Let $f : X \to Y$, $g : Y' \to Y$ be two morphisms, $X' = X \times_Y Y'$, $f' = f_{(Y')} : X' \to Y'$. If g is quasi-compact and surjective and f' quasi-separated, then f is quasi-separated.*

Proof. We have indeed $(X' \times_{Y'} X') = (X \times_Y X)_{(Y')}$ and $\Delta_{f'} = (\Delta_f)_{(Y')}$ (**I**, 5.3.4); as the projection $X' \times_{Y'} X' \to X \times_Y X$ is quasi-compact (1.1.2, (iii)) and surjective (**I**, 3.5.2), we can, by virtue of (**I**, 3.3.11), apply (1.1.4), which shows that since $\Delta_{f'}$ is a quasi-compact morphism, the same is true of Δ_f. □

Proposition (1.2.6). — *Let $f : X \to Y$ be a morphism, (U_α) a covering of Y by open subsets such that the induced preschemes U_α are quasi-separated. For f to be quasi-separated, it is necessary and sufficient that each of the induced preschemes on the open subsets $f^{-1}(U_\alpha)$ be quasi-separated.*

Proof. The inverse image in $X \times_Y X$ of U_α is $X_\alpha \times_{U_\alpha} X_\alpha$, writing $X_\alpha = f^{-1}(U_\alpha)$, and the restriction $X_\alpha \to X_\alpha \times_{U_\alpha} X_\alpha$ of Δ_f is none other than Δ_{f_α}, denoting by f_α the restriction $X_\alpha \to U_\alpha$ of f; by virtue of the definition (1.2.1) and the local character of the notion of quasi-compact morphism (1.1.1), for f to be quasi-separated, it is necessary and sufficient that each of the morphisms f_α be so. But since by hypothesis the morphism $U_\alpha \to \mathrm{Spec}(\mathbf{Z})$ is quasi-separated, saying that f_α is quasi-separated is equivalent to saying that the composite $X_\alpha \xrightarrow{f_\alpha} U_\alpha \to \mathrm{Spec}(\mathbf{Z})$ is quasi-separated (1.2.2, (ii) and (v)); hence the proposition. □

To verify that a morphism is quasi-separated, we are therefore reduced to giving criteria for a prescheme to be quasi-separated: **IV-1** | 228

Proposition (1.2.7). — *Let X be a prescheme, (U_α) a covering of X formed by quasi-compact open subsets. The following properties are equivalent:*

- *a) X is quasi-separated.*
- *b) For every quasi-compact open subset U of X, the canonical immersion $U \to X$ is quasi-compact (in other words, U is retrocompact in X).*
- *b') The intersection of two quasi-compact open subsets of X is quasi-compact.*
- *c) For every pair of indices (α, β), the intersection $U_\alpha \cap U_\beta$ is quasi-compact.*

Proof. The properties *b)* and *b')* are trivially equivalent by definition of a quasi-compact morphism. As a quasi-compact open subset is a finite union of affine open subsets, for two quasi-compact open subsets U, V of X, $U \times_{\mathbf{Z}} V$ is a quasi-compact open subset of $X \times_{\mathbf{Z}} X$ (**I**, 3.2.7), whose inverse image under Δ_X is $U \cap V$, so *a)* implies *b')*. It is trivial that *b')* implies *c)*; finally, if *c)* is satisfied, the $U_\alpha \times_{\mathbf{Z}} U_\beta$ form a covering of $X \times_{\mathbf{Z}} X$ by quasi-compact open subsets, and we know that for the morphism $\Delta_X : X \to X \times_{\mathbf{Z}} X$ to be quasi-compact, it suffices that the inverse images $U_\alpha \cap U_\beta$ under Δ_X be quasi-compact (1.1.1); so *c)* implies *a)*. □

Corollary (1.2.8). — *Every prescheme X whose underlying space is locally Noetherian* (*for example a locally Noetherian prescheme*) *is quasi-separated; every morphism $f : X \to Y$ is then quasi-separated.*

Proposition (1.2.9). — *Let X', X'' be two preschemes, $X = X' \coprod X''$ their coproduct prescheme, $f' : X' \to Y$, $f'' : X'' \to Y$ two morphisms, $f : X \to Y$ the morphism which coincides with f' on X' and with f'' on X''. For f to be quasi-separated, it is necessary and sufficient that f' and f'' be so.*

Proof. Indeed, $X \times_Y X$ is the coproduct of the four preschemes $X' \times_Y X'$, $X' \times_Y X''$, $X'' \times_Y X'$ and $X'' \times_Y X''$, and Δ_f is the morphism which coincides with $\Delta_{f'}$ on X' and with $\Delta_{f''}$ on X''; the proposition then follows immediately from the definitions. □

1.3. Morphisms locally of finite type

(1.3.1). Recall that if A is a ring, a (commutative) A-algebra B is said to be *of finite type* if it is generated by a finite number of elements of B, or, what amounts to the same thing, if it is isomorphic to a quotient of a polynomial algebra $A[T_1, \ldots, T_n]$ by an ideal of this algebra. It is clear that for every (commutative) A-algebra A', $B \otimes_A A'$ is then an A'-algebra of finite type. If B is an A-algebra of finite type and C a B-algebra of finite type, C is an A-algebra of finite type, for if C is a quotient of $B[T_1, \ldots, T_n]$ and B a quotient of $A[S_1, \ldots, S_m]$, $B[T_1, \ldots, T_n]$ is isomorphic to $A[S_1, \ldots, S_m, T_1, \ldots, T_n]/\mathfrak{a}$, where $\mathfrak{a}$ is the kernel of the surjection $A[S_1, \ldots, S_m, T_1, \ldots, T_n] \to B[T_1, \ldots, T_n]$; hence C is also a quotient of $A[S_1, \ldots, S_m, T_1, \ldots, T_n]$, and so it is indeed an A-algebra of finite type.

Definition (1.3.2). — Let $f : X \to Y$ be a morphism of preschemes, x a point of X, $y = f(x)$. We say that f is *of finite type at x* if there exists an affine open neighbourhood V of y and an affine open neighbourhood U of x such that $f(U) \subset V$ and the ring $A(U)$ is an $A(V)$-algebra of finite type. We say that f is *locally of finite type* if it is of finite type at every point of X.

IV-1 | 229

Proposition (1.3.3). — *If Y is a locally Noetherian prescheme and $f : X \to Y$ a morphism locally of finite type, then X is locally Noetherian.*

For the proof, see (**I**, 6.3.7).

Proposition (1.3.4). —

(i) Every local immersion is locally of finite type.
(ii) If two morphisms $f : X \to Y$, $g : Y \to Z$ are locally of finite type, then so is $g \circ f$.
(iii) If $f : X \to Y$ is an S-morphism locally of finite type, $f_{(S')} : X_{(S')} \to Y_{(S')}$ is locally of finite type for every extension $S' \to S$ of the base prescheme.
(iv) If $f : X \to X'$ and $g : Y \to Y'$ are two S-morphisms locally of finite type, $f \times_S g$ is locally of finite type.
(v) If the composition $g \circ f$ of two morphisms is locally of finite type, f is locally of finite type.
(vi) If a morphism f is locally of finite type, the same is true of f_{red}.

For the proof, see (**I**, 6.6.6).

Corollary (1.3.5). — *Let $f : X \to Y$ be a morphism locally of finite type. For every morphism $Y' \to Y$ such that Y' is locally Noetherian, $X \times_Y Y'$ is locally Noetherian.*

Proof. Indeed, $f_{(Y')} : X \times_Y Y' \to Y'$ is locally of finite type by (1.3.4, (iii)), and it suffices to apply (1.3.3). □

Proposition (1.3.6). — *Let $\varphi : A \to B$ be a homomorphism of rings. For the corresponding morphism $f : \operatorname{Spec}(B) \to \operatorname{Spec}(A)$ to be locally of finite type, it is necessary and sufficient that B be an A-algebra of finite type.*

For the proof, see (**I**, 6.3.3), taking into account that f is quasi-compact and using (**I**, 6.6.3).

Proposition (1.3.7). — *For a morphism locally of finite type $f : X \to Y$ to be surjective, it is necessary and sufficient that, for every algebraically closed field Ω, the map $X(\Omega) \to Y(\Omega)$ corresponding to f (**I**, 3.4.1) be surjective.*

For the proof, see (**I**, 6.3.10).

(1.3.8). Let A be a ring. We say that an A-algebra B is *essentially of finite type* if B is A-isomorphic to an A-algebra of the form $S^{-1}C$, where C is an A-algebra *of finite type* and S a multiplicative subset of C.

Proposition (1.3.9). —

(i) If B is an A-algebra essentially of finite type and C a B-algebra essentially of finite type, then C is an A-algebra essentially of finite type.

(ii) Let B be an A-algebra essentially of finite type, A' an A-algebra; then $B' = B \otimes_A A'$ is an A'-algebra essentially of finite type.

Proof. (i) Let $B = S'^{-1}B'$ and $C = T'^{-1}C'$, where B' (resp. C') is an A-algebra (resp. B-algebra) of finite type and S' (resp. T') a multiplicative subset of B' (resp. C'); then C' is of the form $S'^{-1}C''$, where C'' is also a B'-algebra of finite type, so C is also a ring of fractions of C''; as C'' is an A-algebra of finite type, this proves our assertion.

(ii) If B is a ring of fractions of an A-algebra of finite type C, B' is a ring of fractions of the A'-algebra of finite type $C \otimes_A A'$, which proves (ii).

□

(1.3.10). If B is a *local* A-algebra essentially of finite type, B is of the form $C_{\mathfrak{q}}$, where C is an A-algebra of finite type and $\mathfrak{q}$ a prime ideal of C (Bourbaki, *Alg. comm.*, chap. II, § 5, prop. 11). Let $\mathfrak{p}$ be the inverse image in A of the ideal $\mathfrak{q}$; if we set $S = A - \mathfrak{p}$, $C_{\mathfrak{q}}$ is also the localization of $S^{-1}C$ at a prime ideal; as $S^{-1}C$ is an algebra of finite type over $A_{\mathfrak{p}} = S^{-1}A$, we see that B is also an $A_{\mathfrak{p}}$-algebra *essentially of finite type*, and furthermore the homomorphism $A_{\mathfrak{p}} \to B$ is *local*.

Proposition (1.3.11). — *If B is a local A-algebra essentially of finite type, B is A-isomorphic to a quotient of an A-algebra of the form $C_{\mathfrak{q}}$, where $C = A[T_1, \ldots, T_n]$ is a polynomial algebra over A and $\mathfrak{q}$ a prime ideal of C.*

Proof. Indeed, by definition, B is isomorphic to $C'_{\mathfrak{q}'}$, where C' is an A-algebra of finite type and $\mathfrak{q}'$ a prime ideal of C'; but $C' = C/\mathfrak{b}$, where $C = A[T_1, \ldots, T_n]$ and $\mathfrak{b}$ is an ideal of C; so $\mathfrak{q}' = \mathfrak{q}/\mathfrak{b}$, where $\mathfrak{q}$ is a prime ideal of C, and $C'_{\mathfrak{q}'}$ is isomorphic to $C_{\mathfrak{q}}/\mathfrak{b}C_{\mathfrak{q}}$. □

1.4. Morphisms locally of finite presentation

(1.4.1). Given a ring A, we say that an A-algebra B (commutative) is *of finite presentation* if it is isomorphic to a quotient $A[T_1, \ldots, T_n]/\mathfrak{a}$ of a polynomial algebra over A by an ideal *of finite type* $\mathfrak{a}$ of $A[T_1, \ldots, T_n]$. For every (commutative) A-algebra A', $B \otimes_A A'$ is then an A'-algebra of finite presentation, being isomorphic to the quotient of $A'[T_1, \ldots, T_n]$ by the image of the ideal $\mathfrak{a} \otimes_A A'$ in this ring, which is evidently an $A'[T_1, \ldots, T_n]$-module of finite type. If B is an A-algebra of finite presentation and C a B-algebra of finite presentation, then C is an A-algebra of finite presentation. Indeed, let $B = A[S_1, \ldots, S_m]/\mathfrak{a}$ and $C = B[T_1, \ldots, T_n]/\mathfrak{b}$, where $\mathfrak{a}$ (resp. $\mathfrak{b}$) is an ideal of finite type of $A[S_1, \ldots, S_m]$ (resp. $B[T_1, \ldots, T_n]$); the ring $B[T_1, \ldots, T_n]$ is isomorphic to $A[S_1, \ldots, S_m, T_1, \ldots, T_n]/\mathfrak{a}'$, where $\mathfrak{a}'$ is the canonical image of $\mathfrak{a} \otimes_A A[T_1, \ldots, T_n]$, and is therefore an ideal of finite type of $A[S_1, \ldots, S_m, T_1, \ldots, T_n]$; the ideal $\mathfrak{b}$ of $B[T_1, \ldots, T_n]$ is of the form $\mathfrak{b}'/\mathfrak{a}'$, where $\mathfrak{b}'$ is an ideal of $A[S_1, \ldots, S_m, T_1, \ldots, T_n]$; as $\mathfrak{a}'$ and $\mathfrak{b}'/\mathfrak{a}'$ are modules of finite type over $A[S_1, \ldots, S_m, T_1, \ldots, T_n]$, so is $\mathfrak{b}'$, and C, being isomorphic to $A[S_1, \ldots, S_m, T_1, \ldots, T_n]/\mathfrak{b}'$, is therefore an A-algebra of finite presentation. We note finally that if A is *Noetherian*, then so is $A[T_1, \ldots, T_n]$; hence every A-algebra of finite type is an algebra of finite presentation. **IV-1** | 230

Definition (1.4.2). — Let $f : X \to Y$ be a morphism of preschemes, x a point of X, $y = f(x)$. We say that f is *of finite presentation at x* if there exists an affine open neighbourhood V of y and an affine open neighbourhood U of x such that $f(U) \subset V$ and such that the ring $\mathscr{O}(U)$ is an $\mathscr{O}(V)$-algebra of finite presentation. We say that f is *locally of finite presentation* if it is of finite presentation at every point of X.

If Y is locally Noetherian, it amounts to the same to say that f is locally of finite type or locally of finite presentation.

Proposition (1.4.3). — (i) *Every local isomorphism is locally of finite presentation.*

(ii) *If two morphisms $f : X \to Y$, $g : Y \to Z$ are locally of finite presentation, so is $g \circ f$.*

IV-1 | 231

(iii) If $f : X \to Y$ is an S-morphism locally of finite presentation, $f_{(S')} : X_{(S')} \to Y_{(S')}$ is locally of finite presentation for every base extension $S' \to S$ of the base prescheme.
(iv) If $f : X \to X'$ and $g : Y \to Y'$ are two S-morphisms locally of finite presentation, $f \times_S g$ is locally of finite presentation.
(v) If the composition $g \circ f$ of two morphisms is locally of finite presentation and if g is locally of finite type, then f is locally of finite presentation.

Proof. Assertion (i) is trivial. To prove (iii), we may limit to the case where $S = Y$ (**I**, 3.3.11); let x' be a point of $X_{(S')}$, s' and x its projections on S' and X respectively, s the common projection of s' and x on S. By hypothesis, there exists an affine open neighbourhood V (resp. U) of s (resp. x) such that the image of U is contained in V and such that $\mathscr{O}(U)$ is an $\mathscr{O}(V)$-algebra of finite presentation; let V' be an affine open neighbourhood of s' whose image in S is contained in V; then $U \times_V V'$ is an affine open neighbourhood of x' whose image in S' is contained in V' and whose ring $\mathscr{O}(U) \otimes_{\mathscr{O}(V)} \mathscr{O}(V')$ is an $\mathscr{O}(V')$-algebra of finite presentation (1.4.1).

To prove (ii), consider a point $x \in X$, and let $y = f(x)$, $z = g(f(x))$. There is by hypothesis an affine open neighbourhood $W = \operatorname{Spec}(C)$ (resp. $V = \operatorname{Spec}(B)$) of z (resp. y) such that $g(V) \subset W$ and such that B is a C-algebra of finite presentation. On the other hand, there is an affine open neighbourhood $V' = \operatorname{Spec}(B')$ (resp. $U = \operatorname{Spec}(A)$) of y (resp. x) such that $f(U) \subset V'$ and such that A is a B'-algebra of finite presentation. Let $s \in B$ be such that the open set $D(s) = \operatorname{Spec}(B_s)$ in V is a neighbourhood of y contained in V', and let $U' = f^{-1}(D(s)) \subset U$; we have $U' = \operatorname{Spec}(A \otimes_{B'} B_s)$, and $A \otimes_{B'} B_s$ is a B_s-algebra of finite presentation (1.4.1); on the other hand $B_s = B[T]/(1 - sT)$ is a B-algebra of finite presentation by definition; hence by (1.4.1), $A \otimes_{B'} B_s$ is a C-algebra of finite presentation, which proves (ii).

We know that (iv) follows from (i), (ii), and (iii) (**I**, 3.5.1). To prove (v), consider the commutative diagram

$$\begin{array}{ccc} X & \xrightarrow{\Gamma_f} & X \times_Z Y \\ & & \downarrow{\scriptstyle f\times 1} \\ Y & \xrightarrow[\Delta_g]{} & Y \times_Z Y \end{array}$$

which identifies X with the product of the $(Y \times_Z Y)$-preschemes Y and $X \times_Z Y$ (**I**, 5.3.7), Δ_g being the diagonal morphism. If we know that Δ_g is locally of finite presentation, it will follow by (iii) that so is Γ_f. On the other hand, we have the factorisation of f as $X \xrightarrow{\Gamma_f} X \times_Z Y \xrightarrow{p_2} Y$ (**I**, 5.3.13), where the projection p_2 is equal to $(g \circ f) \times_Z 1_Y$; as $g \circ f$ is assumed locally of finite presentation, so is p_2 by (iv), and it will follow finally from (ii) that f is also locally of finite presentation. We thus see that we are reduced to proving the following. □

Corollary (1.4.3.1). — *Let $g : Y \to Z$ be a morphism locally of finite type; then the diagonal morphism $\Delta_g : Y \to Y \times_Z Y$ is locally of finite presentation.*

IV-1 | 232

Proof. We may reduce to the case where $Z = \operatorname{Spec}(A)$, $Y = \operatorname{Spec}(B)$, B being an A-algebra of finite type; the morphism Δ_g then corresponds to the *augmentation homomorphism* $\delta : B \otimes_A B \to B$ such that $\delta(x \otimes y) = xy$. In view of the definition (1.4.2), it suffices to show that the kernel $\mathfrak{J}$ of δ is an ideal *of finite type*, and this follows from (**0**, 20.4.4). □

Proposition (1.4.4). — *Let A be a ring, B an A-algebra, B' a polynomial algebra $A[T_1, \ldots, T_n]$, $u : B' \to B$ a surjective homomorphism of A-algebras. For B to be an A-algebra of finite presentation, it is necessary and sufficient that the kernel $\mathfrak{J}$ of u be an ideal of finite type of B'.*

Proof. The condition is sufficient by definition (1.4.1). To see that it is necessary, we remark that the morphism $g : \operatorname{Spec}(B') \to \operatorname{Spec}(A)$ is locally of finite type; if B is an A-algebra of finite presentation, the morphism $f : \operatorname{Spec}(B) \to \operatorname{Spec}(B')$ corresponding to u is such that $g \circ f : \operatorname{Spec}(B) \to \operatorname{Spec}(A)$ is locally of finite presentation, and so it follows from (1.4.3, (v)) that f is also locally of finite presentation. Now, to show that the ideal $\mathfrak{J}$ is of finite type, it suffices to prove that $\widetilde{\mathfrak{J}}$ is a $\widetilde{B'}$-module of finite type (**II**, 6.1.4.1). Returning to the definition (1.4.2), we are finally reduced to proving the following. □

Lemma (1.4.4.1). — *Let $\mathfrak{a}$ be an ideal of a ring C, s an element of C, such that $C_s/\mathfrak{a}_s$ is a C-algebra of finite presentation; then $\mathfrak{a}_s$ is an ideal of finite type in the ring C_s.*

Proof. By hypothesis, there exists a polynomial C-algebra $C' = C[T_1, \ldots, T_n]$ and a surjective C-homomorphism $v : C' \to C_s/\mathfrak{a}_s$ whose kernel $\mathfrak{b}$ is of finite type. Let $p : C_s \to C_s/\mathfrak{a}_s$ be the canonical homomorphism; for each i, there is a $t_i \in C$ such that $p(t_i/s^k) = v(T_i)$ (we may assume that the exponent k is the same for all indices i). Consider then the C_s-algebra $D = C_s[T_1, \ldots, T_n]$, and the C_s-algebra homomorphism $w : D \to C_s$ such that $w(T_i) = t_i/s^k$; w is evidently surjective, and so is $v' = p \circ w : D \to C_s/\mathfrak{a}_s$. On the other hand, every polynomial P of D can be written as P/s^m, where $P \in C' = C[T_1, \ldots, T_n]$, and we have $v'(P/s^m) = (1/s^m)v(P)$; as $1/s$ is invertible in C_s, the relation $v'(P/s^m) = 0$ in $C_s/\mathfrak{a}_s$ is equivalent to $v(P) = 0$, and hence the kernel $\mathfrak{b}'$ of v' is generated by the image of $\mathfrak{b}$ in the ring D, and *a fortiori* is *of finite type* in D. But $\mathfrak{b}' = v'^{-1}(0) = w^{-1}(p^{-1}(0)) = w^{-1}(\mathfrak{a}_s)$, and as w is surjective, $\mathfrak{a}_s = w(\mathfrak{b}')$, which proves that $\mathfrak{a}_s$ is an ideal of finite type of C_s. □

Corollary (1.4.5). — *Let X, Y be two preschemes, $j : X \to Y$ an immersion, U an open subset of Y such that $j(X)$ is closed in U, $\mathscr{J}$ the quasi-coherent ideal of $\mathscr{O}_U$ that defines the closed subprescheme of Y associated to j. For j to be locally of finite presentation, it is necessary and sufficient that $\mathscr{J}$ be an $\mathscr{O}_U$-module of finite type.*

Proposition (1.4.6). — *Let $\varphi : A \to B$ be a homomorphism of rings. For the corresponding morphism $f : \operatorname{Spec}(B) \to \operatorname{Spec}(A)$ to be locally of finite presentation, it is necessary and sufficient that B be an A-algebra of finite presentation.*

Proof. The condition being trivially sufficient, it remains to prove that it is necessary. If f is locally of finite presentation, it already follows from (1.3.6) that B is an A-algebra of finite type, so there exists **IV-1** | 233
a surjective homomorphism $u : B' = A[T_1, \ldots, T_n] \to B$ of A-algebras; it follows from (1.4.3, (v)) that the immersion $j : \operatorname{Spec}(B) \to \operatorname{Spec}(B')$ is locally of finite presentation; hence by (1.4.5), if $\mathfrak{J}$ is the kernel of u, the $\widetilde{B'}$-module $\widetilde{\mathfrak{J}}$ is of finite type, and hence by (**II**, 6.1.4.1) $\mathfrak{J}$ is an ideal of finite type. □

Proposition (1.4.7). — *Let $\rho : A \to B$ be a homomorphism of rings making B a finite A-algebra. For B to be an A-algebra of finite presentation, it is necessary and sufficient that B be an A-module of finite presentation.*

We will use the following.

Lemma (1.4.7.1). — *If B is a finite A-algebra, there exists a surjective homomorphism of A-algebras $u : B' \to B$, where B' is a finite A-algebra of finite presentation and a free A-module.*

Proof. Indeed, there is a finite system $(a_i)_{1 \leqslant i \leqslant m}$ of generators of the A-algebra B such that each a_i satisfies a relation $F_i(a_i) = 0$, where $F_i \in A[X]$ is a monic polynomial of degree > 0; the A-algebra quotient $B'_i = A[X]/(F_i)$ is therefore free of finite rank over A; let c_i be the class of X in B'_i. There exists an A-homomorphism of algebras $u_i : B'_i \to B$ such that $u_i(c_i) = a_i$; it then suffices to take for B' the tensor product $B'_1 \otimes_A B'_2 \otimes \ldots \otimes_A B'_m$ and to consider the homomorphism $u_1 \otimes u_2 \otimes \ldots \otimes u_m : B' \to B$, which is surjective by construction. Furthermore, if $B'' = A[T_1, \ldots, T_m]$ and if b'_i denotes the canonical image of c_i in B', the A-homomorphism of algebras $v : B'' \to B'$ such that $v(T_i) = b'_i$ $(1 \leqslant i \leqslant m)$ is surjective, and its kernel $\mathfrak{b}'$ is the ideal of B'' generated by the $F_i(T_i)$, and therefore of finite type; this proves that B' is an A-algebra of finite presentation. □

Proof of (1.4.7). This lemma being proved, let us keep the same notation, and let $w = u \circ v : B'' \to B$.[1] Let $\mathfrak{b}$ (resp. $\mathfrak{a}$) be the kernel of w (resp. u); we have $\mathfrak{a} = v(\mathfrak{b})$ since v is surjective. Now by (1.4.4), if B is an A-algebra of finite presentation, $\mathfrak{b}$ is an ideal of finite type of B'', so $\mathfrak{a}$ is an ideal of finite type of B', hence an A-module of finite type since B' is a finite A-algebra. As B' is a free A-module, B is an A-module of finite presentation. Conversely, if B is an A-module of finite presentation,[2] $\mathfrak{a}$ is an A-module of finite type (Bourbaki, *Alg. comm.*, chap. I, § 2, n° 8, lemme 9) and *a fortiori* an ideal of finite type of B'; hence, B is by definition a B'-algebra of finite presentation, and as B' is an A-algebra of finite presentation, B is an A-algebra of finite presentation. □

[1] The French source prints $v \circ u$; with the displayed domains and codomains, the typed composite is $u \circ v$.

[2] The French source prints B' here; the proposition's hypothesis and the exact sequence $0 \to \mathfrak{a} \to B' \to B \to 0$ require B.

1.5. Morphisms of finite type

Proposition (1.5.1). — *Let $f : X \to Y$ be a morphism, (U_α) a covering of Y by open affines. The following conditions are equivalent:*

a) *f is locally of finite type and quasi-compact.*
b) *For all α, $f^{-1}(U_\alpha)$ is a finite union of affine open sets $V_{\alpha i}$ such that each ring $\mathscr{O}(V_{\alpha i})$ is an $\mathscr{O}(U_\alpha)$-algebra of finite type.*
c) *For every affine open subset U of Y, $f^{-1}(U)$ is a finite union of affine open sets V_j such that the rings $\mathscr{O}(V_j)$ are $\mathscr{O}(U)$-algebras of finite type.*

Proof. For the proof, see (**I**, 6.3.2) and (**I**, 6.6.3). □

Definition (1.5.2). — We say that a morphism f is *of finite type* if it satisfies the equivalent conditions of the proposition (1.5.1).

IV-1 | 234

Proposition (1.5.3). — *Let $f : X \to Y$ be a morphism of finite type; if Y is Noetherian, so is X.*

Proof. For the proof, see (**I**, 6.3.7). □

Proposition (1.5.4). — (i) *Let $j : X \to Y$ be an immersion. If j is quasi-compact (which is the case if j is a closed immersion, or if the underlying space of X is Noetherian, or if the space underlying Y is locally Noetherian), then j is of finite type.*

(ii) *The composition of two morphisms of finite type is of finite type.*

(iii) *If $f : X \to Y$ is an S-morphism of finite type, $f_{(S')} : X_{(S')} \to Y_{(S')}$ is of finite type for every base extension $S' \to S$ of the base prescheme.*

(iv) *If $f : X \to X'$ and $g : Y \to Y'$ are two S-morphisms of finite type, $f \times_S g$ is of finite type.*

(v) *If the composition $g \circ f$ of two morphisms is of finite type and if g is quasi-separated or if X is Noetherian, f is of finite type.*

(vi) *If a morphism f is of finite type, so is f_{red}.*

Proof. This follows immediately (except for the case (v) where X is Noetherian, proved in (**I**, 6.3.6)) from the definitions and from (1.1.2), (1.2.4), and (1.3.4). □

Corollary (1.5.5). — *Let $f : X \to Y$ be a morphism of finite type. For every morphism $Y' \to Y$ such that Y' is Noetherian, $X \times_Y Y'$ is Noetherian.*

Proof. This follows from (1.5.4, (iii)) and from (1.5.3). □

Corollary (1.5.6). — *Let X be a prescheme of finite type over a locally Noetherian prescheme S. Then every S-morphism $f : X \to Y$ is of finite type.*

Proof. For the proof, see (**I**, 6.3.9). □

Proposition (1.5.7). — *Let $\varphi : A \to B$ be a homomorphism of rings. For the corresponding morphism $f : \operatorname{Spec}(B) \to \operatorname{Spec}(A)$ to be of finite type, it is necessary and sufficient that φ make B an A-algebra of finite type.*

Proof. For the proof, see (**I**, 6.3.3). □

1.6. Morphisms of finite presentation

Definition (1.6.1). — Let X, Y be two preschemes. We say that a morphism $f : X \to Y$ is *of finite presentation* if it satisfies the following three conditions:

(i) f is locally of finite presentation;

(ii) f is quasi-compact (which, when (i) is satisfied, is equivalent to saying that f is of finite type (1.5.2));

(iii) f is quasi-separated.

We then also say that X is *of finite presentation over Y*, or a *Y-prescheme of finite presentation*.

Condition (iii) is automatically satisfied if f is separated, or if X is locally Noetherian (1.2.8); when Y is locally Noetherian, it amounts to the same to say that f is *of finite presentation* or that f is *of finite type* (the latter condition implying that X is locally Noetherian (1.3.3)).

IV-1 | 235

Proposition (1.6.2). — (i) *Every quasi-compact immersion that is locally of finite presentation (in particular every quasi-compact open immersion) is of finite presentation.*

(ii) *The composition of two morphisms of finite presentation is of finite presentation.*

(iii) *Let X, Y be two S-preschemes, $f : X \to Y$ an S-morphism of finite presentation. Then, for every morphism $S' \to S$, the morphism $f_{(S')} : X_{(S')} \to Y_{(S')}$ is of finite presentation.*

(iv) *Let $f : X \to Y$, $f' : X' \to Y'$ be two S-morphisms of finite presentation; then $f \times_S f' : X \times_S X' \to Y \times_S Y'$ is of finite presentation.*

(v) *If the composition $g \circ f$ of two morphisms is of finite presentation and if g is quasi-separated and locally of finite presentation, then f is of finite presentation.*

Proof. This follows immediately from (1.1.2), (1.2.2), (1.2.4), and (1.4.3). □

It follows in particular from (1.6.2, (iii)) that if f is a morphism of finite presentation and U an open subset of Y, the restriction $f^{-1}(U) \to U$ of f is a morphism of finite presentation. Conversely, let (U_α) be a covering of Y by open affines, and suppose that the restrictions $f^{-1}(U_\alpha) \to U_\alpha$ of f are morphisms of finite presentation; then f is evidently locally of finite presentation, quasi-compact by virtue of (1.1.1), and quasi-separated by virtue of (1.2.6). We can therefore say that the property for a morphism $f : X \to Y$ of being of finite presentation is *local on Y*.

If X is a quasi-separated prescheme, every morphism $f : X \to Y$ is quasi-separated (1.2.3). Hence, if f is quasi-compact and locally of finite presentation, f is of finite presentation.

In particular:

Corollary (1.6.3). — *Let $\varphi : A \to B$ be a homomorphism of rings. For the corresponding morphism $f : \mathrm{Spec}(B) \to \mathrm{Spec}(A)$ to be of finite presentation, it is necessary and sufficient that φ make B an A-algebra of finite presentation.*

Proof. The necessity of the condition follows from (1.4.6). □

Remark (1.6.4). — In the definition (1.6.1), condition (iii) is not a consequence of the two others. Let for example Y be an affine scheme whose underlying space is not Noetherian, and let U be an open subset that is not quasi-compact in Y. Let X be the prescheme obtained by gluing two preschemes Y_1, Y_2 isomorphic to Y along the open subsets U_1, U_2 corresponding to U ($\mathbf{0_I}$, 4.1.7), so that X is the union of two open subsets isomorphic respectively to Y_1 and Y_2 (and that we identify with them), with $Y_1 \cap Y_2 = U$. Furthermore, there is a morphism $f : X \to Y$ that coincides in Y_i with the isomorphism $Y_i \to Y$ ($i = 1, 2$). It is clear that f satisfies condition (i) of (1.6.1), being a local isomorphism; it also satisfies (ii), the inverse image of an open quasi-compact subset of Y being the union of its images in Y_1 and Y_2; but since $Y_1 \cap Y_2$ is not quasi-compact, f is not quasi-separated (1.2.7).

Proposition (1.6.5). — *Let X', X'' be two preschemes, $X = X' \amalg X''$ their sum, $f' : X' \to Y$, $f'' : X'' \to Y$ two morphisms, $f : X \to Y$ the morphism that coincides with f' in X' and with f'' in X''. For f to be of finite presentation, it is necessary and sufficient that f' and f'' be so.*

Proof. It suffices to show that for f to possess one of the three properties of the definition (1.6.1), it is necessary and sufficient that f' and f'' possess it; this is evident for the property of being locally of finite presentation, which is local on X; for the property of being quasi-compact, this was seen in (1.1.6), and for the property of being quasi-separated, in (1.2.9). □ **IV-1 | 236**

1.7. Improvements of earlier results We will give in this number a list of propositions proved in the preceding chapters, whose statements can be improved with the aid of the new finiteness conditions introduced above.

(1.7.1). In the statements of (**I**, 6.4.2), (**I**, 6.4.3), and (**I**, 6.4.9), we can, instead of assuming that X and Y are of finite type over the field K, assume only that they are *locally of finite type* over K; for (**I**, 6.4.2), it suffices to observe that every point of a prescheme X that is closed in every affine open subset of X is closed in X, and an affine scheme locally of finite type over K is *ipso facto* of finite type over K (1.5.1). For (**I**, 6.4.9), we use (1.3.7) and (1.3.4, (v)).

(1.7.2). In (**I**, 6.5.1, (ii)), we can, instead of assuming that S is locally Noetherian and Y of finite type over S, assume only that Y is *locally of finite presentation* over S, as one shows immediately by applying the definition (1.4.2). Similarly in (**I**, 6.5.4, (ii)) and (**I**, 6.5.5, (ii)) it suffices to assume that f is an S-morphism, Y being *locally of finite presentation* over S.

(1.7.3). In (**I**, 7.1.11), for the second assertion, instead of assuming S locally Noetherian and Y of finite type over S, we can assume only Y locally of finite presentation over S (the proof depending on (**I**, 6.5.1, (ii))); similarly in (**I**, 7.1.12) to (**I**, 7.1.15).

(1.7.4). In (**I**, 9.2.2), we can replace the three hypotheses by the single hypothesis (implied by each of the others) that f is *quasi-compact and quasi-separated*, by virtue of (1.2.6) and (1.2.7). We note that in (**I**, 9.2.1), the hypothesis means exactly that f is quasi-compact and quasi-separated.

(1.7.5). In (**I**, 9.3.1), (**I**, 9.3.2), and (**I**, 9.3.3), we can replace the two hypotheses on X by the (weaker) hypothesis that X is a prescheme *quasi-compact and quasi-separated*, the proof using these two properties (by virtue of (1.2.7)).

(1.7.6). In (**I**, 9.3.4) and (**I**, 9.3.5), it suffices to assume X quasi-compact, $\mathscr{F}$ and $\mathscr{J}$ quasi-coherent and of finite type.

(1.7.7). In (**I**, 9.4.7), we can weaken hypothesis b) by assuming only X *quasi-separated*, since it suffices that the canonical immersion $U \to X$ be quasi-compact (1.2.7). We can make the same modification in (**I**, 9.4.8), (**I**, 9.4.9), and (**I**, 9.4.10).

(1.7.8). In (**I**, 9.5.1), the conditions indicated in parentheses in the statement can be replaced by the condition that f be quasi-compact and quasi-separated.

(1.7.9). In (**I**, 9.6.5), we can replace the hypotheses on X by the weaker hypothesis that X is *quasi-compact and quasi-separated*, as the proof shows, which uses only (**I**, 9.4.7). In (**I**, 9.6.6), the hypothesis "X is a quasi-compact scheme" may be replaced by "X is a prescheme quasi-compact and quasi-separated". **IV-1** | 237

(1.7.10). In (**II**, 1.7.15), we can suppose only that Y is quasi-compact and quasi-separated, the proof using only (**I**, 9.6.5).

(1.7.11). In the second assertion of (**II**, 3.4.5), we can substitute for the two hypotheses on Y the weaker hypothesis that Y is quasi-compact and quasi-separated. Similarly in (**II**, 3.4.8).

(1.7.12). In (**II**, 3.8.5), we can similarly suppose only that Y is quasi-compact and quasi-separated, this hypothesis entering through (**I**, 9.4.7).

(1.7.13). In (**II**, 4.4.1), (**II**, 4.4.6), and (**II**, 4.4.7), it suffices to assume that Y is *quasi-compact and quasi-separated*, in view of (1.2.3) in the proof of (**II**, 4.4.7). Similarly, in (**II**, 4.4.10.1), it suffices to assume that Z is quasi-compact and quasi-separated.

(1.7.14). In (**II**, 4.5.2) and (**II**, 4.5.5), it suffices to assume X *quasi-compact and quasi-separated*, this hypothesis entering through (**I**, 9.3.1) and (**I**, 9.3.2).

(1.7.15). In (**II**, 4.6.8), it suffices still to assume X *quasi-compact and quasi-separated*, this hypothesis entering through (**I**, 9.4.7).

(1.7.16). In (**II**, 5.1.2), it suffices to assume that X is quasi-compact and quasi-separated (the hypothesis entering through (**II**, 4.5.2) and (**II**, 4.5.5)). Similarly in (**II**, 5.1.9), where we use (**I**, 9.6.5).

(1.7.17). In (**II**, 5.2.1), it suffices always to assume X quasi-compact and quasi-separated (the hypothesis entering through (**II**, 4.5.2)).

(1.7.18). In (**II**, 5.2.2), one must assume f *quasi-compact* and X *quasi-separated*; the current proof is in fact insufficient (with the hypotheses made), for from the fact that for every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$ we have $\mathrm{R}^1 f_*(\mathscr{F}) = 0$, it does not follow, necessarily, for an affine open subset U of Y, that the same property holds for quasi-coherent $(\mathscr{O}_X|f^{-1}(U))$-modules, if one does not know that such a module is the restriction of a quasi-coherent $\mathscr{O}_X$-module (the same remark applying to conditions b) and c′)); when f is quasi-compact and X quasi-separated, this extension is possible by virtue of (**I**, 9.4.7), modified above (1.7.7).

(1.7.19). In (**II**, 5.3.2), it suffices to assume Y *quasi-compact and quasi-separated* (this hypothesis entering through (**II**, 4.4.6) and (**II**, 4.4.7)). Similarly in (**II**, 5.5.3, (ii)).

(1.7.20). In (**III**, 1.2.2), (**III**, 1.2.3), and (**III**, 1.2.4), we can replace the two hypotheses on X by the weaker hypothesis that X is a prescheme *quasi-compact and quasi-separated*, the proof using only (**I**, 9.3.3).

(1.7.21). In (**III**, 1.4.10) to (**III**, 1.4.14), we can replace "separated" by "quasi-separated", this hypothesis serving only to be able to apply (**I**, 9.2.2) (see above (1.7.4)). Similarly, in (**III**, 1.4.15), it suffices to assume that the morphism u is *quasi-separated and quasi-compact*.

(1.7.22). In (**III**, 2.1.3), we can again replace the hypotheses by the weaker hypothesis that X is a prescheme quasi-compact and quasi-separated, the reasoning being the same as in (**III**, 1.2.2).

1.8. Morphisms of finite presentation and constructible sets **IV-1** | 238

(1.8.1). Let X be a prescheme; we know that every quasi-compact open subset of X is a finite union of affine open subsets, and conversely. For an open subset U of X to be *retrocompact* in X ($\mathbf{0}_{\mathbf{III}}$, 9.1.1), it is necessary and sufficient that for every *open affine* subset V of X, $U \cap V$ be quasi-compact. When X is *quasi-separated* (1.2.1), every quasi-compact open subset of X is retrocompact in X (1.2.7), so every locally constructible part of X is retrocompact in X ($\mathbf{0}_{\mathbf{III}}$, 9.1.13); if *in addition* X is *quasi-compact*, constructible subsets and locally constructible subsets of X coincide ($\mathbf{0}_{\mathbf{III}}$, 9.1.12), as do constructible open subsets and quasi-compact open subsets ($\mathbf{0}_{\mathbf{III}}$, 9.1.5).

Proposition (1.8.2). — *Let X, Y be two preschemes, $f : X \to Y$ a morphism. For every constructible (resp. locally constructible) part Z of Y, $f^{-1}(Z)$ is a constructible (resp. locally constructible) part of X.*

Proof. Suppose Z locally constructible; for every $x \in X$, there will be an affine open neighbourhood V of $f(x)$ such that $Z \cap V$ is constructible in V; if the proposition is proved for constructible parts, $f^{-1}(Z) \cap f^{-1}(V)$ will be constructible in $f^{-1}(V)$, so $f^{-1}(Z)$ will be locally constructible. It therefore suffices to consider the case where Z is constructible, and taking into account ($\mathbf{0}_{\mathbf{III}}$, 9.1.3), we are reduced to the case where Z is open and *retrocompact* in Y, in other words such that the canonical injection $Z \to Y$ is a quasi-compact morphism; it then suffices to see that $f^{-1}(Z)$ is *retrocompact in* X, in other words such that the canonical injection $f^{-1}(Z) \to X$ is a quasi-compact morphism; but this follows from (1.1.2, (iii)), since $f^{-1}(Z) = Z \times_Y X$ (**I**, 4.4.1). □

Lemma (1.8.3). — *Let X be a prescheme quasi-compact and quasi-separated, Z a constructible part of X. There exists then an affine scheme X' and a morphism of finite presentation $f : X' \to X$ such that $f(X') = Z$.*

Proof. Since X is quasi-compact, it is a finite union of affine open subsets X_i ($i \in \mathrm{I}$), and since X is quasi-separated, it follows from (1.2.7) that each of the canonical immersions $g_i : X_i \to X$ is of finite presentation; one concludes that if $f_i : X'_i \to X_i$ is a morphism of finite presentation, the same is true of $g_i \circ f_i : X'_i \to X$ (1.6.2), and if X' is the prescheme sum of the X'_i, the morphism $h : X' \to X$ which coincides with $g_i \circ f_i$ in each X'_i is also of finite presentation (1.6.5). Since $Z \cap X_i$ is constructible in X_i ($\mathbf{0}_{\mathbf{III}}$, 9.1.8), we see that we are reduced to proving the lemma when X_i is *affine* of ring A. Since Z is then a finite union of sets of the form $U \cap \complement V$, where U and V are quasi-compact open subsets ($\mathbf{0}_{\mathbf{III}}$, 9.1.3), one sees, by considering yet another suitable sum of preschemes, that one can reduce to the case where $Z = U \cap \complement V$; since moreover U is a finite union of affine open subsets, one can even restrict ourselves to the case where U is *affine*. Since V is quasi-compact, it is a finite union of open subsets of the form X_{f_i}, where $f_i \in A$; let $\mathfrak{J}$ be the ideal of A generated by the f_i, and let Z' be the closed affine subscheme of X that it defines (and which is by construction of finite presentation over X); one has by definition $V = \complement Z'$, so $U \cap \complement V = U \cap Z'$. Consider the affine scheme $X' = Z' \times_X U$ and let $f : X' \to X$ be the structural morphism; we just saw that the canonical immersion $Z' \to X$ **IV-1** | 239 is of finite presentation, and it is the same for the open immersion $U \to X$, which is quasi-compact since U and X are affine; one concludes therefore from (1.6.2, (iv)) that f is of finite presentation, and one has $f(X') = Z' \cap U$ (**I**, 3.4.8), which completes the proof. □

Theorem (1.8.4). — (Chevalley). — *Let $f : X \to Y$ be a morphism of finite presentation. For every locally constructible part Z of X, $f(Z)$ is locally constructible in Y.*

Proof. Let $y \in Y$ and V an open affine neighbourhood of y; since f is quasi-compact and quasi-separated, the same is true of its restriction $f^{-1}(V) \to V$, so $f^{-1}(V)$ is a quasi-compact and quasi-separated prescheme (1.2.3); since $Z \cap f^{-1}(V)$ is constructible in $f^{-1}(V)$ (1.8.1), we see that one can restrict ourselves to the case where Y is affine and Z constructible; X is then quasi-compact and quasi-separated, so by (1.8.3) there exists a morphism of finite presentation $g : X' \to X$ such that $Z = g(X')$; since $f \circ g$ is of finite presentation, we see that we are reduced to the case where $Z = X$; in other words, it will suffice to prove the □

Lemma (1.8.4.1). — *Let Y be an affine scheme, $f : X \to Y$ a morphism quasi-compact and locally of finite presentation; then $f(X)$ is a constructible part of Y.*

Proof. Since X is quasi-compact, it is a finite union of affine open subsets; one can therefore restrict ourselves to the case where $Y = \operatorname{Spec}(A)$, $X = \operatorname{Spec}(B)$, B being an A-algebra of finite presentation (1.4.6). Now we have the □

Lemma (1.8.4.2). — *Let A_0 be a ring, $(A_\lambda)_{\lambda \in \mathrm{L}}$ an inductive system of A_0-algebras, $A = \varinjlim A_\lambda$; if B is an A-algebra of finite presentation, there exist a λ and an A_λ-algebra of finite presentation B_λ such that B is isomorphic to $B_\lambda \otimes_{A_\lambda} A$.*

Proof. By hypothesis, B is isomorphic to an algebra of the form $A[\mathrm{T}_1, \ldots, \mathrm{T}_n]/\mathfrak{J}$, where the T_i are indeterminates and $\mathfrak{J}$ an ideal of finite type; let (F_j) $(1 \leqslant j \leqslant m)$ be a system of generators of $\mathfrak{J}$. Let $\varphi_\lambda : A_\lambda \to A$ be the canonical homomorphism. Since L is filtering, there exists λ such that each of the coefficients of each of the polynomials F_j is the image by φ_λ of an element of A_λ. In other words, there exists a system of polynomials $(\mathrm{F}_{j\lambda})_{1 \leqslant j \leqslant m}$ of $A_\lambda[\mathrm{T}_1, \ldots, \mathrm{T}_n]$ such that $\mathrm{F}_j = \varphi_\lambda(\mathrm{F}_{j\lambda})$ for $1 \leqslant j \leqslant m$. If $\mathfrak{J}_\lambda$ is the ideal of $A_\lambda[\mathrm{T}_1, \ldots, \mathrm{T}_n]$ generated by the $\mathrm{F}_{j\lambda}$, $\mathfrak{J}$ is the image of $\mathfrak{J}_\lambda \otimes_{A_\lambda} A$ in $A[\mathrm{T}_1, \ldots, \mathrm{T}_n] = A_\lambda[\mathrm{T}_1, \ldots, \mathrm{T}_n] \otimes_{A_\lambda} A$; the ring $B_\lambda = A_\lambda[\mathrm{T}_1, \ldots, \mathrm{T}_n]/\mathfrak{J}_\lambda$ has the required property. □

We apply this lemma here by considering A as the inductive limit of its sub-**Z**-algebras *of finite type*. One sees that there exist such a sub-**Z**-algebra A_0 of A, and an A_0-algebra of finite presentation B_0 such that B is isomorphic to $B_0 \otimes_{A_0} A$; let us set $X_0 = \operatorname{Spec}(B_0)$, $Y_0 = \operatorname{Spec}(A_0)$, so that $X = X_0 \times_{Y_0} Y$, f being the projection $X \to Y$; let $f_0 : X_0 \to Y_0$, $g_0 : Y \to Y_0$ be the structural morphisms; it follows from (**I**, 3.4.8) that $f(X) = g_0^{-1}(f_0(X_0))$; taking into account (1.8.2), it therefore suffices to show that $f_0(X_0)$ is constructible. In other words, one is finally reduced to proving the

Corollary (1.8.5). — *Let Y be a Noetherian prescheme, $f : X \to Y$ a morphism of finite type. For every constructible part Z of X, $f(Z)$ is a constructible part of Y.*

IV-1 | 240

Proof. One reduces as above to proving that $f(X)$ is constructible. Let us apply the criterion ($\mathbf{0_{III}}$, 9.2.3): one must prove that for every irreducible closed part T of Y, $T \cap f(X) = f(f^{-1}(T))$ is rare in T or contains a non-empty open subset of T; taking a subscheme of Y whose underlying space is T (**I**, 5.2.1) and considering its inverse image by f, one sees finally (taking into account (1.5.4, (iii))) that one is reduced to proving that if one supposes Y *irreducible and f dominant*, $f(X)$ contains a non-empty open subset of Y. One can moreover suppose Y affine; then X is a finite union of affine open subsets V_i, and since $f(X)$ is dense in Y, the same is true of at least one of the $f(V_i)$. One can therefore also suppose X affine; if (X_j) is the (finite) family of irreducible components of X, one sees as above that at least one of the $f(X_j)$ is dense in Y; one can therefore suppose X irreducible. Finally, by replacing f by f_{red} (1.5.4, (vi)) one can suppose X and Y *integral*. Then $X = \mathrm{Spec}(B)$, $Y = \mathrm{Spec}(A)$, where A is an integral Noetherian ring, B an integral A-algebra of finite type containing A (**I**, 1.2.7). It suffices to show that there exists $g \in A$ such that, for every $y \in \mathrm{D}(g)$ (that is to say such that $g \notin \mathfrak{p}_y$) the ideal $\mathfrak{p}_y$ is the intersection of A and a prime ideal of B, for this will show that $\mathrm{D}(g) \subset f(X)$. Finally it suffices to prove the □

Lemma (1.8.5.1). — *Let A be an integral ring, B an integral A-algebra of finite type. There exists $g \in A$ such that every homomorphism of A into an algebraically closed field Ω, non-zero on g, extends to a homomorphism of B into Ω.*

Proof. This is a classical result of commutative algebra (Bourbaki, *Alg. comm.*, chap. V, § 3, n° 1, cor. 3 of th. 1). □

Corollary (1.8.6). — *Let Y be an irreducible prescheme, η its generic point, $f : X \to Y$ a morphism locally of finite type. If $f^{-1}(\eta)$ is not empty, there exists a neighbourhood U open of η in Y such that $f^{-1}(y)$ is non-empty for every $y \in U$. If $\mathscr{F}$ is a quasi-coherent $\mathscr{O}_X$-module of finite type, and if $\mathscr{F}_\eta = \mathscr{F} \otimes_{\mathscr{O}_Y} k(\eta)$ is not zero, then there exists a neighbourhood U' of η in Y such that $\mathscr{F}_y = \mathscr{F} \otimes_{\mathscr{O}_Y} k(y)$ is not zero for every $y \in U'$.*

Proof. If p_y is the canonical projection of the fibre $f^{-1}(y) = X \times_Y \mathrm{Spec}(k(y))$ to X, one has $\mathscr{F}_y = p_y^*(\mathscr{F})$, so $\mathrm{Supp}(\mathscr{F}_y) = p_y^{-1}(\mathrm{Supp}(\mathscr{F})) = \mathrm{Supp}(\mathscr{F}) \cap f^{-1}(y)$ by virtue of (**I**, 9.1.13.1) and (**I**, 3.6.1), since $\mathscr{F}$ is of finite type; moreover $\mathrm{Supp}(\mathscr{F})$ is closed in X ($\mathbf{0}_{\mathbf{I}}$, 5.2.2), and if Z is a closed subscheme of X having as underlying space $\mathrm{Supp}(\mathscr{F})$ (**I**, 5.2.1), and j the canonical immersion $Z \to X$, $f \circ j$ is locally of finite type (1.3.4); this proves that the first assertion implies the second. To prove the first assertion, let us first note that one can suppose X and Y reduced (1.3.4, (vi)), in other words Y *integral*. Let ξ be a point of $f^{-1}(\eta)$; one can replace X and Y by affine open neighbourhoods of ξ and η respectively, and thus suppose that $X = \mathrm{Spec}(B)$, $Y = \mathrm{Spec}(A)$, B being an A-algebra of finite type. Moreover, if Z is the reduced closed subscheme of X having $\overline{\{\xi\}}$ as underlying set (**I**, 5.2.1), one can, as above, replace X by Z, in other words suppose B *integral* (**I**, 5.1.4). Since the morphism f is then dominant, the corresponding homomorphism $\varphi : A \to B$ is injective (**I**, 1.2.7); the corollary therefore follows finally from the lemma (1.8.5.1). □

IV-1 | 241

Proposition (1.8.7). — *Let S be a prescheme, $g : X \to S$, $h : Y \to S$ two morphisms of finite presentation, $f : X \to Y$ an S-morphism. For every $s \in S$, let $X_s = g^{-1}(s) = X \times_S \mathrm{Spec}(k(s))$, $Y_s = h^{-1}(s) = Y \times_S \mathrm{Spec}(k(s))$, $f_s = f \times 1 : X_s \to Y_s$. Then the set of $s \in S$ such that f_s is surjective (resp. radicial) is locally constructible.*

Proof. Let E be the set of $s \in S$ such that f_s is surjective; the set $S - E$ is equal to $h(Y - f(X))$; now f is of finite presentation (1.6.2, (v)) so $f(X)$ is locally constructible in Y (1.8.4); since h is of finite presentation, $h(Y - f(X))$ is locally constructible in S, and therefore also E.

To show that the set E' of $s \in S$ such that f_s is radicial is locally constructible, we will use the □

Lemma (1.8.7.1). — *Let U, V be two preschemes; for a morphism $f : U \to V$ to be radicial, it is necessary and sufficient that the diagonal morphism $\Delta_f : U \to U \times_V U$ is surjective. Consequently, every radicial morphism is separated.*

Proof. Indeed, Δ_f being an immersion (**I**, 5.3.9), is a morphism locally of finite type (1.3.4); to say that Δ_f is surjective therefore means that for every algebraically closed field K, the corresponding map $U(K) \to (U \times_V U)(K) = U(K) \times_{V(K)} U(K)$ is surjective (1.3.7) and (**I**, 3.4.2.1); but by definition of a fibre product of sets, this means that the map $U(K) \to V(K)$ corresponding to f is injective, and this is equivalent to saying that f is radicial (**I**, 3.5.5).

This being so, Δ_{f_s} is deduced from $\Delta_f : X \to X \times_Y X$ by the base change $\mathrm{Spec}(k(s)) \to S$ (**I**, 5.3.4). Since f is of finite presentation, it is the same for the structural morphism $X \times_Y X \to Y$ (1.6.2, (iv)), so also for Δ_f (1.6.2, (v)); it therefore suffices to apply the first part of the proposition to Δ_f, using the lemma (1.8.7.1). □

1.9. Pro-constructible sets and ind-constructible sets

Lemma (1.9.1). — *Let $(A_\alpha)_{\alpha\in\mathrm{I}}$ be an inductive system of rings with index set* I *filtering to the right, and let $A = \varinjlim A_\alpha$. For $A = 0$, it is necessary and sufficient that there exists an index γ such that $A_\gamma = 0$ (and one then has $A_\beta = 0$ for every $\beta \geqslant \gamma$).*

Proof. Indeed, for every $\alpha \in \mathrm{I}$, the canonical homomorphism $\varphi_\alpha : A_\alpha \to A$ sends the unit element to the unit element; to say that $A = 0$ means that $\varphi_\alpha(1) = 0$, or again $\varphi_\alpha(1) = \varphi_\alpha(0)$; one knows that this is equivalent to saying that there exists an index $\gamma \geqslant \alpha$ such that the homomorphism $\varphi_{\gamma\alpha} : A_\alpha \to A_\gamma$ is such that $\varphi_{\gamma\alpha}(1) = \varphi_{\gamma\alpha}(0)$, and this last relation is equivalent to $A_\gamma = 0$, whence the lemma. □

Proposition (1.9.2). — *Let B be a ring, $(A_\alpha)_{\alpha\in\mathrm{I}}$ an inductive system of B-algebras with index set* I *filtering to the right, and let $A = \varinjlim A_\alpha$; set $Y = \mathrm{Spec}(B)$, $X = \mathrm{Spec}(A)$, $X_\alpha = \mathrm{Spec}(A_\alpha)$, and let $u : X \to Y$, $u_\alpha : X_\alpha \to Y$ be the morphisms corresponding to the structural homomorphisms $B \to A$, $B \to A_\alpha$. Then:*

(1.9.2.i). *For $X = \varnothing$, it is necessary and sufficient that there exists $\gamma \in \mathrm{I}$ such that $X_\gamma = \varnothing$, and one then has $X_\alpha = \varnothing$ for $\alpha \geqslant \gamma$.*

IV-1 | 242

(1.9.2.ii). *We have*

(1.9.2.1) $$u(X) = \bigcap_{\alpha\in\mathrm{I}} u_\alpha(X_\alpha).$$

The assertion (i) is nothing other than the translation of (1.9.1). To prove (ii), note that, since u factors as $X \longrightarrow X_\alpha \xrightarrow{u_\alpha} Y$, the left-hand side is contained in the right-hand side. Conversely, let $y \in Y - u(X)$; one has $u^{-1}(y) = \varnothing$, and $u^{-1}(y)$ is the space underlying the $k(y)$-prescheme $\mathrm{Spec}(A \otimes_B k(y))$; since in the category of B-modules the functor $\varinjlim$ commutes with the tensor product, $A \otimes_B k(y)$ is the inductive limit of the system of rings $A_\alpha \otimes_B k(y)$; the lemma (1.9.1) shows that there exists α such that $A_\alpha \otimes_B k(y) = 0$, that is to say $u_\alpha^{-1}(y) = \varnothing$, so $y \notin u_\alpha(X_\alpha)$.

Proposition (1.9.3). — *Let X be a quasi-compact and quasi-separated prescheme, let E be a part of X, let $(X_\alpha)_{\alpha\in\mathrm{I}}$ be an affine open cover of X, and, for every $\alpha \in \mathrm{I}$, let $E_\alpha = E \cap X_\alpha$. The following conditions are equivalent:*

- *a) There exists a quasi-compact morphism $f : X' \to X$ such that $E = f(X')$.*
- *a′) For every α, there exists a quasi-compact morphism $f_\alpha : X'_\alpha \to X_\alpha$ such that $E_\alpha = f_\alpha(X'_\alpha)$.*
- *a″) For every α, there exist an affine scheme X'_α and a morphism $f_\alpha : X'_\alpha \to X_\alpha$ such that $f_\alpha(X'_\alpha) = E_\alpha$.*
- *b) E is an intersection of constructible parts of X.*
- *b′) $F = X - E$ is a union of constructible parts of X.*

Proof. It is clear that *b*) and *b′*) are equivalent. The condition *a*) implies *a′*) by taking for X'_α the prescheme induced on the open subset $f^{-1}(X_\alpha)$ of X' and for f_α the restriction of f. To see that *a′*) implies *a″*), it suffices to remark that X'_α is a union of affine open subsets $X''_{\alpha\lambda}$ ($\lambda \in \mathrm{L}$); let X''_α be the prescheme *sum* of the $X''_{\alpha\lambda}$ ($\lambda \in \mathrm{L}$), which is an affine scheme; if $g_\alpha : X''_\alpha \to X'_\alpha$ is the morphism coinciding with the identity in each $X''_{\alpha\lambda}$, it is clear that if one sets $f'_\alpha = f_\alpha \circ g_\alpha$, one has $E_\alpha = f'_\alpha(X''_\alpha)$ since g_α is surjective. To show that *a″*) implies *a*), note that there is a finite part J of I such that the X_α for $\alpha \in \mathrm{J}$ cover X; let X' be the prescheme sum of the X'_α for $\alpha \in \mathrm{J}$, and let $f : X' \to X$ be the morphism coinciding with $j_\alpha \circ f_\alpha$ for every $\alpha \in \mathrm{J}$, where $j_\alpha : X_\alpha \to X$ is the canonical injection. Since E is the union of the $E \cap X_\alpha$ for $\alpha \in \mathrm{J}$, one has $E = f(X')$ and it remains to see that f is a quasi-compact morphism; but the hypothesis that X is quasi-separated implies that j_α is quasi-compact (1.2.7), so $j_\alpha \circ f_\alpha$ is quasi-compact (1.1.1) and (1.1.2), and hence so is f (1.1.6).

It remains therefore to prove the equivalence of *a″*) and *b*). Let us first prove that *a″*) implies *b*): let us consider a finite part J of I such that the X_α for $\alpha \in \mathrm{J}$ cover X; it will suffice to show that, for every $\alpha \in \mathrm{J}$, E_α is an intersection of constructible parts $\mathrm{F}_{\alpha\lambda}$ of X_α ($\lambda \in \mathrm{L}_\alpha$); indeed, every $\mathrm{F}_{\alpha\lambda}$ is also a constructible part of X by virtue of ($\mathbf{0}_{\mathbf{III}}$, 9.1.8, (ii)), since the hypothesis that X is quasi-separated implies that every X_α is retrocompact in X (1.2.7); since E is the union of the E_α for $\alpha \in \mathrm{J}$, it is the intersection of the finite unions $\bigcup_{\alpha\in\mathrm{J}} \mathrm{F}_{\alpha,\lambda(\alpha)}$, over all choices of $\lambda(\alpha) \in \mathrm{L}_\alpha$; these finite unions are constructible parts of X, which proves our assertion. We may therefore reduce to the case where **IV-1 | 243**

$X = \mathrm{Spec}(A)$ and $E = f(X')$, with $X' = \mathrm{Spec}(A')$ affine and $f : X' \to X$ corresponding to a homomorphism of rings $A \to A'$. Let us note now that A' is the inductive limit of the family (A'_λ) of its sub-A-algebras *of finite type*, ordered by inclusion; if $X'_\lambda = \mathrm{Spec}(A'_\lambda)$, f factors as $X' \to X'_\lambda \xrightarrow{f_\lambda} X$ and it follows from (1.9.2, (ii)) that $f(X') = \bigcap_\lambda f_\lambda(X'_\lambda)$; if one shows that $f_\lambda(X'_\lambda)$ is an intersection of constructible parts of X, it will be the same for $f(X')$. We may therefore reduce to the case where A' is an A-algebra *of finite type*. Now, we have the following lemma: □

Lemma (1.9.3.1). — *Let A be a ring, A' an A-algebra of finite type. Then A' is A-isomorphic to a filtering inductive limit $\varinjlim A''_\mu$ where the A''_μ are A-algebras of finite presentation* (1.4.1).

Proof. Indeed, one can write $A' = B/\mathfrak{J}$, with $B = A[\mathrm{T}_1, \ldots, \mathrm{T}_n]$ and $\mathfrak{J}$ an ideal of B. But $\mathfrak{J}$ is inductive limit of the ideals *of finite type* $\mathfrak{J}'_\mu$ of B, contained in $\mathfrak{J}$, ordered by inclusion; since in the category of B-modules the functor $\varinjlim$ is exact, one concludes that $A' = \varinjlim B/\mathfrak{J}'_\mu$ up to A-isomorphism. □

The same reasoning as above then permits us to reduce to the case where A' is an A-algebra of finite presentation; but then $f(X')$ is constructible in X by virtue of the theorem of Chevalley (1.8.4),[3] which proves *b*).

Let us prove finally that *b*) implies *a''*). If E is an intersection of a family $(G_\lambda)_{\lambda\in\mathrm{L}}$ of constructible parts of X, each E_α is an intersection of the $G_\lambda \cap X_\alpha$, which are constructible in X_α ($\mathbf{0}_{\mathbf{III}}$, 9.1.8, (i)), and one is reduced to the case where $X = \mathrm{Spec}(A)$ is affine.

One knows then (1.8.3) that for every $\lambda \in \mathrm{L}$ there exists a morphism $f_\lambda : X'_\lambda \to X$, where $X'_\lambda = \mathrm{Spec}(A'_\lambda)$ is affine, such that $f_\lambda(X'_\lambda) = G_\lambda$. It therefore suffices to prove the following lemma:

Lemma (1.9.3.2). — *Let $(A'_\lambda)_{\lambda\in\mathrm{L}}$ be a family of A-algebras, $X = \mathrm{Spec}(A)$, $X'_\lambda = \mathrm{Spec}(A'_\lambda)$, and let $f_\lambda : X'_\lambda \to X$ be the structural morphism. For every finite part J of L, set $A'_\mathrm{J} = \bigotimes_{\lambda\in\mathrm{J}} A'_\lambda$ (tensor product of A-algebras), $X'_\mathrm{J} = \mathrm{Spec}(A'_\mathrm{J})$, and let $f_\mathrm{J} : X'_\mathrm{J} \to X$ be the structural morphism. One then has $f_\mathrm{J}(X'_\mathrm{J}) = \bigcap_{\lambda\in\mathrm{J}} f_\lambda(X'_\lambda)$. If $A' = \varinjlim A'_\mathrm{J}$, J running through the set of finite parts of L, $X' = \mathrm{Spec}(A')$ and $f : X' \to X$ is the structural morphism, one has $f(X') = \bigcap_{\lambda\in\mathrm{L}} f_\lambda(X'_\lambda)$.*

Proof. The first assertion follows from (**I**, 3.4.7); the second follows from (1.9.2, (ii)), which gives the relation $f(X') = \bigcap_\mathrm{J} f_\mathrm{J}(X'_\mathrm{J})$. □

Definition (1.9.4). — Let X be a topological space. We say that a part E of X is *pro-constructible* (resp. *ind-constructible*) in X if, for every $x \in X$, there exists an open neighbourhood U of x in X such that $E \cap U$ is an intersection (resp. a union) of locally constructible parts of U.

Taking into account (1.2.7), ($\mathbf{0}_{\mathbf{III}}$, 9.1.8), and ($\mathbf{0}_{\mathbf{III}}$, 9.1.12), the equivalent conditions of the proposition (1.9.3) are therefore expressed by saying that E is *pro-constructible* in X, the locally constructible parts of X being identical to the constructible parts of X under the hypotheses of (1.9.3).

IV-1 | 244

Proposition (1.9.5). — *Let X be a prescheme.*

(i) *For a part E of X to be pro-constructible, it is necessary and sufficient that $X - E$ be ind-constructible.*
(ii) *Every finite union and every intersection of pro-constructible parts of X are pro-constructible. Every finite intersection and every union of ind-constructible parts of X are ind-constructible.*
(iii) *Every intersection (resp. union) of locally constructible parts of X is pro-constructible (resp. ind-constructible). Conversely, if X is quasi-compact and quasi-separated, every pro-constructible (resp. ind-constructible) part of X is intersection (resp. union) of constructible parts of X.*
(iv) *Let (U_α) be an open cover of X. For a part E of X to be pro-constructible (resp. ind-constructible) in X, it is necessary and sufficient that for every α, $E \cap U_\alpha$ be pro-constructible (resp. ind-constructible) in U_α.*[4]
(v) *Every pro-constructible part E of X is retrocompact in X. For a locally closed part E of X to be retrocompact, it is necessary and sufficient that it be pro-constructible in X.*
(vi) *Let $f : X' \to X$ be a morphism of preschemes; for every pro-constructible (resp. ind-constructible) part E of X, $f^{-1}(E)$ is pro-constructible (resp. ind-constructible) in X'.*

[3] The French source cites (1.8.5), but Chevalley's theorem is (1.8.4).

[4] The French source prints *rep.* in place of *resp.* in this item.

(vii) *Let $f : X' \to X$ be a quasi-compact morphism; for every pro-constructible part E' of X', $f(E')$ is pro-constructible in X; in particular $f(X')$ is pro-constructible in X.*

(viii) *Let $f : X' \to X$ be a morphism locally of finite presentation; for every ind-constructible part E' of X', $f(E')$ is ind-constructible in X; in particular $f(X')$ is ind-constructible in X.*

(ix) *Suppose that X is quasi-compact and quasi-separated; then, for a part E of X to be pro-constructible, it is necessary and sufficient that there exist an affine scheme X' and a (necessarily quasi-compact) morphism $f : X' \to X$ such that $E = f(X')$.*

Proof. Properties (i), (ii), (iv) and the first assertion of (iii) follow from the definition (1.9.4) and are valid for any topological space, using the mutual distributivity of intersection and union and the fact that if T is locally constructible in X, $T \cap U$ is locally constructible in U for every open subset U of X. If X is quasi-compact and quasi-separated and E is pro-constructible in X, there is a finite open cover (U_i) of X by affine open subsets such that $E \cap U_i$ is an intersection of constructible parts $\mathrm{M}_{i\lambda}$ of U_i ($\lambda \in \mathrm{L}_i$); the $\mathrm{M}_{i\lambda}$ are also constructible parts of X by virtue of (1.2.7) and (**0**$_{\mathrm{III}}$, 9.1.8, (ii)), and, since E is the union of the $E \cap U_i$, it is the intersection of the finite unions $\bigcup_i \mathrm{M}_{i,\lambda(i)}$ (where $\lambda(i) \in \mathrm{L}_i$ for every i), which are constructible parts of X; this proves the second assertion of (iii). The assertion (ix) follows from (iii) and (1.9.3). To prove the first assertion of (v), we may restrict ourselves to the case where X is affine, and then prove that E is quasi-compact (**0**$_{\mathrm{III}}$, 9.1.1); but since X is then quasi-separated, there exists by virtue of (ix) a quasi-compact morphism $f : X' \to X$ such that $E = f(X')$; since X' is quasi-compact, the same is true of E under a continuous map.

To prove (vi), one can restrict ourselves, by virtue of (iv), to the case where X is affine; the conclusion follows then from (iii) and (1.8.2).

To prove (vii) as well, one can restrict ourselves to the case where X is affine; then X' is a finite **IV-1** | 245
union of affine open subsets X'_i and $f(E')$ is the union of the $f(E' \cap X'_i)$, so one can also suppose that X' is affine, by virtue of (ii); but then $E' = g(X'')$, where $g : X'' \to X'$ is a quasi-compact morphism, by virtue of (ix), and one has $f(E') = f(g(X''))$, so $f \circ g$[5] is quasi-compact, and therefore $f(E')$ is pro-constructible.

One deduces from (vii) the proof of the second assertion of (v): indeed, let E be a locally closed and retrocompact part of X, and consider the sub-prescheme of X having E as underlying space (**I**, 5.2.1); the canonical injection $j : E \to X$ is a quasi-compact morphism, and it follows from (vii) that $E = j(E)$ is pro-constructible in X.

Finally, to prove (viii), one can still suppose X affine; moreover, if (X'_α) is an open affine cover of X' such that $E' \cap X'_\alpha$ is union of constructible parts of X'_α ((iii) and (iv)), $f(E')$ is union of the $f(E' \cap X'_\alpha)$, and by virtue of the theorem of Chevalley (1.8.4), each $f(E' \cap X'_\alpha)$ is union of constructible parts, whence the conclusion. □

(1.9.6). Examples (1.9.6). — Every finite part of a prescheme X is pro-constructible: indeed, it suffices to consider the parts $\{x\}$ reduced to a single point (1.9.5, (ii)), and $\{x\}$ is the image of $\mathrm{Spec}(k(x))$ by the canonical morphism $\mathrm{Spec}(k(x)) \to X$, which is quasi-compact; whence the conclusion by (1.9.5, (vii)). On the other hand, a part $\{x\}$ reduced to a point is not necessarily ind-constructible; for example, let A be a Noetherian integral ring having an infinity of maximal ideals, and let x be the generic point of $X = \mathrm{Spec}(A)$; if $\{x\}$ were ind-constructible in X, it would be constructible by virtue of (1.9.5, (iii)) and therefore would contain a non-empty open subset of X (**0**$_{\mathrm{III}}$, 9.2.2); but this contradicts the hypothesis that A has an infinity of maximal ideals, by virtue of the Artin–Tate theorem (**0**, 16.3.3).

Every closed part of a prescheme X is pro-constructible, by (1.9.5, (v)). Every open part of X is therefore ind-constructible, but an open part U of X is pro-constructible only if it is *retrocompact*, by virtue again of (1.9.5, (v)).

Finally, if X is a *Noetherian* prescheme, therefore quasi-separated (1.2.8), it follows from (1.9.5, (iii)) and (**0**$_{\mathrm{III}}$, 9.1.7) that the ind-constructible parts of X are the *unions of locally closed parts* of X.

Theorem (1.9.7). — *Let X be a quasi-compact prescheme, E an ind-constructible part of X, $(\mathrm{F}_\lambda)_{\lambda \in \mathrm{L}}$ a family of pro-constructible parts of X such that $\bigcap_{\lambda \in \mathrm{L}} \mathrm{F}_\lambda \subset E$; then there exists a finite part J of L such that $\bigcap_{\lambda \in \mathrm{J}} \mathrm{F}_\lambda \subset E$.*

[5] The French source prints $g \circ f$ here; the displayed domains require $f \circ g : X'' \to X$.

Proof. Let us write $F = X - E$; then the sets F and $F \cap \mathrm{F}_\lambda$ are pro-constructible, so one is reduced to the following corollary. □

Corollary (1.9.8). — *Let X be a quasi-compact prescheme, $(\mathrm{F}_\lambda)_{\lambda \in \mathrm{L}}$ a family of pro-constructible parts of X whose intersection is empty; then there exists a finite subfamily $(\mathrm{F}_\lambda)_{\lambda \in \mathrm{J}}$ whose intersection is empty.*

Proof. Covering X by a finite number of affine open subsets, and using (1.9.5, (iv)), one is reduced to the case where X is affine; by virtue of (1.9.5, (ix)), one has $\mathrm{F}_\lambda = f_\lambda(X'_\lambda)$, where $X'_\lambda = \operatorname{Spec}(A'_\lambda)$ **IV-1** | 246 is affine, and f_λ is a morphism $X'_\lambda \to X$; then, with the notations of (1.9.3.2), on the one hand, by hypothesis $f(X') = \varnothing$, hence $X' = \varnothing$; but this implies by (1.9.2, (i)) that there exists a finite part J of L such that $X'_\mathrm{J} = \varnothing$, hence $f_\mathrm{J}(X'_\mathrm{J}) = \varnothing$; but $f_\mathrm{J}(X'_\mathrm{J}) = \bigcap_{\lambda \in \mathrm{J}} \mathrm{F}_\lambda = \varnothing$. □

Corollary (1.9.9). — *Let X be a quasi-compact prescheme, F a pro-constructible part of X, $(\mathrm{E}_\lambda)_{\lambda \in \mathrm{L}}$ a family of ind-constructible parts of X such that $\mathrm{F} \subset \bigcup_{\lambda \in \mathrm{L}} \mathrm{E}_\lambda$; then there exists a finite part J of L such that $\mathrm{F} \subset \bigcup_{\lambda \in \mathrm{J}} \mathrm{E}_\lambda$. In particular, from every covering of X by ind-constructible parts, one can extract a finite covering of X.*

Proof. This follows from (1.9.7) by passing to complements. □

Proposition (1.9.10). — *Let X be a prescheme. For a part E of X to be ind-constructible, it is necessary that, for every $x \in X$, the intersection $E \cap \overline{\{x\}}$ be a neighbourhood of x in $\overline{\{x\}}$. If X is locally Noetherian, this condition is sufficient.*

Proof. Suppose E ind-constructible, and let Y be the intersection of $\overline{\{x\}}$ and an open affine subset of X containing x; then there is therefore a sub-prescheme of X having Y for underlying space (**I**, 5.2.1), and if $j : Y \to X$ is the canonical injection, $E \cap Y = j^{-1}(E)$ is ind-constructible in Y (1.9.5, (vi)). As Y is quasi-compact and separated, $E \cap Y$ is therefore a union of constructible parts of Y (1.9.5, (iii)); consequently, there are two open subsets U, V in Y such that $x \in U \cap \complement V \subset E \cap Y$ ($\mathbf{0}_{\mathrm{III}}$, 9.1.3). But as x is the generic point of the irreducible space Y, V is necessarily empty and we have $U \subset E \cap Y$.

Suppose now X locally Noetherian, and let E be a part of X satisfying the condition of the statement. By virtue of the definition (1.9.4), one can restrict to the case where X is *Noetherian*. Then, for every $x \in E$, $E \cap \overline{\{x\}}$ contains a non-empty open part of the form $U \cap \overline{\{x\}}$, where U is open in X; this shows that E is a union of locally closed parts of X, and hence is ind-constructible (1.9.6). □

Proposition (1.9.11). — *Let X be a prescheme, E a part of X. The following properties are equivalent:*

a) *E is locally constructible.*
b) *E is ind-constructible and pro-constructible.*
c) *E and $X - E$ are pro-constructible.*
d) *E and $X - E$ are ind-constructible.*

Proof. It clearly suffices to prove that *d*) implies *a*), and one can restrict to the case where X is affine. Then, by (1.9.5, (iii)), E (resp. $X - E$) is a union of a family (E_λ) (resp. (E'_μ)) of constructible parts of X; as the E_λ and the E'_μ form a covering of X, it follows from (1.9.9) that there are finitely many indices λ_i, μ_j such that the E_{λ_i} and the E'_{μ_j} form a covering of X; this implies that E is a union of the E_{λ_i}, and hence is constructible. □

Corollary (1.9.12). — *Let $f : X \to Y$ be a surjective morphism, either quasi-compact, or locally of finite presentation. For a part E of Y to be locally constructible (resp. pro-constructible, resp. ind-constructible), it is necessary and sufficient that $f^{-1}(E)$ be so in X.*

IV-1 | 247

Proof. We know that the condition is necessary by (1.8.2) and (1.9.5, (vi)); to prove sufficiency, one is reduced to the case where X is affine by virtue of (1.9.5, (iv)); moreover, by virtue of (1.9.11), one can restrict to the case where $f^{-1}(E)$ is pro-constructible, *or* the case where $f^{-1}(E)$ is ind-constructible. If f is surjective and quasi-compact, and $f^{-1}(E)$ is pro-constructible, it follows from (1.9.5, (vii)) that $E = f(f^{-1}(E))$ is pro-constructible. If f is surjective and locally of finite presentation, and $f^{-1}(E)$ is ind-constructible, $E = f(f^{-1}(E))$ is ind-constructible by (1.9.5, (viii)), which completes the proof. □

(1.9.13). Let X be a prescheme, $\mathscr{T}$ its topology; it follows from (1.9.5, (i) and (ii)) that the ind-constructible (resp. pro-constructible) parts of X are the open parts (resp. closed parts) for a topology on X, called the *constructible topology*, which we will denote by $\mathscr{T}^{\text{cons}}$; we will denote by X^{cons} the set X equipped with the topology $\mathscr{T}^{\text{cons}}$.

Proposition (1.9.14). — *Let X be a prescheme, $\mathscr{T}$ its topology, $\mathscr{T}^{\text{cons}}$ the constructible topology on X.*

(i) *The topology $\mathscr{T}^{\text{cons}}$ is finer than $\mathscr{T}$.*
(ii) *The locally constructible parts of X are identical to the parts that are both open and closed in the space X^{cons}.*
(iii) *For every morphism $f : X \to Y$, the underlying map of X^{cons} to Y^{cons} is continuous; we denote it f^{cons}.*
(iv) *If the morphism $f : X \to Y$ is quasi-compact, f^{cons} is a closed map; in particular, if f is quasi-compact and bijective, f^{cons} is a homeomorphism.*
(v) *If the morphism $f : X \to Y$ is locally of finite presentation, f^{cons} is an open map; in particular, if f is bijective and locally of finite presentation, f^{cons} is a homeomorphism.*
(vi) *For every open subset U of X, the topology induced by $\mathscr{T}^{\text{cons}}$ on U is identical to the topology of U^{cons}.*

Proof. Indeed, (i) follows from the fact that every open set for $\mathscr{T}$ is open for $\mathscr{T}^{\text{cons}}$ (1.9.6), and (ii) is a restatement of (1.9.11); (iii), (iv), and (v) are restatements respectively of (1.9.5, (vi)), (1.9.5, (vii)), and (1.9.5, (viii)). Finally, to prove (vi), it suffices to remark that the canonical injection $j : U \to X$ is locally of finite presentation (1.4.3), hence $j^{\text{cons}} : U^{\text{cons}} \to X^{\text{cons}}$ is a continuous open map. □

Proposition (1.9.15). — *Let X be a prescheme.*

(i) *For X^{cons} to be quasi-compact, it is necessary and sufficient that X be quasi-compact.*
(ii) *For X^{cons} to be separated, it is necessary and sufficient that X be quasi-separated, and then X^{cons} is locally compact and totally disconnected.*
(iii) *For X^{cons} to be compact, it is necessary and sufficient that X be quasi-compact and quasi-separated.*
(iv) *Every point of X admits, for the topology $\mathscr{T}^{\text{cons}}$, an open and compact neighbourhood.*
(v) *For a morphism $f : X \to Y$ to be quasi-compact, it is necessary and sufficient that the map $f^{\text{cons}} : X^{\text{cons}} \to Y^{\text{cons}}$ be proper.*

Proof. (i) As $\mathscr{T}^{\text{cons}}$ is finer than $\mathscr{T}$, it is clear that if X^{cons} is quasi-compact, so is X; the converse follows from (1.9.9).

(ii) Suppose X quasi-separated, and let us show that X^{cons} is totally disconnected: indeed, if x, y are two distinct points of X and if, for example, $x \notin \overline{\{y\}}$, there exists an affine open neighbourhood **IV-1** | 248
U of x which does not contain y; as X is quasi-separated, U is retrocompact in X (1.2.7), hence U and $X - U$ are locally constructible in X, and therefore open in X^{cons} by virtue of (1.9.11), whence our assertion. For every open affine subset U of X, the topology induced by $\mathscr{T}^{\text{cons}}$ is that of U^{cons} by virtue of (1.9.14, (vi)); it follows from the above that X^{cons} is locally compact, since U is open in X^{cons} and U^{cons} is compact. It remains to show that if X^{cons} is separated, then X is quasi-separated; consider indeed an open affine subset U of X; the topology induced on U by $\mathscr{T}^{\text{cons}}$ is that of U^{cons} (1.9.14, (vi)), hence U is compact for this induced topology, since U^{cons} is compact by the first part of the reasoning. If V is a second open affine subset in X, $U \cap V$ is therefore a compact subset of the separated space X^{cons}, being the intersection of two compact subsets of this space; as the topology induced by $\mathscr{T}^{\text{cons}}$ on $U \cap V$ is that of $(U \cap V)^{\text{cons}}$ (1.9.14, (vi)) and the identity $(U \cap V)^{\text{cons}} \to U \cap V$ is continuous, one concludes that $U \cap V$ is quasi-compact for the topology induced by $\mathscr{T}$; X is therefore quasi-separated by virtue of (1.2.7).

(iii) is an immediate corollary of (i) and (ii).

(iv) For every $x \in X$, an open affine neighbourhood U of x for $\mathscr{T}$ is also a neighbourhood of x for $\mathscr{T}^{\text{cons}}$ and it is compact by virtue of (iii) and (1.9.14, (vi)), the topology induced on U by $\mathscr{T}^{\text{cons}}$ being identical to that of U^{cons}.

(v) Suppose f quasi-compact; then we already know (1.9.14, (iv)) that f^{cons} is a closed map. Let on the other hand y be a point of Y, and let us set

$$Z = f^{-1}(y) = X \times_Y \operatorname{Spec}(k(y));$$

Z is quasi-compact (1.1.2, (iii)) and, as the canonical morphism $p : Z \to X$ is injective, it follows from (i) and from the fact that the map p^{cons} is continuous that the topology induced by that of X^{cons} on $f^{-1}(y)$ makes $f^{-1}(y)$ a quasi-compact space. This proves that f^{cons} is a proper map (Bourbaki, *Top. gén.*, chap. I^er, 3^e éd., § 10, n^o 2, th. 1). Conversely, suppose the continuous map f^{cons} proper, and let V be an open quasi-compact subset of Y; if $h : V \to Y$ is the canonical injection, $h^{\text{cons}} : V^{\text{cons}} \to Y^{\text{cons}}$ is continuous and injective and V^{cons} is quasi-compact by (i), hence the topology induced on V by that of Y^{cons} makes V a quasi-compact space. The hypothesis that f^{cons} is proper implies that the topology induced on $f^{-1}(V)$ by that of X^{cons} makes $f^{-1}(V)$ a quasi-compact space (*loc. cit.*, prop. 6), hence $f^{-1}(V)$ is also a quasi-compact subspace of X, which shows that the morphism f is quasi-compact. □

(1.9.16). We will show later how one can, for every prescheme X, equip the space X^{cons} with a sheaf of rings which makes it a prescheme whose local rings are all fields, identical to the residue fields at the points of X. Such preschemes arise naturally in the translation, into the language of schemes, of the constructions of Néron [Nér64] in his theory of the reduction of abelian varieties.

IV-1 | 249

1.10. Application to open morphisms

Theorem (1.10.1). — *Let X be a prescheme, E an ind-constructible part of X (1.9.4), x a point of X. For x to be interior to E, it is necessary and sufficient that every generisation ($\mathbf{0}_{\mathbf{I}}$, 2.1.2) x' of x belong to E, in other words (**I**, 2.4.2) that* $\operatorname{Spec}(\mathscr{O}_{X,x}) \subset E$.

Proof. The condition is evidently necessary, since every neighbourhood of x contains the generisations of x. To show that it is sufficient, we may evidently restrict to the case where $X = \operatorname{Spec}(A)$ is affine, x being a prime ideal $\mathfrak{p}$ of A. We know then (1.9.5, (ix)) that there exists an affine scheme $X' = \operatorname{Spec}(A')$ and a morphism $f : X' \to X$ such that $f(X') = X - E$. Let $Y = \operatorname{Spec}(\mathscr{O}_{X,x})$ and $Y' = X' \times_X Y$; the hypothesis means (by virtue of (**I**, 3.6.5)) that $Y' = \varnothing$, in other words $A' \otimes_A A_{\mathfrak{p}} = 0$. As $A_{\mathfrak{p}} = \varinjlim A_t$, where t runs through $A - \mathfrak{p}$ ($\mathbf{0}_{\mathbf{I}}$, 1.4.5), we have $\varinjlim A'_t = 0$, since the functor $\varinjlim$ commutes with the tensor product. Consequently, by (1.9.1), there exists $t \in A - \mathfrak{p}$ such that $A'_t = 0$, and $\mathrm{D}(t)$ is then an open neighbourhood of x in X contained in E. □

Corollary (1.10.2). — *Let $f : X \to Y$ be a morphism locally of finite presentation, and let $y \in Y$. For y to be interior to $f(X)$, it is necessary and sufficient that every generisation y' of y belong to $f(X)$.*

Proof. We know indeed (1.9.5, (viii)) that $f(X)$ is ind-constructible in Y and it suffices to apply (1.10.1). □

We will say that a continuous map $f : X \to Y$ is *open at a point* $x \in X$ if the image under f of *every* neighbourhood of x in X is a neighbourhood of $f(x)$ in Y.

Proposition (1.10.3). — *Let $f : X \to Y$ be a morphism, x a point of X, $y = f(x)$. Consider the following conditions:*

a) *f is open at the point x.*
b) *For every generisation y' of y, there exists a generisation x' of x such that $f(x') = y'$.*
b′) *The image under f of* $\operatorname{Spec}(\mathscr{O}_{X,x})$ *is* $\operatorname{Spec}(\mathscr{O}_{Y,y})$.
c) *For every irreducible closed part Y' of Y containing y, there exists an irreducible component of $X' = f^{-1}(Y')$ containing x and dominating Y'.*

Then we have the implications a) ⇒ b) ⇔ b′) ⇔ c). *If in addition f is locally of finite presentation, the four conditions are equivalent.*

Proof. By definition of a generisation, the image under f of $\operatorname{Spec}(\mathscr{O}_{X,x})$ is always contained in $\operatorname{Spec}(\mathscr{O}_{Y,y})$, so b) and b′) are equivalent. It is immediate that c) implies b), since if y' is a generisation of y, $Y' = \overline{\{y'\}}$ is an irreducible closed part of Y containing y; if x' is the generic point of an irreducible component of $f^{-1}(Y')$ containing x and dominating Y', we have $f(x') = y'$ ($\mathbf{0}_{\mathbf{I}}$, 2.1.5) and x' is a generisation of x. Conversely, b) implies c): indeed, let y' be the generic point of Y' and let x' be a generisation of x such that $f(x') = y'$; let Z' be an irreducible component of $f^{-1}(Y')$ containing x' (and hence x); as $f(x')$ is already dense in Y', so *a fortiori* is $f(Z')$.

To show that a) implies b′), one can evidently restrict to the case where $X = \operatorname{Spec}(B)$ and $Y = \operatorname{Spec}(A)$ are affine, x being a prime ideal $\mathfrak{q}$ of B, so that $\mathscr{O}_{X,x} = B_{\mathfrak{q}} = \varinjlim B_t$, where t runs through $B - \mathfrak{q}$. One has, by (1.9.2), $f(\operatorname{Spec}(\mathscr{O}_{X,x})) = \bigcap_t f(\operatorname{Spec}(B_t)) = \bigcap_t f(\mathrm{D}(t))$, and by hypothesis, for every $t \in B - \mathfrak{q}$, y is interior to $f(\mathrm{D}(t))$, hence $f(\mathrm{D}(t))$ contains $\operatorname{Spec}(\mathscr{O}_{Y,y})$; whence $\operatorname{Spec}(\mathscr{O}_{Y,y}) \subset f(\operatorname{Spec}(\mathscr{O}_{X,x}))$, which establishes our assertion. Finally, when f is locally of finite presentation, b) implies a) by virtue of (1.10.2) applied to the restriction $U \to Y$ of f to an arbitrary open neighbourhood U of x. □ **IV-1 | 250**

Corollary (1.10.4). — *Let $f : X \to Y$ be a morphism. Consider the following conditions:*

a) *f is open.*

b) *For every $x \in X$ and every generisation y' of $y = f(x)$, there exists a generisation x' of x such that $f(x') = y'$.*

b′) *For every $x \in X$, the image under f of $\operatorname{Spec}(\mathscr{O}_{X,x})$ is $\operatorname{Spec}(\mathscr{O}_{Y,f(x)})$.*

c) *For every irreducible closed part Y' of Y, every irreducible component of $f^{-1}(Y')$ dominates Y'.*

Then we have the implications a) $\Rightarrow$ b) $\Leftrightarrow$ b′) $\Leftrightarrow$ c). *If in addition f is locally of finite presentation, the four conditions are equivalent.*

Proof. To say that f is open means that f is open at every point $x \in X$, hence the implications a) $\Rightarrow$ b) $\Leftrightarrow$ b′) follow from the analogous implications in (1.10.3), as well as the implication b) $\Rightarrow$ a) when f is locally of finite presentation. The implication c) $\Rightarrow$ b) also follows from the analogous implication in (1.10.3); let us finally prove that b) implies c). Indeed, let x' be the generic point of an irreducible component of $f^{-1}(Y')$, and let us show that $y' = f(x')$ is the generic point of Y'. Let y'' be a generisation of y'; by hypothesis there exists a generisation x'' of x' such that $f(x'') = y''$, and as $x'' \in f^{-1}(Y')$, we have necessarily $x'' = x'$, hence $y'' = y'$, which completes the proof. □

§2. BASE CHANGE AND FLATNESS

This section (unlike § 6) only exceptionally makes use of Noetherian techniques. The n$^{\text{os}}$ 1 and 2 are essentially nothing more than translations of elementary properties of flatness in commutative Algebra (cf. Bourbaki, *Alg. comm.*, chap. I$^{\text{er}}$), and are included here for the convenience of references. The following numbers are primarily devoted to properties of "descent" by flat or faithfully flat morphisms: if $g : Y' \to Y$ is such a morphism, we want to be able to assert that a subset of Y, or an $\mathscr{O}_Y$-Module, or a morphism $X \to Y$, has a certain property, when we know that its *inverse image* by g possesses this property. We limit ourselves here to properties that do not make use of the general technique of "descent", which will be developed in Chapter V. **IV-2** | 5

2.1. Flat Modules on preschemes

(2.1.1). Let $f : X \to Y$ be a morphism of preschemes, $\mathscr{F}$ an $\mathscr{O}_X$-Module; recall ($\mathbf{0_I}$, 6.7.1) that $\mathscr{F}$ is said to be *f-flat* (or *Y-flat*) *at a point* $x \in X$ if $\mathscr{F}_x$ is a flat $\mathscr{O}_{f(x)}$-module, *f-flat* (or *Y-flat*) if it is f-flat at every point $x \in X$, and finally that the morphism f is said to be *flat at the point* $x \in X$ (resp. *flat*) if $\mathscr{O}_X$ is f-flat at the point x (resp. f-flat). When $f = 1_X$, we will simply say that an $\mathscr{O}_X$-Module $\mathscr{F}$ is *flat at the point* x (resp. *flat*) if it is X-flat at this point (resp. at every point $x \in X$), that is to say if $\mathscr{F}_x$ is a flat $\mathscr{O}_x$-module (resp. if this is the case for every $x \in X$). Recall that we have shown (**III**, 1.4.15.1) the following property:

Proposition (2.1.2). — *Let A, B be two rings, $\varphi : A \to B$ a ring homomorphism, $X = \operatorname{Spec}(B)$, $Y = \operatorname{Spec}(A)$, $f : X \to Y$ the corresponding morphism, and M a B-module. For $\mathscr{F} = \widetilde{M}$ to be f-flat, it is necessary and sufficient that M be a flat A-module.*

Proposition (2.1.3). — *Let $f : X \to Y$ be a morphism of preschemes, $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-Module. The following conditions are equivalent:*

a) *For every base change $g : Y' \to Y$, if we set $X' = X \times_Y Y'$, the functor $\mathscr{G}' \mapsto \mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{G}'$ from the category of quasi-coherent $\mathscr{O}_{Y'}$-Modules to that of quasi-coherent $\mathscr{O}_{X'}$-Modules is exact.*

a′) *Condition* a) *is satisfied for all canonical morphisms* $g : \mathrm{Spec}(\mathscr{O}_y) \to Y$ (**I**, 2.4.1), *where* y *ranges over* Y.

b) $\mathscr{F}$ *is* f*-flat.*

Proof. The questions being local on X and Y, we can restrict to the case where $Y = \mathrm{Spec}(B)$, $X = \mathrm{Spec}(A)$, $\mathscr{F} = \widetilde{M}$, where M is an A-module. It is clear that *a)* implies *a′)*; condition *a′)* implies that for every $x \in X$, the functor $N \mapsto M_{\mathfrak{n}} \otimes_{B_{\mathfrak{n}}} N$ is exact in the category of $B_{\mathfrak{n}}$-modules, $\mathfrak{n}$ being the ideal $\mathfrak{j}_{f(x)}$ of B; this means that $M_{\mathfrak{n}}$ is a flat $B_{\mathfrak{n}}$-module, and it follows from ($\mathbf{0_I}$, 6.3.3) and from (2.1.2) that $\mathscr{F}$ is f-flat. Finally, to see that *b)* implies *a)*, we can also restrict to the case where $Y' = \mathrm{Spec}(A')$ is affine and $\mathscr{G}' = \widetilde{N'}$, where N' is an A'-module; the conclusion then follows from (2.1.2) and from the definition of flatness, since $(M \otimes_A N')^{\sim} = \mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{G}'$. □

Proposition (2.1.4). — *Let* $f : X \to Y$, $g : Y' \to Y$ *be two morphisms of preschemes,* $\mathscr{F}$ *a quasi-coherent* $\mathscr{O}_X$*-Module; set* $X' = X \times_Y Y'$, $f' = f_{(Y')} : X' \to Y'$, $\mathscr{F}' = \mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{O}_{Y'}$, *and let* $g' : X' \to X$ *be the canonical projection. Let* x' *be a point of* X', *and set* $x = g'(x')$, $y' = f'(x')$, *and* $y = g(y') = f(x)$. *If* $\mathscr{F}$ *is* f*-flat at the point* x, $\mathscr{F}'$ *is* f'*-flat at the point* x'; *in particular, if* $\mathscr{F}$ *is* f*-flat,* $\mathscr{F}'$ *is* f'*-flat; if* f *is flat,* f' *is flat.* **IV-2 | 6**

Proof. It suffices to prove the first assertion; applying three times (**I**, 3.6.5), as well as (**I**, 2.4.4), we can reduce to the case where $Y = \mathrm{Spec}(\mathscr{O}_y)$, $X = \mathrm{Spec}(\mathscr{O}_x)$, $Y' = \mathrm{Spec}(\mathscr{O}_{y'})$, $\mathscr{F} = \widetilde{M}$, where $M = \mathscr{F}_x$. The hypothesis and (2.1.2) then imply that $\mathscr{F}$ is f-flat; in other words, we are reduced to proving a special case of the second assertion, and the latter follows immediately from (2.1.3). □

Proposition (2.1.5). — *Consider a commutative diagram of morphisms of preschemes*

$$\begin{tikzcd} X \arrow[d, "f"'] & X' \arrow[l, "g'"'] \arrow[d, "f'"] \\ Y & Y' \arrow[l, "g"] \arrow[d, "h"] \\ & Z \end{tikzcd}$$

where $X' = X \times_Y Y'$ *and* $f' = f_{(Y')}$. *Let* x' *be a point of* X', *and set* $x = g'(x')$, $y' = f'(x')$, $y = f(x) = g(y')$, $z = h(y')$. *Let* $\mathscr{F}$ *be a quasi-coherent* $\mathscr{O}_X$*-Module* f*-flat at the point* x (*resp.* f*-flat*), *and* $\mathscr{G}'$ *a quasi-coherent* $\mathscr{O}_{Y'}$*-Module* h*-flat at the point* y' (*resp.* h*-flat*)*; then* $\mathscr{F} \otimes_{\mathscr{O}_{Y'}} \mathscr{G}'$ *is a quasi-coherent* $\mathscr{O}_{X'}$*-Module* $(h \circ f')$*-flat at the point* x' (*resp.* $(h \circ f')$*-flat*).

Proof. As in (2.1.4), we reduce to the case where $X = \mathrm{Spec}(\mathscr{O}_x)$, $Y = \mathrm{Spec}(\mathscr{O}_y)$, $Y' = \mathrm{Spec}(\mathscr{O}_{y'})$ and $Z = \mathrm{Spec}(\mathscr{O}_z)$, and it suffices then to prove that $\mathscr{F} \otimes_{\mathscr{O}_{Y'}} \mathscr{G}'$ is $(h \circ f')$-flat. Taking into account (2.1.2), the proposition follows from Bourbaki, *Alg. comm.*, chap. Ier, § 2, no 7, prop. 8. □ **IV-2 | 7**

Corollary (2.1.6). — *Let* $f : X \to Y$, $g : Y \to Z$ *be two morphisms of preschemes,* $\mathscr{F}$ *an* $\mathscr{O}_X$*-Module. If* $\mathscr{F}$ *is* f*-flat at the point* $x \in X$ *and if* g *is flat at the point* $f(x)$, $\mathscr{F}$ *is* $(g \circ f)$*-flat at the point* x. *In particular, if* f *and* g *are flat morphisms, so is* $g \circ f$.

Proof. This is the special case of (2.1.5) with $Y' = Y$, $\mathscr{G}' = \mathscr{O}_{Y'}$. □

Corollary (2.1.7). — *If* $f : X \to X'$, $g : Y \to Y'$ *are two flat* S*-morphisms,* $f \times_S g : X \times_S Y \to X' \times_S Y'$ *is a flat morphism.*

Proof. This follows from (2.1.4) and (2.1.6) (cf. (**I**, 3.5.1)). □

Proposition (2.1.8). — *Let* $f : X \to Y$ *be a morphism of preschemes,*

$$0 \longrightarrow \mathscr{F}' \longrightarrow \mathscr{F} \longrightarrow \mathscr{F}'' \longrightarrow 0$$

an exact sequence of quasi-coherent $\mathscr{O}_X$*-Modules, such that* $\mathscr{F}''$ *is* Y*-flat.*

(i) *For every morphism* $g : Y' \to Y$ *and every quasi-coherent* $\mathscr{O}_{Y'}$*-Module* $\mathscr{G}'$, *the sequence* $0 \to \mathscr{F}' \otimes_{\mathscr{O}_Y} \mathscr{G}' \to \mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{G}' \to \mathscr{F}'' \otimes_{\mathscr{O}_Y} \mathscr{G}' \to 0$ *of* $\mathscr{O}_{X'}$*-Modules* (*where* $X' = X \times_Y Y'$) *is exact.*

(ii) *For* $\mathscr{F}$ *to be* Y*-flat, it is necessary and sufficient that* $\mathscr{F}'$ *be so.*

Proof. We can evidently suppose X, Y, Y' affine; the conclusion then follows from (2.1.2) and from $(\mathbf{0_I}, 6.1.2)$. □

Corollary (2.1.9). — *Let $\mathscr{L}^\bullet$ be a complex of quasi-coherent $\mathscr{O}_X$-Modules, i an index such that if $d^i : \mathscr{L}^i \to \mathscr{L}^{i+1}$ is the derivation operator, $\mathscr{B}^{i+1}(\mathscr{L}^\bullet) = \operatorname{Im}(d^i)$ and $\mathscr{Z}^{i+1}(\mathscr{L}^\bullet) = \operatorname{Coker}(d^i)$ are Y-flat. Then, with the notations of (2.1.8), the canonical homomorphism*

$$\mathscr{H}^i(\mathscr{L}^\bullet) \otimes_{\mathscr{O}_Y} \mathscr{G}' \longrightarrow \mathscr{H}^i(\mathscr{L}^\bullet \otimes_{\mathscr{O}_Y} \mathscr{G}')$$

is bijective.

Proof. As the tensor product is right exact, we have

$$\mathscr{Z}^{i+1}(\mathscr{L}^\bullet) \otimes_{\mathscr{O}_Y} \mathscr{G}' = \operatorname{Coker}(d^i \otimes 1) = \mathscr{Z}^{i+1}(\mathscr{L}^\bullet \otimes_{\mathscr{O}_Y} \mathscr{G}')$$

and $\mathscr{Z}^i(\mathscr{L}^\bullet) \otimes_{\mathscr{O}_Y} \mathscr{G}' = \mathscr{Z}^i(\mathscr{L}^\bullet \otimes_{\mathscr{O}_Y} \mathscr{G}')$. Moreover, in the exact sequence

$$0 \longrightarrow \mathscr{B}^{i+1}(\mathscr{L}^\bullet) \longrightarrow \mathscr{L}^{i+1} \longrightarrow \mathscr{Z}^{i+1}(\mathscr{L}^\bullet) \longrightarrow 0$$

$\mathscr{Z}^{i+1}(\mathscr{L}^\bullet)$ is Y-flat, so it follows from (2.1.8, (i)) that the exact sequence

$$0 \longrightarrow \mathscr{B}^{i+1}(\mathscr{L}^\bullet) \otimes_{\mathscr{O}_Y} \mathscr{G}' \longrightarrow \mathscr{L}^{i+1} \otimes_{\mathscr{O}_Y} \mathscr{G}' \longrightarrow \mathscr{Z}^{i+1}(\mathscr{L}^\bullet \otimes_{\mathscr{O}_Y} \mathscr{G}') \longrightarrow 0$$

whence $\mathscr{B}^{i+1}(\mathscr{L}^\bullet) \otimes_{\mathscr{O}_Y} \mathscr{G}' = \operatorname{Im}(d^i \otimes 1) = \mathscr{B}^{i+1}(\mathscr{L}^\bullet \otimes_{\mathscr{O}_Y} \mathscr{G}')$. Then, as in the exact sequence

$$0 \longrightarrow \mathscr{H}^i(\mathscr{L}^\bullet) \longrightarrow \mathscr{Z}^i(\mathscr{L}^\bullet) \longrightarrow \mathscr{B}^{i+1}(\mathscr{L}^\bullet) \longrightarrow 0$$

$\mathscr{B}^{i+1}(\mathscr{L}^\bullet)$ is Y-flat, it follows from (2.1.8, (i)) and from what precedes that the sequence

$$0 \longrightarrow \mathscr{H}^i(\mathscr{L}^\bullet) \otimes_{\mathscr{O}_Y} \mathscr{G}' \longrightarrow \mathscr{Z}^i(\mathscr{L}^\bullet \otimes_{\mathscr{O}_Y} \mathscr{G}') \longrightarrow \mathscr{B}^{i+1}(\mathscr{L}^\bullet \otimes_{\mathscr{O}_Y} \mathscr{G}') \longrightarrow 0$$

is exact, which proves the corollary. □

Corollary (2.1.10). — *Let $f : X \to Y$ be a morphism of preschemes, $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-Module which is Y-flat, $\mathscr{L}_\bullet = (\mathscr{L}_i)$ a left resolution of $\mathscr{F}$ formed of quasi-coherent $\mathscr{O}_X$-Modules which are Y-flat. Then, for every morphism $g : Y' \to Y$ and every quasi-coherent $\mathscr{O}_{Y'}$-Module $\mathscr{G}'$, the complex $\mathscr{L}_\bullet \otimes_{\mathscr{O}_Y} \mathscr{G}' = (\mathscr{L}_i \otimes_{\mathscr{O}_Y} \mathscr{G}')_{i \geqslant 0}$ is a left resolution of $\mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{G}'$. Moreover, if $\mathscr{Z}_i(\mathscr{L}_\bullet) = \operatorname{Ker}(\mathscr{L}_i \to \mathscr{L}_{i-1})$, the $\mathscr{Z}_i(\mathscr{L}_\bullet)$ are Y-flat, and we have $\mathscr{Z}_i(\mathscr{L}_\bullet) \otimes_{\mathscr{O}_Y} \mathscr{G}' = \mathscr{Z}_i(\mathscr{L}_\bullet \otimes_{\mathscr{O}_Y} \mathscr{G}') = \operatorname{Ker}(\mathscr{L}_i \otimes_{\mathscr{O}_Y} \mathscr{G}' \to \mathscr{L}_{i-1} \otimes_{\mathscr{O}_Y} \mathscr{G}')$. Setting $\mathscr{R}_i = \operatorname{Im}(\mathscr{L}_{i+1} \to \mathscr{L}_i) = \mathscr{Z}_i(\mathscr{L}_\bullet)$; we then have the exact sequences* **IV-2 | 8**

$$0 \leftarrow \mathscr{F} \leftarrow \mathscr{L}_0 \leftarrow \mathscr{R}_0 \leftarrow 0$$

$$0 \leftarrow \mathscr{R}_i \leftarrow \mathscr{L}_{i+1} \leftarrow \mathscr{R}_{i+1} \leftarrow 0 \qquad (i \geqslant 0)$$

and since $\mathscr{F}$ and $\mathscr{L}_i$ are Y-flat, we deduce from (2.1.8, (ii)) by induction that all the $\mathscr{R}_i$ are also Y-flat; using (2.1.8, (i)), we thus have the exact sequences

$$0 \leftarrow \mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{G}' \leftarrow \mathscr{L}_0 \otimes_{\mathscr{O}_Y} \mathscr{G}' \leftarrow \mathscr{R}_0 \otimes_{\mathscr{O}_Y} \mathscr{G}' \leftarrow 0$$

$$0 \leftarrow \mathscr{R}_i \otimes_{\mathscr{O}_Y} \mathscr{G}' \leftarrow \mathscr{L}_{i+1} \otimes_{\mathscr{O}_Y} \mathscr{G}' \leftarrow \mathscr{R}_{i+1} \otimes_{\mathscr{O}_Y} \mathscr{G}' \leftarrow 0 \qquad (i \geqslant 0)$$

which prove the corollary.

Proposition (2.1.11). — *Let $f : X \to Y$ be a flat morphism, $\mathscr{F}$ a quasi-coherent $\mathscr{O}_Y$-Module of finite presentation. If $\mathscr{J}$ is the Ideal of $\mathscr{O}_Y$ annihilator of $\mathscr{F}$, $f^*(\mathscr{J})$ is the Ideal of $\mathscr{O}_X$ annihilator of $f^*(\mathscr{F})$.*

Proof. We have indeed by definition an exact sequence $(\mathbf{0_I}, 5.3.7)$

$$0 \longrightarrow \mathscr{J} \longrightarrow \mathscr{O}_Y \longrightarrow \mathscr{H}om_{\mathscr{O}_Y}(\mathscr{F}, \mathscr{F})$$

whence, since f is flat, an exact sequence

$$0 \longrightarrow f^*(\mathscr{J}) \longrightarrow \mathscr{O}_X \longrightarrow f^*(\mathscr{H}om_{\mathscr{O}_Y}(\mathscr{F}, \mathscr{F}))$$

and since $\mathscr{F}$ is an $\mathscr{O}_Y$-Module of finite presentation, $f^*(\mathscr{H}om_{\mathscr{O}_Y}(\mathscr{F}, \mathscr{F}))$ canonically identifies with $\mathscr{H}om_{\mathscr{O}_X}(f^*(\mathscr{F}), f^*(\mathscr{F}))$ $(\mathbf{0_I}, 6.7.6)$, whence the conclusion. □

Proposition (2.1.12). — *Let X be a prescheme, $\mathscr{F}$ an $\mathscr{O}_X$-Module of finite presentation, x a point of X. The following conditions are equivalent:*

a) *$\mathscr{F}_x$ is a flat $\mathscr{O}_x$-module.*
b) *There exists an open neighbourhood U of x such that $\mathscr{F}|U$ is a locally free $(\mathscr{O}_X|U)$-Module.*

Proof. Indeed, $\mathscr{F}_x$ is a module of finite presentation over $\mathscr{O}_x$, and $\mathscr{O}_x$ is a local ring; it amounts to the same thing to say that $\mathscr{F}_x$ is a flat $\mathscr{O}_x$-module or a free $\mathscr{O}_x$-module (Bourbaki, *Alg. comm.*, chap. II, § 3, n° 2, cor. 2 of prop. 5); whence the conclusion, taking into account ($\mathbf{0_I}$, 5.2.7). We note that the proposition is valid for any *ringed space with local rings*. □

Proposition (2.1.13). — *Let $f : X \to Y$ be a morphism of preschemes. If f is flat at a point $x \in X$ and if the ring $\mathscr{O}_x$ is reduced (resp. integral and integrally closed), then the ring $\mathscr{O}_{f(x)}$ is reduced (resp. integral and integrally closed). If f is faithfully flat and if X is reduced (resp. normal), then Y is reduced (resp. normal).* **IV-2** | 9

Proof. Set $\mathscr{O}_{f(x)} = A$, $\mathscr{O}_x = B$. If B is a flat A-module, it is also a faithfully flat A-module ($\mathbf{0_I}$, 6.6.2), so A identifies with a subring of B; if B is reduced, so is A. Suppose now that B is integral and integrally closed, and let L be its field of fractions; then $A \subset B$ is integral; denote by $K \subset L$ its field of fractions. The hypothesis implies that $B \cap K = A$ (Bourbaki, *Alg. comm.*, chap. I, § 3, n° 5, prop. 10). If then $t \in K$ is integral over A, it is also integral over B, so belongs to B by hypothesis, and thus $t \in A$, which proves that A is integrally closed. □

Proposition (2.1.14). — *Let $f : X \to Y$ be a faithfully flat morphism. If X is locally integral and if the space underlying Y is locally Noetherian, then Y is locally integral.*

Proof. Indeed, every $y \in Y$ is of the form $f(x)$ for some $x \in X$ and by hypothesis $\mathscr{O}_y$ identifies with a subring of $\mathscr{O}_x$ ($\mathbf{0_I}$, 6.6.1); as $\mathscr{O}_x$ is integral, so is $\mathscr{O}_y$ and this proves the proposition (**I**, 5.1.4). □

2.2. Faithfully flat Modules on preschemes

Proposition (2.2.1). — *Let $f : X \to Y$ be a morphism of preschemes, $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-Module. The following conditions are equivalent:*

- a) *For every base change $g : Y' \to Y$, if we set $X' = X \times_Y Y'$, the functor $\mathscr{G}' \mapsto \mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{G}'$, from the category of quasi-coherent $\mathscr{O}_{Y'}$-Modules to that of quasi-coherent $\mathscr{O}_{X'}$-Modules, is exact and faithful.*
- a′) *Condition* a) *is satisfied for all canonical morphisms $g : \mathrm{Spec}(\mathscr{O}_y) \to Y$ (**I**, 2.4.1), where y ranges over Y.*
- a″) *Condition* a) *is satisfied for all canonical immersions $Y' \to Y$, where Y' ranges over the set of affine open sub-preschemes of Y.*
- b) *$\mathscr{F}$ is Y-flat and, for every $y \in Y$, if we denote by X_y the fibre $f^{-1}(y)$, the $\mathscr{O}_{X_y}$-Module $\mathscr{F}_y = \mathscr{F} \otimes_{\mathscr{O}_Y} k(y)$ is nonzero.*

Proof. It is clear that *a)* implies *a′)* and *a″)*; condition *a′)* implies first that $\mathscr{F}$ is Y-flat (2.1.3); on the other hand it implies that for every $y \in Y$, the functor $N \mapsto \mathscr{F} \otimes_{\mathscr{O}_y} \widetilde{N}$ is faithful in the category of $\mathscr{O}_y$-modules; taking in particular $N = k(y)$, we obtain the second assertion of *b)*. To show that *b)* implies *a)*, we can restrict to the case where Y is affine, since the question is local over Y. Likewise, to prove that *a″)* implies *a)*, we are reduced to proving that, when Y is affine, the fact that $\mathscr{G} \mapsto \mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{G}$ is an exact and faithful functor implies condition *a)*. In other words, we are reduced to proving the following more precise proposition: □

Proposition (2.2.2). — *Let $Y = \mathrm{Spec}(A)$ be an affine scheme, $f : X \to Y$ a morphism of preschemes, $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-Module. Condition* a) *of* (2.2.1) *is equivalent to each of the following:* **IV-2** | 10

- b′) *$\mathscr{F}$ is Y-flat and, for every closed point y of Y, we have $\mathscr{F}_y \neq 0$.*
- c) *The functor $\mathscr{G} \mapsto \mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{G}$ from the category of quasi-coherent $\mathscr{O}_Y$-Modules to that of quasi-coherent $\mathscr{O}_X$-Modules is exact and faithful.*

Proof. If *b′)* holds and y is a closed point of Y, there is at least one $x \in f^{-1}(y)$ such that $(\mathscr{F}_y)_x \neq 0$; let $U = \mathrm{Spec}(B)$ be an affine open neighbourhood of x, and write $\mathscr{F}|_U = \widetilde{M}$, where M is a B-module. Then *b′)* implies that $M/\mathfrak{j}_y M$ is nonzero and hence, since M is a flat A-module (2.1.2), that $M \otimes_A A_y$ is a faithfully flat A_y-module ($\mathbf{0_I}$, 6.4.5). The relation $(\mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{G}) \otimes_{\mathscr{O}_Y} \mathscr{O}_y = 0$ for a closed point y of Y implies

$$(\mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{O}_y) \otimes_{\mathscr{O}_y} \mathscr{G}_y = 0,$$

and therefore $\mathscr{G}_y = 0$. But if $\mathscr{G}_y = 0$ for every closed point y of Y, we conclude that $\mathscr{G} = 0$: indeed, if $\mathscr{G} = \widetilde{N}$, the annihilator of every element of N is contained in no maximal ideal of A, and hence is all of A. The relation $\mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{G} = 0$ implies therefore $\mathscr{G} = 0$, in other words the functor $\mathscr{G} \mapsto \mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{G}$ is faithful; we know moreover that this functor is exact (2.1.3), which shows that *b′)* implies *c)*.

Finally, to see that *c)* implies *a)*, we can restrict to the case where Y' is also affine. The morphism $g : Y' \to Y$ is then affine, and so is the projection $g' : X' \to X$ (**II**, 1.5.5). Moreover, the functor $\mathscr{H}' \mapsto g'_*(\mathscr{H}')$ is exact in the category of quasi-coherent $\mathscr{O}_{X'}$-Modules (**I**, 1.6.4); if $g'_*(\mathscr{H}') = 0$, then $\mathscr{H}' = 0$, so this functor is also faithful. Consequently, to show that $\mathscr{G}' \mapsto \mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{G}'$ is exact and faithful, it suffices to show that the functor

$$\mathscr{G}' \longmapsto g'_*(g'^*(\mathscr{F}) \otimes_{\mathscr{O}_{X'}} f'^*(\mathscr{G}'))$$

is exact and faithful. The fact that g is affine implies that we have a canonical isomorphism

(2.2.2.1) $$\mathscr{F} \otimes_{\mathscr{O}_X} f^*(g_*(\mathscr{G}')) \xrightarrow{\sim} g'_*(g'^*(\mathscr{F}) \otimes_{\mathscr{O}_{X'}} f'^*(\mathscr{G}')).$$

Indeed, we know (**II**, 1.5.2) that we have a canonical isomorphism

$$f^*(g_*(\mathscr{G}')) \xrightarrow{\sim} g'_*(f'^*(\mathscr{G}')),$$

and on the other hand a canonical homomorphism $\mathscr{F} \to g'_*(g'^*(\mathscr{F}))$ ($\mathbf{0_I}$, 4.4.3.2); composing the homomorphism $\mathscr{F} \otimes_{\mathscr{O}_X} f^*(g_*(\mathscr{G}')) \to g'_*(g'^*(\mathscr{F})) \otimes_{\mathscr{O}_X} g'_*(f'^*(\mathscr{G}'))$ with the canonical homomorphism ($\mathbf{0_I}$, 4.2.2.1), we deduce the homomorphism (2.2.2.1); the verification that it is an isomorphism is immediate by reducing to the case where X is affine. This being so, the functor $\mathscr{G}' \mapsto g_*(\mathscr{G}')$ is exact and faithful, and by hypothesis the same is true of the functor $\mathscr{G} \mapsto \mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{G} = \mathscr{F} \otimes_{\mathscr{O}_X} f^*(\mathscr{G})$ from quasi-coherent $\mathscr{O}_Y$-Modules to quasi-coherent $\mathscr{O}_X$-Modules. Their composite is therefore exact and faithful, which completes the proof of (2.2.1) and (2.2.2). □

Corollary (2.2.3). — *Let $X = \mathrm{Spec}(B)$, $Y = \mathrm{Spec}(A)$ be two affine schemes, $f : X \to Y$ a morphism, $\mathscr{F} = \widetilde{M}$ a quasi-coherent $\mathscr{O}_X$-Module. For $\mathscr{F}$ to satisfy the equivalent conditions of* (2.2.1) (*or* (2.2.2)), *it is necessary and sufficient that the A-module M be faithfully flat.*

Proof. Indeed, condition *c)* of (2.2.2) means that the functor $N \mapsto M \otimes_A N$ from the category of A-modules to that of B-modules is exact and faithful, and the conclusion follows from ($\mathbf{0_I}$, 6.4.1). □

Definition (2.2.4). — When the equivalent conditions of (2.2.1) are satisfied, we say that the quasi-coherent $\mathscr{O}_X$-Module $\mathscr{F}$ is *faithfully flat relative to f* (or to Y).

We note that this notion is local over Y, but *not over* X; in particular we can have $\mathscr{F}_x = 0$ **IV-2 | 11**
for certain $x \in X$, in other words $\mathrm{Supp}(\mathscr{F})$ is not necessarily equal to X. However, it follows immediately from criterion (2.2.1)*(b)* that for every $y \in Y$, there exists at least one $x \in f^{-1}(y)$ such that $(\mathscr{F}_y)_x = \mathscr{F}_x \otimes_{\mathscr{O}_y} k(y) \neq 0$, and *a fortiori* $\mathscr{F}_x \neq 0$; in other terms:

Corollary (2.2.5). — *If $\mathscr{F}$ is a quasi-coherent $\mathscr{O}_X$-Module, faithfully flat relative to f, then*

$$f(\mathrm{Supp}(\mathscr{F})) = Y.$$

In particular, f is a surjective morphism.

This result admits a partial converse:

Corollary (2.2.6). — *Let $\mathscr{F}$ be a quasi-coherent $\mathscr{O}_X$-Module of finite type. For $\mathscr{F}$ to be faithfully flat relative to f, it is necessary and sufficient that $\mathscr{F}$ be f-flat and that $f(\mathrm{Supp}(\mathscr{F})) = Y$.*

Proof. Indeed, by (**I**, 9.1.13) and (**I**, 3.6.1), we have $\mathrm{Supp}(\mathscr{F}_y) = f^{-1}(y) \cap \mathrm{Supp}(\mathscr{F})$, so in this case criterion (2.2.1)*(b)* is precisely the condition of the corollary. In particular, the $\mathscr{O}_X$-Module $\mathscr{O}_X$ is faithfully flat relative to f if and only if f is flat and surjective, that is to say if and only if the *morphism f is faithfully flat* ($\mathbf{0_I}$, 6.7.8). □

Let us spell out the properties intervening in definition (2.2.4):

Proposition (2.2.7). — *Let $f : X \to Y$ be a morphism of preschemes, $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-Module faithfully flat relative to f. Then, for a sequence $\mathscr{G}' \to \mathscr{G} \to \mathscr{G}''$ of quasi-coherent $\mathscr{O}_Y$-Modules to be exact, it is necessary and sufficient that the corresponding sequence $\mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{G}' \to \mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{G} \to \mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{G}''$ be so. In particular, for a homomorphism $u : \mathscr{G} \to \mathscr{G}'$ of quasi-coherent $\mathscr{O}_Y$-Modules to be injective* (*resp. surjective, bijective, zero*), *it is necessary and sufficient that $1_{\mathscr{F}} \otimes f^*(u) : \mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{G} \to \mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{G}'$ be* *so. For a quasi-coherent $\mathscr{O}_Y$-Module $\mathscr{G}$ to be zero, it is necessary and sufficient that $\mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{G} = 0$. For a quasi-coherent $\mathscr{O}_Y$-Module $\mathscr{G}$, the map $\mathscr{G}' \mapsto \mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{G}'$ from the set of quasi-coherent $\mathscr{O}_Y$-submodules of $\mathscr{G}$ to the set of quasi-coherent $\mathscr{O}_X$-submodules of $\mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{G}$ is injective.*

Proof. To prove the last assertion, that is to say that for two quasi-coherent sub-$\mathscr{O}_Y$-Modules $\mathscr{G}'$, $\mathscr{G}''$ of $\mathscr{G}$, the relation $\mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{G}' = \mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{G}''$ implies $\mathscr{G}' = \mathscr{G}''$, we can reduce to the case where $\mathscr{G}' \subset \mathscr{G}''$ (by replacing $\mathscr{G}''$ by $\mathscr{G}' + \mathscr{G}''$), and it then suffices to apply the second assertion of the statement to the injection $u : \mathscr{G}' \to \mathscr{G}''$. □

Corollary (2.2.8). — *Let $f : X \to Y$ be a faithfully flat morphism, $\mathscr{G}$ a quasi-coherent $\mathscr{O}_Y$-Module. The canonical map*

$$\Gamma(Y, \mathscr{G}) \longrightarrow \Gamma(X, f^*(\mathscr{G})) \tag{2.2.8.1}$$

is injective.

Proof. Indeed, there are canonical identifications ($\mathbf{0_I}$, 5.1.1)

$$\Gamma(Y, \mathscr{G}) \simeq \mathrm{Hom}_{\mathscr{O}_Y}(\mathscr{O}_Y, \mathscr{G}),$$
$$\Gamma(X, f^*(\mathscr{G})) \simeq \mathrm{Hom}_{\mathscr{O}_X}(\mathscr{O}_X, f^*(\mathscr{G})).$$

By virtue of (2.2.1) and (2.2.4), the hypothesis implies that the functor $\mathscr{G} \mapsto f^*(\mathscr{G})$ is exact and faithful in the category of quasi-coherent $\mathscr{O}_Y$-Modules, and thus a homomorphism $u : \mathscr{O}_Y \to \mathscr{G}$ is zero if and only if $f^*(u) : f^*(\mathscr{O}_Y) = \mathscr{O}_X \to f^*(\mathscr{G})$ is zero. □

Remark (2.2.9). — The assertions of (2.2.7) and (2.2.8) are still true when the $\mathscr{O}_Y$-Modules $\mathscr{G}', \mathscr{G}, \mathscr{G}''$ appearing there are arbitrary (not necessarily quasi-coherent). Indeed, for every $y \in Y$, there exists $x \in f^{-1}(y)$ such that $\mathscr{F}_x$ is a flat $\mathscr{O}_y$-module faithfully flat, and thus the functor $\mathscr{G}_y \mapsto \mathscr{G}_y \otimes_{\mathscr{O}_y} \mathscr{F}_x$ is **IV-2** | 12
faithful; since moreover for *every* $x \in f^{-1}(y)$ the functor $\mathscr{G}_y \mapsto \mathscr{G}_y \otimes_{\mathscr{O}_y} \mathscr{F}_x$ is exact, we immediately deduce the conclusion.

Proposition (2.2.10). — *Let $f : X \to Y$, $g : Y' \to Y$, $h : Y' \to Z$ be three morphisms of preschemes, $X' = X \times_Y Y'$, $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-Module faithfully flat relative to Y, $\mathscr{G}'$ a quasi-coherent $\mathscr{O}_{Y'}$-Module. For $\mathscr{G}'$ to be flat* (*resp. faithfully flat*) *relative to Z, it is necessary and sufficient that $\mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{G}'$ be a flat* (*resp. faithfully flat*) *$\mathscr{O}_{X'}$-Module relative to Z.*

Proof. We know already that if $\mathscr{G}'$ is Z-flat, so is $\mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{G}'$ (2.1.5). Consider a base change $Z'' \to Z$ and set $X'' = X' \times_Z Z''$; if $\mathscr{G}'$ is faithfully flat relative to Z, the functor

$$\mathscr{H}'' \longmapsto \mathscr{H}'' \otimes_Z \mathscr{G}' \longrightarrow (\mathscr{H}'' \otimes_Z \mathscr{G}') \otimes_{\mathscr{O}_Y} \mathscr{F} = \mathscr{H}'' \otimes_Z (\mathscr{G}' \otimes_{\mathscr{O}_Y} \mathscr{F}) \tag{2.2.10.1}$$

from the category of $\mathscr{O}_{Z''}$-Modules to that of $\mathscr{O}_{X''}$-Modules is composed of two exact and faithful functors, so this functor is also exact and faithful. Conversely, if this composite functor is exact (resp. exact and faithful), the same is true of $\mathscr{H}'' \mapsto \mathscr{H}'' \otimes_Z \mathscr{G}'$, since the functor $\mathscr{M}' \mapsto \mathscr{M}' \otimes_{\mathscr{O}_Y} \mathscr{F}$ from quasi-coherent $\mathscr{O}_{Y'}$-Modules to quasi-coherent $\mathscr{O}_{X'}$-Modules is exact and faithful by hypothesis. □

Corollary (2.2.11). —

(i) *Let $f : X \to Y$, $g : Y' \to Y$ be two morphisms, $X' = X \times_Y Y'$, $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-Module. If $\mathscr{F}$ is faithfully flat relative to Y, $\mathscr{F}' = \mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{O}_{Y'}$ is faithfully flat relative to Y'.*

(ii) *Let $f : X \to Y$, $g : Y \to Z$ be two morphisms, $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-Module faithfully flat relative to Y. For g to be a faithfully flat morphism, it is necessary and sufficient that $\mathscr{F}$ be faithfully flat relative to Z.*

(iii) *Let $f : X \to Y$, $g : Y \to Z$ be two morphisms, $\mathscr{G}$ a quasi-coherent $\mathscr{O}_Y$-Module. Suppose the morphism f is faithfully flat. For $\mathscr{G}$ to be flat* (*resp. faithfully flat*) *relative to Z, it is necessary and sufficient that $f^*(\mathscr{G})$ be flat* (*resp. faithfully flat*) *relative to Z.*

(iv) *Let $f : X \to Y$, $g : Y \to Z$ be two morphisms, x a point of X. Suppose f is flat at the point x. For $g \circ f$ to be flat at the point x, it is necessary and sufficient that g be flat at the point $f(x)$.*

Proof. To prove (i), we apply (2.2.10), replacing Z by Y' and $\mathscr{G}'$ by $\mathscr{O}_{Y'}$. To prove (ii), we apply (2.2.10) taking $Y' \to Y$ the identity and replacing $\mathscr{G}'$ by $\mathscr{O}_Y$. To prove (iii), we apply (2.2.10), again taking $Y' \to Y$ to be the identity, and replacing $\mathscr{F}$ by $\mathscr{O}_X$ and $\mathscr{G}'$ by $\mathscr{G}$. Finally, (iv) is deduced from (ii) by replacing X by $\mathrm{Spec}(\mathscr{O}_x)$, $\mathscr{F}$ by $\mathscr{O}_X$, Y by $\mathrm{Spec}(\mathscr{O}_{f(x)})$ and Z by $\mathrm{Spec}(\mathscr{O}_{g(f(x))})$, and taking into account ($\mathbf{0_I}$, 6.6.2). □

Corollary (2.2.12). — *Let Y be an affine scheme, $f : X \to Y$ a quasi-compact morphism, $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-Module. If $\mathscr{F}$ is faithfully flat relative to f, there exists an affine scheme X' and a surjective local isomorphism $g : X' \to X$ such that $g^*(\mathscr{F})$ is faithfully flat relative to $f \circ g$.* **IV-2 | 13**

Proof. Indeed, X is quasi-compact, hence a finite union of affine open subsets X_i; it suffices to take for X' the affine scheme given by the disjoint sum of the preschemes induced on the open subsets X_i, and for $g : X' \to X$ the canonical morphism. It is clear that g is a surjective local isomorphism, hence faithfully flat, and the hypothesis implies that $g^*(\mathscr{F})$ is faithfully flat relative to $f \circ g$, by virtue of (2.2.11)(iii). □

Corollary (2.2.13). —

(i) *Let $f : X \to Y$, $g : Y' \to Y$ be two morphisms, $X' = X \times_Y Y'$, $f' = f_{(Y')} : X' \to Y'$. If f is a faithfully flat morphism, so is f'.*

(ii) *If $f : X \to X'$, $g : Y \to Y'$ are two faithfully flat S-morphisms,*

$$f \times_S g : X \times_S Y \longrightarrow X' \times_S Y'$$

is faithfully flat.

(iii) *Let $f : X \to Y$, $g : Y \to Z$ be two morphisms such that f is faithfully flat. For g to be a flat* (*resp. faithfully flat*) *morphism, it is necessary and sufficient that $g \circ f$ be a flat* (*resp. faithfully flat*) *morphism.*

Proposition (2.2.14). — *Let $f : X \to Y$ be a faithfully flat morphism and quasi-compact. If X is locally Noetherian, so is Y.*

Proof. The question being local on Y, we can suppose $Y = \mathrm{Spec}(A)$ affine; as f is quasi-compact, it follows from (2.2.12) that we can also restrict to the case where $X = \mathrm{Spec}(B)$ is affine. Then B is a Noetherian ring by hypothesis, and a faithfully flat A-module (2.2.3); so A is Noetherian ($\mathbf{0_I}$, 6.5.2). □

Proposition (2.2.15). — *Let $f : X \to Y$ be a faithfully flat morphism. If $\mathfrak{S}(X)$ and $\mathfrak{S}(Y)$ denote respectively the sets of sub-preschemes of X and of Y, the map $Z \mapsto f^{-1}(Z)$ of $\mathfrak{S}(Y)$ to $\mathfrak{S}(X)$ is injective.*

Proof. Since f is surjective, on the underlying sets of a sub-prescheme Z of Y we have $f(f^{-1}(Z)) = Z$. On the other hand, if U is an open subset of Y containing Z and in which Z is closed, then $f^{-1}(U)$ is open in X, $f^{-1}(Z)$ is closed in $f^{-1}(U)$, and the restriction $f^{-1}(U) \to U$ of f is a faithfully flat morphism. We can therefore restrict to considering only the *closed* sub-preschemes of Y. Now, if Z is a closed sub-prescheme of Y corresponding to a quasi-coherent Ideal $\mathscr{J}$ of $\mathscr{O}_Y$, we know that $f^{-1}(Z)$ corresponds to the quasi-coherent Ideal $f^*(\mathscr{J})\mathscr{O}_X$ of $\mathscr{O}_X$ (**I**, 4.4.5), and since f is flat, $f^*(\mathscr{J})\mathscr{O}_X$ identifies with $f^*(\mathscr{J})$. But the map $\mathscr{J} \mapsto f^*(\mathscr{J})$ from the set of quasi-coherent Ideals of $\mathscr{O}_Y$ to the set of quasi-coherent Ideals of $\mathscr{O}_X$ is injective (2.2.7), whence the conclusion. □

Corollary (2.2.16). — *Let X, Y be two S-preschemes; if $S' \to S$ is a faithfully flat morphism, the map $f \mapsto f_{(S')}$ from $\mathrm{Hom}_S(X, Y)$ to $\mathrm{Hom}_{S'}(X_{(S')}, Y_{(S')})$ is injective.*

Proof. We have $X_{(S')} \times_{S'} Y_{(S')} = (X \times_S Y)_{(S')}$ (**I**, 3.3.10), so the morphism projection $X_{(S')} \times_{S'} Y_{(S')} \to X \times_S Y$ is faithfully flat (2.2.13). The elements of $\mathrm{Hom}_S(X, Y)$ correspond bijectively to the sub-preschemes of $X \times_S Y$ that are their graphs (**I**, 5.3.11); if Z_f is the graph of $f \in \mathrm{Hom}_S(X, Y)$, then $Z_{f_{(S')}} = g^{-1}(Z_f)$ (**I**, 5.3.12). It suffices therefore to apply (2.2.15). □

Proposition (2.2.17). — *Let A be a ring, B an A-algebra such that B is a faithfully flat A-module and of finite presentation. Then the structural homomorphism $\varphi : A \to B$ is an isomorphism of the A-module A onto a direct summand of the A-module B. If A is a local ring, B is a free A-module and there exists a basis of this module containing the identity element of B.*

Proof. By virtue of Bourbaki, *Alg. comm.*, chap. II, § 3, n° 3, prop. 12, it suffices to prove the proposition when A is a local ring; we know then (*loc. cit.*, n° 2, cor. 2 of prop. 5) that B is an A-module free of finite type, and the conclusion follows from *loc. cit.*, prop. 5. □ **IV-2 | 14**

2.3. Topological properties of flat morphisms

Lemma (2.3.1). — *Let $f : X \to Y$ be a quasi-compact and quasi-separated morphism, $g : Y' \to Y$ a flat morphism; set $X' = X \times_Y Y'$, $f' = f_{(Y')} : X' \to Y'$. Then, for every quasi-coherent $\mathscr{O}_X$-Module $\mathscr{F}$, the canonical homomorphism*

$$g^*(f_*(\mathscr{F})) \longrightarrow f'_*(\mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{O}_{X'}) \tag{2.3.1.1}$$

is bijective.

Proof. This is a special case of (**III**, 1.4.15) (improved in (1.7.21)). □

Proposition (2.3.2). — *Let S be a prescheme, $f : X \to Y$ a quasi-compact and quasi-separated S-morphism, and let Z be the sub-prescheme of Y which is the closed image of X under f* ((**I**, 9.5.3) *and* (1.7.8)). *Let $j : Z \to Y$ be the canonical injection, so that $f = j \circ g$, where $g : X \to Z$ is a morphism* (loc. cit.). *Let $h : S' \to S$ be a flat morphism, and set $f' = f_{(S')} : X_{(S')} \to Y_{(S')}$. Then $j' = j_{(S')} : Z_{(S')} \to Y_{(S')}$ identifies with the canonical injection of the sub-prescheme of $Y_{(S')}$ which is the closed image of $X_{(S')}$ under f'.*

Proof. Since the morphism $Y_{(S')} \to Y$ is flat (2.1.4), we may reduce to the case $S = Y$ (**I**, 3.3.11). If $f = (\psi, \theta)$, then Z is the closed sub-prescheme of S defined by the quasi-coherent Ideal $\mathscr{J} \subset \mathscr{O}_S$ which is the kernel of

$$\theta : \mathscr{O}_S \longrightarrow f_*(\mathscr{O}_X)$$

(**I**, 9.5.2). Since h is flat, the quasi-coherent Ideal $\mathscr{J}\mathscr{O}_{S'}$ identifies with the kernel of

$$h^*(\theta) : \mathscr{O}_{S'} \longrightarrow h^*(f_*(\mathscr{O}_X)).$$

If $f' = (\psi', \theta')$, then $\theta' : \mathscr{O}_{S'} \to f'_*(\mathscr{O}_{X'})$ is the composite of $h^*(\theta)$ with the canonical homomorphism

$$h^*(f_*(\mathscr{O}_X)) \longrightarrow f'_*(\mathscr{O}_{X'})$$

of (2.3.1.1). The conclusion follows from (2.3.1) and (**I**, 9.5.2), since f' is quasi-compact and quasi-separated (1.1.2 and 1.2.2). □

(2.3.3). We will say that a morphism $f : X \to Y$ is *quasi-flat* if there exists a quasi-coherent $\mathscr{O}_X$-Module $\mathscr{F}$ *of finite type* which is f-flat and whose support is equal to X. We will say that f is *quasi-faithfully flat* if it is quasi-flat and surjective. Every flat (resp. faithfully flat) morphism is quasi-flat (resp. quasi-faithfully flat), for then $\mathscr{F} = \mathscr{O}_X$ satisfies the preceding conditions.

It follows immediately from (2.1.4) and from (**I**, 9.1.13), that if f is quasi-flat, then, for every morphism $Y' \to Y$, the morphism $f_{(Y')} : X \times_Y Y' \to Y'$ is quasi-flat. Similarly (taking into account (**I**, 3.5.2)), if f is quasi-faithfully flat, so is $f_{(Y')}$.

Proposition (2.3.4). — *Let $f : X \to Y$ be a quasi-flat morphism* (2.3.3). *Then f possesses the following properties* (*which are equivalent by virtue of* (1.10.4)):

(i) *For every $x \in X$ and every generization y' of $y = f(x)$, there exists a generization x' of x such that $f(x') = y'$.*
(ii) *For every $x \in X$, the image under f of* $\operatorname{Spec}(\mathscr{O}_{X,x})$ *is* $\operatorname{Spec}(\mathscr{O}_{Y,y})$. **IV-2** | 15
(iii) *For every closed irreducible part Y' of Y, every irreducible component of $f^{-1}(Y')$ dominates Y'.*

Proof. It suffices, for example, to prove (ii). By hypothesis, there is an $\mathscr{O}_X$-Module quasi-coherent of finite type $\mathscr{F}$, which is f-flat and such that $\operatorname{Supp}(\mathscr{F}) = X$. For every $x \in X$, $\mathscr{F}_x$ is then an $\mathscr{O}_x$-module of finite type, nonzero, and moreover $\mathscr{F}_x$ is an $\mathscr{O}_y$-module *flat*, for the homomorphism $\rho : \mathscr{O}_y \to \mathscr{O}_x$. As the latter is local and $\mathscr{F}_x \neq 0$, the Nakayama lemma shows that $\mathscr{F}_x \otimes_{\mathscr{O}_y} k(y) \neq 0$, so $\mathscr{F}_x$ is a faithfully flat $\mathscr{O}_y$-module (**0**, 6.4.1). It follows that for every prime ideal $\mathfrak{q}$ of $\mathscr{O}_y$, there exists a prime ideal $\mathfrak{p}$ of $\mathscr{O}_x$ such that $\mathfrak{q} = \rho^{-1}(\mathfrak{p})$ (**0**, 6.5.1), which proves (ii). □

Corollary (2.3.5). — *Let $f : X \to Y$ be a morphism satisfying the equivalent conditions (i), (ii), (iii) of* (2.3.4) (*in particular a quasi-flat or open morphism* (1.10.4)).

(i) *Let Z, Z' be two closed irreducible subsets of Y such that $Z \subset Z'$, and let T be an irreducible component of $f^{-1}(Z)$; then there exists an irreducible component T' of $f^{-1}(Z')$ containing T* (*and dominating Z'*).
(ii) *For every irreducible component T of X, $\overline{f(\mathrm{T})}$ is an irreducible component of Y.*

(iii) *Suppose Y irreducible, and, if y is its generic point, suppose that $f^{-1}(y)$ is irreducible. Then X is irreducible.*

Proof. (i) It suffices to apply (2.3.4), (i) by taking for x the generic point of T ($y = f(x)$ is then the generic point of Z) and for y' the generic point of Z'.

(ii) It is clear that $\overline{f(\mathrm{T})} = Z$ is irreducible, and by virtue of (i), Z cannot be strictly contained in a closed irreducible part of Y.

(iii) By virtue of (ii), every irreducible component of X dominates Y, and hence meets $f^{-1}(y)$, where y is the generic point of Y. The conclusion then follows from (**0**, 2.1.8). □

Proposition (2.3.6). — *Let Y be a prescheme whose set of irreducible components is locally finite* (*which is the case if the underlying space is locally Noetherian (cf.* (**I**, 6.1.9))).

(i) *Every closed subset W of Y stable by generization* (**0**, 2.1.2) *is open. In particular, every connected component of Y is open.*

(ii) *Let $f : X \to Y$ be a closed morphism satisfying in addition the equivalent conditions (i), (ii), (iii) of* (2.3.4) (*which will be the case if f is quasi-flat or open*). *Then the image under f of every connected component C of X is a connected component of Y.*

(iii) *Let $f : X \to Y$ be a morphism satisfying the equivalent conditions (i), (ii), (iii) of* (2.3.4), *and such that moreover for every $y \in Y$, the set $f^{-1}(y)$ is finite* (*which will be the case if f is quasi-finite or radicial*). *Then the set of irreducible components of X is locally finite.*

Proof. (i) If $y \in W$, the generic points η_i ($1 \leqslant i \leqslant m$) of the irreducible components Y_i of Y containing y belong to W by hypothesis. Since W is closed, these components themselves are contained in W; and since there is by hypothesis a neighbourhood U of y which is the union of the $U \cap Y_i$ (**0**, 2.1.6), we have $U \subset W$, so W is open. Since for every $y \in Y$, $\overline{\{y\}}$ is connected, a connected component of Y is stable by generization, so the second assertion follows immediately from the first. **IV-2** | 16

(ii) Since C is closed in X, $f(C)$ is closed in Y by hypothesis. Moreover, since C is stable by generization, the hypothesis on f implies that $f(C)$ is stable by generization; so, by virtue of (i), $f(C)$ is open and closed, and since it is connected, it is a connected component of Y.

(iii) Let $x \in X$. By hypothesis, there is an open neighbourhood U of $y = f(x)$ which meets only finitely many irreducible components Y_i of Y ($1 \leqslant i \leqslant n$); let y_i be the generic point of Y_i. For every irreducible component Z of X meeting $f^{-1}(U)$, the generic point z of Z is necessarily in one of the sets $f^{-1}(y_i)$ (2.3.4). Since each of these sets is finite by hypothesis, this proves our assertion. □

Proposition (2.3.7). — *Let $f : X \to Y$ be a morphism, $g : Y' \to Y$ a quasi-flat morphism, $X' = X \times_Y Y'$, $f' = f_{(Y')} : X' \to Y'$.*

(i) *If f is quasi-compact and dominant, so is f'.*

(ii) *If every irreducible component of X dominates an irreducible component of Y, then every irreducible component of X' dominates an irreducible component of Y'.*

Proof. Denote by $g' : X' \to X$ the canonical projection, which is a quasi-flat morphism (2.3.3).

(i) We know already (1.1.2) that f' is quasi-compact; moreover, if y' is a maximal point of Y', $y = g(y')$ is a maximal point of Y, as follows from (2.3.4), (iii). By hypothesis (1.1.5), there exists $x \in X$ such that $f(x) = y$; so (**I**, 3.4.7), there exists $x' \in X'$ such that $f'(x') = y'$.

(ii) Let x' be a maximal point of X', and let $x = g'(x')$; it follows from (2.3.4), (ii) that x is a maximal point of X, and by hypothesis $y = f(x)$ is a maximal point of Y. Set $y' = f'(x')$, so that $g(y') = y$; it remains to show that y' is a maximal point of Y'. By virtue of (**I**, 5.1.7) and (2.3.3), we may reduce to the case where X and Y are reduced, so that $\mathscr{O}_x$ and $\mathscr{O}_y$ are fields. By virtue of (**I**, 3.6.5), applied twice, and (**I**, 2.4.4), we may further reduce to the case where $Y = \operatorname{Spec}(\mathscr{O}_y)$ and $Y' = \operatorname{Spec}(\mathscr{O}_{y'})$. Then f is flat because $\mathscr{O}_y$ is a field (2.1.2), and the same is true of f' (2.1.4); hence (2.3.4), (ii) shows that $y' = f'(x')$ is a maximal point of Y'. □

Corollary (2.3.8). — (Zariski). *Let A, B be two Noetherian local rings, $\mathfrak{m}$, $\mathfrak{n}$ their maximal ideals respectively, $\varphi : A \to B$ a local homomorphism. Suppose the following hypotheses satisfied:*

1° *B is an A-algebra essentially of finite type (1.3.8).*

2° *The $\mathfrak{m}$-adic completion $\widehat{A}$ of A for the $\mathfrak{m}$-adic topology is integral.*

3° *φ is injective.*

Then the $\mathfrak{m}$-adic topology of A is induced by the $\mathfrak{n}$-adic topology of B.

Proof. Set $B' = B \otimes_A \widehat{A}$; by hypothesis 1°, B' is of the form $S^{-1}(C \otimes_A \widehat{A})$, where C is an A-algebra **IV-2** | 17
of finite type and S is a multiplicative subset of C; hence B' is Noetherian. As A identifies with a subring of $\widehat{A}$ (**0**, 7.3.5), A is integral by hypothesis 2°. Hypothesis 3° implies that there exists a prime ideal $\mathfrak{q}$ of B inducing the zero ideal of A (**0**, 1.5.8); consequently, the local homomorphism $A \to B/\mathfrak{q}$ is injective. We can therefore restrict to proving the conclusion of (2.3.8) under the added hypothesis that B is a local ring which is *integral*. Apply (2.3.7), (ii) to $Y = \operatorname{Spec}(A)$, $X = \operatorname{Spec}(B)$, $Y' = \operatorname{Spec}(\widehat{A})$, and $X' = \operatorname{Spec}(B')$. Since $Y' \to Y$ is flat and the integral scheme X dominates the integral scheme Y, every irreducible component of X' dominates Y'. If y, x, and y' are the closed points of Y, X, and Y' respectively, there is a point $x' \in X'$ (in fact unique) lying above x and y' (**I**, 3.4.9), and $\operatorname{Spec}(\mathscr{O}_{x'})$ therefore dominates $\operatorname{Spec}(\mathscr{O}_{y'})$. Consequently, there is a commutative diagram of local homomorphisms of Noetherian local rings

$$\begin{tikzcd} B = \mathscr{O}_x \arrow[r] & \mathscr{O}_{x'} \\ A = \mathscr{O}_y \arrow[u, "\varphi"] \arrow[r, "u"'] & \mathscr{O}_{y'} = \widehat{A} \arrow[u, "v"'] \end{tikzcd}$$

in which u and v are injective (**I**, 1.2.7). Identify A and $\widehat{A}$ with subrings of $\mathscr{O}_{x'}$, and let $\mathfrak{r}$ be the maximal ideal of $\mathscr{O}_{x'}$. Then $\bigcap_k(\mathfrak{r}^k \cap \widehat{A}) = 0$ (**0**, 7.3.5); since $\widehat{A}$ is complete and these ideals are open in $\widehat{A}$, it follows (Bourbaki, *Alg. comm.*, chap. III, § 2, n° 7, prop. 8) that the topology of $\widehat{A}$ is induced by the $\mathfrak{r}$-preadic topology of $\mathscr{O}_{x'}$. *A fortiori*, the same is true of the topology of A (**0**, 7.3.5). Moreover, $\mathfrak{n}^k \cap A \subset \mathfrak{r}^k \cap A$, so the $\mathfrak{n}$-preadic topology of B induces on A a topology finer than the $\mathfrak{m}$-preadic topology; but $\mathfrak{m}^k \subset \mathfrak{n}^k \cap A$, so these two topologies are identical. □

Remark (2.3.9). — We will see further on (7.8.3, (vii)) that for the Noetherian local rings A most commonly used in Algebraic Geometry, the hypothesis that A is integral and integrally closed implies that the same is true of $\widehat{A}$. This is why, in Algebraic Geometry over a base field, one generally states (2.3.8) under the hypothesis that A is *integral and integrally closed*.

Theorem (2.3.10). — *Let $f : X \to Y$ be a quasi-flat morphism (2.3.3). Then, for every pro-constructible part (1.9.4) Z of Y, we have $\overline{f^{-1}(Z)} = f^{-1}(\overline{Z})$.*

Proof. Since f is continuous, we have $\overline{f^{-1}(Z)} \subset f^{-1}(\overline{Z})$ and it amounts to proving that for every $x \in X$ such that $f(x) \in \overline{Z}$, x is adherent to $f^{-1}(Z)$; it is clear that the question is local on Y, so we can suppose Y affine. By virtue of the hypothesis, there exists an affine scheme Y' and a morphism $g : Y' \to Y$ such that $g(Y') = Z$ (1.9.5, (ix)). Let Y_1 be the closed image of Y' under g (**I**, 9.5.3), and let X_1 be the closed sub-prescheme $f^{-1}(Y_1)$ of X; if $f_1 : X_1 \to Y_1$ is the restriction of f to X_1, we know that f_1 is quasi-flat (2.3.3); we can therefore replace X, Y by X_1, Y_1 respectively, in other words suppose that g is *dominant*. Set then $X' = X \times_Y Y'$, and let f' and g' be the projections of X' into Y' and X respectively, so that we have the commutative diagram

$$\begin{tikzcd} X \arrow[d, "f"'] & X' \arrow[l, "g'"'] \arrow[d, "f'"] \\ Y & Y' \arrow[l, "g"] \end{tikzcd}$$

Since f is quasi-flat and g is quasi-compact and dominant, it follows from (2.3.7), (i) (with the roles of f and g interchanged) that g' is dominant, which proves the theorem. □

Corollary (2.3.11). — *Let f be a quasi-flat and quasi-compact morphism, F a closed part of X such that $F = f^{-1}(f(F))$; then $F = f^{-1}(\overline{f(F)})$.*

Proof. Let Y' be the reduced sub-prescheme of X having F as underlying space (**I**, 5.2.1), and let **IV-2** | 18
$j : Y' \to X$ be the canonical injection. Then $f \circ j$ is quasi-compact (1.1.2), so $Z = f(F)$ is pro-constructible in Y (1.9.5, (vii)), and the corollary follows from the fact that F is closed.

We can further write the result of (2.3.11) in the form $F = f^{-1}(f(X) \cap \overline{f(F)})$. In other words, the closed subsets of the subspace $f(X)$ of Y are the parts $Z \subset f(X)$ such that $f^{-1}(Z)$ is closed in X; this also means that *the topology induced by Y on $f(X)$ is the quotient of that of X by the equivalence relation defined by f*. In particular: □

Corollary (2.3.12). — *Let $f : X \to Y$ be a quasi-faithfully flat morphism (2.3.3) and quasi-compact. Then the topology of Y is the quotient of that of X by the equivalence relation defined by f, in other words, for $Z \subset Y$ to be open (resp. closed) in Y, it is necessary and sufficient that $f^{-1}(Z)$ be open (resp. closed) in X.*

Proof. Indeed, we then have $f(X) = Y$. □

Corollary (2.3.13). — *Let X, Y be two S-preschemes, $f : X \to Y$ an S-morphism faithfully flat and quasi-compact. For Y to be separated over S, it is necessary and sufficient that the canonical immersion $j : X \times_Y X \to X \times_S X$ (**I**, 5.3.10) be* closed.

Proof. Let us note for this that we have the commutative diagram (**I**, 5.3.5)

$$\begin{array}{ccc} X \times_Y X & \xrightarrow{j} & X \times_S X \\ {\scriptstyle \pi}\downarrow & & \downarrow{\scriptstyle f \times_S f} \\ Y & \xrightarrow[\Delta_Y]{} & Y \times_S Y \end{array}$$

identifying $X \times_Y X$ with the product of the $(Y \times_S Y)$-preschemes Y and $X \times_S X$. Since f is surjective, so are π and $f \times_S f$; hence the inverse image of the diagonal $\Delta_Y(Y)$ under $f \times_S f$ is the image $j(X \times_Y X)$ (**I**, 3.4.8). Since $f \times_S f$ is faithfully flat and quasi-compact (1.1.2 and 2.2.13), it suffices to apply (2.3.12) to this morphism. □

Corollary (2.3.14). — *Let $f : X \to Y$ be a quasi-faithfully flat and quasi-compact morphism, and let Z be a part of Y. For Z to be a locally closed part pro-constructible of Y, it is necessary and sufficient that $f^{-1}(Z)$ be a locally closed part pro-constructible of X.*

Proof. We already know (1.9.12) that, for Z to be a pro-constructible part of Y, it is necessary and sufficient that $f^{-1}(Z)$ be a pro-constructible part of X. The condition is evidently necessary. To prove that it is sufficient, consider the closed reduced sub-prescheme Y_1 of Y having $\overline{Z}$ as underlying space and let X_1 be its inverse image, so that $f^{-1}(\overline{Z}) = \overline{f^{-1}(Z)}$ by virtue of (2.3.10). As $f^{-1}(Z)$ is locally closed in X, it is open in $\overline{f^{-1}(Z)}$, so in X_1; now, the morphism $f_1 : X_1 \to Y_1$ deduced from f by restriction is quasi-faithfully flat and quasi-compact (1.1.2 and 2.3.3); we deduce from (2.3.12) that Z is open in $\overline{Z}$, which shows that Z is locally closed in Y. □

Remark (2.3.15). — It does not suffice, in (2.3.12), to suppose only that f is *faithfully flat*. For example, take for Y a reduced irreducible algebraic curve (**II**, 7.4.2), and let X be the prescheme sum **IV-2** | 19
$\coprod_{y \in Y} \mathrm{Spec}(\mathscr{O}_y)$ (**I**, 3.1). Let $f : X \to Y$ be the canonical morphism, which is faithfully flat (**I**, 2.4.2). If η denotes the generic point of Y, then $Z = \{\eta\}$ is not open in Y (**II**, 7.4.3), whereas $f^{-1}(Z) = \mathrm{Spec}(\mathscr{O}_\eta)$ is open in X, since $\mathscr{O}_\eta$ is a field.

2.4. Universally open morphisms and flat morphisms

(2.4.1). We have already defined (II, 5.4.9) the notion of *universally closed* morphism; in the same manner, we give the following definitions:

Definition (2.4.2). — We say that a morphism of preschemes $f : X \to Y$ is *universally open* (resp. *universally bicontinuous*, resp. a *universal homeomorphism*) if, for every morphism $g : Y' \to Y$, the morphism $f_{(Y')} : X \times_Y Y' \to Y'$ is open (resp. a homeomorphism onto its image, resp. a homeomorphism onto Y').

We will see further on (14.3.2) that when Y is locally Noetherian, the definition of universally open morphism given here is equivalent to the definition (III, 4.3.9) for morphisms of finite type; the reader can verify that we do not use the latter definition before § 14.

Proposition (2.4.3). —

(i) *An immersion (resp. an open immersion, resp. a closed immersion) is universally bicontinuous (resp. universally open, resp. universally closed).*
(ii) *The composite of two universally open morphisms (resp. universally closed morphisms, resp. universally bicontinuous morphisms, resp. universal homeomorphisms) has the same property.*
(iii) *If $f : X \to Y$ is a universally open (resp. universally closed, resp. universally bicontinuous, resp. a universal homeomorphism) S-morphism, then so is $f_{(S')} : X_{(S')} \to Y_{(S')}$ after every base change $S' \to S$.*
(iv) *If the S-morphisms $f : X \to X'$ and $g : Y \to Y'$ are both universally open (resp. universally closed, resp. universally bicontinuous, resp. universal homeomorphisms), then so is*
$$f \times_S g : X \times_S Y \longrightarrow X' \times_S Y'.$$
(v) *Let $f : X \to Y$ and $g : Y \to Z$ be morphisms, with f surjective. If $g \circ f$ is universally open (resp. universally closed, resp. universally bicontinuous, resp. a universal homeomorphism), then so is g.*
(vi) *A morphism f is universally open (resp. universally closed, resp. universally bicontinuous, resp. a universal homeomorphism) if and only if f_{red} has the same property.*
(vii) *Let (U_α) be an open covering of Y. A morphism $f : X \to Y$ is universally open (resp. universally closed, resp. universally bicontinuous, resp. a universal homeomorphism) if and only if, for every α, its restriction $f^{-1}(U_\alpha) \to U_\alpha$ has the same property.*

Proof. Assertion (i) follows from (I, 4.3.2). Assertion (ii) follows immediately from the definitions. The same is true of (iii), after reducing to the case $Y = S$ and $Y' = S'$, as permitted by (I, 3.3.11); assertion (iv) follows from (ii), (iii), and (I, 3.5.1).

To prove (v), note that after every morphism $Z' \to Z$, the base change
$$f_{(Z')} : X_{(Z')} \longrightarrow Y_{(Z')}$$
is surjective (I, 3.5.2). It is therefore enough to use the following purely topological fact: if f is surjective and $g \circ f$ is open (resp. closed, resp. a homeomorphism onto its image, resp. a bijective homeomorphism), then g has the corresponding property. In the open and closed cases this is Bourbaki, *Top. gén.*, chap. I^er, 3^e éd., § 5, n^o 1, prop. 1. In the other two cases we may replace Z by $g(Y)$ and thus suppose that $g(f(X)) = g(Y) = Z$. Then $g \circ f$ is a homeomorphism of X onto Z; since f is surjective, g is bijective, and since the preceding case shows that g is open, g is a homeomorphism of Y onto Z. To prove (vi), note that a morphism g is open (resp. closed, resp. a homeomorphism onto its image, resp. a bijective homeomorphism) if and only if g_{red} has the same property. On the other hand, for every morphism $Y'' \to Y$, we have **IV-2 | 20**
$$(X_{\mathrm{red}} \times_{Y_{\mathrm{red}}} Y''_{\mathrm{red}})_{\mathrm{red}} = (X \times_Y Y'')_{\mathrm{red}}$$
by (I, 5.1.8); hence the preceding remark shows that if f_{red} is universally open (resp. universally closed, resp. universally bicontinuous, resp. a universal homeomorphism), then so is f. The converse is proved in the same manner, noting here that for every morphism $Y'' \to Y_{\mathrm{red}}$, we have $(X_{\mathrm{red}} \times_{Y_{\mathrm{red}}} Y'')_{\mathrm{red}} = (X \times_Y Y'')_{\mathrm{red}}$ (I, 5.1.8).

Finally, the necessity of condition (vii) follows immediately from (iii). Conversely, suppose the condition satisfied, and let $g : Y' \to Y$ be a morphism; then the $g^{-1}(U_\alpha) = U'_\alpha$ form an open covering of Y' and if one notes f_α the restriction $f^{-1}(U_\alpha) \to U_\alpha$ of f, and f' the morphism $f_{(Y')}$, the restriction $f'^{-1}(U'_\alpha) \to U'_\alpha$ is nothing other than $(f_\alpha)_{(U'_\alpha)}$. We can therefore restrict to proving that f' is open (resp. closed, resp. a homeomorphism onto its image, resp. a homeomorphism onto Y'), which is immediate. □

Proposition (2.4.4). — *A universally bicontinuous morphism $f : X \to Y$ is radicial* (*and hence separated* (**I**, 7.7.1)).

Proof. Indeed, f is universally injective by hypothesis (**I**, 3.5.11). □

Proposition (2.4.5). —

(i) *An integral, surjective, and radicial morphism $f : X \to Y$ is a universal homeomorphism.*
(ii) *Conversely, suppose that Y is locally Noetherian. If a morphism of finite type $f : X \to Y$ is a universal homeomorphism, then it is finite, surjective, and radicial.*

Proof. (i) The three properties of f are preserved by base change (**I**, 3.5.2), (**I**, 3.5.7), and (**II**, 6.1.5). Since an integral morphism is closed (**II**, 6.1.10), f is a homeomorphism of X onto Y.

(ii) The morphism f is of finite type and universally closed by hypothesis, and it is separated by (2.4.4); hence it is proper (**II**, 5.4.1). For every $y \in Y$, the fiber $f^{-1}(y)$ consists of a single point, so (**III**, 4.4.2) implies that f is finite. It is plainly surjective, and it is radicial because it is universally injective (**I**, 3.5.11). □

Theorem (2.4.6). — *Let $f : X \to Y$ be a quasi-flat morphism* (2.3.3) *and locally of finite presentation. Then f is universally open. In particular, a flat morphism locally of finite presentation is universally open.*

Proof. We know that for every base change $Y' \to Y$, $f_{(Y')}$ is quasi-flat (2.3.3) and locally of finite presentation (1.4.3, iii). It suffices therefore to prove that f is an open morphism. But this follows from the criterion (1.10.4) for morphisms locally of finite presentation, conditions *b*), *b*′), and *c*) of (1.10.4) being nothing other than conditions (i), (ii), (iii) of (2.3.4). □ **IV-2 | 21**

Corollary (2.4.7). — *For every prescheme Y, the structural morphism*

$$\mathbf{V}^n_Y \longrightarrow Y, \qquad \mathbf{V}^n_Y = Y \times_{\mathrm{Spec}(\mathbf{Z})} \mathrm{Spec}\big(\mathbf{Z}[T_1, \ldots, T_n]\big),$$

where $\mathbf{V}^n_Y$ is also denoted by $Y[T_1, \ldots, T_n]$, is universally open.

Proof. Indeed, for $Y = \mathrm{Spec}(A)$, $Y[T_1, \ldots, T_n] = \mathrm{Spec}(A[T_1, \ldots, T_n])$, and $A[T_1, \ldots, T_n]$ is a free A-algebra of finite presentation. □

Remark (2.4.8). —

(i) A faithfully flat and quasi-compact morphism $f : X \to Y$ is *not necessarily open*, even when X and Y are Noetherian. For example, let Y be a reduced irreducible algebraic curve (**II**, 7.4.2) with generic point y, let $X = Y \coprod \mathrm{Spec}(k(y))$, and let f be the canonical morphism. It is clear that f is flat and surjective, hence faithfully flat, and it is quasi-compact. But the image under f of the open subset $\mathrm{Spec}(k(y))$ of X is $\{y\}$, which is not open in Y (**II**, 7.4.3).
(ii) For every prescheme X, the canonical morphism $f : X_{\mathrm{red}} \to X$ is a closed immersion and a *universal homeomorphism* by (2.4.3), (vi). But when X is locally Noetherian, f is flat only if X is reduced, in which case $f = 1_X$ (2.2.17).

Proposition (2.4.9). — *Let Y be a discrete prescheme. Then every morphism $f : X \to Y$ is universally open.*

Proof. The question is local on Y (2.4.3), (vii), so we may assume that the underlying space of Y consists of a single point. Replacing f by f_{red} (2.4.3), (vi), we may further assume that Y is the spectrum of a *field* k. For every base change $Y' \to Y$, the inverse images in $X' = X \times_Y Y'$ of the affine open subsets of X cover X', so we may also suppose that $X = \mathrm{Spec}(B)$ is affine, with B a k-algebra. It suffices then to prove that for every k-algebra A', if we set $B' = B \otimes_k A'$, the image of every open subset of the form $U = D(t)$ ($t \in B'$) is open in $\mathrm{Spec}(A')$. Now B is the filtered direct limit of the increasing family (B_α) of its sub-k-algebras *of finite type*. Since filtered direct limits commute with tensor products, B' is the direct limit of the A'-algebras $B_\alpha \otimes_k A' = B'_\alpha$. There exists α such that t is the image in B' of an element $t_\alpha \in B'_\alpha$, so $D(t)$ is the inverse image under the canonical morphism

$u_\alpha : \mathrm{Spec}(B') \to \mathrm{Spec}(B'_\alpha)$ of the open subset $U_\alpha = D(t_\alpha)$ (**I**, 1.2.2.2). But since k is a field, B_α is a k-algebra of finite presentation and a k-module flat, hence B'_α is an A'-algebra of finite presentation and a flat A'-module; we thus conclude from (2.4.6) that the image of U_α by $f'_\alpha : \mathrm{Spec}(B'_\alpha) \to \mathrm{Spec}(A')$ is *open* in $\mathrm{Spec}(A')$. It remains to prove that $f'(U) = f'_\alpha(U_\alpha)$. The inclusion $f'(U) \subset f'_\alpha(U_\alpha)$ is clear, so it remains to show that, for every point $y' \in f'_\alpha(U_\alpha)$, the intersection $V = U \cap f'^{-1}(y')$ is nonempty. Now $V = u_\alpha^{-1}(V_\alpha)$, where $V_\alpha = U_\alpha \cap f'^{-1}_\alpha(y')$; in other words, V_α is a non-empty open subset of the prescheme $\mathrm{Spec}(B'_\alpha \otimes_{A'} k(y')) = \mathrm{Spec}(B_\alpha \otimes_k k(y'))$ and V is its inverse image by the morphism $v : \mathrm{Spec}(B \otimes_k k(y')) \to \mathrm{Spec}(B_\alpha \otimes_k k(y'))$. Since B_α is a subalgebra of B and $k(y')$ is flat over the field k, the homomorphism $B_\alpha \otimes_k k(y') \to B \otimes_k k(y')$ is *injective*. Thus v is dominant (**I**, 1.2.7), which IV-2 | 22
shows that V is nonempty. □

Corollary (2.4.10). — *Let k be a field, X, Y two k-preschemes; then the morphism projection $X \times_k Y \to X$ is universally open. In particular, for every extension K of k, the morphism projection $X_{(K)} \to X$ is universally open.*

Proof. It suffices to apply (2.4.9) to the structural morphism $Y \to \mathrm{Spec}(k)$. □

Remark (2.4.11). — If $f : X \to Y$ is an *open* morphism, then for every subset E of Y we have $f^{-1}(\overline{E}) = \overline{f^{-1}(E)}$ (Bourbaki, *Top. gén.*, chap. I, 3e éd., § 5, no 4, prop. 7). This remark applies for example when f is a morphism *flat* locally of finite presentation (2.4.6), or a morphism projection $X \times_k Y \to X$ where X, Y are preschemes over a field k (2.4.10), and generalises then (2.3.10).

2.5. Permanence of properties of Modules by faithfully flat descent

Proposition (2.5.1). — *Let $f : X \to Y$ be a morphism, let $\mathscr{F}$ be a quasi-coherent $\mathscr{O}_X$-Module, and let $g : Y' \to Y$ be faithfully flat. Set*

$$X' = X \times_Y Y', \qquad f' = f_{(Y')} : X' \longrightarrow Y',$$

let $g' : X' \to X$ be the canonical projection, and set $\mathscr{F}' = g'^*(\mathscr{F})$. Then $\mathscr{F}$ is flat (resp. faithfully flat) relative to f if and only if $\mathscr{F}'$ is flat (resp. faithfully flat) relative to f'.

Proof. Apply (2.2.10), replacing its X, Y', Z, $\mathscr{F}$, and $\mathscr{G}'$ respectively by Y', X, Y, $\mathscr{O}_{Y'}$, and $\mathscr{F}$. This identifies the required flatness (resp. faithful flatness) condition after base change with the corresponding condition relative to $g \circ f'$. On the other hand, g' is faithfully flat (2.2.13) and

$$g \circ f' = f \circ g'.$$

The assertion therefore follows from (2.2.11, iii). □

Proposition (2.5.2). — *Let $f : X' \to X$ be a morphism faithfully flat and quasi-compact, $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-Module, and $\mathscr{F}' = f^*(\mathscr{F})$. Consider, for a quasi-coherent Module, the property of being:*

(i) of finite type;
(ii) of finite presentation;
(iii) locally free of finite type;
(iv) locally free of rank n.

*If **P** denotes any one of these properties, then $\mathscr{F}$ has property **P** if and only if $\mathscr{F}'$ does.*

Proof. For a quasi-coherent $\mathscr{O}_X$-Module to be locally free of finite type, it is necessary and sufficient that it be flat over X and of finite presentation (Bourbaki, *Alg. comm.*, chap. II, § 5, no. 2, cor. 2 of th. 1, taking (2.1.2) into account). By (2.5.1), applied with the identity morphism for f, $\mathscr{F}$ is flat over X if and only if $\mathscr{F}'$ is flat over X'. Thus case (iii) follows from cases (i) and (ii). The same reduction proves (iv), since $f^*(\mathscr{O}_X^n) = \mathscr{O}_{X'}^n$: if $\mathscr{F}$ and $\mathscr{F}'$ are locally free of finite type and $x = f(x')$, their ranks at x and x' are equal, and f is surjective.

To treat cases (i) and (ii), note that the question is local on X, so we may suppose that X is IV-2 | 23
affine. By (2.2.12), there is an affine scheme X'' and a faithfully flat local isomorphism $g : X'' \to X'$. Consequently, it is equivalent for $f^*(\mathscr{F})$ or $g^* f^*(\mathscr{F})$ to have property **P**. We are therefore reduced to

$$X = \mathrm{Spec}(A), \qquad X' = \mathrm{Spec}(A').$$

In view of (2.2.3) and (**II**, 6.1.4.1), it remains only to prove the following lemma. □

Lemma (2.5.3). — *Let* A *be a ring, let* A' *be a faithfully flat* A*-algebra, and let* M *be an* A*-module. Set* $\mathrm{M}' = \mathrm{M} \otimes_{\mathrm{A}} \mathrm{A}'$*. Then* M *is of finite type (resp. of finite presentation) if and only if* M' *is.*

Proof. For the proof, see Bourbaki, *Alg. comm.*, chap. I$^{\mathrm{er}}$, § 3, no. 6, prop. 11. □

Remark (2.5.4). — The assertions of (2.5.2) for properties (i) and (ii) remain valid if f is assumed only *quasi-faithfully flat* (2.3.3) and quasi-compact. Indeed, one is reduced (Bourbaki, *loc. cit.*) to the following lemma.

Lemma (2.5.4.1). — *Let* $\rho : \mathrm{A} \to \mathrm{A}'$ *be a homomorphism of rings such that the corresponding morphism* $f : \mathrm{Spec}(\mathrm{A}') \to \mathrm{Spec}(\mathrm{A})$ *is surjective. Suppose that there is an* A'*-module* N' *of finite type which is flat over* A *and has support* $\mathrm{Spec}(\mathrm{A}')$*. If* $u : \mathrm{P} \to \mathrm{Q}$ *is a homomorphism of* A*-modules such that*

$$u \otimes 1 : \mathrm{P} \otimes_{\mathrm{A}} \mathrm{A}' \longrightarrow \mathrm{Q} \otimes_{\mathrm{A}} \mathrm{A}'$$

is surjective, then u *is surjective.*

Proof. Tensoring the assumed surjection with N' first shows that

$$u \otimes 1_{\mathrm{N}'} : (\mathrm{P} \otimes_{\mathrm{A}} \mathrm{A}') \otimes_{\mathrm{A}'} \mathrm{N}' \longrightarrow (\mathrm{Q} \otimes_{\mathrm{A}} \mathrm{A}') \otimes_{\mathrm{A}'} \mathrm{N}'$$

is surjective. Let $\mathfrak{q}$ be a prime ideal of A' and put $\mathfrak{p} = \rho^{-1}(\mathfrak{q})$. After localization, the corresponding map is

$$u_{\mathfrak{p}} \otimes 1 : \mathrm{P}_{\mathfrak{p}} \otimes_{\mathrm{A}_{\mathfrak{p}}} \mathrm{N}'_{\mathfrak{q}} \longrightarrow \mathrm{Q}_{\mathfrak{p}} \otimes_{\mathrm{A}_{\mathfrak{p}}} \mathrm{N}'_{\mathfrak{q}}$$

(**0**, 1.5.4). By the support hypothesis $\mathrm{N}'_{\mathfrak{q}} \neq 0$, and $\mathrm{N}'_{\mathfrak{q}}$ is flat over $\mathrm{A}_{\mathfrak{p}}$ (**0**, 6.3.1). Nakayama's lemma gives $\mathfrak{q}\mathrm{N}'_{\mathfrak{q}} \neq \mathrm{N}'_{\mathfrak{q}}$, hence a fortiori $\mathfrak{p}\mathrm{N}'_{\mathfrak{q}} \neq \mathrm{N}'_{\mathfrak{q}}$. Thus $\mathrm{N}'_{\mathfrak{q}}$ is faithfully flat over $\mathrm{A}_{\mathfrak{p}}$ (**0**, 6.4.1), and $u_{\mathfrak{p}}$ is surjective. Since f is surjective, every $\mathfrak{p} \in \mathrm{Spec}(\mathrm{A})$ occurs in this way; therefore u is surjective (Bourbaki, *Alg. comm.*, chap. II, § 3, no. 3, th. 1). □

Proposition (2.5.5). — *Let* $f : X \to Y$ *be a morphism, let* $\mathscr{F}$ *be a quasi-coherent* $\mathscr{O}_X$*-Module of finite type which is flat relative to* f*, and let* $\mathscr{G}$ *be a quasi-coherent* $\mathscr{O}_Y$*-Module of finite type. For* $y \in Y$*, set*

$$\mathscr{F}_y = \mathscr{F} \otimes_{\mathscr{O}_Y} k(y).$$

A point $x \in X$ *is a maximal point of* $\mathrm{Supp}(\mathscr{F} \otimes_Y \mathscr{G})$ *if and only if* $y = f(x)$ *is a maximal point of* $\mathrm{Supp}(\mathscr{G})$ *and* x *is a maximal point of* $\mathrm{Supp}(\mathscr{F}_y)$ *in* $f^{-1}(y)$*. When this holds, we have*

(2.5.5.1).

$$\mathrm{length}\big((\mathscr{F} \otimes_Y \mathscr{G})_x\big) = \mathrm{length}(\mathscr{G}_y)\ \mathrm{length}\big((\mathscr{F}_y)_x\big).$$

Proof. It is clear that

$$f\big(\mathrm{Supp}(\mathscr{F} \otimes_Y \mathscr{G})\big) \subset \mathrm{Supp}(\mathscr{G})$$

(**0**, 5.2.2); hence the image under f of every irreducible component of $\mathrm{Supp}(\mathscr{F} \otimes_Y \mathscr{G})$ is contained in an irreducible component of $\mathrm{Supp}(\mathscr{G})$.

We may reduce to the case $\mathrm{Supp}(\mathscr{F}) = X$. Indeed (**Err**$_{\mathbf{III}}$, 30), since $\mathscr{F}$ is of finite type, there is a closed subprescheme $X' \subset X$ with underlying space $\mathrm{Supp}(\mathscr{F})$ and a quasi-coherent $\mathscr{O}_{X'}$-Module $\mathscr{H}$ of finite type such that, for the canonical injection $j : X' \to X$,

$$\mathscr{F} = j_*(\mathscr{H}).$$

Set $f' = f \circ j$. Then $\mathscr{H}$ is flat relative to f', and

$$\mathrm{Supp}(\mathscr{F} \otimes_Y \mathscr{G}) = \mathrm{Supp}(\mathscr{H} \otimes_Y \mathscr{G}).$$

Suppose therefore that $\mathrm{Supp}(\mathscr{F}) = \mathrm{X}$. If Z is an irreducible component of $\mathrm{Supp}(\mathscr{G})$, then

$$f^{-1}(\mathrm{Z}) \subset \mathrm{Supp}(\mathscr{F} \otimes_Y \mathscr{G})$$

(**I**, 9.1.13); and (2.3.4) shows that every irreducible component of $f^{-1}(Z)$ dominates Z. Thus, if x is the generic point of an irreducible component of $\mathrm{Supp}(\mathscr{F} \otimes_Y \mathscr{G})$ contained in $f^{-1}(Z)$, then $y = f(x)$ is the generic point of Z. Moreover, by (**0**, 2.1.8), x is the generic point of an irreducible component of

$$f^{-1}(y) = \mathrm{Supp}(\mathscr{F}_y)$$

(**I**, 9.1.13); conversely, every generic point of one of these components is the generic point of an irreducible component of $f^{-1}(Z)$.

It remains to prove (2.5.5.1). We have

$$(\mathscr{F} \otimes_{\mathrm{Y}} \mathscr{G})_x = \mathscr{F}_x \otimes_{\mathscr{O}_{\mathrm{Y},y}} \mathscr{G}_y$$

(**I**, 9.1.12) and $(\mathscr{F}_y)_x = \mathscr{F}_x/\mathfrak{m}_y\mathscr{F}_x$; hence we are reduced to the following lemma. □

Lemma (2.5.5.2). — *Let* A *and* B *be local rings,* $\rho : \mathrm{A} \to \mathrm{B}$ *a local homomorphism, and* $\mathfrak{m}$ *the maximal ideal of* A*. Let* M *be an* A*-module and* N *a* B*-module which is faithfully flat over* A *and such that* $\mathrm{N}/\mathfrak{m}\mathrm{N}$ *has finite length as a* B*-module. Then*

(2.5.5.3).

$$\mathrm{length}_{\mathrm{B}}(\mathrm{M} \otimes_{\mathrm{A}} \mathrm{N}) = \mathrm{length}_{\mathrm{A}}(\mathrm{M}) \cdot \mathrm{length}_{\mathrm{B}}(\mathrm{N}/\mathfrak{m}\mathrm{N}).$$

Proof. If M has infinite length, then so does $\mathrm{M} \otimes_{\mathrm{A}} \mathrm{N}$. Indeed, every strictly increasing chain of n submodules M_i of M ($1 \leqslant i \leqslant n$) yields pairwise distinct sub-B-modules $\mathrm{M}_i \otimes_{\mathrm{A}} \mathrm{N}$ of $\mathrm{M} \otimes_{\mathrm{A}} \mathrm{N}$. Since $\mathrm{N} \neq \mathfrak{m}\mathrm{N}$, formula (2.5.5.3) holds in this case.

Suppose that M has finite length. If $\mathrm{M} = 0$, both sides of (2.5.5.3) vanish, so assume $\mathrm{M} \neq 0$. Each $\mathfrak{m}^k\mathrm{M}$ has finite length, and if $\mathfrak{m}^k\mathrm{M} \neq 0$, Nakayama's lemma gives $\mathfrak{m}^{k+1}\mathrm{M} \neq \mathfrak{m}^k\mathrm{M}$. Hence some r satisfies $\mathfrak{m}^r\mathrm{M} = 0$. The modules $\mathfrak{m}^k\mathrm{M} \otimes_{\mathrm{A}} \mathrm{N}$ identify with sub-B-modules of $\mathrm{M} \otimes_{\mathrm{A}} \mathrm{N}$, and

$$\frac{\mathfrak{m}^k\mathrm{M} \otimes_{\mathrm{A}} \mathrm{N}}{\mathfrak{m}^{k+1}\mathrm{M} \otimes_{\mathrm{A}} \mathrm{N}} \simeq \frac{\mathfrak{m}^k\mathrm{M}}{\mathfrak{m}^{k+1}\mathrm{M}} \otimes_{\mathrm{A}/\mathfrak{m}} \frac{\mathrm{N}}{\mathfrak{m}\mathrm{N}}$$

for $0 \leqslant k \leqslant r-1$. Its length as a B-module is the product of $\mathrm{length}_{\mathrm{B}}(\mathrm{N}/\mathfrak{m}\mathrm{N})$ and the dimension of the $(\mathrm{A}/\mathfrak{m})$-vector space $\mathfrak{m}^k\mathrm{M}/\mathfrak{m}^{k+1}\mathrm{M}$; the latter dimension is the length of that quotient as an A-module. Summing over $0 \leqslant k \leqslant r-1$ gives (2.5.5.3). □

Remark (2.5.5.4). — When N is an A-module *of finite type*, it is faithfully flat over A if and only if it is flat and $\mathrm{N} \neq 0$; indeed, Nakayama's lemma then shows that $\mathfrak{m}\mathrm{N} \neq \mathrm{N}$.

Lemma (2.5.6). — *Let* B *be a not necessarily commutative ring, let* V *and* W *be isomorphic left* B*-modules, set*

$$\mathrm{C} = \mathrm{End}_{\mathrm{B}}(\mathrm{V}), \qquad \mathrm{M} = \mathrm{Hom}_{\mathrm{B}}(\mathrm{V}, \mathrm{W}),$$

and equip M *with its canonical right* C*-module structure. Then* M *is isomorphic to the right regular module* C_d*. Moreover, for* $u \in \mathrm{M}$*, the following conditions are equivalent:*

a) $\{u\}$ *is a basis of the* C*-module* M*;*
b) u *is an isomorphism from* V *onto* W*.*

Proof. If u is an isomorphism from V onto W, then $v \mapsto u \circ v$ is a bijection from C to M, so *b)* implies *a)*. Conversely, suppose that $\{u\}$ is a basis of M. By hypothesis there is an isomorphism $u' : \mathrm{V} \to \mathrm{W}$, and $\{u'\}$ is also a basis of M. Hence $u = u' \circ w$ for some invertible $w \in \mathrm{C}$, that is, for some automorphism w of V. Thus u is an isomorphism. □

Corollary (2.5.7). — *Under the hypotheses of* (2.5.6)*, suppose in addition that one of the following conditions holds:*

(i) V *and* W *are Noetherian* B*-modules;*
(ii) V *and* W *are modules of finite presentation over a commutative subring of* B*.*

Then conditions a) *and* b) *of* (2.5.6) *are also equivalent to:*

a$'$) u *is a generator of the* C*-module* M*;*
b$'$) u *is an epimorphism of* V *onto* W*.*

Proof. An epimorphism from an A-module E onto itself is bijective in either of the following cases: 1° E is Noetherian (Bourbaki, *Alg.*, chap. VIII, § 2, no. 2, lemma 3); 2° A is commutative and E is of finite presentation (8.9.3)[6]. Therefore *b)* and *b*$'$) are equivalent. If u generates M, and $\{u'\}$ is a basis, **IV-2** | 25
there is $v \in \mathrm{C}$ such that $u' = u \circ v$, so u is surjective. Hence *a*$'$) implies *b*$'$); and *a)* plainly implies *a*$'$). This proves the corollary. □

[6]The reader may verify that (2.5.7) and (2.5.8) are not used before § 9.

Proposition (2.5.8). — *Let* A *be a commutative semilocal ring, let* B *be an* A*-algebra* (*not necessarily commutative*)*, and let* V *and* W *be* B*-modules. Let* A′ *be a commutative* A*-algebra which is faithfully flat as an* A*-module, and set*

$$\mathrm{B}' = \mathrm{B} \otimes_{\mathrm{A}} \mathrm{A}', \qquad \mathrm{V}' = \mathrm{V} \otimes_{\mathrm{A}} \mathrm{A}', \qquad \mathrm{W}' = \mathrm{W} \otimes_{\mathrm{A}} \mathrm{A}'.$$

Thus B′ *is an* A′*-algebra and* V′, W′ *are* B′*-modules. Suppose in addition that one of the following conditions holds:*

(i) A *and* A′ *are Noetherian, and* V *and* W *are* A*-modules of finite type;*
(ii) B *is an* A*-module of finite type, and* V *is both a projective* B*-module of finite type and an* A*-module of finite presentation.*

If V′ *and* W′ *are isomorphic as* B′*-modules, then* V *and* W *are isomorphic as* B*-modules.*

Proof. In case (ii), W′, being isomorphic to V′, is an A′-module of finite type. It follows that W is an A-module of finite type (Bourbaki, *Alg. comm.*, chap. I^er, § 3, no. 6, prop. 11). Thus in both cases V and W are A-modules of finite type.

(2.5.8.1). *Under either hypothesis* (i) *or* (ii), $\mathrm{Hom}_{\mathrm{B}}(\mathrm{V},\mathrm{W})$ *is an* A*-module of finite type.*

This is immediate in case (i), because $\mathrm{Hom}_{\mathrm{A}}(\mathrm{V},\mathrm{W})$ is then an A-module of finite type and $\mathrm{Hom}_{\mathrm{B}}(\mathrm{V},\mathrm{W})$ is an A-submodule. In case (ii), V is a direct factor of a free B-module B^n. Consequently, $\mathrm{Hom}_{\mathrm{B}}(\mathrm{V},\mathrm{W})$ is a direct factor of

$$\mathrm{Hom}_{\mathrm{B}}(\mathrm{B}^n,\mathrm{W}) = \mathrm{W}^n.$$

It is therefore of finite type over A.

Set

$$\mathrm{C} = \mathrm{End}_{\mathrm{B}}(\mathrm{V}), \qquad \mathrm{M} = \mathrm{Hom}_{\mathrm{B}}(\mathrm{V},\mathrm{W}).$$

These are A-modules of finite type in both cases. Under either hypothesis, the canonical homomorphism

(2.5.8.2).

$$\mathrm{Hom}_{\mathrm{A}}(\mathrm{V},\mathrm{W}) \otimes_{\mathrm{A}} \mathrm{A}' \longrightarrow \mathrm{Hom}_{\mathrm{A}'}(\mathrm{V}',\mathrm{W}')$$

is bijective (Bourbaki, *Alg. comm.*, chap. II, § 2, no. 10, prop. 11). Since A′ is flat over A,

$$\mathrm{Hom}_{\mathrm{B}}(\mathrm{V},\mathrm{W}) \otimes_{\mathrm{A}} \mathrm{A}'$$

identifies canonically with a sub-A′-module of $\mathrm{Hom}_{\mathrm{A}}(\mathrm{V},\mathrm{W}) \otimes_{\mathrm{A}} \mathrm{A}'$. Its image under (2.5.8.2) lies in $\mathrm{Hom}_{\mathrm{B}'}(\mathrm{V}',\mathrm{W}')$: if $u \in \mathrm{Hom}_{\mathrm{B}}(\mathrm{V},\mathrm{W})$ and $a' \in \mathrm{A}'$, the image of $u \otimes a'$ is the homomorphism $u' : \mathrm{V}' \to \mathrm{W}'$ satisfying $u'(x \otimes 1) = u(x) \otimes a'$, and

$$u'\big((b \otimes 1)(x \otimes 1)\big) = u(bx) \otimes a' = bu(x) \otimes a' = (b \otimes 1)\big(u(x) \otimes a'\big).$$

(2.5.8.3). *Under either hypothesis* (i) *or* (ii), *the homomorphism*

(2.5.8.4).

$$\mathrm{Hom}_{\mathrm{B}}(\mathrm{V},\mathrm{W}) \otimes_{\mathrm{A}} \mathrm{A}' \longrightarrow \mathrm{Hom}_{\mathrm{B}'}(\mathrm{V}',\mathrm{W}')$$

is bijective.

For $b \in \mathrm{B}$, let $h(b)$ (resp. $h'(b)$) denote the A-endomorphism $x \mapsto bx$ of V (resp. W). Let $(b_\alpha)_{\alpha\in\mathrm{I}}$ be a system of generators of the A-algebra B. The map

$$u \longmapsto (h'(b_\alpha) \circ u - u \circ h(b_\alpha))_{\alpha\in\mathrm{I}}$$

from $\mathrm{Hom}_{\mathrm{A}}(\mathrm{V},\mathrm{W})$ to $(\mathrm{Hom}_{\mathrm{A}}(\mathrm{V},\mathrm{W}))^{\mathrm{I}}$ is A-linear, and its kernel is precisely $\mathrm{Hom}_{\mathrm{B}}(\mathrm{V},\mathrm{W})$. Thus

$$0 \longrightarrow \mathrm{Hom}_{\mathrm{B}}(\mathrm{V},\mathrm{W}) \longrightarrow \mathrm{Hom}_{\mathrm{A}}(\mathrm{V},\mathrm{W}) \longrightarrow (\mathrm{Hom}_{\mathrm{A}}(\mathrm{V},\mathrm{W}))^{\mathrm{I}}.$$

The same reasoning applies after replacing A, B, V, W by A′, B′, V′, W′. Moreover, there is a commutative diagram

(2.5.8.5).

$$\begin{tikzcd}
0 \arrow[r] & \mathrm{Hom}_{\mathrm{B}}(\mathrm{V},\mathrm{W}) \otimes_{\mathrm{A}} \mathrm{A}' \arrow[r] \arrow[d, "r"] & \mathrm{Hom}_{\mathrm{A}}(\mathrm{V},\mathrm{W}) \otimes_{\mathrm{A}} \mathrm{A}' \arrow[r] \arrow[d, "s"] & (\mathrm{Hom}_{\mathrm{A}}(\mathrm{V},\mathrm{W}))^{\mathrm{I}} \otimes_{\mathrm{A}} \mathrm{A}' \arrow[d, "t"] \\
0 \arrow[r] & \mathrm{Hom}_{\mathrm{B}'}(\mathrm{V}',\mathrm{W}') \arrow[r] & \mathrm{Hom}_{\mathrm{A}'}(\mathrm{V}',\mathrm{W}') \arrow[r] & (\mathrm{Hom}_{\mathrm{A}'}(\mathrm{V}',\mathrm{W}'))^{\mathrm{I}}
\end{tikzcd}$$

Here r is (2.5.8.4), s is (2.5.8.2), and t is the composite

$$(\mathrm{Hom}_{\mathrm{A}}(\mathrm{V},\mathrm{W}))^{\mathrm{I}} \otimes_{\mathrm{A}} \mathrm{A}' \xrightarrow{w} (\mathrm{Hom}_{\mathrm{A}}(\mathrm{V},\mathrm{W}) \otimes_{\mathrm{A}} \mathrm{A}')^{\mathrm{I}} \xrightarrow{s^{\mathrm{I}}} (\mathrm{Hom}_{\mathrm{A}'}(\mathrm{V}',\mathrm{W}'))^{\mathrm{I}}$$

where w is the canonical homomorphism (Bourbaki, *Alg.*, chap. II, 3$^{\mathrm{e}}$ ed., § 3, no. 7). Since A′ is flat over A, the rows of (2.5.8.5) are exact.

The map s is an isomorphism, hence so is s^{I}. In case (ii) we may take I finite, and then w is **IV-2** | 26
bijective (Bourbaki, *loc. cit.*, prop. 7). In case (i), let B_1 (resp. B_2) be the image of B under h (resp. h') in $\mathrm{End}_{\mathrm{A}}(\mathrm{V})$ (resp. $\mathrm{End}_{\mathrm{A}}(\mathrm{W})$). Both images are A-modules of finite type, so here too I may be chosen finite. Thus t, and consequently r, is bijective in both cases.

(2.5.8.6). It follows from (2.5.8.4) that, if

$$\mathrm{C}' = \mathrm{C} \otimes_{\mathrm{A}} \mathrm{A}', \qquad \mathrm{M}' = \mathrm{M} \otimes_{\mathrm{A}} \mathrm{A}'$$

then there are canonical bijections

$$\mathrm{C}' \xrightarrow{\sim} \mathrm{End}_{\mathrm{B}'}(\mathrm{V}'), \qquad \mathrm{M}' \xrightarrow{\sim} \mathrm{Hom}_{\mathrm{B}'}(\mathrm{V}',\mathrm{W}')$$

the first an isomorphism of A′-algebras and the second, through the first, an isomorphism of right C′-modules.

(2.5.8.7). *Reduction to the case* $\mathrm{V} = \mathrm{B}_s$. The hypothesis that V′ and W′ are isomorphic B′-modules implies that C'_d and M′ are isomorphic right C′-modules (2.5.6). To prove (2.5.8), it is enough to find $u \in \mathrm{M}$ which generates M as a right C-module. Indeed, $u' = u \otimes 1$ then generates M′ as a right C′-module. In case (i), V′ and W′ are Noetherian A′-modules; in case (ii), they are isomorphic A′-modules of finite presentation. Corollary (2.5.7) therefore shows that u' is a B′-isomorphism $\mathrm{V}' \to \mathrm{W}'$. Since A′ is faithfully flat over A, u is bijective (**0**, 6.4.1).

In case (i), C and M are A-modules of finite type. In case (ii), C is a direct factor of V^n by (2.5.8.1), hence a projective A-module of finite type. After changing notation, we are therefore reduced to proving (2.5.8) when $\mathrm{V} = \mathrm{B}_s$; it is enough to prove that the B-module W has a generator. In this case B is an A-module of finite type.

(2.5.8.8). *Reduction to the case where* A *and* A′ *are fields and* B *is a simple* A*-algebra with centre* A.

Let $\mathfrak{r}$ be the radical of the semilocal ring A. It is enough to prove that $\mathrm{W}/\mathfrak{r}\mathrm{W}$ is a cyclic $(\mathrm{B}/\mathfrak{r}\mathrm{B})$-module. Indeed, a surjection

$$\mathrm{B}_s/\mathfrak{r}\mathrm{B}_s \longrightarrow \mathrm{W}/\mathfrak{r}\mathrm{W}$$

composes with $\mathrm{B}_s \to \mathrm{B}_s/\mathfrak{r}\mathrm{B}_s$ and, since B_s is free as a B-module, lifts to a map $u : \mathrm{B}_s \to \mathrm{W}$. The displayed surjection is $u \otimes 1$ after tensoring over A with $\mathrm{A}/\mathfrak{r}$. Since W is of finite type over A, Nakayama's lemma shows that u is surjective (Bourbaki, *Alg. comm.*, chap. II, § 3, no. 2, cor. 1 of prop. 4).

Put

$$\mathrm{A}_1 = \mathrm{A}/\mathfrak{r}, \qquad \mathrm{A}'_1 = \mathrm{A}' \otimes_{\mathrm{A}} \mathrm{A}_1 = \mathrm{A}'/\mathfrak{r}\mathrm{A}',$$
$$\mathrm{B}_1 = \mathrm{B}/\mathfrak{r}\mathrm{B} = \mathrm{B} \otimes_{\mathrm{A}} \mathrm{A}_1, \quad \mathrm{W}_1 = \mathrm{W}/\mathfrak{r}\mathrm{W} = \mathrm{W} \otimes_{\mathrm{A}} \mathrm{A}_1.$$

The hypotheses remain valid after replacing A, A′, B, $\mathrm{V} = \mathrm{B}_s$, and W by A_1, A'_1, B_1, $\mathrm{V}_1 = (\mathrm{B}_1)_s$, and W_1. Moreover, A'_1 is faithfully flat over A_1, and the corresponding base changes of V_1 and W_1 remain isomorphic. We may therefore suppose that A is a finite product of fields.

The ring B is then Artinian. Let $\mathfrak{N}$ be its radical. It is enough, by the same Nakayama argument, to prove that $\mathrm{W}/\mathfrak{N}\mathrm{W}$ is cyclic over $\mathrm{B}/\mathfrak{N}$. Since

$$\mathrm{B}'/\mathfrak{N}\mathrm{B}' = (\mathrm{B}/\mathfrak{N}) \otimes_{\mathrm{A}} \mathrm{A}',$$
$$\mathrm{W}'/\mathfrak{N}\mathrm{W}' = (\mathrm{W}/\mathfrak{N}\mathrm{W}) \otimes_{\mathrm{A}} \mathrm{A}',$$

and the latter is isomorphic to the right regular module over the former, we may further suppose that $\mathfrak{N} = 0$, that is, that B is a semisimple A-algebra.

Write $A = \prod_{i=1}^{n} k_i$. Then $A' = \prod_{i=1}^{n} A'_i$, where each A'_i is a k_i-algebra and is annihilated by the other factors k_j. Faithful flatness implies $A'_i \neq 0$. Choose a field quotient k'_i of each A'_i and set $A'' = \prod_i k'_i$. Then A'' is faithfully flat over A and is a quotient of A'. After the further base change,

$$B'' = B \otimes_A A'', \qquad W'' = W \otimes_A A'',$$

the module W'' remains isomorphic to B''_s. Hence we may also suppose that A' is a finite product of fields.

Let Z be the centre of B. It is a finite product of fields and an A-module of finite type; B and W are finite, hence projective, Z-modules. Put $Z' = Z \otimes_A A'$. Then

$$B' = B \otimes_Z Z', \qquad W' = W \otimes_Z Z',$$

and Z' is faithfully flat over Z. We may replace A by Z and thus suppose that A is the centre of B.

If k_i are the field factors of A, then $B = \prod_i B_i$, with B_i a simple ring of centre k_i, and $W = \bigoplus_i W_i$, where the other factors B_j annihilate W_i. We may suppose likewise that $A' = \prod_i k'_i$, where k'_i/k_i is a field extension. For every i,

$$(B_i \otimes_{k_i} k'_i)_s \quad \text{and} \quad W_i \otimes_{k_i} k'_i$$

are isomorphic modules over $B_i \otimes_{k_i} k'_i$. It therefore suffices to treat $n = 1$: A and A' are fields, and B is a simple algebra with centre A.

(2.5.8.9). *End of the proof.* Every B-module is a direct sum of modules isomorphic to a minimal ideal of B (Bourbaki, *Alg.*, chap. VIII, § 5, props. 6 and 8). Thus two B-modules of finite rank over A are isomorphic if and only if they have the same rank over A. By hypothesis,

$$[W' : A'] = [B'_s : A'].$$

But

$$[W' : A'] = [W : A], \qquad [B'_s : A'] = [B_s : A],$$

so $[W : A] = [B_s : A]$. This completes the proof.

2.6. Permanence of set-theoretic and topological properties of morphisms by faithfully flat descent

Proposition (2.6.1). — *Let $f : X \to Y$ be an S-morphism of S-preschemes, and let $g : S' \to S$ be a surjective morphism. Set*

$$X' = X_{(S')}, \qquad Y' = Y_{(S')}, \qquad f' = f_{(S')} : X' \longrightarrow Y'.$$

Consider, for a morphism, the property of being:

- *(i) surjective;*
- *(ii) injective;*
- *(iii) with finite fibres (as sets);*
- *(iv) bijective;*
- *(v) radicial.*

If **P** *denotes any one of these properties and f' has property* **P**, *then so does f.*

Proof. The projection $Y' \to Y$ is itself surjective (**I**, 3.5.2); hence, by (**I**, 3.3.11), we may reduce to the case $Y = S$ and $Y' = S'$. For $y \in Y$ (resp. $y' \in Y'$), denote by X_y (resp. $X'_{y'}$) the fibre prescheme $f^{-1}(y)$ (resp. $f'^{-1}(y')$) (**I**, 3.6.2). If $y' \in Y'$ and $y = g(y')$, there is a canonical isomorphism

$$X'_{y'} \xrightarrow{\sim} X_y \otimes_{k(y)} k(y')$$

(**I**, 3.6.4). Since $\operatorname{Spec}(k(y')) \to \operatorname{Spec}(k(y))$ is surjective, so is the projection $X'_{y'} \to X_y$ (**I**, 3.5.2). Therefore, if $X'_{y'}$ is nonempty (resp. has at most one point, resp. is a finite set), the same is true of X_y. Since $g : Y' \to Y$ is surjective, this proves the assertion in cases (i), (ii), and (iii); case (iv) follows from (i) and (ii).

Finally, for (v), it is enough to show that if f' is universally injective (**I**, 3.5.11), then so is f. Let $Y_1 \to Y$ be any morphism and set

$$X_1 = X \times_Y Y_1, \qquad f_1 = f_{(Y_1)}.$$

Also set

$$\begin{aligned} Y_1' &= Y_1 \times_Y Y', \\ X_1' &= X' \times_{Y'} Y_1' = X_1 \times_{Y_1} Y_1', \\ f_1' &= f'_{(Y_1')} = (f_1)_{(Y_1')} : X_1' \longrightarrow Y_1'. \end{aligned}$$

The projection $g_1 = g_{(Y_1)} : Y_1' \to Y_1$ is surjective (**I**, 3.5.2); and, since f' is universally injective, f_1' is injective. Case (ii) then shows that f_1 is injective, which proves the assertion. □

Proposition (2.6.2). — *With the notation of (2.6.1), suppose that $g : S' \to S$ is faithfully flat and quasi-compact. Consider, for a morphism, the property of being:*

(i) open;
(ii) closed;
(iii) quasi-compact and a homeomorphism onto its image subspace;
(iv) a homeomorphism.

If **P** *denotes any one of these properties and f' has property* **P**, *then so does f.*

IV-2 | 28

Proof. The morphism $Y' \to Y$ is faithfully flat and quasi-compact (2.2.13) and (1.1.2); hence, by (**I**, 3.3.11), we may reduce to the case $Y = S$, $Y' = S'$. Let $g' : X' \to X$ be the projection. For every subset M of X we have

$$g^{-1}(f(M)) = f'(g'^{-1}(M))$$

(**I**, 3.4.8). If f' is open (resp. closed), then, for every open (resp. closed) subset M of X, the subset $f'(g'^{-1}(M))$ is open (resp. closed) in Y'. Since g is faithfully flat and quasi-compact, (2.3.12) implies that $f(M)$ is open (resp. closed) in Y. This proves cases (i) and (ii).

Let us prove (iii), which also yields (iv) in view of (2.6.1, (iv)). By (2.6.1, (ii)), f is injective; it remains to prove that f, considered as a map from X onto $f(X)$, is quasi-compact and open. Since f' is quasi-compact, so is f (1.1.4). It is therefore enough to prove, for every closed subset Z of X, that

$$Z = f^{-1}(\overline{f(Z)}).$$

Since g' is surjective, this is equivalent to

$$\begin{aligned} g'^{-1}(Z) &= g'^{-1}\left(f^{-1}(\overline{f(Z)})\right) \\ &= f'^{-1}\left(g^{-1}(\overline{f(Z)})\right). \end{aligned}$$

The composite of the canonical injection $Z \to X$ with f is quasi-compact, where Z denotes here the reduced closed subprescheme of X with underlying space Z. Applying (2.3.10) to the subset $f(Z)$ of Y, the image of the morphism $f|_Z$, gives

$$g^{-1}(\overline{f(Z)}) = \overline{g^{-1}(f(Z))}.$$

If $Z' = g'^{-1}(Z)$, the required formula is consequently equivalent to

$$Z' = f'^{-1}(\overline{f'(Z')}),$$

which follows from the hypothesis that f' is a homeomorphism from X' onto $f'(X')$. □

Remark (2.6.3). — In cases (i) and (ii), the conclusions of (2.6.2) remain valid if g is assumed only *quasi-faithfully flat* (2.3.3) and quasi-compact. Indeed, by (2.1.4), (**I**, 3.5.2), and (**I**, 9.1.13.1), we may again reduce to the case $Y = S$, $Y' = S'$, and the conclusion follows from (2.3.12). In cases (iii) and (iv), the conclusions remain valid if g is assumed only quasi-faithfully flat, provided that f is already assumed quasi-compact; the proof then uses only (2.3.10) and the surjectivity of g.

Finally, if g is faithfully flat and locally of finite presentation, or if g is surjective and S is discrete, the conclusion of (2.6.2) remains valid when **P** is the property

(iii *bis*) of being a homeomorphism onto its image subspace;

as follows from the proof of (2.6.2) and Remark (2.4.11).

Corollary (2.6.4). — *With the notation of (2.6.1), suppose that $g : S' \to S$ is faithfully flat and quasi-compact. Consider, for a morphism, the property of being:*

(i) *universally open;*
(ii) *universally closed;*
(iii) *quasi-compact and universally bicontinuous;*
(iv) *a universal homeomorphism;*
(v) *quasi-compact;*
(vi) *quasi-compact and dominant.*

If **P** *denotes any one of these properties, then f has property* **P** *if and only if f' does.*

Proof. Properties (v) and (vi) are only given for the record, being consequences of (1.1.4), (1.1.6), and (2.3.7). For the other properties, necessity follows from (2.4.3). Conversely, suppose, for example, that f' is universally open, and let $Y_1 \to Y$ be any morphism. Set

$$X_1 = X \times_Y Y_1, \qquad f_1 = f_{(Y_1)}.$$

Also set

$$\begin{aligned} Y'_1 &= Y_1 \times_Y Y', \\ X'_1 &= X' \times_{Y'} Y'_1 = X_1 \times_{Y_1} Y'_1, \\ f'_1 &= f'_{(Y'_1)} = (f_1)_{(Y'_1)} : X'_1 \longrightarrow Y'_1. \end{aligned}$$

The projection $g_1 = g_{(Y_1)} : Y'_1 \to Y_1$ is faithfully flat and quasi-compact (2.2.13) and (1.1.2). Since f' is universally open, f'_1 is open, and (2.6.2) then shows that f_1 is open. Hence f is universally open. The same argument applies in the other cases.

One may again replace "faithfully flat" by "quasi-faithfully flat". Moreover, when g is locally of finite presentation, or when g is surjective and S is discrete, property (iii) may be replaced by

(iii *bis*) universally bicontinuous.

□

IV-2 | 29

2.7. Permanence of various properties of morphisms under faithfully flat descent

Proposition (2.7.1). — *Let $f : X \to Y$ be an S-morphism of S-preschemes, and let $g : S' \to S$ be faithfully flat and quasi-compact. Set*

$$X' = X_{(S')}, \qquad Y' = Y_{(S')}, \qquad f' = f_{(S')} : X' \longrightarrow Y'.$$

Consider, for a morphism, the property of being:

(i) *separated;*
(ii) *quasi-separated;*
(iii) *locally of finite type;*
(iv) *locally of finite presentation;*
(v) *of finite type;*
(vi) *of finite presentation;*
(vii) *proper;*
(viii) *an isomorphism;*
(ix) *a monomorphism;*
(x) *an open immersion;*
(xi) *a quasi-compact immersion;*
(xii) *a closed immersion;*
(xiii) *affine;*
(xiv) *quasi-affine;*
(xv) *finite;*
(xvi) *quasi-finite;*
(xvii) *integral.*

If **P** *denotes any one of these properties, then f has property* **P** *if and only if f' does.*

Proof. It was proved in Chapters I and II and in Chapter IV, § 1, that if f has one of the properties **P** above, then so does f' (without any hypothesis on $g : \mathrm{S}' \to \mathrm{S}$). It remains to prove the converse. Since the projection $Y' \to Y$ is

a faithfully flat and quasi-compact morphism (2.2.13) and (1.1.2), we may, by (**I**, 3.3.11), reduce to the case $\mathrm{S} = Y, \mathrm{S}' = Y'$. **IV-2** | 30

(i) To say that f is separated means that its diagonal $\Delta_f : X \to X \times_Y X$ is closed. Since $\Delta_{f'} = (\Delta_f)_{(Y')}$ (**I**, 5.3.4), if $\Delta_{f'}$ is closed, then so is Δ_f by (2.6.2); hence f is separated.

(ii) This was already proved under weaker hypotheses (1.2.5).

(iii) and (iv). The question is plainly local on X and Y and, in view of (2.2.12), it is therefore enough to prove the following lemma.

Lemma (2.7.1.1). — *Let A be a ring, B an A-algebra, and A' an A-algebra that is faithfully flat as an A-module; put $B' = B \otimes_A A'$. Then B is an A-algebra of finite type* (*resp. of finite presentation*) *if and only if B' is an A'-algebra of finite type* (*resp. of finite presentation*).

Necessity is already known without any hypothesis on A' (1.3.4), (1.3.6), (1.4.3), and (1.4.6). Suppose that B' is an A'-algebra of finite type. Let $(B_\alpha)_{\alpha \in I}$ be the filtered increasing family of finite-type A-subalgebras of B. Then

$$B = \varinjlim_{\alpha} B_\alpha, \qquad B' = \varinjlim_{\alpha} (B_\alpha \otimes_A A'),$$

because tensor product commutes with inductive limits. If (x_i') is a finite set of generators of the A'-algebra B', there is an index α such that every x_i' belongs to the subalgebra $B_\alpha \otimes_A A'$ of B'. Hence $B' = B_\alpha \otimes_A A'$, and faithful flatness gives $B = B_\alpha$ (**0**, 6.4.1).

Now suppose that B' is an A'-algebra of finite presentation. What precedes shows that B is an A-algebra of finite type. Thus there are a polynomial A-algebra $C = A[T_1, \ldots, T_m]$ and a surjective A-homomorphism of algebras $C \to B$. Let $\mathfrak{J}$ be its kernel. We have an exact sequence

$$0 \longrightarrow \mathfrak{J} \longrightarrow C \longrightarrow B \longrightarrow 0,$$

and, since A' is flat over A, an exact sequence

$$0 \longrightarrow \mathfrak{J}' \longrightarrow C' \longrightarrow B' \longrightarrow 0,$$

where

$$C' = C \otimes_A A' = A'[T_1, \ldots, T_m], \qquad \mathfrak{J}' = \mathfrak{J} \otimes_A A'$$

and $\mathfrak{J}'$ is identified with an ideal of C'. Since B' is of finite presentation over A', the C'-module $\mathfrak{J}'$ is of finite type (1.4.4). But $\mathfrak{J}' = \mathfrak{J} \otimes_C C'$, and C' is faithfully flat over C (2.2.13) and (2.2.3). It follows that $\mathfrak{J}$ is a C-module of finite type (Bourbaki, *Algèbre commutative*, Chap. I, § 3, no. 6, Prop. 11). Hence B is an A-algebra of finite presentation.

(v) This follows from (iii) and (2.6.4, (v)), by (1.5.2).

(vi) This follows similarly from (iv), (v), and (ii), by (1.6.1).

(vii) This follows from (i), (v), and (2.6.4, (ii)), by (**II**, 5.4.1).

(viii) Since f' is an isomorphism, it is a universal homeomorphism; hence so is f (2.6.4). In particular, f is quasi-compact and separated (2.4.4). Write $f = (\psi, \theta)$, where ψ is therefore a homeomorphism. It remains to prove that

$$\theta : \mathscr{O}_Y \longrightarrow f_*(\mathscr{O}_X)$$

is an isomorphism of $\mathscr{O}_Y$-modules. If $f' = (\psi', \theta')$, then

$$\theta' : \mathscr{O}_{Y'} \longrightarrow f'_*(\mathscr{O}_{X'})$$

is the composite of $g^*(\theta)$ with the canonical homomorphism

$$g^*\big(f_*(\mathscr{O}_X)\big) \longrightarrow f'_*(\mathscr{O}_{X'})$$

(2.3.2). The latter is bijective by (2.3.1). Thus, if θ' is bijective, then so is $g^*(\theta)$; since g is faithfully flat, θ is bijective (2.2.7). This proves (viii).

(ix) This follows from (viii), (**I**, 5.3.4), and (**I**, 5.3.8), which reduces monomorphisms to isomorphisms.

(x) If f' is an open immersion, then $f'(X')$ is open in Y', and

$$f'(X') = g^{-1}(f(X))$$

(**I**, 3.4.8). It follows from (2.3.12) that $f(X)$ is open. Replacing Y (resp. Y') by the subprescheme induced on $f(X)$ (resp. $f'(X')$), and using (1.1.2) and (2.2.13), we reduce to the case where f' is an isomorphism. Then f is an isomorphism by (viii), proving (x).

(xi) If f' is a quasi-compact immersion, then it is a quasi-compact and quasi-separated morphism (1.2.2); hence so is f, by (ii) and (2.6.4, (v)). Let Z be the closed subprescheme of Y that is the closed image of X under f (1.7.8), and write $f = j \circ q$, where $j : Z \to Y$ is the canonical injection. Then $f' = j' \circ q'$, with $j' = j_{(Y')}$ and $q' = q_{(Y')}$. Moreover, j' identifies with the canonical injection $Z' \to Y'$ of the closed image Z' of X' under f' (2.3.2). The hypothesis on f' now says that q' is an open immersion (**I**, 9.5.10); hence so is q, by (x), and therefore f is an immersion. **IV-2** | 31

(xii) To say that f (resp. f') is a closed immersion is to say that it is a quasi-compact immersion and a closed morphism. Thus (xii) follows from (xi) and (2.6.2, (ii)).

(xiii) and (xiv). Suppose that f' is affine (resp. quasi-affine). Then f' is quasi-compact and quasi-separated (**II**, 5.1.1), and so is f by (ii) and (2.6.4, (v)). Put

$$\mathscr{A} = f_*(\mathscr{O}_X), \qquad \mathscr{A}' = f'_*(\mathscr{O}_{X'}).$$

By (2.3.1), the canonical homomorphism of $\mathscr{O}_{Y'}$-algebras $g^*(\mathscr{A}) \to \mathscr{A}'$ is bijective. Consequently, if $h : Z = \operatorname{Spec}(\mathscr{A}) \to Y$ is the structure morphism, then the structure morphism $h' : Z' = \operatorname{Spec}(\mathscr{A}') \to Y'$ identifies with $h_{(Y')}$ (**II**, 1.5.2). Let $u : X \to Z$ (resp. $u' : X' \to Z'$) be the canonical Y-morphism (resp. Y'-morphism) corresponding to the identity homomorphism of $\mathscr{A}$ (resp. $\mathscr{A}'$) (**II**, 1.2.7). We have a commutative diagram

$$\begin{tikzcd}
X \arrow[d, "u"'] & X' \arrow[l] \arrow[d, "u'"] \\
Z \arrow[d, "h"'] & Z' \arrow[l, "g'"'] \arrow[d, "h'"] \\
Y & Y' \arrow[l, "g"]
\end{tikzcd}$$

and $h' \circ u' = f'$. It follows from (**II**, 1.2.7) that $u' = u_{(Z')}$. The projection $g' : Z' \to Z$ is faithfully flat and quasi-compact (1.1.2) and (2.2.13). The hypothesis on f' says that u' is an isomorphism (resp. an open immersion) (**II**, 5.1.6); by (viii) (resp. (x)), u is an isomorphism (resp. an open immersion). This proves (xiii) (resp. (xiv)).

(xv) If f' is finite, it is affine; hence f is affine by (xiii). With the notation used there, $\mathscr{A}'$ is an $\mathscr{O}_{Y'}$-module of finite type and is isomorphic to $g^*(\mathscr{A})$. It follows from (2.5.2) that $\mathscr{A}$ is an $\mathscr{O}_Y$-module of finite type, and therefore f is finite. **IV-2** | 32

(xvi) To say that f is quasi-finite is to say that f is of finite type and that $f^{-1}(y)$ is finite for every $y \in Y$ (**II**, 6.2.2) and (**I**, 6.4.4). The conclusion therefore follows from (v) and (xv), applied to the fibres.

(xvii) As in (xv), one first sees that f is affine. We may reduce to the case

$$Y = \operatorname{Spec}(A), \qquad Y' = \operatorname{Spec}(A'), \qquad X = \operatorname{Spec}(B), \qquad X' = \operatorname{Spec}(B'),$$

where $B' = B \otimes_A A'$. The ring B is the inductive limit of its finite-type A-subalgebras B_α; hence

$$B' = \varinjlim_\alpha B'_\alpha, \qquad B'_\alpha = B_\alpha \otimes_A A',$$

and each B'_α is a finite-type A'-algebra. By hypothesis, B' is integral over A', so each B'_α is an A'-module of finite type. Hence B_α is an A-module of finite type (2.5.2), and is therefore integral over A. Since every element of B lies in some B_α, the algebra B is integral over A. □

Corollary (2.7.2). — *Under the hypotheses and notation of (2.7.1), suppose that f is quasi-compact. Let $\mathscr{L}$ be an invertible $\mathscr{O}_X$-module and, if $g' : X' \to X$ is the projection, let $\mathscr{L}' = g'^*(\mathscr{L})$ be its inverse image. Then $\mathscr{L}$ is ample (resp. very ample) for f if and only if $\mathscr{L}'$ is ample (resp. very ample) for f'.*

Proof. Necessity holds without any hypothesis on $g : \mathrm{S}' \to \mathrm{S}$ (**II**, 4.4.10) and (**II**, 4.6.13). To prove sufficiency, we may, as in (2.7.1), reduce to the case $\mathrm{S} = Y, \mathrm{S}' = Y'$. The hypothesis on $\mathscr{L}'$ implies that f' is quasi-compact and separated (**II**, 4.6.1); hence so is f, by (2.6.4, (v)) and (2.7.1, (i)). Put

$$\mathscr{E} = f_*(\mathscr{L}), \qquad \mathscr{E}' = f'_*(\mathscr{L}').$$

By (2.3.1), the canonical homomorphism

$$u : g^*(\mathscr{E}) \longrightarrow \mathscr{E}'$$

is bijective. Suppose first that $\mathscr{L}'$ is very ample for f'. The canonical homomorphism $\sigma' : f'^*(\mathscr{E}') \to \mathscr{L}'$ is then surjective, and

$$r' = r_{\mathscr{L}',\sigma'} : X' \longrightarrow \mathbf{P}(\mathscr{E}')$$

is a necessarily quasi-compact immersion (**II**, 4.4.4, (b)) and (1.1.2, (v)). If

$$h : \mathbf{P}(\mathscr{E}) \longrightarrow Y, \qquad h' : \mathbf{P}(\mathscr{E}') \longrightarrow Y'$$

are the structure morphisms, the bijectivity of u implies that h' identifies with $h_{(Y')}$ (**II**, 4.1.3). On the other hand, the projection $g' : X' \to X$ is faithfully flat (2.2.13), and $f \circ g' = g \circ f'$. Let $\sigma : f^*(\mathscr{E}) \to \mathscr{L}$ be the canonical homomorphism. One readily verifies that $g'^*(\sigma)$ is the composite

$$f'^*(g^*(f_*(\mathscr{L}))) \xrightarrow{f'^*(u)} f'^*(f'_*(\mathscr{L}')) \xrightarrow{\sigma'} \mathscr{L}'.$$

This may be checked, for example, by reducing to the case where Y and Y' are affine. Since σ' is surjective and $f'^*(u)$ is bijective, $g'^*(\sigma)$ is surjective; hence σ is surjective by (2.2.7). Thus the morphism

$$r = r_{\mathscr{L},\sigma} : X \longrightarrow \mathbf{P}(\mathscr{E})$$

is everywhere defined (**II**, 3.7.4). Put $P = \mathbf{P}(\mathscr{E})$ and $P' = \mathbf{P}(\mathscr{E}')$, and let $g'' : P' \to P$ be the projection. Then r' identifies with $r_{(P')}$ (**II**, 4.2.10), while g'' is faithfully flat and quasi-compact (1.1.2) and (2.2.13). By (2.7.1, (xi)), r is an immersion, and therefore $\mathscr{L}$ is very ample (**II**, 4.4.4, (b)).

Now suppose that $\mathscr{L}'$ is ample for f'. To prove that $\mathscr{L}$ is ample for f, we may reduce to the case where Y is affine (**II**, 4.6.4); by (2.2.12) and (**II**, 4.6.13), we may also suppose that Y' is affine. Then X and X' are quasi-compact schemes, and we may apply the criterion of (**II**, 4.6.8, (c)). Let $\mathscr{F}$ be a quasi-coherent $\mathscr{O}_X$-module of finite type, and let

$$\sigma : f^*f_*(\mathscr{F} \otimes \mathscr{L}^{\otimes n}) \longrightarrow \mathscr{F} \otimes \mathscr{L}^{\otimes n}$$

be the canonical homomorphism. As above, $g'^*(\sigma)$ is the composite

$$f'^*\big(g^*f_*(\mathscr{F} \otimes \mathscr{L}^{\otimes n})\big) \xrightarrow{f'^*(u)} f'^*f'_*(\mathscr{F}' \otimes \mathscr{L}'^{\otimes n}) \xrightarrow{\sigma'} \mathscr{F}' \otimes \mathscr{L}'^{\otimes n},$$

where $\mathscr{F}' = g'^*(\mathscr{F})$, using (**0**, 4.3.3.1), and where u is the canonical homomorphism

$$g^*f_*(\mathscr{F} \otimes \mathscr{L}^{\otimes n}) \longrightarrow f'_*(\mathscr{F}' \otimes \mathscr{L}'^{\otimes n}).$$

The homomorphism u is bijective for every n by (2.3.1). Moreover, $\mathscr{F}'$ is quasi-coherent and of finite type, so the ampleness of $\mathscr{L}'$ for f' gives an n_0 such that σ' is surjective for $n \geqslant n_0$. Thus $g'^*(\sigma)$ is surjective for $n \geqslant n_0$; since g' is faithfully flat, σ is surjective for these values of n (2.2.7). This completes the proof. □

IV-2 | 33

Remarks (2.7.3). — (i) It follows from (2.6.1), (2.6.4), and (2.5.4.1) that the conclusions of (2.7.1) remain valid in cases (i), (iii), (v), (vii), and (xvi) when g is assumed only quasi-compact and *quasi-faithfully flat* (2.3.3). We already noted that case (ii) of (2.7.1) is valid under the sole assumptions that g is surjective and quasi-compact.

(ii) Under the hypotheses and notation of (2.7.1), it can happen that f is proper and f' is projective while f is not quasi-projective. Indeed, Hironaka [Hir] gave an example of a proper nonprojective morphism $f : X \to Y$, where X and Y are regular algebraic schemes (**0**, 4.1.4) over the same field k, with Y projective over k. Moreover, Y is the union of two affine open subsets Y_i ($i = 1, 2$) such that

$$f_i : X \times_Y Y_i \longrightarrow Y_i$$

is projective for $i = 1, 2$. Let $Y' = Y_1 \amalg Y_2$ be their coproduct as preschemes. The canonical morphism $g : Y' \to Y$, whose restrictions are the canonical injections of Y_1 and Y_2 into Y, is faithfully flat and is quasi-compact by (**I**, 5.5.10). Yet $f' : X \times_Y Y' \to Y'$, whose restriction to each Y_i is f_i, is projective (**II**, 5.5.6), whereas f is not. Consequently there exists an invertible $\mathscr{O}_{X'}$-module $\mathscr{L}'$ that is f'-ample but is not of the form $g'^*(\mathscr{L})$ for an invertible $\mathscr{O}_X$-module $\mathscr{L}$, where $g' : X' \to X$ is the projection, by (2.7.2).

(iii) Under the hypotheses of (2.7.1), it can happen that f' is a local isomorphism while f is not a local immersion. Indeed, let k be a field, let $\bar{k}$ be an algebraic closure of k, and let $K \neq k$ be a finite separable extension of k. The structure morphism $f : X \to Y$, where $X = \mathrm{Spec}(K)$ and $Y = \mathrm{Spec}(k)$, is not a local immersion. But if $Y' = \mathrm{Spec}(\bar{k})$, then $Y' \to Y$ is faithfully flat and quasi-compact, and f' is a local isomorphism, since $X' = X \times_Y Y'$ is a coproduct of finitely many schemes isomorphic to Y'.

2.8. Preschemes over a regular base of dimension 1; closure of a closed subprescheme of the generic fibre

Proposition (2.8.1). — *Let Y be a locally Noetherian, regular, irreducible prescheme of dimension 1, with generic point η. Let $f : X \to Y$ be a morphism, let $X_\eta = f^{-1}(\eta)$ be the fibre at the generic point,*

and let $i : X_\eta \to X$ be the canonical morphism. Let $\mathscr{F}$ be a quasi-coherent $\mathscr{O}_X$-module, put $\mathscr{F}_\eta = i^*(\mathscr{F})$, **IV-2 | 34**
let $\mathscr{G}'$ be an $\mathscr{O}_{X_\eta}$-module quotient of $\mathscr{F}_\eta$, and let $\overline{\mathscr{G}'}$ be the image of $\mathscr{F}$ under the composite homomorphism (**0**, 4.4.3.2)

$$\mathscr{F} \xrightarrow{\rho_{\mathscr{F}}} i_*\big(i^*(\mathscr{F})\big) \longrightarrow i_*(\mathscr{G}').$$

Then $\overline{\mathscr{G}'}$ is a quasi-coherent $\mathscr{O}_X$-module quotient of $\mathscr{F}$, flat over Y, such that

$$i^*\big(\overline{\mathscr{G}'}\big) = \mathscr{G}',$$

and it is the unique $\mathscr{O}_X$-module quotient of $\mathscr{F}$ having these properties.

Proof. Since i is quasi-compact and quasi-separated (1.1.2) and (1.2.2), it follows from (1.7.4) that, for every quasi-coherent $\mathscr{O}_{X_\eta}$-module $\mathscr{H}'$, the $\mathscr{O}_X$-module $i_*(\mathscr{H}')$ is quasi-coherent. Moreover, for every open subset U of X, by definition (**0**, 3.4.1),

$$i_*(\mathscr{H}')|U = (i|U \cap X_\eta)_*\big(\mathscr{H}'|U \cap X_\eta\big).$$

If the proposition is proved when X and Y are affine, the general case follows by gluing, in view of the uniqueness assertion in the affine case. In other words, we are reduced to proving the following lemma.

Lemma (2.8.1.1). — *Let A be a Noetherian regular integral ring of dimension 1 (**0**, 17.3.6), let K be its field of fractions, let M be an A-module, and let N' be a K-module quotient of*

$$M_{(K)} = M \otimes_A K$$

by a sub-K-module P'. Let $\overline{N'}$ be the image of M under the composite homomorphism

$$M \longrightarrow M_{(K)} \longrightarrow N'.$$

Then $\overline{N'}$ is a flat A-module, and it is the unique quotient module N of M that is flat over A and for which the kernel of the surjective homomorphism

$$M_{(K)} \longrightarrow N_{(K)}$$

is equal to P'.

For every maximal ideal $\mathfrak{m}$ of A, the ring $A_\mathfrak{m}$ is a regular local ring of dimension 1, hence a discrete valuation ring. Therefore an A-module N is flat if and only if it is torsion-free (**0**, 6.3.4). Since N' is a K-vector space, it is torsion-free as an A-module, and the same is therefore true of its submodule $\overline{N'}$. Moreover, one immediately verifies that $\overline{N'}_{(K)}$ identifies with N'.

Conversely, let N be an A-module quotient of M having the properties in the statement. Since N is flat over A, the canonical homomorphism

$$N \longrightarrow N_{(K)} = N \otimes_A K$$

is injective. Since $N_{(K)}$ identifies with N', the conclusion follows from the commutativity of the diagram

$$\begin{tikzcd} M \arrow[r] \arrow[d] & N \arrow[d] \\ M_{(K)} \arrow[r] & N_{(K)}. \end{tikzcd}$$

□

Corollary (2.8.2). — *Under the conditions of (2.8.1), the module $\mathscr{F}$ is flat over Y if and only if the canonical homomorphism*

$$\mathscr{F} \longrightarrow i_*(\mathscr{F}_\eta) = i_*\big(i^*(\mathscr{F})\big)$$

is injective.

(2.8.3). The formation of the $\mathscr{O}_X$-module $\overline{\mathscr{G}'}$ is *functorial* in $\mathscr{F}$ and $\mathscr{G}'$. More precisely, let $\mathscr{F}_1$ and $\mathscr{F}_2$ be two quasi-coherent $\mathscr{O}_X$-modules, let $u : \mathscr{F}_1 \to \mathscr{F}_2$ be an $\mathscr{O}_X$-homomorphism, let $\mathscr{G}'_i$ be an $\mathscr{O}_{X_\eta}$-module quotient of $(\mathscr{F}_i)_\eta$ for $i = 1, 2$, and let $v : \mathscr{G}'_1 \to \mathscr{G}'_2$ be a homomorphism making the diagram

$$\begin{tikzcd} (\mathscr{F}_1)_\eta \arrow[r, "i^*(u)"] \arrow[d] & (\mathscr{F}_2)_\eta \arrow[d] \\ \mathscr{G}'_1 \arrow[r, "v"'] & \mathscr{G}'_2 \end{tikzcd}$$

commutative. Such a homomorphism v, when it exists, is uniquely determined by this property. **IV-2** | 35
Then the diagram

$$\begin{tikzcd} \mathscr{F}_1 \arrow[r, "u"] \arrow[d] & \mathscr{F}_2 \arrow[d] \\ i_*(\mathscr{G}'_1) \arrow[r, "i_*(v)"'] & i_*(\mathscr{G}'_2) \end{tikzcd}$$

is commutative, and consequently there is a unique homomorphism

$$w : \overline{\mathscr{G}'_1} \longrightarrow \overline{\mathscr{G}'_2}$$

making the diagram

$$\begin{tikzcd} \mathscr{F}_1 \arrow[r, "u"] \arrow[d] & \mathscr{F}_2 \arrow[d] \\ \overline{\mathscr{G}'_1} \arrow[r, "w"'] & \overline{\mathscr{G}'_2} \end{tikzcd}$$

commutative.

Proposition (2.8.4). — *Suppose that Y satisfies the hypotheses of (2.8.1). Let X_1 and X_2 be two Y-preschemes, let $\mathscr{F}_i$ be a quasi-coherent $\mathscr{O}_{X_i}$-module, and let $\mathscr{G}'_i$ be an $\mathscr{O}_{(X_i)_\eta}$-module quotient of $(\mathscr{F}_i)_\eta$, for $i = 1, 2$. Then*

(2.8.4.1).

$$\overline{\mathscr{G}'_1} \otimes_{\mathscr{O}_Y} \overline{\mathscr{G}'_2} = \overline{\mathscr{G}'_1 \otimes_{k(\eta)} \mathscr{G}'_2}.$$

Proof. Put $X = X_1 \times_Y X_2$. The left-hand side of (2.8.4.1) is a quasi-coherent $\mathscr{O}_X$-module flat over Y (**0**, 6.2.1); its inverse image on X_η is

$$\mathscr{G}'_1 \otimes_{k(\eta)} \mathscr{G}'_2$$

(**I**, 9.1.5), and it is a quotient of $\mathscr{F}_1 \otimes_{\mathscr{O}_Y} \mathscr{F}_2$. The conclusion therefore follows from the uniqueness assertion of (2.8.1). □

Proposition (2.8.5). — *Suppose that X and Y satisfy the hypotheses of (2.8.1), and let Z' be a closed subprescheme of X_η. Then there exists a unique closed subprescheme $\overline{Z'}$ of X that is flat over Y and satisfies*

$$i^{-1}(\overline{Z'}) = Z'.$$

Proof. Let $\mathscr{J}'$ be the quasi-coherent ideal of $\mathscr{O}_{X_\eta}$ defining Z'. Apply (2.8.1) with

$$\mathscr{F} = \mathscr{O}_X, \qquad \mathscr{G}' = \mathscr{O}_{X_\eta}/\mathscr{J}'.$$

If $\overline{\mathscr{G}'} = \mathscr{O}_X/\mathscr{J}$, then

$$\mathscr{J}' = i^*(\mathscr{J})\mathscr{O}_{X_\eta},$$

and hence $i^{-1}(\overline{Z'}) = Z'$ (**I**, 4.4.5). □

The prescheme $\overline{Z'}$ is the *closed image* of Z' under the composite morphism

$$Z' \longrightarrow X_\eta \xrightarrow{i} X,$$

where the first arrow is the canonical injection (**I**, 9.5.3). Its underlying space is the closure of Z' *in* X (**I**, 9.5.4), which justifies the notation. We also say that $\overline{Z'}$ is the closure subprescheme of X of Z'.

Corollary (2.8.6). — *Let X_1 and X_2 be two Y-preschemes, and let Z'_i be a closed subprescheme of $(X_i)_\eta$, for $i = 1, 2$. Then*

(2.8.6.1).

$$\overline{Z'_1} \times_Y \overline{Z'_2} = \overline{Z'_1 \times_{k(\eta)} Z'_2}.$$

Proof. This follows from (2.8.4) and (2.8.5). □

§3. Associated prime cycles and primary decompositions

In this section, we mainly give the translation of results on modules presented in Bourbaki, *Alg. comm.*, chap. IV, which we follow very closely. The notions that follow seem to be of interest only in the case of *locally Noetherian* preschemes. **IV-2** | 36

3.1. Associated prime cycles of a module

Definition (3.1.1). — Let X be a prescheme and $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-module. We say that a point $x \in X$ is *associated* to $\mathscr{F}$ if the maximal ideal $\mathfrak{m}_x$ of $\mathscr{O}_x$ is associated to the $\mathscr{O}_x$-module $\mathscr{F}_x$ (in other words, if $\mathfrak{m}_x$ is the annihilator of an element of $\mathscr{F}_x$). We denote by $\operatorname{Ass}(\mathscr{F})$ the set of $x \in X$ associated to $\mathscr{F}$. We say that a closed irreducible subset Z of X is an *associated prime cycle of* $\mathscr{F}$ if its generic point is associated to $\mathscr{F}$. When $\mathscr{F} = \mathscr{O}_X$, we also say that the points (resp. *prime cycles*) associated to $\mathscr{F}$ are associated to the *prescheme* X.

We say that an associated prime cycle of $\mathscr{F}$ (resp. X) is *embedded* if it is contained in another associated prime cycle of $\mathscr{F}$ (resp. X) (in other words, if it is not *maximal* in the set of these cycles).

If X is locally Noetherian, the *irreducible components* of X are none other than the *maximal* (or *non-embedded*) prime cycles associated to X.

It is clear that if $x \in \operatorname{Ass}(\mathscr{F})$, then $\mathscr{F}_x \neq 0$, in other words

(3.1.1.1) $$\operatorname{Ass}(\mathscr{F}) \subset \operatorname{Supp}(\mathscr{F}).$$

If $x \in X$ is associated to $\mathscr{F}$, it is evidently associated to $\mathscr{F}|U$ for every open neighbourhood U of x, and conversely, if it is associated to $\mathscr{F}|U$ for one of these neighbourhoods, it is associated to $\mathscr{F}$.

We note finally that for a quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$, the existence of embedded associated prime cycles is a *local* question, for if y and z are two points of $\operatorname{Ass}(\mathscr{F})$ such that $y \in \overline{\{z\}}$, every neighbourhood of y contains z.

Proposition (3.1.2). — *Let A be a Noetherian ring, M an A-module, $X = \operatorname{Spec}(A)$, $\mathscr{F} = \widetilde{M}$; for a point $x \in X$ to be associated to $\mathscr{F}$, it is necessary and sufficient that the prime ideal $\mathfrak{j}_x$ of A be associated to the module M (in other words, be the annihilator of an element $f \in M$).*

Proof. This follows from the definition (3.1.1) and from Bourbaki, *loc. cit.*, § 1, no 2, cor. of prop. 5, applied to $S = A - \mathfrak{j}_x$. □

Proposition (3.1.3). — *Let X be a locally Noetherian prescheme, $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-module, x a point of X, and Z the reduced closed sub-prescheme of X having $\overline{\{x\}}$ as underlying space* (**I**, 5.2.1). *The following conditions are equivalent:*

a) $x \in \operatorname{Ass}(\mathscr{F})$. **IV-2** | 37

b) *There exist an open neighbourhood U of x and a section $f \in \Gamma(U, \mathscr{F})$ such that $U \cap Z$ is equal to* $\mathrm{Supp}(\mathscr{O}_U \cdot f)$.

b′) *There exist an open neighbourhood U of x and a section $f \in \Gamma(U, \mathscr{F})$ such that $U \cap Z$ is an irreducible component of* $\mathrm{Supp}(\mathscr{O}_U \cdot f)$.

c) *There exist an open neighbourhood U of x and a submodule of $\mathscr{F}|U$ isomorphic to $\mathscr{O}_Z|U$ ($\mathscr{O}_Z$ being identified with a quotient of $\mathscr{O}_X$).*

c′) *There exist an open neighbourhood U of x and a coherent submodule $\mathscr{G}$ of $\mathscr{F}|U$ such that $U \cap Z$ is an irreducible component of* $\mathrm{Supp}(\mathscr{G})$.

Proof. It is clear that *c)* implies *b)*, for it suffices to take for f the element of $\Gamma(U, \mathscr{F})$ which corresponds to the unit section of $\mathscr{O}_Z|U$. As $U \cap Z$ is irreducible (**0**, 2.1.6), *b)* implies *b′)*, and *b′)* implies *c′)* since $\mathscr{O}_X$ is coherent (**0**, 5.3.4). To see that *c′)* implies *a)*, we can reduce to the case where $U = X = \mathrm{Spec}(A)$ is affine, A being Noetherian, and where $\mathscr{F} = \widetilde{M}$, where M is an A-module, and $\mathscr{G} = \widetilde{N}$, where N is a sub-module of M, of finite type. We then know that the minimal elements of $\mathrm{Supp}(\mathscr{G})$ are the maximal points of $V(\mathrm{Ann}(N))$ (**0**, 1.7.4), and these are also the minimal elements of $\mathrm{Ass}(N)$ (Bourbaki, *Alg. comm.*, chap. IV, § 1, no 3, cor. 1 of prop. 7); as $\mathrm{Ass}(N) \subset \mathrm{Ass}(M) = \mathrm{Ass}(\mathscr{F})$, we see that *c′)* implies *a)*. Finally, *a)* implies *c)* by (3.1.2), taking X affine again, $\mathscr{F} = \widetilde{M}$, and Z defined by the ideal $\mathfrak{j}_x A$ (with the notation of (3.1.2)). ☐

Corollary (3.1.4). — *Let X be a locally Noetherian prescheme and $\mathscr{F}$ a coherent $\mathscr{O}_X$-module. Then the maximal prime cycles associated to $\mathscr{F}$ are the irreducible components of* $\mathrm{Supp}(\mathscr{F})$, *and the generic points of these components are the points $x \in X$ such that $\mathscr{F}_x$ is an $\mathscr{O}_x$-module of finite nonzero length.*

Proof. Indeed, if x is the generic point of an irreducible component Z of $\mathrm{Supp}(\mathscr{F})$, the equivalence of *a)* and *c′)* in (3.1.3) shows that x belongs to $\mathrm{Ass}(\mathscr{F})$, and Z is an associated prime cycle of $\mathscr{F}$, necessarily maximal by (3.1.1.1); the converse follows trivially from (3.1.1.1). Finally, the last assertion is local and follows from Bourbaki, *Alg. comm.*, chap. IV, § 2, no 5, cor. 2 of prop. 7. ☐

Corollary (3.1.5). — *Let X be a locally Noetherian prescheme and $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-module. For $\mathscr{F} = 0$, it is necessary and sufficient that* $\mathrm{Ass}(\mathscr{F}) = \varnothing$.

Proof. The question being local, we reduce to the case where X is affine, and the conclusion follows immediately from (3.1.2) and from Bourbaki, *Alg. comm.*, chap. IV, § 1, no 1, cor. 1 of prop. 2. ☐

Proposition (3.1.6). — *Let X be a locally Noetherian prescheme and $\mathscr{F}$ a coherent $\mathscr{O}_X$-module; then* $\mathrm{Ass}(\mathscr{F})$ *is* locally finite *(that is to say, every point of X admits a neighbourhood whose intersection with* $\mathrm{Ass}(\mathscr{F})$ *is finite).*

Proof. It suffices to consider the case where X is affine, hence Noetherian, and then the proposition follows from (3.1.2) and from Bourbaki, *Alg. comm.*, chap. IV, § 1, no 4, cor. of th. 2. ☐

Proposition (3.1.7). — *Let X be a prescheme.*

(i) *Let $0 \to \mathscr{F}' \to \mathscr{F} \to \mathscr{F}'' \to 0$ be an exact sequence of quasi-coherent $\mathscr{O}_X$-modules. Then* $\mathrm{Ass}(\mathscr{F}') \subset \mathrm{Ass}(\mathscr{F}) \subset \mathrm{Ass}(\mathscr{F}') \cup \mathrm{Ass}(\mathscr{F}'')$.

(ii) *Let $\mathscr{F}$ be a quasi-coherent $\mathscr{O}_X$-module, $(\mathscr{F}_\alpha)$ a family of quasi-coherent $\mathscr{O}_X$-submodules of $\mathscr{F}$ such that $\mathscr{F}$ is the union of the $\mathscr{F}_\alpha$. Then* $\mathrm{Ass}(\mathscr{F}) = \bigcup_\alpha \mathrm{Ass}(\mathscr{F}_\alpha)$.

(iii) *For every family $(\mathscr{F}_\alpha)$ of quasi-coherent $\mathscr{O}_X$-modules, we have* $\mathrm{Ass}(\bigoplus_\alpha \mathscr{F}_\alpha) = \bigcup_\alpha \mathrm{Ass}(\mathscr{F}_\alpha)$.

Proof. We immediately reduce to the corresponding propositions for modules (Bourbaki, *loc. cit.*, § 1, no 1, formula (1), prop. 3 and cor. 1 of prop. 3). ☐

IV-2 | 38

Proposition (3.1.8). — *Let X be a locally Noetherian prescheme, $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-module, U an open subset of X, and $\mathscr{J}$ a coherent ideal of $\mathscr{O}_X$ defining a closed sub-prescheme of X having $X - U$ as underlying space. The following conditions are equivalent:*

a) $\mathrm{Ass}(\mathscr{F}) \subset U$.

b) *For every affine open subset V of X, every section of $\mathscr{F}$ over V whose restriction to $V \cap U$ is zero is itself zero.*

c) *The canonical homomorphism $\mathscr{F} \to \mathscr{H}om_{\mathscr{O}_X}(\mathscr{J}, \mathscr{F})$ is injective.*

Proof. The question being local, we can suppose $X = \mathrm{Spec}(A)$ affine, A being a Noetherian ring, $\mathscr{F} = \widetilde{M}$, where M is an A-module, and $\mathscr{J} = \widetilde{\mathfrak{J}}$, where $\mathfrak{J}$ is an ideal of A. The homomorphism $M \to \mathrm{Hom}_A(\mathfrak{J}, M)$ sends $m \in M$ to the homomorphism $x \mapsto xm$ of $\mathfrak{J}$ into M; to say that it is not injective means that there exists $m \neq 0$ in M such that $\mathfrak{J}m = 0$.

Let us first show that *c)* implies *a)*. If $\mathrm{Ass}(\mathscr{F})$ met $X - U$, there would be a prime ideal $\mathfrak{p} \in \mathrm{Ass}(M)$ containing $\mathfrak{J}$, hence an element $m \neq 0$ of M such that $\mathfrak{p}m = 0$, and therefore $\mathfrak{J}m = 0$, contradicting *c)*.

Next, *b)* implies *c)*. Indeed, if $\mathfrak{J}m = 0$ for some $m \neq 0$ in M, then for every prime ideal $\mathfrak{q}$ not containing $\mathfrak{J}$ there exists $a \in \mathfrak{J}$ with $a \notin \mathfrak{q}$. The relation $am = 0$ then implies that the canonical image of m in $M_{\mathfrak{q}}$ is zero. Thus m would define a nonzero section of $\mathscr{F}$ over X whose restriction to U is zero, contrary to *b)*.

Finally, *a)* implies *b)*. The canonical homomorphism

$$M \longrightarrow \prod_{\mathfrak{p} \in \mathrm{Ass}(M)} M_{\mathfrak{p}}$$

is injective: if N is its kernel, then $\mathrm{Ass}(N) \subset \mathrm{Ass}(M)$; if there existed $\mathfrak{p} \in \mathrm{Ass}(N)$, there would be an element $n \in N$ whose annihilator is $\mathfrak{p}$, while the definition of N would give an $s \notin \mathfrak{p}$ such that $sn = 0$, a contradiction. Hence $\mathrm{Ass}(N) = \varnothing$, and therefore $N = 0$. Under *a)*, a section $m \in M$ whose restriction to U is zero has zero image in $M_{\mathfrak{p}}$ for every $\mathfrak{p} \in \mathrm{Ass}(M)$; consequently $m = 0$. □

Corollary (3.1.9). — *Let X be a locally Noetherian prescheme, $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-module, and f a section of $\mathscr{O}_X$ over X. For f to be $\mathscr{F}$-regular* (**0**, 15.2.2), *it is necessary and sufficient that* $\mathrm{Ass}(\mathscr{F}) \subset X_f$.

Proof. Indeed, it is immediate that to say that f is $\mathscr{F}$-regular means that the canonical homomorphism $\mathscr{F} \to \mathscr{H}om_{\mathscr{O}_X}(f\mathscr{O}_X, \mathscr{F})$ is injective, and it suffices to apply (3.1.8) to the ideal $\mathscr{J} = f\mathscr{O}_X$. □

Proposition (3.1.10). — *Let X and Y be locally Noetherian preschemes and $f : X \to Y$ an integral morphism. Then, for every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$, we have* $f(\mathrm{Ass}(\mathscr{F})) = \mathrm{Ass}(f_*(\mathscr{F}))$.

Proof. The question being local on Y, and the morphism f being affine, we are immediately reduced to the case where Y is affine, in other words, to the following lemma. □

IV-2 | 39

Lemma (3.1.10.1). — *Let A and B be two Noetherian rings, $\rho : A \to B$ a ring homomorphism making B an integral A-algebra, and M a B-module. Then the prime ideals $\mathfrak{p} \in \mathrm{Ass}(M_{[\rho]})$ are the inverse images by ρ of the prime ideals $\mathfrak{q} \in \mathrm{Ass}(M)$.*

Proof. Indeed, if $\mathfrak{q} \in \mathrm{Ass}(M)$, then $\mathfrak{q}$ is the annihilator in B of an element $x \in M$, and hence $\rho^{-1}(\mathfrak{q})$ is the annihilator in A of x. Conversely, suppose $\mathfrak{p} \in \mathrm{Ass}(M_{[\rho]})$, so that $\mathfrak{p}$ is the inverse image under ρ of the annihilator $\mathfrak{b}$ in B of an element $x \in M$. It follows from the first Cohen–Seidenberg theorem that there exists a prime ideal $\mathfrak{q}$ of B containing $\mathfrak{b}$ and whose inverse image is $\mathfrak{p}$ (Bourbaki, *Alg. comm.*, chap. V, § 2, no 1, cor. 2 of th. 1). By considering a prime ideal minimal among those contained in $\mathfrak{q}$ and containing $\mathfrak{b}$, we may evidently suppose that $\mathfrak{q}$ itself is one of these minimal primes. Since $B.x \subset M$ is isomorphic to $B/\mathfrak{b}$, we then have $\mathfrak{q} \in \mathrm{Ass}(B/\mathfrak{b}) \subset \mathrm{Ass}(M)$ (Bourbaki, *Alg. comm.*, chap. IV, § 1, no 4, th. 2). □

Corollary (3.1.11). — *Under the hypotheses of* (3.1.10), *for $\mathscr{F}$ to have no embedded associated prime cycle, it suffices that the same be true of $f_*(\mathscr{F})$.*

Proof. Suppose indeed that $f_*(\mathscr{F})$ has no embedded associated prime cycle. Note that if A is an integral algebra over a field k, all prime ideals of A are maximal (Bourbaki, *Alg. comm.*, chap. V, § 2, no 1, prop. 1); it follows from (**I**, 6.2.2) that the fibres of f are *discrete* spaces. If x and x' are two distinct points of $\mathrm{Ass}(\mathscr{F})$, neither can be adherent to the other when $f(x) = f(x')$; and if $f(x) \neq f(x')$, then (3.1.10) and the hypothesis imply that neither of the two points $f(x)$ and $f(x')$ can be adherent to the other, so the same is true of x and x'. □

Remark (3.1.12). — Under the hypotheses of (3.1.10), it may happen, on the contrary, that $\mathscr{F}$ has no embedded associated prime cycle whereas $f_*(\mathscr{F})$ does. For example, take $Y = \mathrm{Spec}(k[\mathrm{T}])$, where k is a field (an "affine line"), and let X be the disjoint union of $X_1 = Y$ and $X_2 = \mathrm{Spec}(k)$, the morphism $X_2 \to Y$ corresponding to the canonical homomorphism $k[\mathrm{T}] \to k[\mathrm{T}]/\mathfrak{m}$, where $\mathfrak{m}$ is the maximal ideal (T). It is clear that the morphism $f : X \to Y$ is finite. If one takes $\mathscr{F} = \mathscr{O}_X$, then $\mathscr{F}$ has no embedded associated prime cycle, but $f_*(\mathscr{F}) = \widetilde{M}$, where M is the direct sum of the $k[\mathrm{T}]$-modules $k[\mathrm{T}]$ and k; hence $\mathrm{Ass}(M)$ consists of the generic point (0) of Y and the point $\mathfrak{m}$.

Proposition (3.1.13). — *Let X be a locally Noetherian prescheme, U an open subset of X, and $i : U \to X$ the canonical inclusion. For every quasi-coherent $\mathscr{O}_U$-module $\mathscr{F}$, we have $\mathrm{Ass}(i_*(\mathscr{F})) = \mathrm{Ass}(\mathscr{F})$.*

Proof. Recall that $i_*(\mathscr{F})$ is a quasi-coherent $\mathscr{O}_X$-module (**I**, 2.2) and (**I**, 7.4); as $i_*(\mathscr{F})|U = \mathscr{F}$, we have $\mathrm{Ass}(i_*(\mathscr{F})) \cap U = \mathrm{Ass}(\mathscr{F})$, and it therefore remains to prove that $\mathrm{Ass}(i_*(\mathscr{F})) \subset U$. But by (3.1.8), this relation means that for every affine open subset V of X, every section of $i_*(\mathscr{F})$ over V which is zero on $U \cap V$, is zero, a condition which is trivially satisfied since $\Gamma(V, i_*(\mathscr{F})) = \Gamma(U \cap V, \mathscr{F}) = \Gamma(U \cap V, i_*(\mathscr{F}))$. □

IV-2 | 40

3.2. Irredundant decompositions

Proposition (3.2.1). — *Let X be a locally Noetherian prescheme and U a dense open subset of X. The following conditions are equivalent:*

a) *X is reduced.*
b) *The induced sub-prescheme on U is reduced, and X has no embedded associated prime cycle.*
c) *X has no embedded associated prime cycle and, for every generic point x of an irreducible component of X, one has $\mathrm{length}(\mathscr{O}_x) = 1$.*

The prime cycles associated with X are then precisely the irreducible components of X.

Proof. It is clear that if X is reduced, then so is the sub-prescheme induced on U. Moreover, since the existence of embedded associated prime cycles is a local question, we may restrict to the case where $X = \mathrm{Spec}(A)$ is affine and A is Noetherian. If A is reduced, its minimal prime ideals form a reduced primary decomposition of (0) (Bourbaki, *Alg. comm.*, chap. IV, § 2, no 5, prop. 10) and are precisely the elements of $\mathrm{Ass}(A)$; hence A has no embedded associated prime ideals. Thus *a)* implies *b)*. It is immediate that *b)* implies *c)*, since a generic point x of an irreducible component belongs to U, and consequently $\mathscr{O}_x$ is a field. Finally, *c)* implies *a)*. Indeed, let $\mathscr{N}$ be the nilradical of $\mathscr{O}_X$, which is a coherent ideal. By hypothesis, $\mathrm{Supp}(\mathscr{N})$ contains none of the generic points of the irreducible components of X. If $\mathrm{Supp}(\mathscr{N})$ were nonempty and x were one of its maximal points, criterion (3.1.3), *c')*, would give $x \in \mathrm{Ass}(\mathscr{O}_X)$; then $\overline{\{x\}}$ would be an embedded associated prime cycle of X, contrary to the hypothesis. Hence $\mathscr{N} = 0$. □

Definition (3.2.2). — Let X be a locally Noetherian prescheme and $\mathscr{F}$ a coherent $\mathscr{O}_X$-module. We say that $\mathscr{F}$ is *reduced* if it satisfies the following two conditions: 1° $\mathscr{F}$ has no embedded associated prime cycle; 2° for every maximal point x of $\mathrm{Supp}(\mathscr{F})$, one has $\mathrm{length}(\mathscr{F}_x) = 1$.

Condition 1° means that the prime cycles associated with $\mathscr{F}$ are the irreducible components of $\mathrm{Supp}(\mathscr{F})$ (3.1.4), and condition 2° means that for every generic point x of such a component one has $\mathrm{length}(\mathscr{F}_x) = 1$.

For an affine scheme X, this definition gives in particular the notion of a *reduced module* over a Noetherian ring A: a finitely generated A-module M is said to be *reduced* if it has no embedded associated prime ideals and if, for every $\mathfrak{p} \in \mathrm{Ass}(M)$, one has $\mathrm{length}_{A_\mathfrak{p}}(M_\mathfrak{p}) = 1$. Returning to a locally Noetherian prescheme X and a coherent $\mathscr{O}_X$-module $\mathscr{F}$, we say that $\mathscr{F}$ is *reduced at a point* $x \in X$ if $\mathscr{F}_x$ is a reduced $\mathscr{O}_x$-module. Equivalently, on the local scheme $\mathrm{Spec}(\mathscr{O}_x)$, the module associated with $\mathscr{F}_x$ is reduced. Thus x belongs to no embedded associated prime cycle of $\mathscr{F}$ and $\mathrm{length}(\mathscr{F}_z) = 1$ *for every maximal point z of* $\mathrm{Supp}(\mathscr{F})$ *such that* $x \in \overline{\{z\}}$. It is clear that if $\mathscr{F}$ is a reduced coherent $\mathscr{O}_X$-module, then it is reduced at every point of X. Conversely, if $\mathscr{F}$ is *reduced at a point* x, there exists an open neighbourhood U of x such that $\mathscr{F}|U$ is a reduced $\mathscr{O}_U$-module: it suffices to take U meeting no embedded associated prime cycle of $\mathscr{F}$ (such a neighbourhood exists because these cycles form a locally finite family of closed subsets of X). To say that $\mathscr{O}_X$ is reduced at x is equivalent to saying that X is *reduced at the point* x.

IV-2 | 41

Proposition (3.2.3). — *Let X be a locally Noetherian prescheme, U an open subset of X, and $\mathscr{F}$ a coherent $\mathscr{O}_X$-module such that $U \cap \operatorname{Supp}(\mathscr{F})$ is dense in $\operatorname{Supp}(\mathscr{F})$. The following conditions are equivalent:*

a) *$\mathscr{F}$ is reduced.*
b) *$\mathscr{F}|U$ is reduced, and $\mathscr{F}$ has no embedded associated prime cycle.*
c) *There exist a reduced closed sub-prescheme X' of X and a coherent torsion-free $\mathscr{O}_{X'}$-module $\mathscr{F}'$ of rank 1 on every irreducible component of X' such that, if $j : X' \to X$ is the canonical inclusion, then $j_*(\mathscr{F}') = \mathscr{F}$.*

Moreover, when these conditions hold, X' is defined by the ideal $\mathscr{J}$ of $\mathscr{O}_X$ that annihilates $\mathscr{F}$.

Proof. To see that *c)* implies *a)*, we may, by (3.1.3), restrict to the case where $X' = X$ is integral, with generic point x. We may further suppose that $X = \operatorname{Spec}(A)$ is affine and $\mathscr{F} = \widetilde{M}$, where A is integral and M is a torsion-free A-module of rank 1. The annihilator of every element of M is then zero, so $\operatorname{Ass}(\mathscr{F}) = \{x\}$ and $\mathscr{F}_x$ is isomorphic to $\mathscr{O}_x$, the field of fractions of A; hence the conditions of Definition (3.2.2) are satisfied. Since the existence of embedded associated prime cycles is a local question, if $\mathscr{F}$ has no such cycles and $U \cap \operatorname{Supp}(\mathscr{F})$ is dense in $\operatorname{Supp}(\mathscr{F})$, then $\operatorname{Ass}(\mathscr{F}) = \operatorname{Ass}(\mathscr{F}|U)$. Thus *a)* and *b)* are equivalent. If *a)* holds, take for X' the reduced closed sub-prescheme of X whose underlying space is $\operatorname{Supp}(\mathscr{F})$ (**I**, 5.2.1), and put $\mathscr{F}' = j^*(\mathscr{F})$. A point x of $\operatorname{Ass}(\mathscr{F})$ is necessarily a maximal point of X', and since $\operatorname{length}(\mathscr{F}_x) = 1$, $\mathscr{F}'_x$ is isomorphic to $\mathscr{F}_x$, hence to the residue field $\boldsymbol{k}(x) = \mathscr{O}_{X',x}$. This proves that $\mathscr{F}'$ is torsion-free and of rank 1 (**I**, 7.4.6) and (**I**, 7.4.2). Finally, the last assertion is immediate, since for every $y \in X'$ the annihilator of the $\mathscr{O}_{X',y}$-module $\mathscr{F}'_y$ is zero. □

Definition (3.2.4). — Let X be a locally Noetherian prescheme and $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-module. We say that $\mathscr{F}$ is *irredundant* if $\operatorname{Ass}(\mathscr{F})$ consists of a single element x; if $\mathscr{F}$ is of finite type, we say that $\mathscr{F}$ is *integral* if, in addition, $\mathscr{F}$ is reduced (in other words, if $\operatorname{length}(\mathscr{F}_x) = 1$). We say that a quasi-coherent $\mathscr{O}_X$-submodule $\mathscr{G}$ of a quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$ is *primary in* $\mathscr{F}$ if $\mathscr{F}/\mathscr{G}$ is irredundant.

For an affine scheme X, this definition gives in particular the notion of an *integral module* over a Noetherian ring A: an A-module M is said to be *integral* if it is of finite type, if M is primary (that is, if $\operatorname{Ass}(M)$ consists of a single prime ideal $\mathfrak{p}$), and if, in addition, $\operatorname{length}_{A_\mathfrak{p}}(M_\mathfrak{p}) = 1$. Returning to an arbitrary locally Noetherian prescheme X and a coherent $\mathscr{O}_X$-module $\mathscr{F}$, we say that $\mathscr{F}$ is *integral at a point* $x \in X$ if $\mathscr{F}_x$ is an integral $\mathscr{O}_x$-module. Equivalently, x belongs to only one associated prime cycle of $\mathscr{F}$ (necessarily a nonembedded one), and $\operatorname{length}(\mathscr{F}_z) = 1$ at its generic point z. It is clear that if $\mathscr{F}$ is an integral coherent $\mathscr{O}_X$-module, then it is integral at every point of X. Conversely, if $\mathscr{F}$ is *integral at a point* x, there exists an open neighbourhood U of x such that $\mathscr{F}|U$ is an integral $\mathscr{O}_U$-module: it suffices to take U such that $\mathscr{F}|U$ is a reduced $\mathscr{O}_U$-module (3.2.2).

We say that a locally Noetherian prescheme X is *irredundant* if $\mathscr{O}_X$ is irredundant (which implies that X is *irreducible*). For X to be *integral*, it is necessary and sufficient that the $\mathscr{O}_X$-module $\mathscr{O}_X$ be integral (**I**, 2.1.8) and (3.2.1). If $\mathscr{O}_X$ is integral at a point x, that is, if the ring $\mathscr{O}_x$ is integral, we say that X is *integral at the point* x. We say that a closed sub-prescheme Y of X is *primary in* X if the ideal $\mathscr{J}$ of $\mathscr{O}_X$ defining Y is primary in $\mathscr{O}_X$. **IV-2** | 42

Definition (3.2.5). — Let X be a locally Noetherian prescheme and $\mathscr{F}$ a coherent $\mathscr{O}_X$-module. An *irredundant decomposition* of $\mathscr{F}$ is a family $(\mathscr{F}_\alpha)_{\alpha\in I}$ of quotient $\mathscr{O}_X$-modules of $\mathscr{F}$ such that the $\mathscr{F}_\alpha$ are irredundant, the family $(\operatorname{Supp}(\mathscr{F}_\alpha))_{\alpha\in I}$ is locally finite, and the canonical homomorphism $\mathscr{F} \to \bigoplus_{\alpha\in I}\mathscr{F}_\alpha$ is injective. We say that such a decomposition is *reduced* if the sets $\operatorname{Ass}(\mathscr{F}_\alpha)$ are pairwise distinct and there is no proper subset $J \subsetneq I$ for which the subfamily $(\mathscr{F}_\alpha)_{\alpha\in J}$ is also an irredundant decomposition of $\mathscr{F}$.

If $(\mathscr{F}_\alpha)_{\alpha\in I}$ is an irredundant decomposition (resp. a reduced irredundant decomposition) of $\mathscr{F}$ and $\mathscr{F}_\alpha = \mathscr{F}/\mathscr{G}_\alpha$, we also say that the family $(\mathscr{G}_\alpha)_{\alpha\in I}$ of $\mathscr{O}_X$-submodules of $\mathscr{F}$ is a *primary decomposition of* 0 *in* $\mathscr{F}$. The injectivity of the canonical homomorphism $\mathscr{F} \to \bigoplus_{\alpha\in I}\mathscr{F}_\alpha$ is equivalent to the condition $\bigcap_{\alpha\in I}\mathscr{G}_\alpha = 0$.

If $(\mathscr{F}_\alpha)$ is an irredundant decomposition of $\mathscr{F}$, to say that it is reduced is equivalent to saying that the sets $\operatorname{Ass}(\mathscr{F}_\alpha)$ are pairwise distinct and contained in $\operatorname{Ass}(\mathscr{F})$. If $\operatorname{Ass}(\mathscr{F}_\alpha) = \{x_\alpha\}$ for every

$\alpha \in I$, then $\alpha \mapsto x_\alpha$ is a bijection from I onto $\mathrm{Ass}(\mathscr{F})$. These properties are local and therefore follow from Bourbaki, *Alg. comm.*, chap. IV, § 2, no 3, prop. 4.

Proposition (3.2.6). — *Let X be a locally Noetherian prescheme and $\mathscr{F}$ a coherent $\mathscr{O}_X$-module. Then there exists a reduced irredundant decomposition $(\mathscr{F}^{(x)})_{x\in\mathrm{Ass}(\mathscr{F})}$ formed of coherent $\mathscr{O}_X$-modules such that, for every $x \in \mathrm{Ass}(\mathscr{F})$, one has $\mathrm{Ass}(\mathscr{F}^{(x)}) = \{x\}$. For every $x \in \mathrm{Ass}(\mathscr{F})$ such that $\overline{\{x\}}$ is not embedded, $\mathscr{F}^{(x)}$ is uniquely determined as the image of the canonical homomorphism $\mathscr{F} \to i_*(i^*(\mathscr{F}))$, where i is the canonical morphism $\mathrm{Spec}(\boldsymbol{k}(x)) \to X$.*

Proof. For every $x \in \mathrm{Ass}(\mathscr{F})$, let U be an affine open neighbourhood of x, with ring A, and write $\mathscr{F}|U = \widetilde{M}$, where M is a finitely generated A-module. We know (Bourbaki, *Alg. comm.*, chap. IV, § 1, no 1, prop. 4) that there exists a submodule N of M such that, on setting $P = M/N$, one has $\mathrm{Ass}(P) = \{x\}$ and $\mathrm{Ass}(N) = \mathrm{Ass}(M) - \{x\}$. Let $\mathscr{G} = \widetilde{P}$, a quasi-coherent $\mathscr{O}_U$-module, and let $j : U \to X$ be the canonical inclusion. Let $u : j^*(\mathscr{F}) \to \mathscr{G}$ be the surjective homomorphism corresponding to $M \to P$. It induces a homomorphism $j_*(u) : j_*(j^*(\mathscr{F})) \to j_*(\mathscr{G})$, and hence, by composition, a homomorphism

$$v : \mathscr{F} \xrightarrow{\rho_{\mathscr{F}}} j_*(j^*(\mathscr{F})) \xrightarrow{j_*(u)} j_*(\mathscr{G})$$

whose restriction to U is u. We denote by $\mathscr{F}^{(x)}$ the image of $\mathscr{F}$ under this homomorphism; it is a coherent $\mathscr{O}_X$-module (**I**, 6.1.1). By (3.1.13), one has $\mathrm{Ass}(j_*(\mathscr{G})) = \{x\}$, and therefore, by (3.1.7), $\mathrm{Ass}(\mathscr{F}^{(x)}) = \{x\}$, since $\mathscr{F}^{(x)} \neq 0$.

Let $\mathscr{N}^{(x)} = \mathrm{Ker}(v)$. Then $\mathscr{N}^{(x)}|U = \widetilde{N}$, and hence $x \notin \mathrm{Ass}(\mathscr{N}^{(x)})$. It follows that the homomorphism $\mathscr{F} \to \bigoplus_{x\in\mathrm{Ass}(\mathscr{F})} \mathscr{F}^{(x)}$ is injective. Indeed, its kernel $\mathscr{H}$ is contained in every $\mathscr{N}^{(x)}$, so $\mathrm{Ass}(\mathscr{H})$ is contained in the intersection of the sets $\mathrm{Ass}(\mathscr{N}^{(x)})$, which is empty; consequently, by (3.1.5), $\mathscr{H} = 0$. Since $\mathrm{Ass}(\mathscr{F})$ is locally finite (3.1.6), it is clear that $(\mathscr{F}^{(x)})_{x\in\mathrm{Ass}(\mathscr{F})}$ is a reduced irredundant decomposition of $\mathscr{F}$ satisfying the conditions of the statement. Finally, when $\overline{\{x\}}$ is not embedded, the characterization of $\mathscr{F}^{(x)}$ follows from Bourbaki, *Alg. comm.*, chap. IV, § 2, no 3, prop. 5, since the question is local, together with (**I**, 1.6.7). □

IV-2 | 43

Corollary (3.2.7). — *Under the hypotheses of (3.2.6), if $\mathscr{F}$ has no embedded associated prime cycle, there exists a unique reduced irredundant decomposition of $\mathscr{F}$.*

Corollary (3.2.8). — *Let X be a Noetherian prescheme and $\mathscr{F}$ a coherent $\mathscr{O}_X$-module. There exists a finite filtration $(\mathscr{F}_i)_{0\leqslant i\leqslant n}$ of $\mathscr{F}$ such that $\mathscr{F}_0 = \mathscr{F}$ and $\mathscr{F}_n = 0$, formed of coherent $\mathscr{O}_X$-modules, and such that the quotients $\mathscr{F}_i/\mathscr{F}_{i+1}$ are either zero or irredundant, with $\mathrm{Ass}(\mathscr{F}_i/\mathscr{F}_{i+1}) \subset \mathrm{Ass}(\mathscr{F})$.*

Proof. Indeed, by (3.2.6), $\mathscr{F}$ is isomorphic to an $\mathscr{O}_X$-submodule of a finite direct sum $\bigoplus_{j=1}^n \mathscr{G}_j$, where the $\mathscr{G}_j$ are irredundant and coherent. Since every quasi-coherent $\mathscr{O}_X$-submodule of $\mathscr{G}_j$ is either zero or irredundant (3.1.7), the modules

$$\mathscr{F}_i = \mathscr{F} \cap \left(\bigoplus_{j=1}^{n-i} \mathscr{G}_j\right)$$

satisfy the requirements, since $\mathscr{F}_i/\mathscr{F}_{i+1}$ is isomorphic to a coherent $\mathscr{O}_X$-submodule of $\mathscr{G}_{n-i}$. □

3.3. Relations with flatness

Proposition (3.3.1). — *Let $f : X \to Y$ be a morphism, $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-module that is f-flat, and $\mathscr{E}$ a quasi-coherent $\mathscr{O}_Y$-module. If, for every $y \in Y$, we set $\mathscr{F}_y = \mathscr{F} \otimes_{\mathscr{O}_Y} \boldsymbol{k}(y)$, then*

$$\mathrm{Ass}(\mathscr{E} \otimes_{\mathscr{O}_Y} \mathscr{F}) \supset \bigcup_{y \in \mathrm{Ass}(\mathscr{E})} \mathrm{Ass}(\mathscr{F}_y) \tag{3.3.1.1}$$

and the two sides are equal if Y is locally Noetherian.

Proof. (Of course, $\mathscr{F}_y$ is a sheaf on the fibre $f^{-1}(y)$, and this fibre is identified with a subspace of X (**I**, 3.6.1).) The question being local on X and on Y, we reduce to the case where X and Y are affine, and the proposition is then proved in Bourbaki, *Alg. comm.*, chap. IV, § 2, no 6, th. 2. □

Corollary (3.3.2). — *Let Y be a locally Noetherian prescheme with no embedded associated prime cycles, $f : X \to Y$ a morphism, and $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-module that is f-flat. Then, for every $x \in \mathrm{Ass}(\mathscr{F})$, $f(x)$ is a maximal point of Y.*

Proof. It suffices to apply (3.3.1) with $\mathscr{E} = \mathscr{O}_Y$, since $\mathrm{Ass}(\mathscr{O}_Y)$ is by hypothesis the set of maximal points of Y. □

Corollary (3.3.3). — *Under the hypotheses of (3.3.1), suppose in addition that X and Y are locally Noetherian and that $\mathscr{E}$ and $\mathscr{F}$ are coherent. Then the following conditions are equivalent:*

a) *$\mathscr{E} \otimes_Y \mathscr{F}$ has no embedded associated prime cycle.*
b) *For every point $y \in \mathrm{Ass}(\mathscr{E}) \cap f(\mathrm{Supp}(\mathscr{F}))$, $\overline{\{y\}}$ is a nonembedded associated prime cycle of $\mathscr{E}$ and $\mathscr{F}_y$ has no embedded associated prime cycle.*

Proof. Suppose *a)* is satisfied. The hypotheses imply that $\mathscr{E} \otimes_Y \mathscr{F}$ is a coherent $\mathscr{O}_X$-module (**0**, 5.3.11) **IV-2** | 44
and (**0**, 5.3.5); its associated prime cycles are therefore the irreducible components of $\mathrm{Supp}(\mathscr{E} \otimes_Y \mathscr{F})$ (3.1.4), and for every maximal point x of $\mathrm{Supp}(\mathscr{E} \otimes_Y \mathscr{F})$, $f(x) = y$ is a maximal point of $\mathrm{Supp}(\mathscr{E})$ and x is a maximal point of $\mathrm{Supp}(\mathscr{F}_y)$ (2.5.5). As, by virtue of (3.3.1) and the fact that $y \in f(\mathrm{Supp}(\mathscr{F}))$ implies $\mathscr{F}_y \neq 0$ (**I**, 9.1.13), every point of $\mathrm{Ass}(\mathscr{E}) \cap f(\mathrm{Supp}(\mathscr{F}))$ is the image by f of a maximal point of $\mathrm{Supp}(\mathscr{E} \otimes_Y \mathscr{F})$, we see that condition *b)* is satisfied.

Conversely, suppose *b)* is satisfied, and let us show that if z, z' are two distinct points of $\mathrm{Ass}(\mathscr{E} \otimes_Y \mathscr{F})$, neither of the two can be adherent to the other. In the first place, if $f(z) = f(z') = y$, we have $y \in \mathrm{Ass}(\mathscr{E})$ and z and z' belong to $\mathrm{Ass}(\mathscr{F}_y)$ by (3.3.1), whence $y \in f(\mathrm{Supp}(\mathscr{F}))$; as by hypothesis neither of the two points z, z' is adherent to the other *within* $f^{-1}(y)$, neither can be adherent to the other *within* X. If $y = f(z)$ and $y' = f(z')$ are distinct, they belong to $\mathrm{Ass}(\mathscr{E}) \cap f(\mathrm{Supp}(\mathscr{F}))$, hence neither of the two can be adherent to the other in Y; it follows from the continuity of f that neither of the points z, z' can be adherent to the other in X. □

Proposition (3.3.4). — *Let X and Y be locally Noetherian preschemes, $f : X \to Y$ a morphism, $\mathscr{E}$ a coherent $\mathscr{O}_Y$-module, and $\mathscr{F}$ a coherent $\mathscr{O}_X$-module that is f-flat. Then the following conditions are equivalent:*

a) *$\mathscr{E} \otimes_Y \mathscr{F}$ is reduced (3.2.2).*
b) *For every point $y \in \mathrm{Ass}(\mathscr{E}) \cap f(\mathrm{Supp}(\mathscr{F}))$, $\overline{\{y\}}$ is a nonembedded associated prime cycle of $\mathscr{E}$, $\mathrm{length}(\mathscr{E}_y) = 1$, and $\mathscr{F}_y$ is reduced.*

Proof. Suppose *a)* is satisfied. We already know from (3.3.3) that, for every $y \in \mathrm{Ass}(\mathscr{E})$ lying in $f(\mathrm{Supp}(\mathscr{F}))$, $\overline{\{y\}}$ is a nonembedded associated prime cycle of $\mathscr{E}$ and $\mathscr{F}_y$ has no embedded associated prime cycle. Furthermore, by (2.5.5), for every $x \in \mathrm{Ass}(\mathscr{E} \otimes_Y \mathscr{F}) \cap f^{-1}(y)$, we have

$$1 = \mathrm{length}((\mathscr{E} \otimes_Y \mathscr{F})_x) = \mathrm{length}(\mathscr{E}_y)\,\mathrm{length}((\mathscr{F}_y)_x),$$

hence $\mathrm{length}(\mathscr{E}_y) = \mathrm{length}((\mathscr{F}_y)_x) = 1$, which proves *b)*.

Conversely, suppose *b)* is satisfied; we already know that every point $x \in \mathrm{Ass}(\mathscr{E} \otimes_Y \mathscr{F})$ is a maximal point of $\mathrm{Supp}(\mathscr{E} \otimes_Y \mathscr{F})$, that $y = f(x)$ is a maximal point of $\mathrm{Supp}(\mathscr{E})$ and x a maximal point of $\mathrm{Supp}(\mathscr{F}_y)$ (3.3.1) and (3.3.3); in addition it follows from the hypothesis and from (2.5.5) that $\mathrm{length}((\mathscr{E} \otimes_Y \mathscr{F})_x) = 1$, which proves *a)*. □

Corollary (3.3.5). — *Let X and Y be locally Noetherian preschemes and let $f : X \to Y$ be a flat morphism. If Y is reduced at the points of $f(X)$ and $f^{-1}(y)$ is a reduced $\boldsymbol{k}(y)$-prescheme for every $y \in f(X)$, then X is reduced.*

Proof. Since the nilradical $\mathscr{N}_Y$ is coherent, the set of points where Y is reduced is open (**0**, 5.2.2), and we may restrict to the case where Y is reduced. It suffices then to apply (3.3.4) with $\mathscr{E} = \mathscr{O}_Y$ and $\mathscr{F} = \mathscr{O}_X$. □

Proposition (3.3.6). — *Let $f : X \to S$ and $g : Y \to S$ be two morphisms, $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-module, and $\mathscr{G}$ a quasi-coherent $\mathscr{O}_Y$-module. Suppose that: 1º $\mathscr{G}$ is g-flat; 2º X is locally Noetherian, and for every $s \in S$, $g^{-1}(s)$ is locally Noetherian (which will hold if Y is also locally Noetherian). Let $Z = X \times_S Y$; for every pair (x, y) such that $x \in X$, $y \in Y$, and $f(x) = g(y) = s$, let $\mathrm{T}_{x,y}$ be the prescheme $\operatorname{Spec}(\boldsymbol{k}(x) \otimes_{\boldsymbol{k}(s)} \boldsymbol{k}(y))$,* **IV-2** | 45 *and let $\mathrm{I}_{x,y}$ be the image of $\operatorname{Ass}(\mathscr{O}_{\mathrm{T}_{x,y}})$ by the canonical monomorphism $\mathrm{T}_{x,y} \to Z$ (**I**, 3.4.9). Then*

(3.3.6.1)
$$\operatorname{Ass}(\mathscr{F} \otimes_S \mathscr{G}) = \bigcup_{x \in \operatorname{Ass}(\mathscr{F})} \Bigg(\bigcup_{y \in \operatorname{Ass}(\mathscr{G}_{f(x)})} \mathrm{I}_{x,y} \Bigg)$$

where for all $s \in S$, $\mathscr{G}_s = \mathscr{G} \otimes_{\mathscr{O}_S} \boldsymbol{k}(s)$.

Proof. Let $p : Z \to X$, $q : Z \to Y$ be the canonical projections, so that we have the commutative diagram

$$\begin{tikzcd} X \arrow[d, "f"'] & Z \arrow[l, "p"'] \arrow[d, "q"] \\ S & Y \arrow[l, "g"] \end{tikzcd}$$

Set $\mathscr{G}' = q^*(\mathscr{G})$, so that $\mathscr{F} \otimes_S \mathscr{G} = \mathscr{F} \otimes_X \mathscr{G}'$; as $\mathscr{G}'$ is p-flat (2.1.4), it follows from (3.3.1) that

(3.3.6.2)
$$\operatorname{Ass}(\mathscr{F} \otimes_S \mathscr{G}) = \bigcup_{x \in \operatorname{Ass}(\mathscr{F})} \operatorname{Ass}(\mathscr{G}'_x)$$

with $\mathscr{G}'_x = \mathscr{G}' \otimes_{\mathscr{O}_X} \boldsymbol{k}(x)$. If $s = f(x)$, we have $\mathscr{G}'_x = \mathscr{G}_s \otimes_{\boldsymbol{k}(s)} \boldsymbol{k}(x)$, and $p^{-1}(x) = g^{-1}(s) \otimes_{\boldsymbol{k}(s)} \boldsymbol{k}(x)$; furthermore, as the field $\boldsymbol{k}(x)$ is a flat $\boldsymbol{k}(s)$-module, the morphism $p^{-1}(x) \to g^{-1}(s)$ is flat; applying (3.3.1) to this morphism, we get

(3.3.6.3)
$$\operatorname{Ass}(\mathscr{G}'_x) = \bigcup_{y \in \operatorname{Ass}(\mathscr{G}_s)} \operatorname{Ass}(\mathscr{O}_{\mathrm{T}_{x,y}})$$

whence the proposition. □

We note that if, in the statement, we suppress hypothesis 2º, we can still conclude, by virtue of (3.3.1), the relation

(3.3.6.4)
$$\operatorname{Ass}(\mathscr{F} \otimes_S \mathscr{G}) \supset \bigcup_{x \in \operatorname{Ass}(\mathscr{F})} \Bigg(\bigcup_{y \in \operatorname{Ass}(\mathscr{G}_{f(x)})} \mathrm{I}_{x,y} \Bigg).$$

Corollary (3.3.7). — *Under the hypotheses of (3.3.6), suppose in addition that S is also locally Noetherian and that $f(\operatorname{Ass}(\mathscr{F})) \subset \operatorname{Ass}(\mathscr{O}_S)$. Then*

(3.3.7.1)
$$\operatorname{Ass}(\mathscr{F} \otimes_S \mathscr{G}) = \bigcup_{(x,y) \in C} \mathrm{I}_{x,y}$$

where C is the set of pairs (x, y) such that $x \in \operatorname{Ass}(\mathscr{F})$, $y \in \operatorname{Ass}(\mathscr{G})$ and $f(x) = g(y)$.

Proof. Since $\mathscr{G}$ is g-flat, it follows from (3.3.1) that the relation "$s \in \operatorname{Ass}(\mathscr{O}_S)$ and $y \in \operatorname{Ass}(\mathscr{G}_s)$" is equivalent to "$y \in \operatorname{Ass}(\mathscr{G})$"; the conclusion follows from (3.3.6.1). □

Remarks (3.3.8). — We shall see later (4.2.2) that under the hypotheses of (3.3.6), $\mathrm{T}_{x,y}$ is a prescheme *with no embedded associated prime cycle*; it will follow that if $\mathscr{F}$ and the $\mathscr{G}_s$ have no embedded associated prime cycles, the same is true of $\mathscr{F} \otimes_S \mathscr{G}$.

Corollary (3.3.9). — *Under the conditions of (3.3.7), we have*

$$q(\mathrm{Ass}(\mathscr{F} \otimes_S \mathscr{G})) \subset \mathrm{Ass}(\mathscr{G}) \tag{3.3.9.1}$$

(where $q : X \times_S Y \to Y$ is the canonical projection).

Proof. Indeed, if $(x, y) \in Z$, we have $q(\mathrm{I}_{x,y}) = \{y\} \subset \mathrm{Ass}(\mathscr{G})$. □

IV-2 | 46

3.4. Properties of the sheaves $\mathscr{F}/t\mathscr{F}$

Proposition (3.4.1). — *Let X be a locally Noetherian prescheme, t a section of $\mathscr{O}_X$ over X, and Y the closed sub-prescheme of X defined by the ideal $t\mathscr{O}_X$. Let $\mathscr{F}$ be a coherent $\mathscr{O}_X$-module, let S be the reduced closed sub-prescheme of X having $\mathrm{Supp}(\mathscr{F})$ as underlying space, and let (S_i) be the family of reduced closed sub-preschemes of X whose underlying spaces are the irreducible components of S; denote by s_i the generic point of S_i. Finally, let Z be an irreducible component of $\mathrm{Supp}(\mathscr{F}/t\mathscr{F}) = S \cap Y$, z its generic point.*

(i) *For every i such that $Z \subset S_i$, Z is an irreducible component of $S_i \cap Y$.*

(ii) *If Z is not equal to any of the S_i, then*

$$\mathrm{length}((\mathscr{F}/t\mathscr{F})_z) \geqslant \sum_i \mathrm{length}(\mathscr{F}_{s_i}) \tag{3.4.1.1}$$

where the sum on the right-hand side is extended to all i such that $Z \subset S_i$.

(iii) *Suppose that Z is not equal to any of the S_i. For the two sides of (3.4.1.1) to be equal, it is necessary and sufficient that the following two conditions be satisfied:*

*α) t_z is $\mathscr{F}_z$-regular (**0**, 15.1.4).*

β) For every i such that $Z \subset S_i$, the canonical image of the germ t_z in $\mathscr{O}_{S_i,z}$ generates the maximal ideal of this ring (which implies that $\mathscr{O}_{S_i,z}$ is a discrete valuation ring and that the image of t_z is a uniformizer of this ring).

Proof. *(i)* If $j : Y \to X$ is the canonical injection, then

$$\mathscr{F}/t\mathscr{F} = \mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{O}_Y = j^*\mathscr{F},$$

and hence

$$\mathrm{Supp}(\mathscr{F}/t\mathscr{F}) = j^{-1}(S) = S \cap Y$$

by (**I**, 9.1.13), which proves the assertion.

(ii) and (iii) The points s_i such that $Z \subset S_i$ are precisely those belonging to $\mathrm{Spec}(\mathscr{O}_z)$. Thus, to prove *(ii)* and *(iii)*, we may replace X by $\mathrm{Spec}(\mathscr{O}_z)$. If $M = \mathscr{F}_z$, we may therefore suppose that $\mathscr{F} = \widetilde{M}$, and then $\mathscr{F}_{s_i} = M_{\mathfrak{p}_i}$, where the $\mathfrak{p}_i$ are the minimal prime ideals of $\mathscr{O}_z$. Moreover, since M is an $\mathscr{O}_z$-module of finite type, we have $S = S'_{\mathrm{red}}$, where

$$S' = \mathrm{Spec}(\mathscr{O}_z/\mathfrak{a})$$

and $\mathfrak{a}$ is the annihilator of M in $\mathscr{O}_z$ (**0**, 1.7.4). The two sides of (3.4.1.1) have the same values whether M is regarded as an $\mathscr{O}_z$-module or as an $(\mathscr{O}_z/\mathfrak{a})$-module. We may therefore finally replace X by $S' = \mathrm{Spec}(A)$, where A is a Noetherian local ring and M is a faithful A-module. Since Z is closed in S, the hypothesis that $Z \neq S_i$ for every i means that $s_i \notin Z$, and hence that $\dim(A) > 0$. Finally, to say that z is the generic point of Z, an irreducible component of $S_i \cap V(t)$, means that A/tA has dimension 0 (in other words, that it is a local Artinian ring). We are thus reduced to the following lemma. □

Lemma (3.4.1.2). — *Let A be a Noetherian local ring of dimension > 0, let $\mathfrak{p}_i$ be the minimal prime ideals of A, let $\mathfrak{m}$ be its maximal ideal, and let $t \in \mathfrak{m}$ be such that A/tA is Artinian. Then, for every A-module of finite type M,*

$$\mathrm{length}(M/tM) \geqslant \sum_i \mathrm{length}(M_{\mathfrak{p}_i}). \tag{3.4.1.3}$$

Moreover, equality holds if and only if the following two conditions are satisfied:

α) t is M-regular;

β) for every i such that $M_{\mathfrak{p}_i} \neq 0$, the image of t in $A/\mathfrak{p}_i$ generates the maximal ideal of that ring (which implies that $A/\mathfrak{p}_i$ is a discrete valuation ring).

IV-2 | 47

Proof. Since A does not have dimension 0 and A/tA is Artinian, necessarily $\dim(A) = 1$ (**0**, 16.3.4), and $t \notin \mathfrak{p}_i$ for every i. The principal ideal (t) is therefore an ideal of definition of A, and hence contains a power of the maximal ideal $\mathfrak{m}$. Let N be the submodule of M consisting of the elements annihilated by a power of t (or, equivalently in view of what we have just proved, by a power of $\mathfrak{m}$), and put $P = M/N$. Then t is P-regular: if $tx \in N$ for some $x \in M$, then $t^k(tx) = 0$ for some integer k, and hence $x \in N$. We shall use the following elementary lemma.

Lemma (3.4.1.4). — *Let A be a ring and*

$$0 \longrightarrow M' \longrightarrow M \longrightarrow M'' \longrightarrow 0$$

an exact sequence of A-modules. If $t \in A$ is M''-regular, then the sequence

$$0 \longrightarrow M'/tM' \longrightarrow M/tM \longrightarrow M''/tM'' \longrightarrow 0$$

is exact.

Proof. Since $M/tM = M \otimes_A (A/tA)$, it suffices to prove exactness at M'/tM'. Suppose that the image $x \in M$ of an element $x' \in M'$ is of the form $x = ty$, with $y \in M$. For the images x'', y'' of x, y in M'', we have $x'' = ty''$. But $x'' = 0$, so the hypothesis gives $y'' = 0$. Thus y is the image of an element $y' \in M'$, and the relation $x = ty$ gives $x' = ty'$ because $M' \to M$ is injective. □

It follows from this lemma that

(3.4.1.5) $$\operatorname{length}(M/tM) = \operatorname{length}(N/tN) + \operatorname{length}(P/tP).$$

On the other hand, $N_{\mathfrak{p}_i} = 0$ for every i, since $t \notin \mathfrak{p}_i$, and hence $M_{\mathfrak{p}_i} = P_{\mathfrak{p}_i}$. Thus, to prove (3.4.1.3), it suffices to prove it with P in place of M. Furthermore, if the two sides of (3.4.1.3) are equal, then the same inequality for P, together with (3.4.1.5), gives $\operatorname{length}(N/tN) = 0$. Consequently $N/tN = 0$, and Nakayama's lemma gives $N = 0$, since N is of finite type. But $N = 0$ means that t is M-regular. We may therefore reduce to the case $M = P$, that is, suppose from the outset that t is M-regular. This implies that $\mathfrak{m} \notin \operatorname{Ass}(M)$, since t cannot annihilate a nonzero element of M. Because $\dim(A) = 1$, it follows that

$$\operatorname{Ass}(M) \subset \{\mathfrak{p}_i\}_i.$$

We now argue by induction on

$$n = \sum_i \operatorname{length}(M_{\mathfrak{p}_i}).$$

If $n = 0$, then $M_{\mathfrak{p}_i} = 0$ for every i, and hence $M = 0$, since none of the $\mathfrak{p}_i$ belongs to $\operatorname{Ass}(M)$. Both sides of (3.4.1.3) are then zero, and condition *β)* is vacuous. If $n > 0$, the argument at the beginning of the proof of (3.4.1) allows us, moreover, to suppose that M is faithful. It follows that $M_{\mathfrak{p}_i} \neq 0$ for every i (Bourbaki, *Alg. comm.*, chap. II, § 2, no 2, cor. 2 of prop. 4), and consequently

$$\operatorname{Ass}(M) = \{\mathfrak{p}_i\}_i.$$

Suppose first that $n = 1$. There is then only one minimal prime ideal $\mathfrak{p}$ of A, and the assertion that $M_{\mathfrak{p}}$ has length 1 means that it is isomorphic, as an $A_{\mathfrak{p}}$-module, to the residue field IV-2 | 48

$$k = A_{\mathfrak{p}}/\mathfrak{p}A_{\mathfrak{p}}.$$

Thus $M_{\mathfrak{p}}$ is annihilated by $\mathfrak{p}A_{\mathfrak{p}}$, and consequently $\mathfrak{p}$ is the annihilator of M (Bourbaki, *Alg. comm.*, chap. II, § 2, no 4, formula (9)). Since M is faithful, $\mathfrak{p} = 0$, and hence A is integral. Because $M \neq 0$, Nakayama's lemma gives $M/tM \neq 0$, so that $\operatorname{length}(M/tM) \geqslant 1$; this proves (3.4.1.3) in this case. Moreover, if $\operatorname{length}(M/tM) = 1$, then M is cyclic (Bourbaki, *Alg. comm.*, chap. II, § 3, no 2, cor. 2 of prop. 4), and hence isomorphic to a quotient $A/\mathfrak{b}$. Since M is faithful, necessarily $\mathfrak{b} = 0$, and M is isomorphic to A. As $\operatorname{length}(A/tA) = 1$, the ideal tA is the maximal ideal $\mathfrak{m}$. Since A is a Noetherian integral local ring, it follows that A is a discrete valuation ring (Bourbaki, *Alg. comm.*, chap. VI, § 3, no 6, prop. 9), with uniformizer t. Conversely, if A is a discrete valuation ring, t is its uniformizer, $\operatorname{length}(M_{\mathfrak{p}}) = 1$, and t is M-regular, then M is torsion-free and therefore isomorphic to a submodule of A (as M is of finite type), hence to A itself. Thus

$$\operatorname{length}(M/tM) = \operatorname{length}(A/tA) = 1.$$

Suppose now that $n \geqslant 2$. There exists an exact sequence

$$0 \longrightarrow M' \longrightarrow M \longrightarrow M'' \longrightarrow 0$$

with $M' \neq 0$, $M'' \neq 0$, and

$$\mathrm{Ass}(M) = \mathrm{Ass}(M') \cup \mathrm{Ass}(M'').$$

Indeed, if $\mathrm{Ass}(M)$ has more than one element, this follows from Bourbaki, *Alg. comm.*, chap. IV, § 1, no 1, prop. 4. If, on the contrary, $\mathrm{Ass}(M)$ consists of a single prime ideal, that ideal is necessarily the unique minimal prime ideal $\mathfrak{p}$ of A. The hypothesis then gives $\mathrm{length}(M_{\mathfrak{p}}) \geqslant 2$, and it is enough to take for M' the inverse image of a submodule of $M_{\mathfrak{p}}$ distinct from both 0 and $M_{\mathfrak{p}}$. Since t is M-regular, it belongs to none of the prime ideals in $\mathrm{Ass}(M)$ (Bourbaki, *Alg. comm.*, chap. IV, § 1, no 1, cor. 2 of prop. 2). For the same reason, t is both M'-regular and M''-regular. By (3.4.1.4), the sequence

$$0 \longrightarrow M'/tM' \longrightarrow M/tM \longrightarrow M''/tM'' \longrightarrow 0$$

is exact. For every i, so is the sequence

$$0 \longrightarrow M'_{\mathfrak{p}_i} \longrightarrow M_{\mathfrak{p}_i} \longrightarrow M''_{\mathfrak{p}_i} \longrightarrow 0.$$

Consequently

$$\mathrm{length}(M/tM) = \mathrm{length}(M'/tM') + \mathrm{length}(M''/tM''),$$
$$\mathrm{length}(M_{\mathfrak{p}_i}) = \mathrm{length}(M'_{\mathfrak{p}_i}) + \mathrm{length}(M''_{\mathfrak{p}_i}).$$

The induction hypothesis now proves (3.4.1.3). Moreover, the two sides can be equal only if the analogous inequalities for M' and M'' are both equalities. By the induction hypothesis, this is equivalent to condition *β)* for those $\mathfrak{p}_i$ such that $M'_{\mathfrak{p}_i} \neq 0$ or $M''_{\mathfrak{p}_i} \neq 0$; these are precisely the ideals for which $M_{\mathfrak{p}_i} \neq 0$. □

IV-2 | 49

Corollary (3.4.2). — *Under the general hypotheses of* (3.4.1), *suppose that Z is not equal to any of the S_i and that* $\mathrm{length}((\mathscr{F}/t\mathscr{F})_z) = 1$. *Then there is a unique S_i containing Z, and for this value of i,* $\mathrm{length}(\mathscr{F}_{s_i}) = 1$; *moreover, $\mathscr{O}_{S_i,z}$ is a discrete valuation ring with uniformizer t_z, and t_z is $\mathscr{F}_z$-regular.*

Proof. This follows from (3.4.1), the two sides of (3.4.1.1) being then equal. □

Proposition (3.4.3). — *Let X be a locally Noetherian prescheme, t a section of $\mathscr{O}_X$ over X, and Y the closed sub-prescheme of X defined by the ideal $t\mathscr{O}_X$. Let $\mathscr{F}$ be a coherent $\mathscr{O}_X$-module, let T be an associated prime cycle of $\mathscr{F}$, let T' be an irreducible component of $T \cap Y$, and let x be the generic point of T'. Suppose that t_x is $\mathscr{F}_x$-regular; then $x \in$* $\mathrm{Ass}(\mathscr{F}/t\mathscr{F})$.

Proof. As in the proof of (3.4.1), we may reduce to the case $X = \mathrm{Spec}(\mathscr{O}_x)$. Taking (3.1.2) into account, the proposition is then a consequence of (**0**, 16.4.6.3). □

Proposition (3.4.4). — *Let X be a locally Noetherian prescheme, t a section of $\mathscr{O}_X$ over X, and Y the closed sub-prescheme of X defined by the ideal $t\mathscr{O}_X$. Let $\mathscr{F}$ be a coherent $\mathscr{O}_X$-module, and let (S_i) be the family of irreducible components of* $\mathrm{Supp}(\mathscr{F})$. *Let y be a point of Y such that t_y is $\mathscr{F}_y$-regular and no embedded associated prime cycle of $\mathscr{F}/t\mathscr{F}$ contains y. Then the irreducible components of* $\mathrm{Supp}(\mathscr{F}/t\mathscr{F})$ *containing y are precisely the irreducible components of the $S_i \cap Y$ containing y, and the associated prime cycles of $\mathscr{F}$ containing y are non-embedded.*

Proof. Let us first prove the last assertion. Let $T \supset T_1$ be two associated prime cycles of $\mathscr{F}$ containing y. If x is the generic point of an irreducible component of $T \cap Y$ containing y, then x is a generization of y, and hence belongs to every neighbourhood of y. The hypothesis that t_y is $\mathscr{F}_y$-regular therefore implies that t_x is $\mathscr{F}_x$-regular (**0**, 15.2.4), so (3.4.3) gives $x \in \mathrm{Ass}(\mathscr{F}/t\mathscr{F})$. Let x_1 be the generic point of an irreducible component of $T_1 \cap Y$ containing y, and let x be the generic point of an irreducible component of $T \cap Y$ containing x_1. The preceding argument shows that x_1 and x both belong to $\mathrm{Ass}(\mathscr{F}/t\mathscr{F})$. Since $x_1 \in \overline{\{x\}}$, the hypothesis implies $x_1 = x$.

Again denote by T and T_1 the integral closed sub-preschemes of X having these spaces as their respective underlying spaces, and set

$$A = \mathscr{O}_{T,x}, \qquad A_1 = \mathscr{O}_{T_1,x}.$$

Then $A_1 = A/\mathfrak{p}$ for a prime ideal $\mathfrak{p}$ of A. By the definitions of x and x_1, the rings A/tA and A_1/tA_1 are Artinian. On the other hand, we saw above that t_x is $\mathscr{F}_x$-regular, so $x \notin \operatorname{Ass}(\mathscr{F})$, and consequently A_1 is not Artinian. Thus $\dim A = \dim A_1 = 1$. This implies $\mathfrak{p} = 0$ and $A = A_1$ (**0**, 16.1.2.2). Since $\operatorname{Spec}(A)$ and $\operatorname{Spec}(A_1)$ are respectively dense in T and T_1, it follows that $T = T_1$.

The S_i containing y are therefore all the associated prime cycles of $\mathscr{F}$ containing y. If x is the generic point of an irreducible component of $S_i \cap Y$ containing y, then (**0**, 15.2.4) again shows that t_x is $\mathscr{F}_x$-regular, and (3.4.3) gives $x \in \operatorname{Ass}(\mathscr{F}/t\mathscr{F})$. This proves the first assertion of (3.4.4). □

Proposition (3.4.5). — *Let X be a locally Noetherian prescheme, t a section of $\mathscr{O}_X$ over X, and Y the closed sub-prescheme of X defined by the ideal $t\mathscr{O}_X$. Let $\mathscr{F}$ be a coherent $\mathscr{O}_X$-module and y a point of Y. Suppose that t_y is $\mathscr{F}_y$-regular and that $\mathscr{F}/t\mathscr{F}$ is integral at y (3.2.4). Then $\mathscr{F}$ is integral at the point y.* **IV-2 | 50**

Proof. Taking into account (3.4.4), it suffices to prove that y is contained in a *unique* irreducible component of $\operatorname{Supp}(\mathscr{F})$, and that if s is the generic point of this component, $\operatorname{length}(\mathscr{F}_s) = 1$. By hypothesis, y belongs to only one irreducible component of $\operatorname{Supp}(\mathscr{F}/t\mathscr{F})$, and if z is the generic point of this component, then $\operatorname{length}((\mathscr{F}/t\mathscr{F})_z) = 1$. The conclusion follows from (3.4.2). □

Proposition (3.4.6). — *The hypotheses being those of (3.4.1), let x be a point of Y. Suppose that Y does not contain any of the S_i containing x, and that $\mathscr{F}/t\mathscr{F}$ is reduced at the point x (3.2.2). Then t_x is $\mathscr{F}_x$-regular and $\mathscr{F}$ is reduced at the point x. Moreover, if z_j is the generic point of an irreducible component of $\operatorname{Supp}(\mathscr{F}/t\mathscr{F})$ containing x, then z_j is contained in a unique S_i, and $\mathscr{O}_{S_i,z_j}$ is a discrete valuation ring with uniformizer t_{z_j}.*

Proof. The assertion that t_x is $\mathscr{F}_x$-regular follows by applying the following lemma to the ring $\mathscr{O}_x$.

Lemma (3.4.6.1). — *Let A be a Noetherian ring, M an A-module of finite type, $\mathfrak{p}_i$ the minimal elements of $\operatorname{Supp}(M)$, and $t \in A$. Suppose that t belongs to none of the $\mathfrak{p}_i$ and that M/tM is a reduced A-module (3.2.2). Then t is M-regular.*

Proof. Every prime ideal $\mathfrak{p} \in \operatorname{Supp}(M)$ contains one of the $\mathfrak{p}_i$. Since t belongs to none of the $\mathfrak{p}_i$, multiplication by t on $M_\mathfrak{p}$ is not nilpotent (Bourbaki, *Alg. comm.*, chap. IV, § 1, no 4, cor. of prop. 9). Let N be the submodule of M consisting of the elements annihilated by a power of t, and set $P = M/N$. We shall prove that $N = 0$. Since t is P-regular, (3.4.1.4) gives an exact sequence

$$0 \longrightarrow N/tN \longrightarrow M/tM \longrightarrow P/tP \longrightarrow 0.$$

Since N is of finite type, it is annihilated by a power of t, and it therefore suffices to prove that $N/tN = 0$. As N/tN is a submodule of M/tM, it suffices to prove that $(N/tN)_\mathfrak{p} = 0$ for every $\mathfrak{p} \in \operatorname{Ass}(M/tM)$, or equivalently that

$$u_\mathfrak{p} : (M/tM)_\mathfrak{p} \longrightarrow (P/tP)_\mathfrak{p}$$

is bijective for every $\mathfrak{p} \in \operatorname{Ass}(M/tM)$. Now $(P/tP)_\mathfrak{p} \neq 0$. Indeed,

$$\mathfrak{p} \in \operatorname{Supp}(M/tM) = \operatorname{Supp}(M) \cap V(t)$$

by (**0**, 1.7.5), so the image of t in $A_\mathfrak{p}$ lies in the maximal ideal $\mathfrak{p}A_\mathfrak{p}$. The equality $P_\mathfrak{p} = tP_\mathfrak{p}$ would therefore imply $P_\mathfrak{p} = 0$ by Nakayama's lemma. We would then have $M_\mathfrak{p} = N_\mathfrak{p}$, and multiplication by t on $M_\mathfrak{p}$ would be nilpotent, contradicting the observation above because $\mathfrak{p} \in \operatorname{Supp}(M)$. Finally, since M/tM is reduced, $\operatorname{length}((M/tM)_\mathfrak{p}) = 1$. As $(P/tP)_\mathfrak{p} \neq 0$, the map $u_\mathfrak{p}$ is necessarily bijective. This proves the lemma. □

By hypothesis, no embedded associated prime cycle of $\mathscr{F}/t\mathscr{F}$ contains x. It follows from (3.4.4) that no embedded associated prime cycle of $\mathscr{F}$ contains x. On the other hand, applying (3.4.2) to an irreducible component of $\operatorname{Supp}(\mathscr{F}/t\mathscr{F})$ containing x, we find that $\operatorname{length}(\mathscr{F}_{s_i}) = 1$ for every S_i containing x. This completes the proof that $\mathscr{F}_x$ is reduced. The final assertions also follow from (3.4.2). □

Corollary (3.4.7). — *Let A be a Noetherian local ring, $\mathfrak{m}$ its maximal ideal, M an A-module of finite type, and $(x_i)_{1 \leqslant i \leqslant k}$ a family of elements of $\mathfrak{m}$ forming part of a system of parameters for M (**0**, 16.3.6). If the* **IV-2 | 51** *A-module*

$$N = M\Big/\Big(\sum_{i=1}^{k} x_i M\Big)$$

is integral (3.2.4), then M is integral and the sequence $(x_i)_{1\leqslant i\leqslant k}$ is M-regular.

Proof. Induction on k immediately reduces us to the case $k = 1$; write x for x_1. The hypothesis that x forms part of a system of parameters for M implies

$$\dim(N) = \dim(M) - 1$$

by (**0**, 16.3.7). Put $n = \dim(N)$. There is therefore a minimal element $\mathfrak{p}$ of $\mathrm{Supp}(M)$ such that

$$\dim(M/\mathfrak{p}M) = n + 1$$

by (**0**, 16.3.4); for every integer $j > 0$ one also has

$$\dim(M/\mathfrak{p}^j M) = n + 1$$

by (**0**, 16.3.5). Moreover, x forms part of a system of parameters for $M/\mathfrak{p}^j M$ (**0**, 16.3.5). Set

$$M' = M/\mathfrak{p}^j M, \qquad N' = M'/xM';$$

then $\dim(N') = n$.

There is an evident surjective homomorphism $v : N \to N'$. We claim that it is bijective. Indeed, if $P = \mathrm{Ker}(v)$, then $\mathrm{Ass}(P) \subset \mathrm{Ass}(N)$. Since N is integral, if $P \neq 0$, then $\mathrm{Ass}(P)$ and $\mathrm{Ass}(N)$ would both consist of the unique point $\mathfrak{q}$ of

$$\mathrm{Ass}(N) = \mathrm{Supp}(N).$$

But $\dim(N') = \dim(N)$ implies $N'_{\mathfrak{q}} \neq 0$, and $\mathrm{length}(N_{\mathfrak{q}}) = 1$ implies $\mathrm{length}(N'_{\mathfrak{q}}) = 1$, since $N_{\mathfrak{q}} \to N'_{\mathfrak{q}}$ is surjective. Thus $P_{\mathfrak{q}} = 0$, a contradiction. Hence v is bijective.

It follows that N', being isomorphic to N, is integral. Moreover, the support of N', which is the intersection of $\mathrm{Supp}(M')$ with $V(x)$, cannot contain $\mathrm{Supp}(M')$, and the latter is irreducible by construction. Since M'/xM' is integral, and hence reduced, (3.4.6) shows that x is M'-regular. Consequently the kernel of multiplication by x on M is contained in

$$\mathfrak{p}^j M \subset \mathfrak{m}^j M$$

for every integer j, and this kernel is therefore zero by (**0**, 7.3.5). Thus x is M-regular. Applying (3.4.5), we conclude that M is integral. □

Remark (3.4.8). — The analogue of (3.4.7) obtained by replacing "integral" by "reduced" need not be true. For example, let $C = K[X, Y, Z]$ be the polynomial ring over a field K, let

$$B = C/\mathfrak{p}\mathfrak{q}, \qquad \mathfrak{p} = CZ, \qquad \mathfrak{q} = CX^2 + CY,$$

and let A be the local ring of B corresponding to the maximal ideal that is the image of $CX + CY + CZ$ in B. If x, z are the canonical images of X, Z in A, then $xz \neq 0$ but $x^2z^2 = 0$. On the other hand, A/xA is isomorphic to $K[Y, Z]/(YZ)$, so $\dim(A/xA) = 1$ whereas $\dim(A) = 2$. Thus x belongs to a system of parameters of A (**0**, 16.3.4), and A/xA is reduced, but A is not.

Proposition (3.4.9). — *Let A be a Noetherian ring, M an A-module of finite type, and $f \in A$ an M-regular element such that M/fM has no embedded associated prime ideals. If $\mathfrak{p}_i$ $(1 \leqslant i \leqslant m)$ are the prime ideals associated to M/fM, then, for every integer $n > 0$, $f^n M$ is the intersection of the inverse images of the $f^n M_{\mathfrak{p}_i}$ under the canonical maps $M \to M_{\mathfrak{p}_i}$ $(1 \leqslant i \leqslant m)$.*

Proof. It suffices to prove that the $\mathfrak{p}_i$ are also the prime ideals associated to $M/f^n M$, for then the $\mathfrak{p}_i$-saturations of $f^n M$ are the components of the necessarily unique reduced primary decomposition of $f^n M$ in M. Now, we have

$$\mathrm{Ass}(f^{n-1}M/f^n M) \subset \mathrm{Ass}(M/f^n M) \subset \mathrm{Ass}(M/f^{n-1}M) \cup \mathrm{Ass}(f^{n-1}M/f^n M)$$

by (3.1.7). Since f is M-regular, $f^{n-1}M/f^n M$ is isomorphic to M/fM, and the result follows by induction on n. □

§4. Change of base field for algebraic preschemes

4.1. Dimension of algebraic preschemes We shall develop in § 5 the general theory of the dimension of preschemes. The theory of the dimension of algebraic preschemes, however, can be developed more elementarily and also has many special features; we therefore give here a rapid account independent of the general theory. **IV-2 | 52**

If K is a field and L an extension of K, we write $\operatorname{tr.deg}_K L$ for the transcendence degree of L over K.

Definition (4.1.1). — Let k be a field and X a prescheme locally of finite type over k. The *dimension* of X is the number

(4.1.1.1)
$$\dim(X) = \sup_x \operatorname{tr.deg}_k \kappa(x),$$

where x runs through the set of maximal points of X.

We shall see in (5.2.2) that Definition (4.1.1) depends only apparently on the base field k over which X is locally of finite type, and that the number $\dim(X)$ so defined agrees with the dimension of the underlying space of X (**0**, 14.1.2). Evidently,

$$\dim(X) = \dim(X_{\text{red}}).$$

Each $\kappa(x)$ is an extension of finite type of k (**I**, 6.3.3), hence has finite transcendence degree over k. If X is of finite type over k and nonempty, it is Noetherian (**I**, 6.3.7), hence has only finitely many irreducible components; consequently $\dim(X)$ is finite and nonnegative. Definition (4.1.1) gives

$$\dim(\varnothing) = -\infty.$$

If (X_α) denotes the family of reduced closed sub-preschemes of X whose underlying spaces are the irreducible components of X (**I**, 5.2.1), then clearly

(4.1.1.2)
$$\dim(X) = \sup_\alpha \dim(X_\alpha).$$

The calculation of the dimension is thus reduced to the case of integral preschemes locally of finite type over k. Finally,

(4.1.1.3)
$$\dim(X) = \dim(U)$$

for every induced sub-prescheme on an everywhere dense open subset U of X. The notion of dimension is thereby reduced to the case of an affine scheme of finite type over k.

Theorem (4.1.2). — *Let X and Y be two preschemes locally of finite type over a field k, and let $f : X \to Y$ be a k-morphism.*

IV-2 | 53

(i) *If f is quasi-compact and dominant, then*
$$\dim(Y) \leqslant \dim(X).$$

(ii) *If f is quasi-finite, then*
$$\dim(X) \leqslant \dim(Y).$$

(iii) *Suppose that X is of finite type over k. For $\dim(X) \geqslant n$ (respectively $\dim(X) \leqslant n$, respectively $\dim(X) = n$), it is necessary and sufficient that there exist an open subset U dense in X and a k-morphism*
$$g : U \longrightarrow \mathbf{V}_k^n = \operatorname{Spec}\big(k[T_1, \ldots, T_n]\big)$$
that is surjective (respectively finite, respectively finite and surjective). If X is affine, one may take $U = X$.

Proof. (i) Let y be a maximal point of Y. The fibre $f^{-1}(y)$ contains a maximal point x of X (1.1.5); hence $\kappa(x)$ is an extension of $\kappa(y)$, and therefore

$$\operatorname{tr.deg}_k \kappa(y) \leqslant \operatorname{tr.deg}_k \kappa(x) \leqslant \dim(X).$$

This proves (i).

(ii) If x is a maximal point of X, then $\kappa(x)$ is a finite extension of $\kappa(f(x))$ (**II**, 6.2.2), and hence has the same transcendence degree over k. On considering the reduced closed sub-prescheme of Y whose underlying space is $\overline{\{f(x)\}}$, we are reduced to the following corollary. □

Corollary (4.1.2.1). — *Let Y be a k-prescheme locally of finite type. For every sub-prescheme Z of Y, one has*

$$\dim(Z) \leqslant \dim(Y).$$

Suppose in addition that all the irreducible components of Y have the same dimension. Then Z is rare in Y if and only if

$$\dim(Z) < \dim(Y).$$

Proof. Let z be a maximal point of Z. By considering one of the reduced closed sub-preschemes of Y whose underlying space is an irreducible component of Y containing z, we reduce to the case in which Y is integral, with generic point y. Then, by taking in Y an affine open neighbourhood of z, we reduce to the case in which Y is affine and of finite type over k. Write

$$Y = \operatorname{Spec}(A), \qquad Z = \operatorname{Spec}(A/\mathfrak{a}),$$

where A is an integral ring and $\mathfrak{a}$ is an ideal of A distinct from A.

By the normalization lemma (Bourbaki, *Alg. comm.*, chap. V, § 3, no. 1, th. 1), there exists a finite sequence $(x_i)_{1\leqslant i\leqslant n}$ of elements of A, algebraically independent over k, such that A is integral over

$$B = k[x_1, \ldots, x_n]$$

and $\mathfrak{a} \cap B$ is generated by a subfamily $(x_i)_{1\leqslant i\leqslant p}$, possibly empty, of $(x_i)_{1\leqslant i\leqslant n}$. Let

$$g : Y \longrightarrow \operatorname{Spec}(B) = \mathbf{V}_k^n$$

be the finite dominant morphism corresponding to the canonical injection $B \to A$. Since

$$C = B/(\mathfrak{a} \cap B) \cong k[x_{p+1}, \ldots, x_n],$$

g induces on Z a finite dominant morphism

$$Z \longrightarrow \mathbf{V}_k^{n-p}.$$

Thus

$$\operatorname{tr.deg}_k \kappa(y) = n, \qquad \operatorname{tr.deg}_k \kappa(z) = n - p,$$

because $\kappa(y)$ and $\kappa(z)$ are finite extensions of $\kappa(g(y))$ and $\kappa(g(z))$, respectively. This proves the first assertion.

If $p = 0$, then necessarily $z = y$, since y is the only point of Y whose image under g is the generic point of $\mathbf{V}_k^n$; in this case Z contains a nonempty open subset of Y. If $p > 0$, then $z \neq y$, and $\overline{\{z\}}$ is rare in $\overline{\{y\}}$. This completes the proof. □

Proof of (4.1.2), continued. The corollary proves (ii).

(iii) The sufficiency of the stated conditions follows immediately from (i), (ii), and (1.5.4)(v). To prove necessity, choose a dense open subset U of X that is the union of pairwise disjoint irreducible affine open subsets U_i $(1 \leqslant i \leqslant m)$, each containing a maximal point of X (**0**, 2.1.6). We may further suppose that X is reduced; if X is affine, we may of course take $U = X$.

The same argument as in (4.1.2.1) shows that, if $\dim(U_i) = n_i$, there exists a k-morphism **IV-2** | 54

$$g_i : U_i \longrightarrow \mathbf{V}_k^{n_i}$$

that is finite and dominant, hence surjective (**II**, 6.1.10). Set

$$n = \dim(X) = \sup_i n_i.$$

For every n_i there is a morphism

$$h_i : \mathbf{V}_k^{n_i} \longrightarrow \mathbf{V}_k^n$$

which is the closed immersion corresponding to the canonical homomorphism

$$k[T_1, \ldots, T_n] \longrightarrow k[T_1, \ldots, T_{n_i}]$$

and is the identity when $n_i = n$. Since U is the disjoint union of the U_i, define g on each U_i to be $h_i \circ g_i$. Then g is finite and surjective.

When $n' \geqslant n$, composing g with the canonical closed immersion

$$\mathbf{V}_k^n \longrightarrow \mathbf{V}_k^{n'}$$

gives a finite morphism $U \to \mathbf{V}_k^{n'}$. When $n' \leqslant n$, compose g with the canonical morphism

$$p : \mathbf{V}_k^n \longrightarrow \mathbf{V}_k^{n'}$$

corresponding to the canonical injection

$$k[T_1, \ldots, T_{n'}] \longrightarrow k[T_1, \ldots, T_n].$$

The morphism p is faithfully flat, hence surjective. □

Remark (4.1.3). — Corollary (4.1.2.1) shows that in formula (4.1.1.1) one may let x run through the set of all points of X.

Corollary (4.1.4). — *Let X be a prescheme locally of finite type over a field k, and let K be an extension of k. Then*

$$\dim(X \otimes_k K) = \dim(X).$$

Proof. It is enough to consider the case in which X is of finite type over k. The morphism

$$u : X \otimes_k K \longrightarrow X$$

is faithfully flat (2.2.13)(i). Thus, if U is an everywhere dense open subset of X, then

$$u^{-1}(U) = U \otimes_k K$$

is dense in $X \otimes_k K$ (2.3.10). If

$$g : U \longrightarrow \mathbf{V}_k^n$$

is finite and surjective, then so is

$$g_{(K)} : U \otimes_k K \longrightarrow \mathbf{V}_K^n$$

(**I**, 3.5.2) and (**II**, 6.1.5). The corollary follows. □

Corollary (4.1.5). — *Let X and Y be two preschemes locally of finite type over a field k. Then*

$$\dim(X \times_k Y) = \dim(X) + \dim(Y).$$

Proof. It is enough to prove the following. Let U and V be affine neighbourhoods of points $x \in X$ and $y \in Y$ such that

$$\operatorname{tr.deg}_k \kappa(x) = m = \dim(U), \qquad \operatorname{tr.deg}_k \kappa(y) = n = \dim(V).$$

Then

$$\dim(U \times_k V) = m + n.$$

Equivalently, by (4.1.2), we may suppose that there exist finite surjective k-morphisms

$$f : X \longrightarrow \mathbf{V}_k^m, \qquad g : Y \longrightarrow \mathbf{V}_k^n.$$

The product morphism

$$f \times g : X \times_k Y \longrightarrow \mathbf{V}_k^{m+n}$$

is finite and surjective (**I**, 3.5.2) and (**II**, 6.1.5), and the result follows. □

4.2. Associated prime cycles on algebraic preschemes

Proposition (4.2.1). — *Let K and L be two extensions of a field k such that $K \otimes_k L$ is Noetherian. Then the prime ideals associated with $K \otimes_k L$ are minimal, and if E is the residue field of the local ring at such an ideal, then*

(4.2.1.1) $$\operatorname{tr.deg}_K E = \operatorname{tr.deg}_k L, \qquad \operatorname{tr.deg}_L E = \operatorname{tr.deg}_k K,$$

whence

(4.2.1.2) $$\operatorname{tr.deg}_k E = \operatorname{tr.deg}_k K + \operatorname{tr.deg}_k L.$$

Proof. It is known that K is an algebraic extension of a purely transcendental extension

$$K' = k(\mathbf{t}), \qquad \mathbf{t} = (t_\alpha)_{\alpha \in I},$$

where $(t_\alpha)_{\alpha\in I}$ is a family of indeterminates. The ring

$$k[\mathbf{t}] \otimes_k L = L[\mathbf{t}]$$

is integral, and hence so is $K' \otimes_k L$, which is a ring of fractions of it; the field of fractions of $K' \otimes_k L$ is $L(\mathbf{t})$. There is a commutative diagram of canonical homomorphisms

IV-2 | 55

(4.2.1.3) $$\begin{tikzcd} K \arrow[r] & K \otimes_k L \arrow[r] & K \otimes_{K'} L(\mathbf{t}) \\ K' \arrow[u] \arrow[r] & K' \otimes_k L \arrow[u] \arrow[r] & L(\mathbf{t}) \arrow[u] \\ k \arrow[u] \arrow[r] & L \arrow[u] & \end{tikzcd}$$

Since K is faithfully flat over K',

$$K \otimes_k L = K \otimes_{K'} (K' \otimes_k L)$$

is faithfully flat over $K' \otimes_k L$, and therefore $K' \otimes_k L$ is Noetherian ($\mathbf{0_I}$, 6.5.2). Moreover, $K' \otimes_k L$ identifies with a subring of $K \otimes_k L$. The contraction to $K' \otimes_k L$ of a prime ideal $\mathfrak{p}$ associated with $K \otimes_k L$ is the zero ideal, since no nonzero element of $K' \otimes_k L$ is a zero-divisor in $K \otimes_k L$ ($\mathbf{0_I}$, 6.3.4) and Bourbaki, *Alg. comm.*, chap. IV, § 1, no. 1, cor. 3 to prop. 2.

Since K is algebraic over K', the ring $K \otimes_k L$ is integral over $K' \otimes_k L$, and the prime ideals of $K \otimes_k L$ lying over the zero ideal of $K' \otimes_k L$ are necessarily pairwise incomparable (Bourbaki, *Alg. comm.*, chap. V, § 2, no. 1, cor. 1 to prop. 1). This proves the first assertion (Bourbaki, *Alg. comm.*, chap. IV, § 1, no. 3, cor. 1 to prop. 7).

Furthermore, the residue field E of $\mathfrak{p}$ is algebraic over the residue field of the zero ideal of $K' \otimes_k L$, namely $L(\mathbf{t})$. Consequently

$$\operatorname{tr.deg}_L E = \operatorname{tr.deg}_L L(\mathbf{t}) = \operatorname{Card}(I) = \operatorname{tr.deg}_k K.$$

This gives the second equality in (4.2.1.1); interchanging the roles of K and L gives the first, and (4.2.1.2) follows. □

Corollary (4.2.2). — *Under the hypotheses of (3.3.6), if the preschemes $T_{x,y}$ are locally Noetherian, they have no immersed associated prime cycle.*

Corollary (4.2.3). — *Under the hypotheses of (3.3.6) (respectively (3.3.7)), if the $T_{x,y}$ are locally Noetherian and if $\mathscr{F}$ and the $\mathscr{G}_s$ $(s \in S)$ (respectively $\mathscr{F}$ and $\mathscr{G}$) have no immersed associated prime cycle, then neither does*

$$\mathscr{F} \otimes_{\mathscr{S}} \mathscr{G}.$$

This follows from (4.2.2), (3.3.2), and the proof of (3.3.6). In particular, since every prescheme over a field k is flat over k, we have thereby proved assertion (i) of the following proposition.

Proposition (4.2.4). — *Let k be a field, and let X and Y be two locally Noetherian k-preschemes such that $X \times_k Y$ is locally Noetherian. Suppose in addition that X and Y are integral. Then:*

(i) *$X \times_k Y$ has no immersed associated prime cycle. Each irreducible component of $X \times_k Y$ dominates X and Y, and the set of these components is in bijective correspondence with the set of irreducible components of*

$$\operatorname{Spec}\big(\mathrm{R}(X) \otimes_k \mathrm{R}(Y)\big),$$

or equivalently with the set of minimal prime ideals of $\mathrm{R}(X) \otimes_k \mathrm{R}(Y)$, where $\mathrm{R}(X)$ and $\mathrm{R}(Y)$ are the fields of rational functions of X and Y, respectively.

(ii) *If a maximal point z of $X \times_k Y$ is identified with a minimal prime ideal $\mathfrak{p}$ of $\mathrm{R}(X) \otimes_k \mathrm{R}(Y)$, then the local ring*

$$\mathscr{O}_{X \times_k Y, z}$$

is isomorphic to the ring of fractions

$$\big(\mathrm{R}(X) \otimes_k \mathrm{R}(Y)\big)_{\mathfrak{p}}.$$

In particular, if $\mathrm{R}(X)$ or $\mathrm{R}(Y)$ is separable over k, then $X \times_k Y$ is reduced.

(iii) *If, in addition, X and Y are locally of finite type over k, then every irreducible component of $X \times_k Y$ has dimension* **IV-2 | 56**

$$\dim(X) + \dim(Y).$$

Proof. Assertion (iii) follows from (4.2.1.2), taking account of (i) and (ii).

To prove (ii), we may plainly reduce to the case in which

$$X = \operatorname{Spec}(A), \qquad Y = \operatorname{Spec}(B)$$

are affine, with A and B integral rings having respective fields of fractions

$$K = \mathrm{R}(X), \qquad L = \mathrm{R}(Y).$$

Assertion (i) shows that every minimal prime ideal $\mathfrak{q}$ of $A \otimes_k B$ is the contraction to $A \otimes_k B$ of a minimal prime ideal $\mathfrak{p}$ of $K \otimes_k L$. Since $K \otimes_k L$ is a ring of fractions of $A \otimes_k B$, the isomorphism

$$(A \otimes_k B)_{\mathfrak{q}} \simeq (K \otimes_k L)_{\mathfrak{p}}$$

follows from ($\mathbf{0_I}$, 1.2.5).

Finally, if, for example, $\mathrm{R}(Y)$ is separable over k, then $\mathrm{R}(X) \otimes_k \mathrm{R}(Y)$ is reduced (Bourbaki, *Alg.*, chap. VIII, § 7, no. 3, th. 1). The local rings at the maximal points of $X \times_k Y$ are therefore also reduced, and it follows that $X \times_k Y$ is reduced (3.2.1). □

Proposition (4.2.5). — *Let k be a field, let X and Y be locally Noetherian k-preschemes, and let $\mathscr{F}$ (respectively $\mathscr{G}$) be a quasi-coherent $\mathscr{O}_X$-Module (respectively $\mathscr{O}_Y$-Module). Let (Z'_λ) (respectively (Z''_μ)) be the family of prime cycles associated with $\mathscr{F}$ (respectively $\mathscr{G}$), and denote again by Z'_λ (respectively Z''_μ) the reduced sub-prescheme of X (respectively Y) having Z'_λ (respectively Z''_μ) as its underlying space. If $Z'_\lambda \times_k Z''_\mu$ is locally Noetherian, then its irreducible components $Z_{\lambda\mu\nu}$ dominate Z'_λ and Z''_μ, and $(Z_{\lambda\mu\nu})$ is the family of distinct prime cycles associated with $\mathscr{F} \otimes_k \mathscr{G}$.*

Proof. It suffices to apply (4.2.4) to the product

$$\operatorname{Spec}\big(\kappa(x)\big) \times_k \operatorname{Spec}\big(\kappa(y)\big).$$

□

Corollary (4.2.6). — *Let k be a field, and let X and Y be two locally Noetherian k-preschemes such that $X \times_k Y$ is locally Noetherian. Let (Z'_λ) (respectively (Z''_μ)) be the family of reduced sub-preschemes of X (respectively Y) whose underlying spaces are the irreducible components of X (respectively Y). Then the irreducible components $Z_{\lambda\mu\nu}$ of $Z'_\lambda \times_k Z''_\mu$ dominate Z'_λ and Z''_μ, and $(Z_{\lambda\mu\nu})$ is the family of irreducible components of $X \times_k Y$.*

Proof. We may reduce to the case in which X and Y are reduced (**I**, 5.1.8). The irreducible components of X (respectively Y) are then the prime cycles associated with $\mathscr{O}_X$ (respectively $\mathscr{O}_Y$) (3.2.1). Apply (4.2.5) with

$$\mathscr{F} = \mathscr{O}_X, \qquad \mathscr{G} = \mathscr{O}_Y,$$

noting that, by definition,

$$\mathscr{O}_X \otimes_k \mathscr{O}_Y = \mathscr{O}_{X \times_k Y}.$$

The corollary follows because $\mathscr{O}_X \otimes_k \mathscr{O}_Y$ has no immersed associated prime cycles, since by hypothesis the same is true of $\mathscr{O}_X$ and $\mathscr{O}_Y$ (4.2.3). □

We apply the preceding results to the case in which Y is the spectrum of an extension K of k.

Proposition (4.2.7). — *Let k be a field, let X be a k-prescheme, and let K be an extension of k such that $X \otimes_k K$ is locally Noetherian. Let $\mathscr{F}$ be a quasi-coherent $\mathscr{O}_X$-Module, let x' be a point of $X \otimes_k K$, and let x be its image in X.*

(i) Let (Z_λ) be the family of reduced sub-preschemes of X whose underlying spaces are the prime cycles associated with $\mathscr{F}$. Then the irreducible components $Z_{\lambda\mu}$ of $Z_\lambda \otimes_k K$ are the prime cycles associated with $\mathscr{F} \otimes_k K$, and $Z_{\lambda\mu}$ dominates Z_λ. Moreover, $Z_{\lambda\mu}$ is immersed if and only if Z_λ is immersed.

(ii) The point x belongs to an immersed prime cycle associated with $\mathscr{F}$ if and only if x' belongs to an immersed prime cycle associated with $\mathscr{F} \otimes_k K$. The Module $\mathscr{F}$ has no immersed associated prime cycle if and only if the same is true of $\mathscr{F} \otimes_k K$.

IV-2 | 57

(iii) The indices λ for which $x \in Z_\lambda$ are precisely those for which there exists an index μ such that $x' \in Z_{\lambda\mu}$. In particular, if x' belongs to only one prime cycle associated with $\mathscr{F} \otimes_k K$, then x belongs to only one prime cycle associated with $\mathscr{F}$.

(iv) If X is locally of finite type over k, then

$$\dim(Z_{\lambda\mu}) = \dim(Z_\lambda).$$

Proof. The hypothesis implies that X itself is locally Noetherian (2.2.13) and (2.2.14). Assertion (i) follows from (4.2.5) and the proof of (4.2.3), with $\mathscr{G} = \mathscr{O}_Y$ and $Y = \operatorname{Spec}(K)$. Assertions (ii) and (iii) follow from (i) and (2.3.5). Finally, (iv) is a special case of (4.2.4), (iii). □

Corollary (4.2.8). — *If X is locally of finite type over k, then the set of dimensions of the prime cycles associated with $\mathscr{F}$ is the same as that of the prime cycles associated with $\mathscr{F} \otimes_k K$. The set of dimensions of the irreducible components is likewise the same for X and $X \otimes_k K$.*

Proposition (4.2.9). — *Suppose that the hypotheses of (4.2.5) hold, and suppose in addition that $\mathscr{F}$ and $\mathscr{G}$ are coherent. Let $(\mathscr{F}_\lambda)_{\lambda\in L}$ and $(\mathscr{G}_\mu)_{\mu\in M}$ be irredundant decompositions of $\mathscr{F}$ and $\mathscr{G}$, respectively. For every pair $(\lambda,\mu) \in L \times M$, let*

$$(\mathscr{H}_{\lambda\mu\nu})_{\nu\in S(\lambda,\mu)}$$

be a reduced irredundant decomposition of $\mathscr{F}_\lambda \otimes_k \mathscr{G}_\mu$, where

$$S(\lambda,\mu) = \operatorname{Ass}(\mathscr{F}_\lambda \otimes_k \mathscr{G}_\mu)$$

(3.2.5). Then $(\mathscr{H}_{\lambda\mu\nu})$, over all triples (λ,μ,ν), is an irredundant decomposition of $\mathscr{F} \otimes_k \mathscr{G}$. It is reduced if $(\mathscr{F}_\lambda)$ and $(\mathscr{G}_\mu)$ are reduced.

Proof. The Module $\mathscr{F} \otimes_k \mathscr{G}$ and each $\mathscr{F}_\lambda \otimes_k \mathscr{G}_\mu$ are coherent, and each $\mathscr{F}_\lambda \otimes_k \mathscr{G}_\mu$ identifies with a quotient of $\mathscr{F} \otimes_k \mathscr{G}$. By definition, each $\mathscr{H}_{\lambda\mu\nu}$ identifies with a coherent quotient of $\mathscr{F}_\lambda \otimes_k \mathscr{G}_\mu$, and hence also with a coherent quotient of $\mathscr{F} \otimes_k \mathscr{G}$.

The family of supports of the $\mathscr{H}_{\lambda\mu\nu}$ is locally finite. Indeed,

$$\operatorname{Supp}(\mathscr{F}_\lambda \otimes_k \mathscr{G}_\mu) \subset \left|\operatorname{Supp}(\mathscr{F}_\lambda) \times_k \operatorname{Supp}(\mathscr{G}_\mu)\right|,$$

where $\operatorname{Supp}(\mathscr{F}_\lambda)$ and $\operatorname{Supp}(\mathscr{G}_\mu)$ denote the corresponding reduced closed sub-preschemes. For fixed λ and μ, the family of supports of the $\mathscr{H}_{\lambda\mu\nu}$ is locally finite by hypothesis; the assertion therefore follows from the local finiteness of the families $(\operatorname{Supp}(\mathscr{F}_\lambda))$ and $(\operatorname{Supp}(\mathscr{G}_\mu))$.

It remains to show that the canonical homomorphism

$$\mathscr{F} \otimes_k \mathscr{G} \longrightarrow \bigoplus_{\lambda,\mu,\nu} \mathscr{H}_{\lambda\mu\nu}$$

is injective. It is the composite

$$\begin{aligned}\mathscr{F} \otimes_k \mathscr{G} &\longrightarrow \left(\bigoplus_\lambda \mathscr{F}_\lambda\right) \otimes_k \left(\bigoplus_\mu \mathscr{G}_\mu\right)\\ &\simeq \bigoplus_{\lambda,\mu} (\mathscr{F}_\lambda \otimes_k \mathscr{G}_\mu) \longrightarrow \bigoplus_{\lambda,\mu,\nu} \mathscr{H}_{\lambda\mu\nu}.\end{aligned}$$

The last homomorphism is injective by definition, and the first is injective because it is the tensor product of the canonical injections

$$\mathscr{F} \longrightarrow \bigoplus_{\lambda} \mathscr{F}_\lambda, \qquad \mathscr{G} \longrightarrow \bigoplus_{\mu} \mathscr{G}_\mu,$$

and $\mathscr{F}$ and $\mathscr{G}$ are flat over k.

Finally, if $(\mathscr{F}_\lambda)$ and $(\mathscr{G}_\mu)$ are reduced, we may suppose that

$$L = \operatorname{Ass}(\mathscr{F}), \qquad M = \operatorname{Ass}(\mathscr{G}).$$

The $\mathscr{H}_{\lambda\mu\nu}$ then form a reduced decomposition because, by (4.2.2), the sets

$$\operatorname{Ass}(\mathscr{F}_\lambda \otimes_k \mathscr{G}_\mu)$$

partition $\operatorname{Ass}(\mathscr{F} \otimes_k \mathscr{G})$ (3.2.5). □

Corollary (4.2.10). — *Under the hypotheses of (4.2.7), suppose in addition that $\mathscr{F}$ is coherent, and let $(\mathscr{F}_\lambda)_{\lambda \in L}$ be an irredundant decomposition of $\mathscr{F}$. For every $\lambda \in L$, let*

$$(\mathscr{F}_{\lambda\mu})_{\mu \in \operatorname{Ass}(\mathscr{F}_\lambda \otimes_k K)}$$

be a reduced irredundant decomposition of $\mathscr{F}_\lambda \otimes_k K$. Then $(\mathscr{F}_{\lambda\mu})$ is an irredundant decomposition of $\mathscr{F} \otimes_k K$. It is reduced if $(\mathscr{F}_\lambda)$ is reduced.

Proof. Apply (4.2.9) with

$$Y = \operatorname{Spec}(K), \qquad \mathscr{G} = \mathscr{O}_Y = K,$$

and with M consisting of a single element. □

IV-2 | 58

4.3. Reminders on tensor products of fields For the reader's convenience, we recall here certain properties of tensor products of fields that we shall use in the following numbers; for the proofs, we refer to [1].

(4.3.1). Recall that an extension L of a field k is called *primary* if the largest separable algebraic extension of k contained in L is k itself.

Proposition (4.3.2). — *Let K and L be two extensions of a field k. If L is a primary extension of k, then* $\operatorname{Spec}(L \otimes_k K)$ *is irreducible and, if ζ is its generic point, $\kappa(\zeta)$ is a primary extension of K. Conversely, if* $\operatorname{Spec}(L \otimes_k K)$ *is irreducible for every finite separable extension K of k, then L is a primary extension of k.*

Proof. See [1], pp. 14-03 to 14-06. □

Corollary (4.3.3). — *If k is separably closed (that is, if its algebraic closure is radicial over k), then* $\operatorname{Spec}(L \otimes_k K)$ *is irreducible for every two extensions K and L of k; conversely, if this conclusion holds for every such pair, then k is separably closed.*

Proof. This follows immediately from (4.3.2). □

Corollary (4.3.4). — *Let L be an extension of a field k, and let L_s be the largest separable algebraic extension of k contained in L (sometimes called the separable algebraic closure of k in L). Suppose that L_s is of finite degree over k, and let K be a Galois extension of k containing L_s. Then* $\operatorname{Spec}(L \otimes_k K)$ *has $[L_s : k]$ irreducible components and is their union, and the residue fields at their generic points are primary extensions of K.*

Proof. Indeed,

$$L \otimes_k K = L \otimes_{L_s} (L_s \otimes_k K),$$

and $L_s \otimes_k K$ is isomorphic to a product of $[L_s : k]$ fields, each isomorphic to K (Bourbaki, *Alg.*, chap. VIII, § 7, no. 3, cor. 2 to th. 1). Thus $L \otimes_k K$ is isomorphic to a product of $[L_s : k]$ rings, each isomorphic to $L \otimes_{L_s} K$. Since L is a primary extension of L_s, the conclusion follows from (4.3.2). □

Proposition (4.3.5). — *Let K and L be two extensions of a field k. If L is a separable extension of k, then the ring $L \otimes_k K$ is reduced. Conversely, if $L \otimes_k K$ is reduced for every finite radicial extension K of k, then L is a separable extension of k.*

Proof. See Bourbaki, *Alg.*, chap. VIII, § 7, no. 3, th. 1. □

Corollary (4.3.6). — *If k is perfect, then $K \otimes_k L$ is reduced for every two extensions K and L of k; conversely, if this conclusion holds for every such pair, then k is perfect.*

Proof. This follows immediately from (4.3.5). □

Corollary (4.3.7). — *Let L be a separable extension of k, and let K be an extension of k such that either K or L is finite over k. Then the residue fields of the semilocal ring $L \otimes_k K$ are separable extensions of K.*

Proof. The ring $L \otimes_k K$ is the direct product of its residue fields E_i. For every extension K' of K, the ring $L \otimes_k K'$ is therefore isomorphic to the direct product of the rings $E_i \otimes_K K'$. Since $L \otimes_k K'$ is reduced, the fields E_i are separable over K by (4.3.5). □

Corollary (4.3.8). — *If K and L are two finite separable extensions of k, then $K \otimes_k L$ is a product of finitely many separable extensions of k.*

IV-2 | 59

Proposition (4.3.9). — *If k is algebraically closed, then the ring $L \otimes_k K$ is an integral domain for every two extensions K and L of k; conversely, if this conclusion holds for every such pair, then k is algebraically closed.*

Proof. This follows from (4.3.3) and (4.3.6), since a field that is both perfect and separably closed is algebraically closed. □

4.4. Irreducible preschemes and connected preschemes over an algebraically closed field

(4.4.1). Let k be a field, let X be a k-prescheme, and let K be an extension of k. Since the morphism

$$\mathrm{Spec}(K) \longrightarrow \mathrm{Spec}(k)$$

is faithfully flat, quasi-compact, and universally open (2.4.9), the same is true of the projection

$$p : X \otimes_k K \longrightarrow X$$

(2.2.13). It therefore follows from (2.3.5) that every irreducible component of $X \otimes_k K$ dominates an irreducible component of X, and, since p is surjective, every irreducible component of X is dominated by an irreducible component of $X \otimes_k K$. Thus p induces a surjective map from the set of irreducible components of $X \otimes_k K$ to the set of irreducible components of X.

Likewise, because p is continuous and surjective, every connected component of X is the image under p of a union of connected components of $X \otimes_k K$. Hence there is a surjective map from the set of connected components of $X \otimes_k K$ to the set of connected components of X. It follows that every irreducible (resp. connected) component Z' of $X \otimes_k K$ is contained in a unique set of the form $p^{-1}(Z)$, where Z is an irreducible (resp. connected) component of X. For every sub-prescheme of X having Z as its underlying space (and again denoted by Z), the space Z' is an irreducible (resp. connected) component of $Z \otimes_k K$.

In particular, suppose that $X \otimes_k K$ has finitely many irreducible (resp. connected) components, say n (resp. n'). This is the case when X is of finite type over k, since then $X \otimes_k K$ is of finite type over K and hence Noetherian. The number of irreducible (resp. connected) components of X is then at most n (resp. at most n'). Equality with n (resp. n') means that, for every reduced sub-prescheme Z of X whose underlying space is an irreducible (resp. connected) component of X, the prescheme $Z \otimes_k K$ is irreducible (resp. connected) (**I**, 5.1.8). Consequently, the number of irreducible (resp. connected) components of $X \otimes_k K$ is independent of K if and only if, for every irreducible (resp. connected) component Z of X, the prescheme $Z \otimes_k K$ is irreducible (resp. connected) for every extension K of k.

In particular, if $X \otimes_k K$ is irreducible (resp. connected), then so is X, as also follows directly from the surjectivity of p. Similarly, if $X \otimes_k K$ is reduced (resp. integral), then so is X, since p is faithfully flat (2.1.13).

In this number and the next, we shall examine more closely what can be said about the irreducible (resp. connected) components of $X \otimes_k K$ as K varies. The preceding observations already show that the number of these components is an increasing function of K.

Lemma (4.4.2). — *Let X' and X be two topological spaces, and let $f : X' \to X$ be a continuous map. Suppose that the following conditions hold:*

(i) *f is open and surjective (resp. the topological space X is canonically identified with the quotient of X' by the equivalence relation defined by f);*

IV-2 | 60

(ii) *for every $x \in X$, the fibre $f^{-1}(x)$ is irreducible (resp. connected).*

Then X' is irreducible (resp. connected) if and only if X is.

Proof. The assertion concerning connectedness is Bourbaki, *Top. gén.*, chap. I, 3rd ed., § 11, no. 3, prop. 7. We prove the assertion concerning irreducibility. The condition is plainly necessary because f is surjective; let us prove that it is sufficient.

Let X'_1 and X'_2 be two closed subsets of X' such that $X' = X'_1 \cup X'_2$, and, for $i = 1, 2$, let X_i be the set of $x \in X$ such that $f^{-1}(x) \subset X'_i$. Then

$$X - X_i = f(X' - X'_i),$$

and, since f is open, X_i is a closed subset of X. For every $x \in X$, the fibre $f^{-1}(x)$ is irreducible by hypothesis and is the union of the two closed subsets

$$X'_1 \cap f^{-1}(x) \quad \text{and} \quad X'_2 \cap f^{-1}(x).$$

One of them must equal $f^{-1}(x)$, so $x \in X_1$ or $x \in X_2$. Thus $X = X_1 \cup X_2$. Since X is irreducible, $X = X_1$ or $X = X_2$, and therefore $X' = X'_1$ or $X' = X'_2$. □

Remark (4.4.3). — If the topology of X is not the quotient of that of X' by the equivalence relation defined by f, it can happen that X and all the fibres $f^{-1}(x)$ are irreducible without X' being connected. For example, take for X an irreducible scheme—the affine line $\operatorname{Spec}(k[T])$ over an algebraically closed field k, say—choose a closed point x_0 of X, and take for X' the topological sum of $\{x_0\}$ and the open subspace $X - \{x_0\}$ of X.

Likewise, if the hypothesis that f is open is replaced by the hypothesis that f is closed, or even proper, then it can happen that X and all the fibres $f^{-1}(x)$ are irreducible without X' being irreducible, even though this replacement does ensure that the topology of X is the quotient of that of X' by the relation defined by f. Again take X to be the affine line over k, and put

$$S = X \times_k \mathbf{P},$$

where $\mathbf{P}$ is the projective line over k. Let x_0 be a closed point of X, let t_0 be a closed point of $\mathbf{P}$, and let

$$p : S \longrightarrow X, \qquad q : S \longrightarrow \mathbf{P}$$

be the projections. Let X' be the reduced sub-prescheme whose underlying space is the closed set

$$p^{-1}(x_0) \cup q^{-1}(t_0),$$

and let f be the restriction of p to X'. Then f is proper, but X' is not irreducible.

Theorem (4.4.4). — *Let k be an algebraically closed field and let X be a k-prescheme. If X is irreducible (resp. connected), then $X \otimes_k K$ is irreducible (resp. connected) for every extension K of k.*

Proof. We saw in (4.4.1) that

$$p : X \otimes_k K \longrightarrow X$$

is faithfully flat and open. To apply (4.4.2), it therefore suffices to verify that every fibre $p^{-1}(x)$ is irreducible. The $\kappa(x)$-prescheme $p^{-1}(x)$ is isomorphic to

$$\operatorname{Spec}\big(\kappa(x) \otimes_k K\big)$$

(**I**, 3.6.2), and is therefore integral by the hypothesis on k and (4.3.9). □

Corollary (4.4.5). — *Let k be an algebraically closed field, let X be a k-prescheme, let K be an extension of k, and let*

$$p : X \otimes_k K \longrightarrow X$$

be the canonical projection. If Z is an irreducible (resp. connected) subset of X, then $p^{-1}(Z)$ is irreducible (resp. connected). In particular, if X_0 is an irreducible component (resp. the connected component) of X containing Z, then $p^{-1}(X_0)$ is an irreducible (resp. connected) component of $X \otimes_k K$ containing $p^{-1}(Z)$.

Proof. The second assertion follows from (4.4.1) and the first assertion applied after replacing Z by X_0. To prove the first, let X' be the underlying space of $X \otimes_k K$, and put $Z' = p^{-1}(Z)$.

The equivalence relation R defined by p on X' is open. The induced relation $R_{Z'}$ on the saturated subset Z' is therefore also open, and Z identifies with the quotient space $Z'/R_{Z'}$ (Bourbaki, *Top. gén.*, chap. I, 3rd ed., § 5, no. 2, prop. 4). We may thus apply (4.4.2) to Z and Z', proving the first assertion of (4.4.5). □ **IV-2 | 61**

Corollary (4.4.6). — *Under the hypotheses and notation of (4.4.5), the map*

$$Z \longmapsto p^{-1}(Z)$$

is a bijection from the set of irreducible (resp. connected) components of X to the set of irreducible (resp. connected) components of $X \otimes_k K$. Its inverse is

$$Z' \longmapsto p(Z').$$

4.5. Geometrically irreducible and geometrically connected preschemes

Proposition (4.5.1). — *Let k be a field, let X be a k-prescheme, and let Ω be an algebraically closed extension of k. Let n (resp. n') be the cardinality of the set of irreducible components (resp. connected components) of $X \otimes_k \Omega$. This cardinality is independent of the chosen algebraically closed extension Ω. Moreover, for every extension K of k, the cardinality of the set of irreducible components (resp. connected components) of $X \otimes_k K$ is at most n (resp. at most n').*

Proof. Two algebraically closed extensions Ω and Ω' of k may always be regarded as subextensions of a common extension E of k. Applying (4.4.6) to $X \otimes_k \Omega$ and $X \otimes_k \Omega'$, and to the common extensions E/Ω and E/Ω', proves the first assertion. For the second, take Ω to be an algebraically closed extension of K and use (4.4.1). □

Definition (4.5.2). — The cardinality n (resp. n') of (4.5.1) is called the *geometric number of irreducible components* (resp. *of connected components*) of X relative to k. If $n = 1$ (resp. $n' \leqslant 1$), the k-prescheme X is said to be *geometrically irreducible* (resp. *geometrically connected*).

This recovers the definition given in the special case (**III**, 4.3.4). By (4.5.1), the following properties are equivalent:

(a) X is geometrically irreducible (resp. geometrically connected);
(b) for one algebraically closed extension Ω of k, $X \otimes_k \Omega$ is irreducible (resp. connected);
(c) for every extension K of k, $X \otimes_k K$ is irreducible (resp. connected).

(4.5.3). Let X be a k-prescheme and let Z be a locally closed subset of X. If any sub-prescheme of X having Z as underlying space is again denoted by Z (**I**, 5.2.1), it follows from (**I**, 5.1.8) that, for an extension K of k, the number of irreducible (resp. connected) components of $Z \otimes_k K$ is independent of the chosen sub-prescheme with underlying space Z. The *geometric number of irreducible components* (resp. *of connected components*) of Z is therefore defined to be that of any sub-prescheme of X having Z as underlying space.

Proposition (4.5.4). — *Let X and Y be two k-preschemes, and let $f : X \to Y$ be a surjective k-morphism. If X is geometrically irreducible (resp. geometrically connected), then so is Y.*

IV-2 | 62

Proof. For every extension K of k, the morphism

$$f_K : X \otimes_k K \longrightarrow Y \otimes_k K$$

is surjective (**I**, 3.5.2). Since $X \otimes_k K$ is irreducible (resp. connected) by hypothesis, the same is true of $Y \otimes_k K$. □

Definition (4.5.5). — A morphism $f : X \to Y$ of preschemes is said to be *irreducible* (resp. *connected*) if, for every $y \in Y$, the $\kappa(y)$-prescheme $f^{-1}(y)$ is geometrically irreducible (resp. geometrically connected).

Proposition (4.5.6). — (i) *Let X be a k-prescheme and let K be an extension of k. The geometric number of irreducible components (resp. connected components) of the K-prescheme $X \otimes_k K$, relative to K, is equal to the geometric number of irreducible components (resp. connected components) of X, relative to k. In particular, $X \otimes_k K$ is geometrically irreducible (resp. geometrically connected) as a K-prescheme if and only if X is so as a k-prescheme.*

(ii) *Let $f : X \to Y$ and $g : Y' \to Y$ be two morphisms, and put*

$$X' = X_{(Y')} = X \times_Y Y', \qquad f' = f_{(Y')} : X' \longrightarrow Y'.$$

If f is irreducible (resp. connected), then so is f'. The converse holds if g is surjective.

Proof. For (i), if Ω is an algebraically closed extension of K, then

$$X \otimes_k \Omega = (X \otimes_k K) \otimes_K \Omega,$$

which proves the assertion.

For (ii), for every $y' \in Y'$, put $y = g(y')$. Then

$$f'^{-1}(y') = f^{-1}(y) \otimes_{\kappa(y)} \kappa(y')$$

(**I**, 3.6.4), so both assertions follow from (i). □

Proposition (4.5.7). — *Let $f : X \to Y$ be a surjective irreducible (resp. connected) morphism, let $g : Y' \to Y$ be a morphism, and put $X' = X \times_Y Y'$. Suppose in addition that Y' is irreducible (resp. connected), and that f is universally open (resp. flat and quasi-compact, or universally open, or universally closed). Then X' is irreducible (resp. connected).*

Proof. All the properties of f under consideration are stable under base change, so it is enough to treat the case $Y' = Y$. The result then follows from (4.4.2), taking (2.3.12) into account. □

Corollary (4.5.8). — *Let X and Y be two k-preschemes.*

(i) *If X is geometrically irreducible (resp. geometrically connected) and Y is irreducible (resp. connected), then $X \times_k Y$ is irreducible (resp. connected).*

(ii) *If X and Y are geometrically irreducible (resp. geometrically connected), then so is $X \times_k Y$.*

Proof. For (i), the structure morphism $X \to \operatorname{Spec}(k)$ is surjective and universally open (2.4.9), and it is also irreducible (resp. connected). It is therefore enough to apply (4.5.7).

For (ii), if Ω is an algebraically closed extension of k, then

$$(X \times_k Y) \otimes_k \Omega = (X \otimes_k \Omega) \times_\Omega (Y \otimes_k \Omega)$$

(**I**, 3.3.10). By hypothesis and (4.5.6), the two factors on the right are geometrically irreducible (resp. geometrically connected) Ω-preschemes, so (i) applies. □

Proposition (4.5.9). — *Let X be a k-prescheme. The following conditions are equivalent:*

(a) *X is geometrically irreducible; in other words, $X \otimes_k K$ is irreducible for every extension K of k;*

(b) *$X \otimes_k K$ is irreducible for every finite separable extension K of k;*

(c) *X is irreducible and, if x is its generic point, $\kappa(x)$ is a primary extension of k.*

Proof. It is clear that (a) implies (b). To see that (b) implies (c), let K be a finite separable extension of k and let

$$p : X \otimes_k K \longrightarrow X$$

be the canonical projection. The maximal points of $X \otimes_k K$ are those of the fibre

$$p^{-1}(x) = \operatorname{Spec}(\kappa(x) \otimes_k K)$$

(2.3.4) and $(\mathbf{0}_{\mathrm{I}}, 2.1.8)$. Thus, saying that this fibre is irreducible for every finite separable extension K of k is equivalent, by (4.3.2), to saying that $\kappa(x)$ is a primary extension of k. Conversely, if (c) holds, the same argument, again using (4.3.2), shows that $X \otimes_k K$ is irreducible for every extension K of k. Hence (c) implies (a). □

Corollary (4.5.10). — *Let X be an irreducible k-prescheme, let x be its generic point, let k' be the separable algebraic closure of k in $\kappa(x)$, and let k'' be a Galois extension of k, of finite degree or not, containing k'. Suppose that k' is finite over k. Then the irreducible components of $X \otimes_k k''$ are geometrically irreducible; their number is $[k' : k]$, and this is also the geometric number of irreducible components of X.*

Proof. As in (4.5.9), it is enough to consider the maximal points of

$$\mathrm{Spec}\big(\kappa(x) \otimes_k k''\big).$$

By (4.3.4), there are $[k' : k]$ of them, and their residue fields, which are also the residue fields at the maximal points of $X \otimes_k k''$, are primary extensions of k''. The result follows from (4.5.9). □

Corollary (4.5.11). — *Let X be a k-prescheme. Suppose that X has only finitely many maximal points x_i $(1 \leqslant i \leqslant r)$ and that, for each i, the separable algebraic closure k'_i of k in $\kappa(x_i)$ has finite degree over k. Then there is a finite separable extension L of k such that the irreducible components of $X \otimes_k L$ are geometrically irreducible. Their number, equal to*

$$\sum_i [k'_i : k],$$

is the geometric number of irreducible components of X.

Proof. The maximal points of $X \otimes_k L$ are those of the various fibres

$$\mathrm{Spec}\big(\kappa(x_i) \otimes_k L\big),$$

by (2.3.4) and $(\mathbf{0}_{\mathrm{I}}, 2.1.8)$, applied to the irreducible components of X and their inverse images in $X \otimes_k L$. It therefore suffices to take for L a finite Galois extension of k containing all the k'_i and to apply (4.5.10). □

Notice that (4.5.11) applies in particular to every k-prescheme X of finite type over k. Indeed, X is then Noetherian, so it has only finitely many irreducible components; moreover, each $\kappa(x_i)$ is an extension of finite type of k, and therefore so is the algebraic closure of k in $\kappa(x_i)$ ([1], p. 6-06, Lemma 5).

Remarks (4.5.12). — (i) The notions defined in (4.5.2) depend on the base field k. For brevity, when it is necessary to name the base field, we may say "k-irreducible" (resp. "k-connected") instead of "geometrically irreducible (resp. connected) relative to k". This terminology is natural in the context of schemes, but is exactly opposite to Weil's. For Weil, "k-irreducible" (resp. "k-connected", "k-normal", and so on) designates an intrinsic property of a prescheme X, independent of the field k chosen as base field (that is, independent of the chosen morphism $X \to \mathrm{Spec}(k)$); we express these properties simply by saying that X is irreducible (resp. connected, normal, and so on). On the other hand, Weil says "absolutely irreducible", "absolutely connected", "absolutely normal", and so on, for the corresponding notions relative to $X \otimes_k \Omega$, where Ω is a suitable algebraically closed extension of k. This terminology is explained by his different point of view: an "algebraic variety" V is first given as a geometric object over an algebraically closed field Ω; the datum of a smaller "field of definition" k (that is, a scheme over k which yields V after extension of the base field to Ω) is an additional and, to some extent, secondary structure. Thus his use of "absolute" or "intrinsic" on the one hand and "relative to k" on the other is opposite to ours.[7] We shall therefore avoid the qualifier "absolute", which may cause confusion; whenever we use the abbreviated terminology introduced above, in conflict with established terminology, we shall refer to (4.5.12) to avoid ambiguity. **IV-2 | 64**

(ii) Proposition (4.5.9) gives a "birational" criterion—one depending only on the residue field at the generic point—for a k-prescheme X to be geometrically irreducible. There is no analogous criterion for geometric connectedness. For example, take

$$X = \mathrm{Spec}\big(\mathbf{R}[[T, U]]/(T^2 + U^2)\big),$$

[7] Zariski's point of view is already closer to ours, and his terminology is not generally in conflict with that introduced here.

where T and U are indeterminates. Then X is an integral $\mathbf{R}$-scheme, and its field of rational functions $\kappa(x)$ is $\mathbf{C}((T))$, as is readily verified. The scheme $X \otimes_{\mathbf{R}} \mathbf{C}$ is the union of two irreducible components, the two "isotropic lines", which have a point in common: the maximal ideal in $\mathbf{C}[[T,U]]/(T^2+U^2)$ induced by the maximal ideal $(T)+(U)$ of $\mathbf{C}[[T,U]]$. Thus $X \otimes_{\mathbf{R}} \mathbf{C}$ is connected. Let X' be the open complement of the closed point of X corresponding to the maximal ideal $(T)+(U)$ of $\mathbf{R}[[T,U]]$. Then $X' \otimes_{\mathbf{R}} \mathbf{C}$ is not connected, although X and X' have the same field of rational functions.

Proposition (4.5.13). — *Let X and Y be two k-preschemes and let $f : Y \to X$ be a k-morphism. Suppose that Y is nonempty and geometrically connected, and that X is connected. Then X is geometrically connected.*

Proof. Let Ω be an algebraic closure of k, put

$$X' = X \otimes_k \Omega, \qquad Y' = Y \otimes_k \Omega,$$

and let $f' = f_{(\Omega)} : Y' \to X'$. It is enough to prove that X' is connected. Let U' be a nonempty open-and-closed subset of X'. The projections

$$p : X' \longrightarrow X, \qquad q : Y' \longrightarrow Y$$

are open (2.4.10), and they are closed because Ω/k is algebraic (**II**, 6.1.10). Consequently $U = p(U')$ is a nonempty open-and-closed subset of X, and hence $U = X$. Since Y is nonempty, it follows from (**I**, 3.4.7) that

$$V' = f'^{-1}(U')$$

is nonempty. It is also open and closed in Y', which is connected by hypothesis, so $V' = Y'$. We conclude that $U' = X'$: otherwise, applying the same argument to the open-and-closed subset $X' \setminus U'$ would give $f'^{-1}(X' \setminus U') = Y'$, which is impossible because Y' is nonempty. □

Corollary (4.5.13.1). —
(i) *Let X and Y be two k-preschemes and let $f : Y \to X$ be a k-morphism. If Y is nonempty and geometrically connected, then the connected component X_0 of X containing $f(Y)$ is geometrically connected.*
(ii) *Let X be a k-prescheme. If Y is a geometrically irreducible irreducible component of X, then the connected component X_0 of X containing Y is geometrically connected.*

Proof. For (i), we may suppose that Y is reduced, so that f factors as

$$Y \xrightarrow{g} X_0 \xrightarrow{j} X,$$

where X_0 denotes the reduced sub-prescheme of X whose underlying space is the connected component X_0 (**I**, 5.2.2). Apply (4.5.13) to g.

For (ii), choose a prescheme structure on the underlying space Y. Since a geometrically irreducible prescheme is in particular geometrically connected, (i) applies to the canonical injection $Y \to X$. □

IV-2 | 65

Corollary (4.5.14). — *Let X be a k-prescheme. If $x \in X$ is such that $\kappa(x)$ is a primary extension of k (in particular, if x is a rational point of X), then the connected component of x in X is geometrically connected.*

Proof. Apply (4.5.13.1) to $Y = \operatorname{Spec}(\kappa(x))$ and to the canonical morphism $Y \to X$. By (4.5.9), the prescheme Y is geometrically irreducible. □

Proposition (4.5.15). — *Let X be a k-prescheme, let $x \in X$, and let k' be the separable algebraic closure of k in $\kappa(x)$. Suppose that:*

(i) *X is connected;*
(ii) *k' is a finite extension of k.*

Then the geometric number of connected components of X is at most $[k' : k]$. Moreover, if k'' is a finite Galois extension of k containing k', the connected components of $X \otimes_k k''$ are geometrically connected.

Condition (ii) is satisfied in particular when X is locally of finite type over k.

Proof. By (ii), there are finite Galois extensions k'' of k containing k'. Put $X'' = X \otimes_k k''$. The projection $p : X'' \to X$ is faithfully flat and finite, hence closed (**II**, 6.1.10). It follows from (2.3.6), (ii), that the image under p of every connected component X''_α of X'' is all of X. Thus X''_α contains a point $x''_\alpha \in p^{-1}(x)$.

The number of points of $p^{-1}(x)$ is the number of irreducible components of

$$\operatorname{Spec}(\kappa(x) \otimes_k k'')$$

(**I**, 3.4.9), namely $[k' : k]$ by (4.3.4). Therefore the number of connected components of X'' is at most $[k' : k]$. For every $x''_\alpha \in p^{-1}(x)$, the field $\kappa(x''_\alpha)$ is a primary extension of k'', by (4.3.5) and (**I**, 3.4.9). Corollary (4.5.14), applied to x''_α and X'', now shows that every connected component of X'' is geometrically connected. □

Corollary (4.5.16). — *Let X be a k-prescheme, let (X_α) be the family of its connected components, and choose $x_\alpha \in X_\alpha$ for every α. Suppose that:*

(i) *the family (X_α) is finite;*
(ii) *for every α, the separable algebraic closure k'_α of k in $\kappa(x_\alpha)$ is a finite extension of k.*

Then the geometric number of connected components of X is at most

$$\sum_\alpha [k'_\alpha : k],$$

and there exists a finite separable extension k'' of k such that all the connected components of $X \otimes_k k''$ are geometrically connected.

Proof. By (i), the connected components of X are open. Apply (4.5.15) to each sub-prescheme induced on the open subset X_α. To obtain one extension k'' with the asserted property, take a finite Galois extension of k containing all the k'_α. □

IV-2 | 66

Corollary (4.5.17). — *Suppose that the k-prescheme X contains a point x such that the separable algebraic closure of k in $\kappa(x)$ is finite over k. Then X is geometrically connected if and only if $X \otimes_k K$ is connected for every finite separable extension K of k.*

Remark (4.5.18). — We shall see in § 8 (8.4.5) that the conclusion of (4.5.17) remains valid if, instead of the hypothesis in its statement, one assumes that X is quasi-compact.

Proposition (4.5.19). — *Let X be a k-prescheme, let Z be a subset of X, let k' be an algebraically closed extension of k, put*

$$X' = X \otimes_k k',$$

and let $p : X' \to X$ be the canonical projection. Suppose that $Z' = p^{-1}(Z)$ is contained in a single irreducible component X'_0 of X'. Then

$$X'_0 = p^{-1}(X_0),$$

where $X_0 = p(X'_0)$ is an irreducible component of X containing Z; moreover, X_0 is geometrically irreducible. If, in addition, X'_0 is the only irreducible component of X' which meets Z', then X_0 is the only irreducible component of X which meets Z.

To prove that $X'_0 = p^{-1}(X_0)$, we shall use the following lemma.

Lemma (4.5.19.1). — *Let T and T' be preschemes, let $p : T' \to T$ be a morphism, put*

$$T'' = T' \times_T T',$$

and let $p_1, p_2 : T'' \to T'$ be the canonical projections. A subset U' of T' is of the form $p^{-1}(U)$, for some subset $U \subset T$, if and only if

$$p_1^{-1}(U') = p_2^{-1}(U').$$

Proof. The structure morphism $q : T'' \to T$ is, by definition, both $p \circ p_1$ and $p \circ p_2$, so the condition is necessary. Conversely, suppose the condition holds. Let $u' \in U'$ and let $t' \in p^{-1}(p(u'))$. Since $p(t') = p(u')$, there is a point $t'' \in T''$ such that

$$p_1(t'') = u', \qquad p_2(t'') = t'$$

(I, 3.4.7). Thus $t'' \in p_1^{-1}(U') = p_2^{-1}(U')$, and consequently $t' = p_2(t'') \in U'$. This proves the lemma. □

Proof of (4.5.19). Form the fibre product

$$X'' = X' \times_X X'$$

relative to $p : X' \to X$, and let $p_1, p_2 : X'' \to X'$ be the canonical projections. By (4.5.19.1), it is enough to prove that

$$p_1^{-1}(X'_0) = p_2^{-1}(X'_0).$$

Put

$$S = \mathrm{Spec}(k), \qquad S' = \mathrm{Spec}(k'), \qquad S'' = S' \times_S S' = \mathrm{Spec}(k' \otimes_k k').$$

Then X'' may also be written $X' \times_{S'} S''$. If $\varphi'' : X'' \to S''$ is the structure morphism, it is enough to show, for every $s'' \in S''$, that

$$p_1^{-1}(X'_0) \cap \varphi''^{-1}(s'') = p_2^{-1}(X'_0) \cap \varphi''^{-1}(s'').$$

Put

$$T = \mathrm{Spec}(\kappa(s'')), \qquad U = X'' \times_{S''} T = \varphi''^{-1}(s''),$$

and let $v : U \to X''$ be the canonical projection. We must prove that

$$U_1 = v^{-1}\big(p_1^{-1}(X'_0)\big), \qquad U_2 = v^{-1}\big(p_2^{-1}(X'_0)\big),$$

which are irreducible components of U by (4.4.5), are equal. The relevant morphisms form the commutative diagram

(4.5.19.2)
$$\begin{tikzcd}
X \arrow[d] & X' \arrow[l, "p"'] \arrow[d] & X'' \arrow[l, shift left, "p_1"'] \arrow[l, shift right, "p_2"] \arrow[d, "\varphi''"] & U \arrow[l, "v"'] \arrow[d] \\
S & S' \arrow[l] & S'' \arrow[l, shift left] \arrow[l, shift right] & T \arrow[l]
\end{tikzcd}$$

By construction, U_1 and U_2 both contain $w^{-1}(Z)$, where

$$w = p \circ p_1 \circ v = p \circ p_2 \circ v.$$

There is a field K which is a common extension of k' and $\kappa(s'')$. If $P = \mathrm{Spec}(K)$, the diagram **IV-2 | 67**

$$\begin{tikzcd}
S' \arrow[d] & P \arrow[l] \arrow[d] \\
S & T \arrow[l]
\end{tikzcd}$$

is commutative. Putting $Q = X \otimes_k K$, the diagram

$$\begin{tikzcd}
X' \arrow[d, "p"'] & Q \arrow[l, "q"'] \arrow[d, "r"] \\
X & U \arrow[l, "w"]
\end{tikzcd}$$

is likewise commutative. The two irreducible components $r^{-1}(U_1)$ and $r^{-1}(U_2)$ of Q (4.4.5) therefore contain $q^{-1}(Z')$. By (4.4.5), their images

$$q\big(r^{-1}(U_1)\big) \quad \text{and} \quad q\big(r^{-1}(U_2)\big)$$

are irreducible components of X' containing Z'. Both are therefore X'_0. Again by (4.4.5), $r^{-1}(U_1) = r^{-1}(U_2)$, and hence $U_1 = U_2$.

Since p is surjective and X'_0 dominates an irreducible component of X, the subset $X_0 = p(X'_0)$ is an irreducible component of X containing Z. Since $p^{-1}(X_0) = X'_0$ is an irreducible component of X', the component X_0 is geometrically irreducible.

For the last assertion, let X_1 be another irreducible component of X meeting Z. Choose $z \in Z \cap X_1$. There is an irreducible component of X' which meets Z' and dominates X_1 (2.3.5). By hypothesis X'_0 is the only such component, so necessarily $X_1 = X_0$. □

Remark (4.5.20). — The fact that Z' is contained in a single irreducible component X'_0 of X' does *not* imply that $X_0 = p(X'_0)$ is the only irreducible component of X containing Z. Indeed, take $k = \mathbf{R}$, $k' = \mathbf{C}$, and let X be the k-scheme obtained by gluing[8] the following two schemes at a nongeneric point of each:

$$X_1 = \operatorname{Spec}\big(\mathbf{R}[S,T]/(S^2+T^2+1)\big), \qquad X_2 = \operatorname{Spec}\big(\mathbf{C}[T]\big);$$

the local rings of these two curves at each of their closed points have the same residue field, isomorphic to $\mathbf{C}$. The schemes X_1 and X_2 identify with the two irreducible components of X. If x is their common point, then $p^{-1}(x)$ consists of two distinct points y' and z'; the inverse image $p^{-1}(X_1)$ is irreducible, while $p^{-1}(X_2)$ is the union of two irreducible components Y' and Z' of X', with $y' \in Y'$ and $z' \in Z'$. Thus $p^{-1}(x)$ is contained in only one irreducible component of X'.

Proposition (4.5.21). — *Let k be a separably closed field and let k' be an algebraic closure of k. For every k-prescheme X, the canonical projection*

$$X \otimes_k k' \longrightarrow X$$

is a universal homeomorphism.

In particular, the irreducible components (resp. connected components) of X are geometrically irreducible (resp. geometrically connected). **IV-2** | 68

Proof. By definition, k'/k is radicial. The morphism $\operatorname{Spec}(k') \to \operatorname{Spec}(k)$ is integral, surjective, and radicial, so the first assertion follows from (2.4.5), (i). The second follows from the first and (4.5.1). □

4.6. Geometrically reduced algebraic preschemes

Proposition (4.6.1). — *Let k be a field, let X be a k-prescheme, and let Ω be a perfect extension of k. The following conditions are equivalent:*

(a) *for every reduced k-prescheme S, the prescheme $X \times_k S$ is reduced;*
(b) *for every extension K of k, the prescheme $X \otimes_k K$ is reduced;*
(c) *the prescheme $X \otimes_k \Omega$ is reduced;*
(d) *for every finite radicial extension k' of k, the prescheme $X \otimes_k k'$ is reduced;*
(e) *X is reduced and, for every irreducible component X_α of X, with generic point x_α, the field $\kappa(x_\alpha)$ is a separable extension of k.*

Proof. The implications *(a)⇒(b) ⇒(c)* are immediate. Since k' may be regarded as a subextension of Ω, (4.4.1) shows that *(c)* implies *(d)*.

Suppose *(d)*. Taking $k' = k$ first shows that X is reduced. To prove that $\kappa(x_\alpha)$ is separable over k, it suffices to show that $\kappa(x_\alpha) \otimes_k k'$ is reduced for every finite radicial extension k' of k (4.3.5). We may reduce to the case $X = \operatorname{Spec}(A)$, where A is a reduced k-algebra. Then $A \otimes_k k'$ is reduced by hypothesis (**I**, 5.1.4), and $\kappa(x_\alpha) \otimes_k k'$ is a ring of fractions of this ring; hence it is reduced ($\mathbf{0}_I$, 1.2.8). Thus *(d)* implies *(e)*.

Finally, suppose *(e)*. We may reduce to the affine case $X = \operatorname{Spec}(A)$ and $S = \operatorname{Spec}(B)$, where A and B are k-algebras. The fields $\kappa(x_\alpha)$ are the fields of fractions of the quotient rings $A/\mathfrak{p}_\alpha$, where $\mathfrak{p}_\alpha = \mathfrak{j}_{x_\alpha}$ are the minimal prime ideals of A. Since $\bigcap_\alpha \mathfrak{p}_\alpha = 0$, the algebra A embeds in $\prod_\alpha A/\mathfrak{p}_\alpha$, and hence in $\prod_\alpha \kappa(x_\alpha)$. Likewise, B may be regarded as a subalgebra of a product $\prod_\beta L_\beta$ of extensions of k. It follows that $A \otimes_k B$ embeds in

$$\left(\prod_\alpha \kappa(x_\alpha)\right) \otimes_k \left(\prod_\beta L_\beta\right),$$

and this tensor product itself embeds in

$$\prod_{\alpha,\beta} \big(\kappa(x_\alpha) \otimes_k L_\beta\big)$$

[8] The technique of gluing preschemes will be developed in detail in Chapter V. For the case considered here, which concerns algebraic curves, see [38], pp. 68–71.

(Bourbaki, *Alg.*, chap. II, 3rd ed., § 7, nº 7, prop. 15). By hypothesis the rings $\kappa(x_\alpha) \otimes_k L_\beta$ are reduced (4.3.5); hence $A \otimes_k B$ is reduced. Thus *(e)* implies *(a)*. □

Definition (4.6.2). — If the equivalent conditions *(a)–(e)* of (4.6.1) hold, X is said to be *separable* (or *geometrically reduced*, or *universally reduced*) over k. A k-prescheme X is said to be *geometrically integral* over k if, for every extension K of k, the prescheme $X \otimes_k K$ is integral. By (4.6.1), this is equivalent to saying that X is separable and geometrically irreducible over k.

A commutative k-algebra A is said to be *separable* if $\mathrm{Spec}(A)$ is separable over k; equivalently, for every extension K of k, the ring $A_{(K)} = A \otimes_k K$ is reduced. This definition agrees with that of Bourbaki, *Alg.*, chap. VIII, § 7, nº 5, def. 1, when A has finite rank over k (loc. cit., corollary to prop. 7), but not in general: a k-algebra may have nonzero radical even when it is integral. **IV-2** | 69

Corollary (4.6.3). — *Let X be an integral k-prescheme. Then X is geometrically reduced (resp. geometrically integral) over k if and only if its field of rational functions $\mathrm{R}(X)$ is a separable (resp. separable and primary) extension of k.*

Proof. This follows immediately from (4.5.9) and (4.6.1). □

Corollary (4.6.4). — *Let X be a reduced k-prescheme. For every separable extension k' of k, the prescheme $X' = X \otimes_k k'$ is reduced.*

Proof. Apply the equivalence of *(a)* and *(e)* in (4.6.1), replacing X there by $\mathrm{Spec}(k')$ and S by X. □

Proposition (4.6.5). —
(i) *Let X be a k-prescheme and let K be an extension of k. Then X is geometrically reduced (resp. geometrically integral) over k if and only if $X \otimes_k K$ is geometrically reduced (resp. geometrically integral) over K.*
(ii) *Let X and Y be two k-preschemes. If X and Y are geometrically reduced (resp. geometrically integral) over k, then so is $X \times_k Y$.*

Proof. Assertion *(i)* is an immediate consequence of the definitions and (4.4.1). For the reduced assertion in *(ii)*, let Ω be an algebraically closed extension of k. Then

$$(X \times_k Y) \otimes_k \Omega = X \times_k (Y \otimes_k \Omega).$$

Since $Y \otimes_k \Omega$ is reduced, the right-hand side is reduced by (4.6.1.a). The remainder of *(ii)* follows from this and (4.5.8.ii). □

Proposition (4.6.6). — *Let X be a k-prescheme of finite type. There exists a finite radicial extension k' of k such that $(X_{(k')})_{\mathrm{red}}$ is geometrically reduced over k'.*

Proof. Since X is covered by finitely many affine open subsets U_i, we may reduce to the affine case. Indeed, suppose for each i that k_i is a finite radicial extension of k such that $(U_i \otimes_k k_i)_{\mathrm{red}}$ is geometrically reduced over k_i. We may choose a common finite radicial extension k' of k containing all the k_i. By (**I**, 5.1.8),

$$(U_i \otimes_k k')_{\mathrm{red}} \simeq (U_i \otimes_k k_i)_{\mathrm{red}} \otimes_{k_i} k',$$

and this is geometrically reduced over k'. Thus the same holds for $(X \otimes_k k')_{\mathrm{red}}$.

Now let $X = \mathrm{Spec}(A)$, where A is a k-algebra of finite type, and let Ω be an algebraic closure of k. Write $\mathfrak{N}'$ for the nilradical of $A \otimes_k \Omega$. Since $A \otimes_k \Omega$ is Noetherian, $\mathfrak{N}'$ is generated by finitely many elements

$$y_i = \sum_j x_{ij} \otimes \xi_{ij}, \qquad x_{ij} \in A, \quad \xi_{ij} \in \Omega.$$

Let K be a finite subextension of Ω containing all the ξ_{ij}, and let $\mathfrak{N}$ be the ideal of $A \otimes_k K$ generated by the y_i, regarding $A \otimes_k K$ as a subring of $A \otimes_k \Omega$. The y_i are nilpotent in $A \otimes_k K$. Moreover, $\mathfrak{N} \otimes_K \Omega = \mathfrak{N}'$, and hence

$$\mathfrak{N}' \cap (A \otimes_k K) = \mathfrak{N}.$$

Thus $\mathfrak{N}$ contains the nilradical of $A \otimes_k K$ and is therefore equal to it. Since

$$(A \otimes_k \Omega)/\mathfrak{N}' = \big((A \otimes_k K)/\mathfrak{N}\big) \otimes_K \Omega,$$

the prescheme $(X \otimes_k K)_{\mathrm{red}} \otimes_K \Omega$ is reduced. Consequently $(X_{(K)})_{\mathrm{red}}$ is geometrically reduced over K by (4.6.1).

Replacing K by the quasi-Galois extension of k that it generates in Ω, we may further suppose, by (**I**, 5.1.8), that K is quasi-Galois over k. It is then a separable extension of a finite radicial extension k' of k (Bourbaki, *Alg.*, chap. V, § 10, n$^{\text{o}}$ 9, prop. 14). By (**I**, 5.1.8), $(X_{(k')})_{\text{red}} \otimes_{k'} K$ is isomorphic to $(X_{(K)})_{\text{red}}$, and hence is geometrically reduced. It follows from (4.6.5.i) that $(X_{(k')})_{\text{red}}$ is geometrically reduced. □ **IV-2 | 70**

Corollary (4.6.7). — *If K is an extension of finite type of k, there exists a finite radicial extension k' of k such that the residue fields of the semilocal ring $K \otimes_k k'$ are separable over k'.*

Proof. Apply (4.6.6) to $X = \operatorname{Spec}(A)$, where A is a k-algebra of finite type having K as its field of fractions. □

Corollary (4.6.8). — *Let X be a k-prescheme of finite type. There exists a finite extension k' of k such that $(X_{(k')})_{\text{red}}$ is geometrically reduced over k', the irreducible components of $X_{(k')}$ are geometrically irreducible, and its connected components are geometrically connected.*

Proof. This follows immediately from (4.6.6), (4.5.10), and (4.5.15). □

Definition (4.6.9). — Let k be a field, let X be a k-prescheme, and let $x \in X$. We say that X is *geometrically reduced* (or *separable*) (resp. *geometrically punctually integral*) at x over k if, for every extension k' of k and every point x' of $X' = X \otimes_k k'$ above x, the prescheme X' is reduced (resp. integral) at x'; that is, $\mathscr{O}_{X',x'}$ is reduced (resp. integral).

We say that X is *geometrically punctually integral* if it is geometrically punctually integral at all of its points. Equivalently, for every extension k' of k, all local rings of $X \otimes_k k'$ are integral; in that case $X \otimes_k k'$ is also said to be *punctually integral*.

By (4.6.2), X is geometrically reduced over k if and only if it is geometrically reduced over k at every point $x \in X$.

Proposition (4.6.10). — *Let k be a field, let X be a k-prescheme, let k' be an extension of k, and let x' be a point of $X' = X \otimes_k k'$ with image x in X. Then X is geometrically reduced (resp. geometrically punctually integral) at x over k if and only if X' has the corresponding property at x' over k'. In particular, X is geometrically punctually integral over k if and only if X' is geometrically punctually integral over k'.*

Proof. It is enough to prove the first assertion. Necessity is immediate. Suppose conversely that X' is geometrically reduced (resp. geometrically punctually integral) at x' over k'. Let k'' be an extension of k and let x'' be a point of $X'' = X \otimes_k k''$ above x. There is a point z of $X' \times_X X''$ projecting to x' and x'' (**I**, 3.4.7). Let s be the image of z in $\operatorname{Spec}(k' \otimes_k k'')$ (**I**, 3.4.9), put $K = \kappa(s)$, and put $Z = X \otimes_k K$. Then K may be regarded as a composite extension of k' and k'', and z as a point of Z whose images in X' and X'' are, respectively, x' and x''. By hypothesis, $\mathscr{O}_{Z,z}$ is reduced (resp. integral). Since $\mathscr{O}_{Z,z}$ is a faithfully flat $\mathscr{O}_{X'',x''}$-module, it follows that $\mathscr{O}_{X'',x''}$ is reduced (resp. integral) $(\mathbf{0}_I, 6.5.1)$. □

Corollary (4.6.11). — *Suppose that k is perfect (resp. algebraically closed). Then X is geometrically reduced (resp. geometrically punctually integral) at x over k if and only if $\mathscr{O}_{X,x}$ is reduced (resp. integral).*

Proof. Necessity is immediate. Conversely, for every extension k' of k, the prescheme $\operatorname{Spec}(\mathscr{O}_{X,x}) \otimes_k k'$ is reduced (4.6.4) (resp. integral (4.4.4)). For every point x' of $X' = X \otimes_k k'$ above x, the local ring $\mathscr{O}_{X',x'}$ is isomorphic to a local ring of $\operatorname{Spec}(\mathscr{O}_{X,x}) \otimes_k k'$, and is therefore reduced (resp. integral). □ **IV-2 | 71**

Proposition (4.6.12). — *Let k be a field, let X be a k-prescheme, let $x \in X$, and let Ω be a perfect extension of k. The following conditions are equivalent:*

(a) *X is geometrically reduced over k at x; that is, for every extension k' of k and every point x' of $X' = X \otimes_k k'$ above x, the local ring $\mathscr{O}_{X',x'}$ is reduced;*
(b) *the prescheme $X \otimes_k \Omega$ is reduced at one point above x;*
(c) *for every finite radicial extension k' of k, the prescheme $X' = X \otimes_k k'$ is reduced at the unique point x' above x;*
(d) *the prescheme $\operatorname{Spec}(\mathscr{O}_{X,x})$ is geometrically reduced over k;*
(e) *the local ring $\mathscr{O}_{X,x}$ is reduced and, for every irreducible component Z of X containing x, with generic point z, the field $\kappa(z)$ is a separable extension of k.*

Proof. The implications *(d)⇒(a)⇒(b) ⇒(c)* are immediate, using for the last implication (4.6.10), (4.6.11), and the fact that every radicial extension of k is isomorphic to a subextension of Ω.

Suppose *(c)*. By (4.6.1), it suffices to show that $\mathscr{O}_{X,x} \otimes_k k'$ is reduced for every finite radicial extension k' of k. This ring is the local ring of $X' = X \otimes_k k'$ at the unique point x' above x (**I**, 3.5.8) (**I**, 3.5.7), and is reduced by *(c)*. Thus *(c)* implies *(d)*.

Finally, the equivalence of *(d)* and *(e)* follows from the equivalence of *(b)* and *(e)* in (4.6.1), since the irreducible components of X containing x correspond bijectively to the irreducible components of $\operatorname{Spec}(\mathscr{O}_{X,x})$ (**I**, 2.4.2). □

Corollary (4.6.13). — *Under the hypotheses of (4.6.12), suppose in addition that X is locally Noetherian. Then conditions* (a)–(e) *of (4.6.12) are also equivalent to:*

(f) *there exists an open neighbourhood U of x that is geometrically reduced over k.*

Proof. Condition *(f)* plainly implies that X is geometrically reduced at x over k. Conversely, suppose that X is geometrically reduced at x. Since $\mathscr{O}_{X,x}$ is reduced, there is a reduced open neighbourhood U of x in X (**I**, 6.1.13). After shrinking U, we may further suppose that it meets no irreducible component of X that does not contain x. Condition *(e)* of (4.6.12), together with condition *(e)* of (4.6.1), then shows that U is geometrically reduced over k. □

It follows from (4.6.13) that, when X is locally Noetherian, the set of points $x \in X$ at which X is geometrically reduced over k is open; it is the largest open subset of X that is geometrically reduced over k.

(4.6.14). It follows from (4.6.10) and (4.6.11) that, if Ω is an algebraically closed extension of k, saying that X is geometrically punctually integral at x is equivalent to saying that $X \otimes_k \Omega$ is integral at one point above x.

For X to be geometrically punctually integral at x, it is necessary that X be integral at x and that, if z is the generic point of the unique irreducible component of X containing x, the field $\kappa(z)$ be a separable extension of k. This follows from (4.6.10). These conditions are not sufficient, as is shown by (4.5.12.ii). A sufficient but not necessary condition is that X be geometrically reduced at x and belong to only one irreducible component of X, and that this component be geometrically irreducible. If in addition X is locally Noetherian, then x has an open neighbourhood in X that is geometrically integral. **IV-2** | 72

Recall that a locally Noetherian prescheme that is punctually integral is locally integral (**I**, 6.1.13). Thus, if a k-prescheme X locally of finite type over k is geometrically punctually integral over k, then $X \otimes_k k'$ is locally integral for every extension k' of k. In this case X is also said to be *geometrically locally integral*.

Proposition (4.6.15). — (i) *Let k be a field and let X be a k-prescheme of finite type. Then X is geometrically punctually integral if and only if it is geometrically reduced and its geometric number of irreducible components equals its geometric number of connected components.*

(ii) *Let X be a prescheme locally of finite type over k. If X is geometrically punctually integral at x, then x has an open neighbourhood U that is geometrically punctually integral. Equivalently, the set of points x ∈ X at which X is geometrically punctually integral is open in X.*

Proof. (i) Let Ω be an algebraically closed extension of k. The prescheme $X_{(\Omega)}$ is punctually integral (equivalently, locally integral, since it is Noetherian) if and only if it is reduced and the number of its connected components equals the number of its irreducible components (**I**, 6.1.10). Now apply (4.5.1), (4.6.1), and the first observation in (4.6.14).

(ii) The question is local on X, so we may reduce to the case in which X is of finite type over k. By (4.6.13), x has a geometrically reduced open neighbourhood; hence we may suppose that X itself is geometrically reduced. By (4.6.8), there is a finite extension k' of k such that $X' = X \otimes_k k'$ is reduced and its irreducible components are geometrically irreducible. Let $p : X' \to X$ be the canonical projection, which is finite and surjective, and let x'_j $(1 \leqslant j \leqslant r)$ be the points of $p^{-1}(x)$. By hypothesis X' is integral at each x'_j, so each x'_j has an integral open neighbourhood V'_j in X'. Since p is closed (**II**, 6.1.10), there is an open neighbourhood U of x

such that $p^{-1}(U)$ is contained in $\bigcup_j V_j'$. Thus $p^{-1}(U)$ is integral at every point, and hence locally integral. Its irreducible components are consequently open and pairwise disjoint; since they are geometrically irreducible (4.5.9), assertion *(i)* shows that $p^{-1}(U) = U \otimes_k k'$ is geometrically punctually integral. By definition the same is true of U.

□

Proposition (4.6.16). — *Let k be a field, let X be a locally Noetherian k-prescheme, and let $\mathscr{F}$ be a coherent $\mathscr{O}_X$-Module. The following conditions are equivalent:*

(a) *for every extension of finite type k' of k, if $X' = X \otimes_k k'$, then $\mathscr{F}' = \mathscr{F} \otimes_k k'$ is a reduced $\mathscr{O}_{X'}$-Module* (3.2.2);

(b) *for every finite radicial extension k' of k, the Module $\mathscr{F}'$ is a reduced $\mathscr{O}_{X'}$-Module;*

(c) *$\mathscr{F}$ is reduced and, if $\mathscr{J}$ is the Ideal of $\mathscr{O}_X$ annihilating $\mathscr{F}$, the closed sub-prescheme defined by $\mathscr{J}$ is geometrically reduced over k.*

If, moreover, X is locally of finite type over k, these conditions are also equivalent to: **IV-2 | 73**

(d) *for every extension k' of k (or for one algebraically closed extension k' of k), the Module $\mathscr{F}'$ is a reduced $\mathscr{O}_{X'}$-Module.*

Proof. It is clear that *(a)* implies *(b)*. Condition *(b)* first implies that $\mathscr{F}$ is reduced. By (3.2.3), this means the following. If Y is the closed sub-prescheme of X defined by the coherent Ideal $\mathscr{J}$ annihilating $\mathscr{F}$, then Y is reduced and there is a coherent torsion-free $\mathscr{O}_Y$-Module $\mathscr{G}$, of rank 1 on every irreducible component of Y, such that $j_*(\mathscr{G}) = \mathscr{F}$, where $j : Y \to X$ is the canonical immersion.

For every extension k' of k, the annihilator of $\mathscr{F}'$ is $\mathscr{J}' = \mathscr{J} \otimes_k k'$, since the projection $X' \to X$ is flat (2.1.11). The closed sub-prescheme of X' defined by $\mathscr{J}'$ is $Y' = Y \otimes_k k'$. If $j' : Y' \to X'$ is the canonical immersion and $\mathscr{G}' = \mathscr{G} \otimes_k k'$, then $\mathscr{F}' = j'_*(\mathscr{G}')$. For every extension k' for which X' is locally Noetherian, the Module $\mathscr{F}'$ has no embedded associated prime cycle (4.2.7). Moreover, every maximal point y' of Y' lies above a maximal point y of Y; since $\mathscr{G}_y \simeq \mathscr{O}_{Y,y}$, one has $\mathscr{G}'_{y'} \simeq \mathscr{O}_{Y',y'}$. Consequently, by (3.2.3), when X' is locally Noetherian, $\mathscr{F}'$ is reduced if and only if Y' is reduced.

It now follows from conditions *(d)* and *(b)* of (4.6.1) that *(b)* implies *(c)* and *(c)* implies *(a)*. In *(a)*, the finite-type hypothesis on k'/k serves only to ensure that X' is locally Noetherian. When X is locally of finite type over k, the prescheme X' is locally Noetherian for every extension k' of k; this proves the equivalence of *(d)* with the other conditions in that case. □

Definition (4.6.17). — When $\mathscr{F}$ satisfies the equivalent conditions of (4.6.16), it is said to be *geometrically reduced* over k, or *separable* over k.

Proposition (4.6.18). — *Let k be a field, let X be a locally Noetherian k-prescheme, and let $\mathscr{F}$ be a coherent $\mathscr{O}_X$-Module. The following conditions are equivalent:*

(a) *for every extension of finite type k' of k, if $X' = X \otimes_k k'$, then $\mathscr{F}' = \mathscr{F} \otimes_k k'$ is an integral $\mathscr{O}_{X'}$-Module* (3.2.4);

(b) *for every finite extension k' of k, the Module $\mathscr{F}'$ is an integral $\mathscr{O}_{X'}$-Module;*

(c) *$\mathscr{F}$ is reduced (or integral) and, if $\mathscr{J}$ is the Ideal of $\mathscr{O}_X$ annihilating $\mathscr{F}$, the closed sub-prescheme defined by $\mathscr{J}$ is geometrically integral over k.*

If, moreover, X is locally of finite type over k, these conditions are also equivalent to:

(d) *for every extension k' of k (or for one algebraically closed extension k' of k), the Module $\mathscr{F}'$ is an integral $\mathscr{O}_{X'}$-Module.*

Proof. Conditions *(a)*, *(b)*, and *(c)* imply that $\mathscr{F}$ is integral. Hence $\mathrm{Ass}(\mathscr{F})$ consists of one point x, the generic point of $\mathrm{Supp}(\mathscr{F})$. For every extension k' of k for which X' is locally Noetherian, the prime cycles associated to $\mathscr{F}'$ are therefore nonembedded and are the maximal points of $\mathrm{Supp}(\mathscr{F}')$, all lying above x. By (4.6.16), each of conditions *(a)*, *(b)*, and *(c)* also implies that $\mathscr{F}$ is geometrically reduced. It is immediate that *(a)* implies *(b)*, and *(b)* implies that $\mathrm{Supp}(\mathscr{F})$ is geometrically irreducible (4.5.9). Thus *(b)* implies *(c)*, because the closed sub-prescheme Y defined by $\mathscr{J}$ is geometrically reduced and geometrically irreducible, and hence geometrically integral. Conversely, if Y is geometrically integral, then for every extension k' of k, the support $\mathrm{Supp}(\mathscr{F}')$ is **IV-2 | 74** irreducible. Consequently, whenever X' is locally Noetherian, $\mathscr{F}'$ is integral. This proves that *(c)* implies *(a)*, and also that *(c)* implies *(d)* when X is locally of finite type over k. □

Definition (4.6.19). — When $\mathscr{F}$ satisfies the equivalent conditions of (4.6.18), it is said to be *geometrically integral* over k.

Proposition (4.6.20). — *Let k be a field, let X be a locally Noetherian k-prescheme, let $\mathscr{F}$ be a coherent $\mathscr{O}_X$-Module, and let K be an extension of k such that $X \otimes_k K$ is locally Noetherian. If $\mathscr{F}$ is geometrically reduced (resp. geometrically integral) over k, then $\mathscr{F} \otimes_k K$ is geometrically reduced (resp. geometrically integral) over K.*

Proof. For every finite extension K' of K,

$$(X \otimes_k K) \otimes_K K' = X \otimes_k K'$$

is locally Noetherian. The proofs of (4.6.16) and (4.6.18) show that the hypothesis on $\mathscr{F}$ implies that $\mathscr{F} \otimes_k K'$ is reduced (resp. integral), which proves the assertion. □

Proposition (4.6.21). — *Let k be a field, let X and Y be two locally Noetherian k-preschemes such that $X \times_k Y$ is locally Noetherian, let $\mathscr{F}$ be a coherent $\mathscr{O}_X$-Module, and let $\mathscr{G}$ be a coherent $\mathscr{O}_Y$-Module.*

(i) *If $\mathscr{F}$ is geometrically reduced (resp. geometrically integral) and $\mathscr{G}$ is reduced (resp. integral), then $\mathscr{F} \otimes_k \mathscr{G}$ is reduced (resp. integral).*

(ii) *If $\mathscr{F}$ and $\mathscr{G}$ are both geometrically reduced (resp. geometrically integral), then so is $\mathscr{F} \otimes_k \mathscr{G}$.*

Proof. (i) Using (3.2.3), (4.6.16), and (4.6.18), we may reduce to the case in which

$$\operatorname{Supp}(\mathscr{F}) = X, \qquad \operatorname{Supp}(\mathscr{G}) = Y,$$

X is geometrically reduced (resp. geometrically integral), Y is reduced (resp. integral), $\mathscr{F}$ and $\mathscr{G}$ have no embedded associated prime cycles, and

$$\mathscr{F}_x \simeq \mathscr{O}_x, \qquad \mathscr{G}_y \simeq \mathscr{O}_y$$

at every maximal point x of X and y of Y. Then $\mathscr{F} \otimes_k \mathscr{G}$ has no embedded associated prime cycle (4.2.3), and its associated prime cycles are exactly the irreducible components of $X \times_k Y$ (4.2.5). We may therefore reduce further to the case in which X and Y are irreducible. If X is geometrically reduced and Y is reduced, then $X \times_k Y$ is reduced (4.2.4.ii). If X is geometrically integral and Y is integral, then $X \times_k Y$ is moreover irreducible (4.5.8.i), and hence integral. Finally, every maximal point z of $X \times_k Y$ lies above a maximal point x of X and a maximal point y of Y. The hypotheses on $\mathscr{F}$ and $\mathscr{G}$ therefore imply, by (**I**, 9.1.12), that $(\mathscr{F} \otimes_k \mathscr{G})_z \simeq \mathscr{O}_z$.

(ii) The argument is analogous. After reducing to $X = \operatorname{Supp}(\mathscr{F})$ and $Y = \operatorname{Supp}(\mathscr{G})$, the prescheme $X \times_k Y$ is geometrically reduced (resp. geometrically integral) by (4.6.5.ii). □

The definitions in (4.6.18) and (4.6.19) localize as follows.

Definition (4.6.22). — Let k be a field, let X be a locally Noetherian k-prescheme, and let $\mathscr{F}$ be a coherent $\mathscr{O}_X$-Module. We say that $\mathscr{F}$ is *geometrically reduced*, or *separable* (resp. *geometrically punctually integral*), at a point $x \in X$ if, for every finite radicial (resp. finite) extension k' of k, the Module $\mathscr{F} \otimes_k k'$ is reduced (resp. integral) at every point x' of $X \otimes_k k'$ above x; see (3.2.2) and (3.2.4).

If $\mathscr{F}$ is reduced at x, there is an open neighbourhood U of x such that $\mathscr{F}|U$ is reduced (3.2.2). **IV-2** | 75
Arguing as in (4.6.16), one sees that $\mathscr{F}$ is geometrically reduced at x if and only if $\mathscr{F}$ is reduced at x and the closed sub-prescheme Y defined by the annihilator $\mathscr{J}$ of $\mathscr{F}$ is geometrically reduced at x. It follows that x has an open neighbourhood U such that $\mathscr{F}|U$ is geometrically reduced (4.6.11). The arguments of (4.6.16) and (4.6.18) likewise show that, if X is locally of finite type over k, then $\mathscr{F}$ is geometrically punctually integral at x if and only if $\mathscr{F}$ is reduced at x and Y is geometrically punctually integral at x.

4.7. Multiplicities in the primary decomposition on an algebraic prescheme

Lemma (4.7.1). — *Let A and B be two local rings, let $\mathfrak{m}$ be the maximal ideal of A, and let $\rho : A \to B$ be a local homomorphism. Suppose that B is flat as an A-module and that $B/\mathfrak{m}B$ has finite length as a B-module. Then an A-module M has finite length if and only if $M_{(B)}$ has finite length as a B-module, and*

(4.7.1.1) $$\mathrm{length}_B(M_{(B)}) = \mathrm{length}_A(M)\ \mathrm{length}_B(B/\mathfrak{m}B).$$

Proof. This is a special case of (2.5.5.2). □

Corollary (4.7.2). — *Let A and B be two Noetherian rings, and let $\rho : A \to B$ be a ring homomorphism such that B is flat as an A-module. Let $\mathfrak{q}$ be a minimal prime ideal of B, put $\mathfrak{p} = \rho^{-1}(\mathfrak{q})$, and let M be an A-module of finite type. Then $\mathfrak{p}$ is a minimal prime ideal of A, $M_\mathfrak{p}$ has finite length as an $A_\mathfrak{p}$-module, and*

(4.7.2.1) $$\mathrm{length}_{B_\mathfrak{q}}\big((M_{(B)})_\mathfrak{q}\big) = \mathrm{length}_{A_\mathfrak{p}}(M_\mathfrak{p})\ \mathrm{length}_{B_\mathfrak{q}}\big(B_\mathfrak{q}/\mathfrak{p}B_\mathfrak{q}\big).$$

Proof. The ring $B_\mathfrak{q}$ is flat over $A_\mathfrak{p}$ ($\mathbf{0}_I$, 6.3.2), and the homomorphism $A_\mathfrak{p} \to B_\mathfrak{q}$ is local; hence $B_\mathfrak{q}$ is faithfully flat over $A_\mathfrak{p}$ ($\mathbf{0}_I$, 6.6.2). It follows from (2.3.5) that $\mathfrak{p}$ is minimal in A. The ring $A_\mathfrak{p}$ is therefore Artinian (Bourbaki, *Alg. comm.*, chap. IV, § 2, nº 5, prop. 9), so $M_\mathfrak{p}$ has finite length over $A_\mathfrak{p}$. Formula (4.7.2.1) is now a special case of (4.7.1.1). □

Proposition (4.7.3). — *Let k be a field of characteristic exponent p, let X be an integral locally Noetherian prescheme, and let $K = \mathrm{R}(X)$ be the field of rational functions on X. Let k' be an extension of k, let (X'_α) be the family of irreducible components of $X' = X_{(k')}$, and let x'_α be the generic point of X'_α.*

(i) *Suppose that X' is locally Noetherian, as is the case if X is locally of finite type over k or if k' is an extension of finite type of k. Let k'' be any extension of k', set $X'' = X \otimes_k k''$, and let (X''_β) be the family of irreducible components of X'', with generic points x''_β. If x''_β lies above x'_α, set*

$$Z'' = (X'_{\mathrm{red}}) \otimes_{k'} k'',$$

Then

(4.7.3.1) $$\mathrm{length}(\mathscr{O}_{X'',x''_\beta}) = \mathrm{length}(\mathscr{O}_{X',x'_\alpha})\ \mathrm{length}(\mathscr{O}_{Z'',x''_\beta}).$$

In particular, if k'' is a separable extension of k' such that Z'' is locally Noetherian, then

$$\mathrm{length}(\mathscr{O}_{X'',x''_\beta}) = \mathrm{length}(\mathscr{O}_{X',x'_\alpha}).$$

IV-2 | 76

(ii) *If X is locally of finite type over k, or if the extension k'/k is of finite type, then each number*

$$\mathrm{length}(\mathscr{O}_{X',x'_\alpha})$$

is a power of p.

(iii) *Suppose that X is locally of finite type over k. If k' is perfect, all the numbers $\mathrm{length}(\mathscr{O}_{X',x'_\alpha})$ are equal and depend only on the extension K/k, not on the particular perfect extension k'/k under consideration. Moreover, there exists a finite radicial extension k_1 of k such that, if x_1 is the generic point of $X_1 = X \otimes_k k_1$, which is irreducible, then*

$$\mathrm{length}(\mathscr{O}_{X',x'_\alpha}) = \mathrm{length}(\mathscr{O}_{X_1,x_1}) \quad \textit{for every } \alpha.$$

Proof. (i) Recall from (4.2.4) that the finitely many irreducible components X'_α correspond bijectively to the minimal prime ideals $\mathfrak{p}_\alpha$ of $K \otimes_k k'$, and that $\mathscr{O}_{X',x'_\alpha}$ is an Artinian ring isomorphic to $(K \otimes_k k')_{\mathfrak{p}_\alpha}$. These rings therefore depend only on the extensions K/k and k'/k; in particular, with k' fixed, they are the same for every integral k-prescheme having K as its field of rational functions.

Formula (4.7.3.1) follows from (4.7.2.1). Indeed, apply that formula to the Noetherian ring A of an affine neighbourhood of x'_α in X' and to the ring B of a sufficiently small affine neighbourhood of x''_β in X'', where $\mathfrak{p}$ and $\mathfrak{q}$ are the minimal prime ideals corresponding respectively to x'_α and x''_β, and take $M = A$. Here $A/\mathfrak{p}$ is the ring of an affine neighbourhood of x'_α in X'_{red}, while $B = A \otimes_{k'} k''$. If $\mathfrak{q}' = \mathfrak{q}/\mathfrak{p}B$, a minimal prime ideal of $B/\mathfrak{p}B$, then

$$\mathscr{O}_{Z'',x''_\beta} = (B/\mathfrak{p}B)_{\mathfrak{q}'} = B_\mathfrak{q}/\mathfrak{p}B_\mathfrak{q},$$

which proves (4.7.3.1). The last assertion of *(i)* follows because Z'' is reduced in this case (4.2.4), and hence $\mathfrak{p}B_{\mathfrak{q}} = \mathfrak{q}B_{\mathfrak{q}}$.

(ii) If k' is of finite type over k, there is a purely transcendental extension k'_0 of k such that k' is finite over k'_0. Since k'_0/k is separable, *(i)*, applied with k' and k'' replaced by k and k'_0, shows that we may replace X by $X \otimes_k k'_0$; thus we may assume that k'/k is finite. There is then a finite quasi-Galois extension k''/k containing k', and (4.7.3.1) shows that it suffices to prove the assertion for k''. But k'' is separable over a finite radicial extension k_1 of k, so *(i)* reduces us to the case $k' = k_1$ radicial. The ring $K \otimes_k k_1$ is then Artinian and has a unique minimal prime ideal (4.3.2). If $\overline{K}$ is an algebraic closure of K, the length of $K \otimes_k k_1$ divides the length of the Artinian ring $\overline{K} \otimes_k k_1$ by (4.7.1.1). The Artinian $\overline{K}$-algebra $\overline{K} \otimes_k k_1$ has a unique prime ideal, necessarily maximal, and its quotient by that ideal is a finite extension of $\overline{K}$, hence is $\overline{K}$. Its length is therefore its rank over $\overline{K}$, namely $[k_1 : k]$, a power of p.

Suppose next that X is locally of finite type over k. Then X'' is locally Noetherian for every extension k'' of k'. Taking k'' algebraically closed, (4.7.3.1) reduces us to the case in which k' is algebraically closed. Since k' is then separable over the algebraic closure $\overline{k}$ of k, another application of *(i)* reduces us to $k' = \overline{k}$.

After replacing X by an affine open of finite type over k, there is a finite radicial extension k_1/k such that $(X \otimes_k k_1)_{\text{red}}$ is separable over k_1 (4.6.6). Consequently, $(X \otimes_k k_1)_{\text{red}} \otimes_{k_1} \overline{k}$ is reduced (4.6.4). By (4.7.3.1), this again reduces us to the case in which k' is a finite radicial extension of k, and the preceding argument applies. **IV-2** | 77

(iii) Any two extensions k' and k'' of k embed in a common algebraically closed extension of k. To show that the set of numbers $\text{length}(\mathscr{O}_{X',x'_\alpha})$ for perfect k' does not depend on k', it is therefore enough to compare them with those obtained after an algebraically closed extension k''/k'; the assertion then follows from *(i)*, since k''/k' is separable. To prove that all these numbers are equal, we may thus assume $k' = \overline{k}$. For the finite radicial extension k_1/k chosen in *(ii)*, all the points x'_α lie above the unique generic point x_1 of $X_1 = X \otimes_k k_1$. The equality

$$\text{length}(\mathscr{O}_{X',x'_\alpha}) = \text{length}(\mathscr{O}_{X_1,x_1})$$

for every α follows once more from (4.7.3.1) and the choice of k_1.

□

Definition (4.7.4). — Let k be a field, let X be an integral k-prescheme, and let K be the field of rational functions on X. The *radicial multiplicity* of K (or of X) over k is the supremum of the lengths of the Artinian rings $K \otimes_k k_1$, as k_1 ranges over the finite radicial extensions of k. The *separable multiplicity* of K (or of X) over k is the geometric number of irreducible components of X if this number is finite, and $+\infty$ otherwise. Finally, the *total multiplicity* of K (or of X) over k is the product of its radicial and separable multiplicities.

If p is the characteristic exponent of k and the radicial multiplicity of K over k is finite, then it is a power $q = p^f$ of p, by (4.7.3.ii). When $p \neq 1$, the well-defined integer f is called the *inseparability exponent* of K over k; when $p = 1$, the radicial multiplicity is always 1.

To say that the radicial (resp. separable, resp. total) multiplicity of X over k is 1 means that X is geometrically reduced (resp. geometrically irreducible, resp. geometrically integral) over k.

When X is locally of finite type, its radicial multiplicity over k is also the common length of the local rings $A_{\mathfrak{q}}$ at the minimal prime ideals of the total ring of fractions A of $K \otimes_k k'$, for every perfect extension k'/k. Its separable multiplicity is the number of minimal prime ideals of $A = K \otimes_k \Omega$, for every algebraically closed extension Ω/k. Finally, its total multiplicity is the sum of the lengths of the local rings $A_{\mathfrak{q}}$ of $A = K \otimes_k \Omega$ at its minimal prime ideals. In this case all three numbers are finite.

Definition (4.7.5). — Let k be a field, let X be a k-prescheme locally of finite type over k, let $\mathscr{F}$ be a coherent $\mathscr{O}_X$-Module, and let $x \in X$ be such that $\mathscr{F}_x$ has finite length as an $\mathscr{O}_{X,x}$-module. The *geometric length* of $\mathscr{F}$ at x relative to k, or the *radicial multiplicity of x for $\mathscr{F}$*, is

$$\lambda_x(\mathscr{F}) = \text{length}_{\mathscr{O}_{X,x}}(\mathscr{F}_x)\, \mu_r(\kappa(x) \mid k),$$

where $\mu_r(\kappa(x) \mid k)$ denotes the radicial multiplicity of $\kappa(x)$ over k.

When X is integral and x is its generic point, $\operatorname{length}(\mathscr{O}_{X,x}) = 1$. Thus the radicial multiplicity of x for $\mathscr{O}_X$ is precisely the radicial multiplicity of X over k defined in (4.7.4).

IV-2 | 78

Proposition (4.7.6). — *Let*

$$0 \longrightarrow \mathscr{F}' \longrightarrow \mathscr{F} \longrightarrow \mathscr{F}'' \longrightarrow 0$$

be an exact sequence of coherent $\mathscr{O}_X$-Modules. At a point $x \in X$, the geometric length $\lambda_x(\mathscr{F})$ is defined if and only if both $\lambda_x(\mathscr{F}')$ and $\lambda_x(\mathscr{F}'')$ are defined; in that case

$$\lambda_x(\mathscr{F}) = \lambda_x(\mathscr{F}') + \lambda_x(\mathscr{F}''). \tag{4.7.6.1}$$

Proof. This follows immediately from the definition: the length of $\mathscr{F}_x$ is finite if and only if the lengths of $\mathscr{F}'_x$ and $\mathscr{F}''_x$ are finite, and then

$$\operatorname{length}(\mathscr{F}_x) = \operatorname{length}(\mathscr{F}'_x) + \operatorname{length}(\mathscr{F}''_x).$$

□

(4.7.7). Under the hypotheses of (4.7.5), the only points $x \in X$ for which $\mathscr{F}_x$ is a nonzero $\mathscr{O}_{X,x}$-module of finite length are, by (3.1.2), the maximal points of $\operatorname{Supp}(\mathscr{F})$. This follows from Bourbaki, *Alg. comm.*, chap. IV, § 2, n° 5, cor. 2 to prop. 7, since the question is local on X. There is a closed subprescheme Y with underlying space $\operatorname{Supp}(\mathscr{F})$ and a coherent $\mathscr{O}_Y$-Module $\mathscr{G}$ such that $\mathscr{F} = j_*(\mathscr{G})$, where $j : Y \to X$ is the canonical injection. If x is a maximal point of Y, then the geometric lengths of $\mathscr{F}$ and $\mathscr{G}$ at x are equal, because $\mathscr{O}_{X,x}$ and $\mathscr{O}_{Y,x}$ have the same residue field. This gives the following characterization of geometric length.

Proposition (4.7.8). — *Under the hypotheses of (4.7.5), let x be a maximal point of* $\operatorname{Supp}(\mathscr{F})$. *Let k' be a perfect extension of k, and set $X' = X \otimes_k k'$ and $\mathscr{F}' = \mathscr{F} \otimes_k k'$. Then $\lambda_x(\mathscr{F})$ equals* $\operatorname{length}_{\mathscr{O}_{X',x'}}(\mathscr{F}'_{x'})$ *at every maximal point x' of* $\operatorname{Supp}(\mathscr{F}')$ *above x. Moreover, there exists a finite radicial extension k_1 of k such that, on setting $X_1 = X \otimes_k k_1$ and $\mathscr{F}_1 = \mathscr{F} \otimes_k k_1$, the number $\lambda_x(\mathscr{F})$ equals* $\operatorname{length}_{\mathscr{O}_{X_1,x_1}}((\mathscr{F}_1)_{x_1})$ *at every maximal point x_1 of* $\operatorname{Supp}(\mathscr{F}_1)$ *above x.*

Proof. The remark in (4.7.7) reduces us to the case in which x is a maximal point of X. Since the question is local on X, suppose $X = \operatorname{Spec}(A)$ is affine Noetherian and $\mathscr{F} = \widetilde{M}$, where M is an A-module of finite type. Put $B = A \otimes_k k'$, and let $\mathfrak{p}$ and $\mathfrak{q}$ be the minimal prime ideals of A and B corresponding respectively to x and x'. Formula (4.7.2.1) gives

$$\operatorname{length}_{B_\mathfrak{q}}\big((M_{(B)})_\mathfrak{q}\big) = \operatorname{length}_{A_\mathfrak{p}}(M_\mathfrak{p})\ \operatorname{length}_{B_\mathfrak{q}}\big(B_\mathfrak{q}/\mathfrak{p}B_\mathfrak{q}\big).$$

Since $\kappa(x) = A_\mathfrak{p}/\mathfrak{p}A_\mathfrak{p}$, the argument of (4.7.3) shows that the last factor is the length of $(B/\mathfrak{p}B)_{\mathfrak{q}'}$, where $\mathfrak{q}' = \mathfrak{q}/\mathfrak{p}B$. This is a local ring of $(A/\mathfrak{p}) \otimes_k k'$ at a minimal prime ideal, and therefore also a local ring of the total ring of fractions of $\kappa(x) \otimes_k k'$. By definition its length is $\mu_r(\kappa(x) \mid k)$, proving the first assertion. The second follows in the same way by replacing k' with k_1 and using (4.7.3.iii). □

When x is a maximal point of $\operatorname{Supp}(\mathscr{F})$, the geometric length of $\mathscr{F}$ at x is also called the *radicial multiplicity of the maximal prime cycle* $\overline{\{x\}}$ associated with $\mathscr{F}$.

Corollary (4.7.9). — *Under the hypotheses of (4.7.5), let k' be an extension of k, set $X' = X \otimes_k k'$ and $\mathscr{F}' = \mathscr{F} \otimes_k k'$, and let Z be an irreducible component of* $\operatorname{Supp}(\mathscr{F})$. *If Z' is an irreducible component of* $\operatorname{Supp}(\mathscr{F}')$ *dominating Z (4.2.7), then the radicial multiplicities of Z with respect to $\mathscr{F}$ and of Z' with respect to $\mathscr{F}'$ are equal.*

IV-2 | 79

Proof. Choose a perfect extension k'' of k', set $X'' = X \otimes_k k''$ and $\mathscr{F}'' = \mathscr{F} \otimes_k k''$, and choose a maximal point x'' of $\operatorname{Supp}(\mathscr{F}'')$ above the generic point of Z'. It follows from (4.7.8) that $\operatorname{length}(\mathscr{F}''_{x''})$ equals both multiplicities. □

Proposition (4.7.10). — *Let k be a field, let X be a k-prescheme locally of finite type over k, let $\mathscr{F}$ be a coherent $\mathscr{O}_X$-Module, let $x \in X$, and let ξ_i be the generic points of the irreducible components of* $\operatorname{Supp}(\mathscr{F})$ *that contain x. Then $\mathscr{F}$ is geometrically reduced at x (4.6.22) if and only if x belongs to no embedded associated prime cycle of $\mathscr{F}$ and $\lambda_{\xi_i}(\mathscr{F}) = 1$ for every i.*

Proof. First suppose the stated conditions hold. Let k'/k be finite, let x' be a point of $X' = X \otimes_k k'$ above x, and put $\mathscr{F}' = \mathscr{F} \otimes_k k'$. By (4.2.7), x' belongs to no embedded associated prime cycle of $\mathscr{F}'$. Moreover, (4.7.8) shows that $\mathscr{F}'$ has geometric length 1 at every generic point ξ' of an irreducible component of $\operatorname{Supp}(\mathscr{F}')$ containing x'; by (2.3.4), such a point lies above one of the ξ_i. A fortiori, $\operatorname{length}(\mathscr{F}'_{\xi'}) = 1$, so $\mathscr{F}'$ is reduced at x'.

Conversely, (4.2.7) first shows that if, for one finite extension k'/k, the Module $\mathscr{F}'$ is reduced at every point x' above x, then x belongs to no embedded associated prime cycle of $\mathscr{F}$. For each ξ_i, take for k' the field k_1 supplied by (4.7.8). The hypothesis that $\mathscr{F}$ is geometrically reduced at x then implies $\lambda_{\xi_i}(\mathscr{F}) = 1$. □

Proposition (4.7.11). — *Let k be a field, let X be a prescheme locally of finite type over k, let $\mathscr{F}$ be a coherent $\mathscr{O}_X$-Module, let k' be an extension of k, set $X' = X \otimes_k k'$ and $\mathscr{F}' = \mathscr{F} \otimes_k k'$, and let $x' \in X'$ lie above $x \in X$. Then $\mathscr{F}$ is geometrically reduced (resp. geometrically punctually integral) at x if and only if $\mathscr{F}'$ is geometrically reduced (resp. geometrically punctually integral) at x'.*

Proof. Every irreducible component of $\operatorname{Supp}(\mathscr{F}')$ containing x' dominates an irreducible component of $\operatorname{Supp}(\mathscr{F})$ containing x, and conversely every such component downstairs is dominated by one containing x' ((4.2.7.i) and (2.3.4)). The assertion concerning geometric reducedness therefore follows from (4.2.7.ii), (4.7.9), and (4.7.10).

Let Y be the closed sub-prescheme of X defined by the annihilator Ideal $\mathscr{J}$ of $\mathscr{F}$. Then $Y' = Y \otimes_k k'$ is the closed sub-prescheme of X' defined by the annihilator Ideal $\mathscr{J}' = \mathscr{J} \otimes_k k'$ of $\mathscr{F}'$. To say that $\mathscr{F}$ (resp. $\mathscr{F}'$) is geometrically punctually integral at x (resp. x') is to say that $\mathscr{F}$ (resp. $\mathscr{F}'$) is geometrically reduced at x (resp. x') and that Y (resp. Y') is geometrically punctually integral at x (resp. x'). By the assertion just proved, either of the two geometric pointwise-integrality hypotheses implies that Y has a separable neighbourhood of x. The conclusion follows from (4.6.10). □

Definition (4.7.12). — Let k be a field, let X be a k-prescheme locally of finite type over k, let $\mathscr{F}$ be a coherent $\mathscr{O}_X$-Module, and let x be a maximal point of $\operatorname{Supp}(\mathscr{F})$. The *total multiplicity* of x (or of the prime cycle $\overline{\{x\}}$) for $\mathscr{F}$, relative to k, is the product of the radicial multiplicity of x for $\mathscr{F}$ and the separable multiplicity of $\kappa(x)$ over k. **IV-2** | 80

Equivalently, the total multiplicity of x for $\mathscr{F}$ is the product of $\operatorname{length}_{\mathscr{O}_{X,x}}(\mathscr{F}_x)$ and the total multiplicity of $\kappa(x)$ over k (4.7.4). With the notation of (4.7.11), the total multiplicity of x for $\mathscr{F}$ is the sum of the total multiplicities, for $\mathscr{F}'$, of the maximal points x'_i of $\operatorname{Supp}(\mathscr{F}')$ above x. Moreover, there exists a finite extension k'/k for which the total multiplicity of x for $\mathscr{F}$ is

$$\sum_i \operatorname{length}(\mathscr{F}'_{x'_i}).$$

Proposition (4.7.13). — *Under the hypotheses and notation of (4.7.10), it is sufficient, for $\mathscr{F}$ to be geometrically punctually integral at x, that x belong to only one associated prime cycle of $\mathscr{F}$ (necessarily non-embedded), and that the total multiplicity for $\mathscr{F}$ of the generic point ξ of that cycle be* 1.

Proof. Let k'/k be finite, let x' be a point of $X' = X \otimes_k k'$ above x, and put $\mathscr{F}' = \mathscr{F} \otimes_k k'$. The point x' can belong to only one associated prime cycle of $\mathscr{F}'$, since by hypothesis there is only one maximal point of $\operatorname{Supp}(\mathscr{F}')$ above ξ. Moreover, $\mathscr{F}'$ is geometrically reduced at x' by (4.7.10). The conclusion follows. □

4.8. Fields of definition

(4.8.1). Given a prescheme X, throughout this section we denote by $\mathfrak{S}(X)$ the set of sub-preschemes of X, and, as usual, by $\mathfrak{P}(X)$ the set of subsets of the underlying space of X. For every quasi-coherent $\mathscr{O}_X$-Module $\mathscr{F}$, we denote by $\Phi(\mathscr{F})$ the set of quasi-coherent sub-$\mathscr{O}_X$-Modules of $\mathscr{F}$.

(4.8.2). Let k be a field, let X and Y be two k-preschemes, let $\mathscr{F}$ and $\mathscr{G}$ be two quasi-coherent $\mathscr{O}_X$-Modules, and let $K' \subset K$ be two extensions of k. Corresponding to the morphism $\operatorname{Spec}(K) \to \operatorname{Spec}(K')$, there are canonical maps

$$\Phi(\mathscr{F} \otimes_k K') \longrightarrow \Phi(\mathscr{F} \otimes_k K), \tag{4.8.2.1}$$

$$\operatorname{Hom}(\mathscr{F} \otimes_k K', \mathscr{G} \otimes_k K') \longrightarrow \operatorname{Hom}(\mathscr{F} \otimes_k K, \mathscr{G} \otimes_k K), \tag{4.8.2.2}$$

$$\mathfrak{S}(X_{(K')}) \longrightarrow \mathfrak{S}(X_{(K)}), \tag{4.8.2.3}$$

$$\operatorname{Hom}_{K'}(X_{(K')}, Y_{(K')}) \longrightarrow \operatorname{Hom}_K(X_{(K)}, Y_{(K)}), \tag{4.8.2.4}$$

$$\mathfrak{P}(X_{(K')}) \longrightarrow \mathfrak{P}(X_{(K)}). \tag{4.8.2.5}$$

If $p_X : X_{(K)} \to X_{(K')}$ is the canonical projection, then (4.8.2.5) sends M to $p_X^{-1}(M)$, and similarly (4.8.2.3) sends Z to $p_X^{-1}(Z) = Z \otimes_{K'} K$ (**I**, 4.4.1). Map (4.8.2.1) sends

$$\mathscr{H} \longmapsto p_X^*(\mathscr{H}) = \mathscr{H} \otimes_{\mathscr{O}_{X_{(K')}}} \mathscr{O}_{X_{(K)}};$$

(4.8.2.2) sends u to $p_X^*(u)$; and (4.8.2.4) sends f to $f_{(K)}$.

If $\varepsilon_{K,K'}$ denotes any one of these canonical maps, and if $K'' \subset K' \subset K$ are three extensions of k, then

$$\varepsilon_{K,K''} = \varepsilon_{K,K'} \circ \varepsilon_{K',K''}. \tag{4.8.2.6}$$

IV-2 | 81

Proposition (4.8.3). — *The canonical maps (4.8.2.1)–(4.8.2.5) are injective.*

Proof. The morphism p_X is faithfully flat and quasi-compact. The injectivity of (4.8.2.5) follows from the surjectivity of p_X. The injectivity of (4.8.2.1) follows from (2.2.2), that of (4.8.2.2) from (2.2.7), that of (4.8.2.3) from (2.2.15), and that of (4.8.2.4) from (2.2.16). □

Definition (4.8.4). — With the notation of (4.8.2), a quasi-coherent sub-$\mathscr{O}_{X_{(K)}}$-Module of $\mathscr{F} \otimes_k K$ (resp. a homomorphism $\mathscr{F} \otimes_k K \to \mathscr{G} \otimes_k K$, a sub-prescheme of $X_{(K)}$, a K-morphism $X_{(K)} \to Y_{(K)}$, or a subset of $X_{(K)}$) is said to be *defined over* K' if it belongs to the image of (4.8.2.1) (resp. (4.8.2.2), (4.8.2.3), (4.8.2.4), or (4.8.2.5)). The field K' is then called a *field of definition* of the object in question.

Clearly, K itself is a field of definition for every object in any of the five target sets in (4.8.2). One should note, however, that for a K-prescheme Z, to say that a quasi-coherent $\mathscr{O}_Z$-Module $\mathscr{H}$ is "defined over a subfield K' of K" has no meaning unless Z has been *given* in the form $X_{(K)}$ for a prescheme X over a subfield k of K, and unless $\mathscr{H}$ is a sub-$\mathscr{O}_Z$-Module of an $\mathscr{O}_Z$-Module that has been *given* in the form $\mathscr{F} \otimes_k K$, where $\mathscr{F}$ is a quasi-coherent $\mathscr{O}_X$-Module. Analogous remarks apply to the other notions.

It follows from (4.8.2.6) that if an object in one of the five target sets in (4.8.2) is defined over K', then it is also defined over every intermediate field K'' with $K' \subset K'' \subset K$. Finally, if K_1/K is an extension, then an object in a source set of $\varepsilon_{K_1,K}$ is defined over K' if and only if its image under $\varepsilon_{K_1,K}$ is defined over K'; this follows from

$$\varepsilon_{K_1,K'} = \varepsilon_{K_1,K} \circ \varepsilon_{K,K'}.$$

Proposition (4.8.5). — *With the notation of* (4.8.2)*, let* (X_α) *be an open covering of* X*. An element*

$$\mathscr{H} \in \Phi(\mathscr{F} \otimes_k K) \quad \textit{(resp. } u \in \operatorname{Hom}(\mathscr{F} \otimes_k K, \mathscr{G} \otimes_k K),\ Z \in \mathfrak{S}(X_{(K)}),\ \textit{or } M \in \mathfrak{P}(X_{(K)})\textit{)}$$

is defined over K' *if and only if, for every* α*, its restriction*

$$\mathscr{H}|_{(X_\alpha)_{(K)}} \quad \textit{(resp. } u|_{(X_\alpha)_{(K)}},\ Z \cap (X_\alpha)_{(K)},\ \textit{or } M \cap (X_\alpha)_{(K)}\textit{)}$$

is defined over K'.

Proof. This follows immediately from the injectivity of (4.8.2.1), (4.8.2.2), (4.8.2.3), and (4.8.2.5). For example, suppose that for every α there is a quasi-coherent sub-$\mathscr{O}_{(X_\alpha)_{(K')}}$-Module $\mathscr{H}'_\alpha$ such that

$$\mathscr{H}|_{(X_\alpha)_{(K)}} = \mathscr{H}'_\alpha \otimes_{K'} K.$$

For any α, β, injectivity after restriction to $(X_\alpha \cap X_\beta)_{(K')}$ gives

$$\mathscr{H}'_\alpha|_{(X_\alpha \cap X_\beta)_{(K')}} = \mathscr{H}'_\beta|_{(X_\alpha \cap X_\beta)_{(K')}}.$$

The $\mathscr{H}'_\alpha$ therefore glue to a quasi-coherent sub-$\mathscr{O}_{X_{(K')}}$-Module $\mathscr{H}'$ of $\mathscr{F} \otimes_k K'$ such that $\mathscr{H} = \mathscr{H}' \otimes_{K'} K$. The other cases are treated in the same way. □

Lemma (4.8.6). — *Let k be a field, let K/k be an extension, let A be a k-algebra, let M be an A-module, let $\overline{N}$ be an $A_{(K)}$-submodule of $M_{(K)}$, and let K' be an intermediate field of K/k. The following conditions are equivalent:*

(a) *$\overline{N} = N' \otimes_{K'} K$, where N' is an $A_{(K')}$-submodule of $M_{(K')}$;*

(b) *if $X = \operatorname{Spec}(A)$, the quasi-coherent $\mathscr{O}_{X_{(K)}}$-Module $\widetilde{\overline{N}}$ on $X_{(K)} = \operatorname{Spec}(A_{(K)})$ is defined over K';*

(c) *$\overline{N} = N' \otimes_{K'} K$, where N' is a K'-vector subspace of $M_{(K')}$.*

Proof. The equivalence of *(a)* and *(b)* follows immediately from (**I**, 1.6.5), and *(a)* plainly implies *(c)*. **IV-2** | 82
Conversely, if *(c)* holds, then, up to the canonical identification,

$$N' = \overline{N} \cap M_{(K')}.$$

Since $\overline{N}$ and $M_{(K')}$ are $A_{(K')}$-submodules, so is N'. □

Corollary (4.8.7). — *Under the hypotheses of (4.8.6), there is a smallest subfield K' of K containing k for which the equivalent conditions of (4.8.6) hold.*

Proof. It is enough to use condition *(c)*, for which the assertion is Bourbaki, *Alg.*, chap. II, 3rd ed., § 8, n$^{\text{o}}$ 6, prop. 6. □

Lemma (4.8.8). — *With the notation of (4.8.2):*

(i) *Let $\overline{u} : \mathscr{F} \otimes_k K \to \mathscr{G} \otimes_k K$ be an $\mathscr{O}_{X_{(K)}}$-homomorphism, and let*

$$\overline{\mathscr{H}} \subset (\mathscr{F} \otimes_k K) \oplus (\mathscr{G} \otimes_k K)$$

be its graph. Then $\overline{u}$ is defined over K' if and only if $\overline{\mathscr{H}}$ is.

(ii) *Let $\overline{Z}$ be a closed sub-prescheme of $X_{(K)}$, and let $\overline{\mathscr{J}}$ be the quasi-coherent Ideal of $\mathscr{O}_{X_{(K)}}$ defining $\overline{Z}$. Then $\overline{Z}$ is defined over K' if and only if $\overline{\mathscr{J}}$ is.*

(iii) *Let $\overline{f} : X_{(K)} \to Y_{(K)}$ be a K-morphism, and let $\overline{Z}$ be its graph, regarded as a sub-prescheme of $X_{(K)} \times_K Y_{(K)}$ (**I**, 5.3.11). Then $\overline{f}$ is defined over K' if and only if $\overline{Z}$ is.*

Proof. Assertion *(ii)* follows immediately from (**I**, 4.4.5). Necessity in *(iii)* is clear. Conversely, suppose $\overline{Z} = Z'_{(K)}$, where Z' is a sub-prescheme of $(X \times_k Y)_{(K')}$. If $p' : Z' \to X_{(K')}$ is the restriction of the first projection, then $p'_{(K)}$ is an isomorphism, and hence so is p' (2.7.1.viii). Thus Z' is the graph of a K'-morphism $f' : X_{(K')} \to Y_{(K')}$ (**I**, 5.3.11), and $\overline{f} = f'_{(K)}$ (**I**, 5.3.12).

Finally, to prove *(i)*, (4.8.5) permits us to assume $X = \operatorname{Spec}(A)$ affine, with $\mathscr{F} = \widetilde{M}, \mathscr{G} = \widetilde{N}$, and $\overline{u} = \widetilde{\overline{v}}$ for an $A_{(K)}$-homomorphism $\overline{v} : M_{(K)} \to N_{(K)}$. Suppose the graph of $\overline{v}$ is $P'_{(K)}$, where P' is an $A_{(K')}$-submodule of $M_{(K')} \oplus N_{(K')}$. If $p' : P' \to M_{(K')}$ is the restriction of the first projection, then $p' \otimes 1_K$ is an isomorphism of $A_{(K)}$-modules. Faithful flatness $(\mathbf{0}_I, 6.4.1)$ implies that p' is an isomorphism of $A_{(K')}$-modules. Hence P' is the graph of an $A_{(K')}$-homomorphism $v' : M_{(K')} \to N_{(K')}$, and plainly $\overline{v} = v' \otimes 1_K$. □

Proposition (4.8.9). — *Let k be a field, let K/k be an extension, let X be a k-prescheme, let $\mathscr{F}$ be a quasi-coherent $\mathscr{O}_X$-Module, and let $\overline{\mathscr{H}}$ be a quasi-coherent sub-$\mathscr{O}_{X_{(K)}}$-Module of $\mathscr{F} \otimes_k K$. Then $\overline{\mathscr{H}}$ has a smallest field of definition.*

Proof. When X is affine, this is precisely (4.8.7). In general, let (X_α) be an affine open covering of X. For every α, there is a smallest subfield K'_α of K containing k over which $\overline{\mathscr{H}}|_{(X_\alpha)_{(K)}}$ is defined. By (4.8.5), the subfield of K generated by the K'_α is the smallest field of definition of $\overline{\mathscr{H}}$. □

Corollary (4.8.10). — *With the notation of (4.8.9), let $\mathscr{G}$ be a second quasi-coherent $\mathscr{O}_X$-Module and let*

$$\overline{u} : \mathscr{F} \otimes_k K \longrightarrow \mathscr{G} \otimes_k K$$

be an $\mathscr{O}_{X_{(K)}}$-homomorphism. Then $\overline{u}$ has a smallest field of definition.

Proof. By (4.8.8.i), such a field is also the smallest field of definition of the graph of $\overline{u}$, whose existence follows from (4.8.9). □

Corollary (4.8.11). — *Let k be a field, let X be a k-prescheme, let K/k be an extension, and let $\overline{Z}$ be a closed sub-prescheme of $X_{(K)}$. Then $\overline{Z}$ has a smallest field of definition.*

Proof. Let $\overline{\mathscr{J}}$ be the quasi-coherent Ideal of $\mathscr{O}_{X_{(K)}}$ defining $\overline{Z}$. By (4.8.8.ii), a field defines $\overline{Z}$ if and only if it defines $\overline{\mathscr{J}}$, and the assertion follows from (4.8.9). □

Corollary (4.8.12). — *Let k be a field, let X and Y be two k-preschemes with Y separated, let K/k be an extension, and let $\overline{f} : X_{(K)} \to Y_{(K)}$ be a K-morphism. Then $\overline{f}$ has a smallest field of definition.*

Proof. By (4.8.8.iii), the existence of such a field is equivalent to the existence of a smallest field of definition for the graph $\overline{Z}$ of $\overline{f}$. Since $\overline{Z}$ is a closed sub-prescheme of $(X \times_k Y)_{(K)}$ (**I**, 5.4.3), the assertion follows from (4.8.11). □

Proposition (4.8.13). — *Under the hypotheses of (4.8.11) (resp. (4.8.9), (4.8.10), or (4.8.12)), suppose in addition that X is of finite type over k (resp. that X is of finite type over k and $\mathscr{F}$ is coherent; that X is of finite type over k and both $\mathscr{F}$ and $\mathscr{G}$ are coherent; or that X and Y are of finite type over k). Then the smallest field of definition of $\overline{Z}$ (resp. $\overline{\mathscr{H}}$, $\overline{u}$, or $\overline{f}$) is an extension of finite type of k.*

Proof. It is enough to treat (4.8.9), and we may assume that X is affine because it is a finite union of affine opens of finite type over k. With the notation of (4.8.6), it remains to show that if A is a k-algebra of finite type and M an A-module of finite type, then one of the fields K' satisfying the equivalent conditions of (4.8.6) may be chosen of finite type over k.

Let $(m_i)_{1\leq i\leq n}$ generate M over A. Since A is Noetherian, so is $A_{(K)}$, and the $A_{(K)}$-submodule $\overline{N}$ of $M_{(K)}$ has a finite set of generators n_j $(1 \leq j \leq r)$. Write

$$n_j = \sum_i (m_i \otimes 1) b_{ij}, \qquad b_{ij} \in A_{(K)},$$

and then

$$b_{ij} = \sum_h a_{ijh} \otimes c_{ijh}, \qquad a_{ijh} \in A, \quad c_{ijh} \in K.$$

The extension K' of k generated by the finitely many c_{ijh} has the required property. □

Proposition (4.8.14). — *Let k be a field, let X be a k-prescheme of finite type, and let K/k be an extension containing a perfect extension of k. Then the smallest field of definition of the closed sub-prescheme $(X_{(K)})_{\mathrm{red}}$ of $X_{(K)}$ is a finite radicial extension of k.*

Proof. If p is the characteristic exponent of k, the hypothesis implies that $k' = k^{p^{-\infty}}$ is contained in K. The prescheme $(X_{(k')})_{\mathrm{red}}$ is geometrically reduced over k' (4.6.1). Thus

$$(X_{(k')})_{\mathrm{red}} \otimes_{k'} K$$

is reduced and is consequently equal to $(X_{(K)})_{\mathrm{red}}$ (**I**, 5.1.8). In other words, k' is a field of definition of $(X_{(K)})_{\mathrm{red}}$. Since k'/k is algebraic, the conclusion follows from (4.8.13). □

Remarks (4.8.15). — (i) The conclusion of (4.8.14) need not hold if K is not assumed to contain a perfect extension of k. For example, let k_0

be a field of characteristic $p > 0$, let $k = k_0(s,t)$ be the field of rational functions in two indeterminates, let **IV-2** | 84

$$L = k(s^{1/p}, t^{1/p}), \qquad X = \mathrm{Spec}(L),$$

let u be a third indeterminate, and put

$$K = k\big(u, s^{1/p} + ut^{1/p}\big).$$

One readily verifies that k is algebraically closed in K and that $L \otimes_k K$ has a nonzero nilradical, so $X_{(K)}$ is not reduced. But $(X_{(K)})_{\mathrm{red}}$ is not defined over k, while K contains no intermediate extension of finite degree over k other than k itself. Hence the smallest field of definition of $(X_{(K)})_{\mathrm{red}}$ cannot be finite over k.

(ii) Given an object in one of the target sets in (4.8.2) and an extension K_1/K, the object has a smallest field of definition if and only if its image under $\varepsilon_{K_1,K}$ does; the two smallest subfields are necessarily the same, as observed in (4.8.4).

4.9. Fields of definition of subsets of a prescheme

Proposition (4.9.1). — *Let k be a field, let X be a k-prescheme, let K/k be an extension, let $\overline{T}$ be a closed subset of $X_{(K)}$, and let K' be an intermediate field of K/k. The following conditions are equivalent:*

(a) *$\overline{T}$ is defined over K'.*
(b) *The open subset $\overline{U} = X_{(K)} - \overline{T}$ of $X_{(K)}$ is defined over K'.*
(b′) *The sub-prescheme of $X_{(K)}$ induced on the open subset $\overline{U}$ is defined over K'.*
(c) *There exists a closed sub-prescheme $\overline{Z}$ of $X_{(K)}$, defined over K', whose underlying space is $\overline{T}$.*

Proof. Let $g : X_{(K)} \to X_{(K')}$ be the canonical projection. To say that $\overline{T}$ is defined over K' means that there is a closed subset T' of $X_{(K')}$ such that $\overline{T} = g^{-1}(T')$. Since

$$g^{-1}(X_{(K')} - T') = X_{(K)} - g^{-1}(T')$$

for every subset T' of $X_{(K')}$, conditions (4.9.1.a), (4.9.1.b), and (4.9.1.bprime) are equivalent.

If $\overline{Z}$, whose underlying space is $\overline{T}$, is defined over K', then

$$\overline{Z} = Z' \otimes_{K'} K$$

for a closed sub-prescheme Z' of $X_{(K')}$. If T' is the underlying space of Z', then $\overline{T} = g^{-1}(T')$ (**I**, 4.4.1); thus (4.9.1.c) implies (4.9.1.a). Conversely, if (4.9.1.a) holds, choose a closed sub-prescheme Z' of $X_{(K')}$ whose underlying space is T' (**I**, 5.2.1), and take $\overline{Z} = Z' \otimes_{K'} K$. □

Corollary (4.9.2). — *With the notation of (4.9.1), suppose that K' is a field of definition of $\overline{T}$. Every intermediate field K'' with $k \subset K'' \subset K'$ for which K'/K'' is radicial is also a field of definition of $\overline{T}$.*

Proof. The canonical projection

$$g : X_{(K')} \longrightarrow X_{(K'')}$$

is integral, surjective, and radicial, hence is a homeomorphism (2.4.5). □

Remark (4.9.3). — It follows from (4.9.2) that a closed subset $\overline{T}$ of $X_{(K)}$ need not have a smallest field of definition. For example, let $K = k(t)$, where t is an indeterminate and k is a perfect field of characteristic $p > 0$. A closed subset $\overline{F}$ of $X_{(K)}$ can have a smallest field of definition only if it is already defined over k. Indeed, for every subfield K' of K containing k with $K' \neq k$, one has $(K')^p \neq K'$, the field $(K')^p$ contains k, and $K'/(K')^p$ is radicial. Thus, if K' is a field of definition of $\overline{F}$, then so is $(K')^p$. Nevertheless, one has the following result.

IV-2 | 85

Proposition (4.9.4). — *With the notation of (4.9.1), suppose that K/K' is separable. Then K' is a field of definition of $\overline{T}$ if and only if it is a field of definition of the reduced sub-prescheme of $X_{(K)}$ whose underlying space is $\overline{T}$.*

Proof. The condition is sufficient by (4.9.1). Conversely, suppose that $\overline{T} = g^{-1}(T')$, where T' is a closed subset of $X_{(K')}$, and let Z' be the reduced sub-prescheme of $X_{(K')}$ whose underlying space is T'. Then

$$\overline{Z} = Z' \otimes_{K'} K = \operatorname{Spec}(K) \times_{K'} Z'$$

is reduced by (4.6.1.e) and the separability of K/K', and its underlying space is $\overline{T}$. □

Corollary (4.9.5). — *Suppose that one of the following hypotheses holds:*

(a) *k has characteristic zero.*
(b) *K/k is algebraic and X is of finite type over k.*

Then every closed subset $\overline{T}$ of $X_{(K)}$ has a smallest field of definition. This field is a separable extension of k, and under (4.9.5.b) it is finite over k.

Proof. Under (4.9.5.a), K is separable over each of its subfields. It follows from (4.9.4) that the fields of definition of $\overline{T}$ are exactly those of the reduced sub-prescheme of $X_{(K)}$ whose underlying space is $\overline{T}$. The assertion therefore follows from (4.8.11).

Under (4.9.5.b), the extension K is radicial over a separable extension K_1 of k. For every intermediate field K' of K/k, the extension $K'/(K' \cap K_1)$ is radicial. By (4.9.2), K' is a field of definition of $\overline{T}$ if and only if $K' \cap K_1$ is. This reduces the question to the case $K' = K_1$, hence to the case of a separable algebraic extension of k, and the argument finishes as under (4.9.5.a). □

Proposition (4.9.6). — *Let k be a field, let X be a k-prescheme, let K/k be an extension, let $\overline{U}$ be a subset of $X_{(K)}$ that is both open and closed, and let $\overline{V}$ be its complement. For an intermediate field K' of K/k, the following conditions are equivalent:*

(a) *K' is a field of definition of the subset $\overline{U}$ of $X_{(K)}$.*
(a′) *K' is a field of definition of the closed sub-prescheme of $X_{(K)}$ induced on the open subset $\overline{U}$.*
(b) *K' is a field of definition of the subset $\overline{V}$ of $X_{(K)}$.*
(b′) *K' is a field of definition of the closed sub-prescheme of $X_{(K)}$ induced on the open subset $\overline{V}$.*

Proof. It is clear that (a′) implies (a), and (a) implies (b′) by (4.9.1). Since $\overline{U}$ and $\overline{V}$ play symmetric roles, (b′) implies (b), and (b) implies (a′). □

Corollary (4.9.7). — *Under the hypotheses of (4.9.6), there is a smallest field of definition K' for the subset $\overline{U}$ of $X_{(K)}$. It is also the smallest field of definition of the subset $\overline{V}$ and of the closed sub-preschemes of $X_{(K)}$ induced on the open subsets $\overline{U}$ and $\overline{V}$. If, in addition, X is of finite type over k, then K'/k is finite and separable.*

Proof. In view of (4.9.6) and (4.8.11), only the last assertion remains to be proved. By (4.8.15.ii), we may reduce to the case in which K is algebraically closed. Let $\bar{k}$ be the algebraic closure of k contained in K, and let W_i $(1 \leq i \leq m)$ be the connected components of $X_{(\bar{k})}$.

If **IV-2 | 86**

$$p : X_{(K)} \longrightarrow X_{(\bar{k})}$$

is the canonical projection, then the $p^{-1}(W_i)$ are the connected components of $X_{(K)}$ (4.4.6). Thus $\overline{U}$ is a union of some of these components and is therefore defined over $\bar{k}$. The conclusion follows from (4.9.5.b). □

§5. Dimension, depth, and regularity in locally Noetherian preschemes

This section merely restates, in geometric language and with various technical complements, the notions and results of commutative algebra set out in Chapter 0, §§ 16 and 17. **IV-2 | 86**

5.1. Dimension of preschemes

(5.1.1). Let A be a ring and let $\mathfrak{J}$ be an ideal of A. Recall (**0**, 16.1) that the definitions in the theory of the dimension of a ring (**0**, 16.1.1) and those in the theory of the combinatorial dimension of topological spaces (**0**, 14.1.2) give the following relations:

(5.1.1.1) $$\dim(\mathrm{Spec}(A)) = \dim(A),$$

(5.1.1.2) $$\dim(\mathrm{V}(\mathfrak{J})) = \dim(A/\mathfrak{J}),$$

(5.1.1.3) $$\mathrm{codim}(\mathrm{V}(\mathfrak{J}), \mathrm{Spec}(A)) = \mathrm{ht}(\mathfrak{J}).$$

(5.1.1.4) $\mathrm{Spec}(A)$ is a catenary space if and only if A is a catenary ring.
(5.1.1.5) $\mathrm{Spec}(A)$ is equidimensional if and only if A is equidimensional, if and only if the minimal prime ideals $\mathfrak{p}_\alpha$ of A are such that the rings $A/\mathfrak{p}_\alpha$ all have the same dimension.
(5.1.1.6) $\mathrm{Spec}(A)$ is equicodimensional if and only if A is equicodimensional, if and only if all maximal ideals of A have the same height.

Recall that a Noetherian ring A is said to be *biequidimensional* if $\mathrm{Spec}(A)$ is biequidimensional; that is, if $\mathrm{Spec}(A)$ is Noetherian and A is equidimensional, equicodimensional, catenary, and of finite dimension.

Proposition (5.1.2). — *Let X be a prescheme, let Y be an irreducible closed subset of X, and let y be the generic point of Y. Then*

(5.1.2.1) $$\mathrm{codim}(Y, X) = \dim(\mathscr{O}_{X,y}).$$

Proof. Indeed, the irreducible closed subsets of X containing y are canonically in bijection with the irreducible closed subsets of $\mathrm{Spec}(\mathscr{O}_{X,y})$ (**I**, 2.4.2), and hence with the prime ideals of $\mathscr{O}_{X,y}$; formula (5.1.2.1) follows from the definitions.

In particular, this recovers the fact that the generic points of the irreducible components of X are the only points $x \in X$ such that $\dim(\mathscr{O}_x) = 0$ (**I**, 1.1.14). □

IV-2 | 87

Corollary (5.1.3). — *For every closed subset Y of a prescheme X, one has*

(5.1.3.1) $$\mathrm{codim}(Y, X) = \inf_{y \in Y} \dim(\mathscr{O}_{X,y}).$$

Moreover, if X is locally Noetherian, then for every $x \in Y$,

(5.1.3.2) $$\mathrm{codim}_x(Y, X) = \inf_{\substack{y \in Y \\ x \in \overline{\{y\}}}} \dim(\mathscr{O}_{X,y}).$$

Proof. Formula (5.1.3.2) follows from (5.1.3.1) and (**0**, 14.2.6). This corollary allows us to *define*, for any subset Y of a prescheme X, the *codimension* $\mathrm{codim}(Y, X)$ of Y in X to be the right-hand side of (5.1.3.1). □

Proposition (5.1.4). — *For every prescheme X, one has*

(5.1.4.1) $$\dim(X) = \sup_{x \in X} \dim(\mathscr{O}_x).$$

If every irreducible closed subset of X contains a closed point, then one also has

(5.1.4.2) $$\dim(X) = \sup_{x \in F} \dim(\mathscr{O}_x),$$

where F is the set of closed points of X.

Proof. It suffices to observe, by (**I**, 2.4.2), that the chains of irreducible closed subsets of X correspond bijectively to the chains of irreducible closed subsets of a local scheme of X. When every irreducible closed subset of X contains a closed point, one may plainly restrict to the local schemes at closed points of X.

Every irreducible closed subset of X contains a closed point when X is quasi-compact (**0**, 2.1.3); we shall see below (5.1.11) that the same is true when X is locally Noetherian. □

Corollary (5.1.5). — *A prescheme X is catenary if and only if the local ring $\mathscr{O}_x$ is catenary for every $x \in X$. If, in addition, every irreducible closed subset of X contains a closed point, then for X to be catenary it is enough that $\mathscr{O}_x$ be catenary for every closed point x of X.*

Proof. The argument is the same as in (5.1.4), since it is a matter of comparing chains of irreducible closed subsets with the same endpoints. □

(5.1.6). We now examine the more special properties tied to Noetherian hypotheses.

Recall (**0**, 16.2.3) that a Noetherian local ring $A \neq 0$ has finite dimension, equal to the minimum number of generators of an ideal of definition of A. For every prime ideal $\mathfrak{p}$ of A, its height, equal to $\dim(A_{\mathfrak{p}})$, is therefore also finite. Together with (5.1.2.1), (5.1.3.1), and (5.1.4.1), these facts show the following.

Proposition (5.1.7). — *For every nonempty closed subset Y of a locally Noetherian prescheme X, the number* $\operatorname{codim}(Y, X)$ *is finite. If X is Noetherian and affine and Y is an irreducible closed subset of X, then* $\operatorname{codim}(Y, X)$ *is the minimum number of sections s_i of $\mathscr{O}_X$ over X such that Y is an irreducible component of the set of points $x \in X$ for which $s_i(x) = 0$ for every i.*

Corollary (5.1.8). — *Let X be a locally Noetherian prescheme, let $\mathscr{L}$ be an invertible $\mathscr{O}_X$-module, and let f be a section of $\mathscr{L}$ over X. Every irreducible component of the set Z of points $x \in X$ such that $f(x) = 0$ has codimension at most 1 in X; it has codimension 1 if Z contains no irreducible component of X.*

Proof. We may restrict to the case $\mathscr{L} = \mathscr{O}_X$. If y is a generic point of an irreducible component Y of Z, the ideal (f_y) of $\mathscr{O}_{X,y}$ must be such that $\mathscr{O}_{X,y}/(f_y)$ has only one prime ideal. Thus f_y generates an ideal of definition of the Noetherian local ring $\mathscr{O}_{X,y}$, and $\operatorname{codim}(Y, X) \leqslant 1$ by (5.1.7). If Z contains no irreducible component of X, then $\operatorname{codim}(Y, X)$ cannot be 0 by (**0**, 14.2.1). □

IV-2 | 88

Proposition (5.1.9). — *Let X be a locally Noetherian prescheme and let Y be a closed subset of X. If $x \in Y$ and $\mathscr{O}_{X,x}$ is a catenary ring, then*

$$\begin{aligned} \operatorname{codim}_x(Y, X) &= \dim(\mathscr{O}_{X,x}) - \operatorname{codim}(\overline{\{x\}}, Y) \\ &= \dim(\mathscr{O}_{X,x}) - \dim(\mathscr{O}_{Y,x}). \end{aligned} \tag{5.1.9.1}$$

Proof. Let Y_i ($1 \leqslant i \leqslant n$) be the irreducible components of Y containing x; there are only finitely many because Y is locally Noetherian. Let y_i be the generic point of Y_i. Put $A = \mathscr{O}_{X,x}$, and let $\mathfrak{p}_i$ be the prime ideal of A corresponding to $Y_i \cap \operatorname{Spec}(A)$. The irreducible closed subsets of Y containing x correspond bijectively to the prime ideals of A containing one of the $\mathfrak{p}_i$, so

$$\dim(\mathscr{O}_{Y,x}) = \sup_i \dim(A/\mathfrak{p}_i).$$

On the other hand, $\mathscr{O}_{X,y_i} = A_{\mathfrak{p}_i}$, and the hypothesis on A gives

$$\dim(A) = \dim(A/\mathfrak{p}_i) + \dim(A_{\mathfrak{p}_i})$$

by (**0**, 16.1.4). The conclusion follows from

$$\operatorname{codim}_x(Y, X) = \inf_i \dim(\mathscr{O}_{X,y_i})$$

using (5.1.2.1) and (**0**, 14.2.6). □

Proposition (5.1.10). — (i) *In every prescheme X, every nonempty locally constructible subset E contains a point x such that $\{x\}$ is locally closed in X; equivalently, x is isolated in $\overline{\{x\}}$.*

(ii) *Let X be a locally Noetherian prescheme and let $x \in X$ be such that $\{x\}$ is locally closed in X. Then* $\dim(\overline{\{x\}}) \leqslant 1$*; consequently, every point $y \neq x$ of $\overline{\{x\}}$ is closed in X.*

Proof. (5.1.10.i) is a special case of the following lemma. □

Lemma (5.1.10.1). — *Let X be a topological space with the following property: for every nonempty locally closed subset Z of X, there exist a subset Z' of Z, locally closed in X (or, equivalently, in Z), and a point $x \in Z'$ that is closed in Z'. Then every nonempty locally closed subset Z of X contains a point x isolated in $\overline{\{x\}}$.*

Proof. Let $Z' \subset Z$ be a locally closed subset of Z containing a point x that is closed in Z'. There is an open neighbourhood U of x in X such that x is closed in U; hence

$$U \cap \overline{\{x\}} = \{x\},$$

which says precisely that x is isolated in $\overline{\{x\}}$.

The lemma applies to the underlying space of every prescheme X. Indeed, Z is then itself the underlying space of a prescheme (**I**, 5.2.1), and one may take for Z' an affine open subset of Z, which is a quasi-compact Kolmogorov space and therefore contains a closed point (**0**, 2.1.3). □

Proof of (5.1.10.ii). Let Z be the reduced sub-prescheme of X whose underlying space is $\overline{\{x\}}$. The hypothesis implies that $\{x\}$ is open in Z. Thus, for every $z \in Z$, the generic point x of $\operatorname{Spec}(\mathscr{O}_{Z,z})$ is isolated in $\operatorname{Spec}(\mathscr{O}_{Z,z})$. The ring $A = \mathscr{O}_{Z,z}$ is a Noetherian local integral domain, and the hypothesis implies that there exists $f \in A$ such that A_f is a field. It follows from (**0**, 16.3.3) that $\dim(A) \leqslant 1$. Since $\dim(\mathscr{O}_{Z,z}) \leqslant 1$ for every $z \in Z$, one has $\dim(Z) \leqslant 1$. □

Corollary (5.1.11). — *If X is a locally Noetherian prescheme, every nonempty closed subset of X contains a closed point.*

Proof. Every closed subset of X is constructible (**0**, 9.1.1) and (**0**, 9.1.5), so it suffices to apply (5.1.10). □

(5.1.12). Let X be a prescheme, let $\mathscr{F}$ be a quasi-coherent $\mathscr{O}_X$-module of finite type, and let $S = \operatorname{Supp}(\mathscr{F})$ be its support, which is closed in X (**0**, 5.2.2). For every $x \in X$, regard $\operatorname{Supp}(\mathscr{F}_x)$ as a closed subset of the local scheme $\operatorname{Spec}(\mathscr{O}_x)$. By definition (**0**, 16.1.7),

$$\dim(\mathscr{F}_x) = \dim(\operatorname{Supp}(\mathscr{F}_x)).$$

But

$$\operatorname{Supp}(\mathscr{F}_x) = S \cap \operatorname{Spec}(\mathscr{O}_{X,x}) = \operatorname{Spec}(\mathscr{O}_{S,x}),$$

where in the last expression S denotes any closed sub-prescheme of X whose underlying space is S. The irreducible components of $\operatorname{Spec}(\mathscr{O}_{S,x})$ are the intersections of $\operatorname{Spec}(\mathscr{O}_{X,x})$ with the irreducible components of S containing x, and correspond bijectively to the latter. Hence, by (5.1.1.1),

$$\dim(\mathscr{F}_x) = \dim(\mathscr{O}_{S,x}). \tag{5.1.12.1}$$

It also follows from (5.1.2.1) that, if X is locally Noetherian,

$$\dim(\mathscr{F}_x) = \operatorname{codim}(\overline{\{x\}}, S). \tag{5.1.12.2}$$

We say that $\mathscr{F}$ is *equidimensional at the point $x \in X$* if $\mathscr{F}_x$ is an equidimensional $\mathscr{O}_{X,x}$-module; that is (**0**, 16.1.7), if $\operatorname{Supp}(\mathscr{F}_x)$ is equidimensional as a closed subset of $\operatorname{Spec}(\mathscr{O}_{X,x})$. Equivalently, the ring $\mathscr{O}_{S,x}$ is equidimensional.

The *dimension* of $\mathscr{F}$, denoted $\dim(\mathscr{F})$, is the dimension of its support $\operatorname{Supp}(\mathscr{F})$. Equations (5.1.4.1) and (5.1.12.1) give

$$\dim(\mathscr{F}) = \sup_{x \in X} \dim(\mathscr{F}_x). \tag{5.1.12.3}$$

If $X = \operatorname{Spec}(A)$ is affine and $\mathscr{F} = \widetilde{M}$, where M is a finite A-module, then $\dim(\mathscr{F}) = \dim(M)$ by (**0**, 16.1.7) and (5.1.4.1).

Proposition (5.1.13). — *Let X be a prescheme, let $\mathscr{F}$ be a quasi-coherent $\mathscr{O}_X$-module of finite type, let $x \in X$, and let x' be a generization of x in X. Then*

$$\dim(\mathscr{F}_{x'}) \leqslant \dim(\mathscr{F}_x). \tag{5.1.13.1}$$

Proof. This follows immediately from (5.1.12.1) and the definitions. □

5.2. Dimension of an algebraic prescheme **IV-2 | 90**

Proposition (5.2.1). — *Let k be a field, let X be an irreducible prescheme locally of finite type over k, and let ξ be its generic point. Then X is biequidimensional and*

$$\dim(X) = \operatorname{tr.deg}_k \kappa(\xi).$$

Proof. Every local ring $\mathscr{O}_x$ is a local ring of a finite-type k-algebra, hence is a quotient of a regular local ring (**0**, 17.3.9). Such rings are catenary (**0**, 16.5.12); consequently X is a catenary space (5.1.5). Since X is irreducible, it follows from (5.1.1) that it is enough to prove, for every closed point $x \in X$, that

(5.2.1.1) $$\dim(\mathscr{O}_x) = \operatorname{tr.deg}_k \kappa(\xi).$$

We may plainly suppose that X is reduced and affine, hence integral, with ring A, where A is a finite-type k-algebra. Put

$$n = \operatorname{tr.deg}_k \kappa(\xi), \qquad K = \kappa(\xi) = \operatorname{Frac}(A).$$

There exists a k-subalgebra

$$B = k[t_1, \ldots, t_n] \subset A,$$

where the t_i are algebraically independent over k, such that A is a finite B-algebra (Bourbaki, *Algèbre commutative*, chap. V, § 3, n° 1, th. 1). Let $\mathfrak{m} = \mathfrak{j}_x$, which is maximal by hypothesis. Then $\mathfrak{n} = B \cap \mathfrak{m}$ is a maximal ideal of B (ibid., chap. V, § 2, n° 1, prop. 1), and $A_\mathfrak{m}$ is a local ring of the finite $B_\mathfrak{n}$-algebra $S^{-1}A$, where $S = B - \mathfrak{n}$. Since $B_\mathfrak{n}$ is integrally closed and $S^{-1}A$ is integral,

$$\dim(A_\mathfrak{m}) = \dim(B_\mathfrak{n})$$

by (**0**, 16.1.6).

We may therefore reduce to $A = k[t_1, \ldots, t_n]$. The residue field $k' = \kappa(x)$ is then a finite extension of k (**I**, 6.4.2). Put $A' = k'[t_1, \ldots, t_n]$. By (**I**, 2.4.6) and (**I**, 3.3.14), there exists a maximal ideal $\mathfrak{m}'$ of A' lying above $\mathfrak{m}$ such that k' is the residue field of $A'_{\mathfrak{m}'}$. Since A' is integral and finite over A, the preceding argument gives

$$\dim(A'_{\mathfrak{m}'}) = \dim(A_\mathfrak{m}),$$

so we are reduced to the case $A/\mathfrak{m} = k$.

In that case $\mathfrak{m}$ is generated by the polynomials $t_i - a_i$, where $a_i \in k$ is the image of t_i in $A/\mathfrak{m}$. Replacing t_i by $t_i - a_i$, we are finally reduced to

$$\mathfrak{m} = \sum_{i=1}^{n} At_i.$$

The completion of $A_\mathfrak{m}$ is then the formal power-series ring $k[[t_1, \ldots, t_n]]$. It has the same dimension as $A_\mathfrak{m}$ (**0**, 16.2.4), while $\dim(k[[t_1, \ldots, t_n]]) = n$ by (**0**, 17.1.4). This proves (5.2.1.1). □

Corollary (5.2.2). — *For a prescheme X locally of finite type over a field k, $\dim(X)$ agrees with the number defined in (4.1.1).*

Proof. Let X_α be the reduced sub-preschemes whose underlying spaces are the irreducible components of X. Then

$$\dim(X) = \sup_\alpha \dim(X_\alpha)$$

by (**0**, 14.1.2.1), and it suffices to apply (5.2.1) to the X_α. □

Corollary (5.2.3). — *Let X be a prescheme locally of finite type over a field k, and let $x \in X$. Then*

(5.2.3.1) $$\dim_x(X) = \dim(\mathscr{O}_x) + \operatorname{tr.deg}_k \kappa(x).$$

Proof. There is an open neighbourhood U of x in X such that $\dim_x(X) = \dim(U)$ (**0**, 14.1.4.1). We may suppose that the irreducible components of U are the $X_i \cap U$, where the X_i are the irreducible components of X containing x.

Since $U \cap X_i$ is dense in X_i, formula (4.1.1.3) gives $\dim(X_i) = \dim(U \cap X_i)$, and hence **IV-2 | 91**

$$\dim_x(X) = \sup_i \dim(X_i).$$

The minimal prime ideals of $\mathscr{O}_x$ correspond to the generic points of the X_i, so

$$\dim(\mathscr{O}_{X,x}) = \sup_i \dim(\mathscr{O}_{X_i,x})$$

by (**0**, 16.1.1.1). We are therefore reduced to the case where X is irreducible. Since X is biequidimensional by (5.2.1),

$$\dim(X) = \dim(\overline{\{x\}}) + \operatorname{codim}(\overline{\{x\}}, X)$$

by (**0**, 14.3.5.1). Finally,

$$\dim(\overline{\{x\}}) = \operatorname{tr.deg}_k \kappa(x)$$

by (5.2.1), while

$$\operatorname{codim}(\overline{\{x\}}, X) = \dim(\mathscr{O}_x)$$

by (5.1.2). □

Corollary (5.2.4). — *Let X be a prescheme locally of finite type over a field k, let $\mathscr{L}$ be an invertible $\mathscr{O}_X$-module, and let f be a section of $\mathscr{L}$ over X such that the set*

$$Y = \{x \in X \mid f(x) = 0\}$$

is rare in X. Then

$$\dim(Y) \leqslant \dim(X) - 1.$$

Equality holds if Y meets every irreducible component of X having maximum dimension.

Proof. If (X_α) is the family of irreducible components of X, then

$$\dim(Y) = \sup_\alpha \dim(Y \cap X_\alpha).$$

We are therefore reduced to the case where X is irreducible, because $Y \cap X_\alpha$ is rare in X_α and every X_α has nonempty interior in X. We may also suppose that $Y \neq \varnothing$. For every maximal point x of Y, biequidimensionality gives

$$\dim(\overline{\{x\}}) = \dim(X) - \operatorname{codim}(\overline{\{x\}}, X).$$

Since Y is rare in X,

$$\operatorname{codim}(\overline{\{x\}}, X) = 1$$

by (5.1.8), and the result follows. □

Remarks (5.2.5). — (i) Unlike an algebraic k-prescheme, a locally Noetherian prescheme X need not be catenary; see (5.6.11). It is catenary, however, if all its local rings $\mathscr{O}_x$ are quotients of regular local rings (**0**, 16.5.12), and in particular if X is regular (**I**, 4.1.4).

Nevertheless, even an integral scheme $X = \operatorname{Spec}(A)$ with A regular need not be biequidimensional. In other words, the closed points of X need not all have the same codimension (**0**, 14.3.3). For example, let B be a discrete valuation ring, let $\mathfrak{m} = B\pi$ be its maximal ideal, let $k = B/\mathfrak{m}$ be its residue field, let K be its fraction field, and put $A = B[T]$. The ring A has maximal ideals of height 2, such as $(\pi) + (T)$, but also maximal ideals of height 1, such as the principal ideal $(\pi T - 1)$. Indeed, a nonzero principal prime ideal has height 1 (5.1.8), while

$$A/(\pi T - 1) \simeq B_\pi = K$$

by (**0**, 1.2.3); thus $(\pi T - 1)$ is maximal and has height 1.

(ii) If X is locally of finite type over a field, then $\dim(U) = \dim(X)$ for every dense open subset U of X (4.1.1.3). This does not extend to regular Noetherian preschemes, even when they are biequidimensional. For example, let B be a discrete valuation ring with maximal ideal $\mathfrak{m}$. Then $X = \operatorname{Spec}(B)$ has two points, (0) and $\mathfrak{m}$, the latter being its only closed point. One has $\dim(X) = 1$, whereas the open subset $U = \{(0)\}$ has dimension 0 (see § 10).[9]

[9] The printed French text has $X = \operatorname{Spec}(A)$ here; the ring just specified, and the asserted two-point spectrum, require $X = \operatorname{Spec}(B)$.

5.3. Dimension of the support of a module and Hilbert polynomial This section uses the results of Chapter III; it will not be used in the remainder of this chapter. **IV-2 | 92**

Proposition (5.3.1). — *Let A be an Artinian local ring, let X be a projective scheme over* $\operatorname{Spec}(A)$*, let $\mathscr{L}$ be an invertible $\mathscr{O}_X$-module that is very ample relative to A, and let $\mathscr{F}$ be a nonzero coherent $\mathscr{O}_X$-module. Put*

$$\mathscr{F}(n) = \mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{L}^{\otimes n} \qquad (n \in \mathbf{Z}).$$

Then the degree of the Hilbert polynomial

$$P(n) = \chi_A(\mathscr{F}(n))$$

of $\mathscr{F}$ relative to A (**III**, 2.5.3) *equals* $\dim(\operatorname{Supp}(\mathscr{F}))$.

Proof. We argue by induction on

$$d = \dim(\operatorname{Supp}(\mathscr{F})).$$

There is a closed subprescheme Y of X whose underlying space is $\operatorname{Supp}(\mathscr{F})$, together with a coherent $\mathscr{O}_Y$-module $\mathscr{G}$ such that $\mathscr{F} = j_*(\mathscr{G})$, where $j : Y \to X$ is the canonical injection (**Err**$_{\mathbf{III}}$, 30). The Hilbert polynomials of $\mathscr{F}$ and $\mathscr{G}$ are plainly the same, so we may restrict to the case $X = \operatorname{Supp}(\mathscr{F})$.

Suppose first that $d = 0$. Every point of X is then closed, and X is an Artinian scheme (**I**, 6.2.2); hence $\mathscr{F}(n) = \mathscr{F}$ for every integer n. Consequently, by (**III**, 2.5.3),

$$\chi_A(\mathscr{F}(n)) = \operatorname{length}_A(\Gamma(X, \mathscr{F}))$$

for all sufficiently large n, and the Hilbert polynomial therefore has degree 0.

Suppose now that $d > 0$, and put $Z = \operatorname{Ass}(\mathscr{F})$, a finite set (3.1.6). There are an integer $m > 0$ and a section $f \in \Gamma(X, \mathscr{L}^{\otimes m})$ such that X_f is a neighbourhood of Z (**II**, 4.5.4). Multiplication by f is an injective homomorphism

$$\mu_f : \mathscr{F} \longrightarrow \mathscr{F}(m)$$

by (3.1.8); thus there is an exact sequence

(5.3.1.1) $$0 \longrightarrow \mathscr{F} \xrightarrow{\mu_f} \mathscr{F}(m) \longrightarrow \mathscr{G} \longrightarrow 0,$$

where $\mathscr{G}$ is coherent. By Nakayama's lemma, the points $x \in \operatorname{Supp}(\mathscr{G})$ are exactly those for which $f(x) = 0$. We shall deduce that

(5.3.1.2) $$\dim(\operatorname{Supp}(\mathscr{G})) = d - 1.$$

This follows from the next lemma. □

Lemma (5.3.1.3). — *Let A be an Artinian local ring, let X be a projective scheme over* $\operatorname{Spec}(A)$*, and let $\mathscr{L}$ be an invertible $\mathscr{O}_X$-module that is ample relative to A. For every section g of $\mathscr{L}$ over X, the set*

$$X \setminus X_g = \{x \in X \mid g(x) = 0\}$$

meets every irreducible component of X having nonzero dimension.

Proof. Indeed, X_g is an affine open subset of X (**II**, 5.5.7). If it contains an irreducible component X' of X, the reduced closed subprescheme of X whose underlying space is X' is both projective and affine over A, hence finite over A (**III**, 4.4.2). It is therefore an Artinian scheme and has dimension 0. □

Proof of (5.3.1), *continued.* Since Z contains the maximal points of X, the open subset X_f is dense; hence $\operatorname{Supp}(\mathscr{G})$ is rare in X. Equation (5.3.1.2) now follows from the lemma and (5.2.4).

From the exact sequence (5.3.1.1), for every n we obtain the exact sequence **IV-2 | 93**

$$0 \longrightarrow \mathscr{F}(n) \longrightarrow \mathscr{F}(n+m) \longrightarrow \mathscr{G}(n) \longrightarrow 0.$$

For all sufficiently large n, there is therefore also an exact sequence (**III**, 2.2.3)

$$0 \longrightarrow \Gamma(X, \mathscr{F}(n)) \longrightarrow \Gamma(X, \mathscr{F}(n+m)) \longrightarrow \Gamma(X, \mathscr{G}(n)) \longrightarrow 0.$$

Taking (**III**, 2.5.3) into account, we have, for all sufficiently large n,

$$\chi_A(\mathscr{G}(n)) = \chi_A(\mathscr{F}(n+m)) - \chi_A(\mathscr{F}(n)).$$

By (5.3.1.2) and the induction hypothesis, the polynomial $\chi_A(\mathscr{G}(n))$ has degree $d - 1$. The preceding relation therefore implies that $\chi_A(\mathscr{F}(n))$ has degree d. □

5.4. Dimension of the image of a morphism

Proposition (5.4.1). — *Let X and Y be locally Noetherian preschemes, and let $f : X \to Y$ be a morphism.*

(i) *If f is quasi-finite, then*

$$\dim(X) \leqslant \dim(\overline{f(X)}) \leqslant \dim(Y).$$

(ii) *If f is surjective and open (respectively, surjective and closed), then*

$$\dim(X) \geqslant \dim(Y).$$

Proof. (i) We may replace f by f_{red} (**II**, 6.2.4), and therefore suppose that X and Y are reduced. Let Z be the reduced closed subprescheme of Y whose underlying space is $\overline{f(X)}$. Then $f = j \circ g$, where $j : Z \to Y$ is the canonical injection and $g : X \to Z$ is quasi-finite (**I**, 5.2.2), (**II**, 6.2.4). We may thus restrict to the case in which $f(X)$ is dense in Y.

For every $x \in X$, the ring $\mathscr{O}_x$ is then a quasi-finite $\mathscr{O}_{f(x)}$-module (**II**, 6.2.2); consequently

$$\mathfrak{m}_{f(x)}\mathscr{O}_x$$

is an ideal of definition of $\mathscr{O}_x$ (**0**, 7.4.4). If $A \to B$ is a local homomorphism of Noetherian local rings, with maximal ideal $\mathfrak{m}$ of A, and if $\mathfrak{m}B$ is an ideal of definition of B, then

$$\dim(B) \leqslant \dim(A)$$

by (**0**, 16.3.10). Part (i) now follows from (5.1.4).

(ii) By the definition of dimension (**0**, 14.1.2), it is enough to prove the following. For every sequence $(y_i)_{0 \leqslant i \leqslant n}$ of distinct points of Y such that

$$y_i \in \overline{\{y_{i+1}\}} \qquad (0 \leqslant i \leqslant n-1),$$

there is a sequence $(x_i)_{0 \leqslant i \leqslant n}$ of points of X such that

$$x_i \in \overline{\{x_{i+1}\}} \qquad (0 \leqslant i \leqslant n-1)$$

and $f(x_i) = y_i$ for every i.

Suppose first that f is surjective and open. We construct the x_i by induction on i. Surjectivity gives an $x_0 \in X$ such that $f(x_0) = y_0$. Suppose the x_i have been chosen for $i \leqslant m$ so that $f(x_i) = y_i$ for $i \leqslant m$ and $x_i \in \overline{\{x_{i+1}\}}$ for $i < m$. Since f is open and y_{m+1} is a generization of y_m, there is an $x_{m+1} \in f^{-1}(y_{m+1})$ that is a generization of x_m (1.10.3). The induction therefore continues.

Suppose now that f is surjective and closed. We construct the x_i by descending induction on i. Surjectivity gives an x_n such that $f(x_n) = y_n$. Suppose the x_i have been chosen with the required properties for $i > m$. Because f is closed, **IV-2 | 94**

$$f(\overline{\{x_{m+1}\}}) = \overline{\{f(x_{m+1})\}} = \overline{\{y_{m+1}\}}$$

(Bourbaki, *Topologie générale*, chap. I, 3rd ed., § 5, n° 4, prop. 9). There is therefore an $x_m \in \overline{\{x_{m+1}\}}$ such that $f(x_m) = y_m$, and the descending induction continues.

□

Corollary (5.4.2). — *Let X and Y be locally Noetherian preschemes, and let $f : X \to Y$ be a finite morphism, hence a closed morphism. Then*

$$\dim(X) = \dim(\overline{f(X)}).$$

If f is moreover surjective, then $\dim(X) = \dim(Y)$.

Remarks (5.4.3). — (i) We saw in (4.1.2) that if X and Y are preschemes locally of finite type over a field k, and f is a k-morphism, the inequality

$$\dim(Y) \leqslant \dim(X)$$

already holds when f is quasi-compact and dominant. By contrast, if one assumes only that X and Y are locally Noetherian, it is possible to have $\dim(Y) > \dim(X)$ even when f is of finite type, bijective, and a local immersion.

For example, let A be a discrete valuation ring, let K be its fraction field, and let k be its residue field. Put $Y = \mathrm{Spec}(A)$, and denote by a the generic point of Y and by b its closed point; thus $\kappa(a) = K$ and $\kappa(b) = k$. Let

$$X = \mathrm{Spec}(K) \amalg \mathrm{Spec}(k),$$

and let $f : X \to Y$ agree on the two summands with the respective canonical morphisms (**I**, 2.4.5). The morphism f is plainly a bijective local immersion, since $\{a\}$ is open in Y. It is also of finite type: if π is a uniformizer of A, then $K = A[\pi^{-1}]$, so K is a finitely generated A-algebra. Nevertheless,

$$\dim(X) = 0 \qquad \text{and} \qquad \dim(Y) = 1.$$

(ii) Let $A \subset B$ be Noetherian rings, with B a finite A-algebra. Corollary (5.4.2) again gives

$$\dim(B) = \dim(A)$$

(**0**, 16.1.5). Suppose in addition that A is a Noetherian local ring. Then B is a Noetherian semilocal ring (Bourbaki, *Algèbre commutative*, chap. IV, § 2, n° 5, cor. 3 of prop. 9). If $\mathfrak{n}_i$ $(1 \leqslant i \leqslant r)$ are the maximal ideals of B, then

(5.4.3.1) $$\dim(A) = \sup_i \dim(B_{\mathfrak{n}_i}).$$

Under these hypotheses one need not have

$$\dim(B_{\mathfrak{n}_i}) = \dim(A)$$

for every i; replacing B by the direct product of B with the residue field k of A gives an immediate example. There are even examples in which A and B are integral domains of dimension 2 and some of the $B_{\mathfrak{n}_i}$ have dimension strictly less than $\dim(A)$ (5.6.11). We shall see later, in (5.6.4) and (5.6.10), that this last phenomenon cannot occur when A is a quotient of a regular local ring.

5.5. Dimension formula for a morphism of finite type

(5.5.1). **IV-2 | 94**

Recall (**0**, 16.3.9) that if A and B are Noetherian local rings, k is the residue field of A, and $\varphi : A \to B$ is a local homomorphism, then

(5.5.1.1) $$\dim(B) \leqslant \dim(A) + \dim(B \otimes_A k).$$

We deduce the following.

Proposition (5.5.2). — *Let X and Y be locally Noetherian preschemes, let $f : X \to Y$ be a morphism, let $x \in X$, and put $y = f(x)$. Then*

(5.5.2.1) $$\dim(\mathscr{O}_x) \leqslant \dim(\mathscr{O}_y) + \dim\big(\mathscr{O}_x \otimes_{\mathscr{O}_y} \kappa(y)\big).$$

In particular, if x is a maximal point of the fibre $f^{-1}(y)$, then

(5.5.2.2) $$\dim(\mathscr{O}_x) \leqslant \dim(\mathscr{O}_y),$$

because

$$\mathscr{O}_x \otimes_{\mathscr{O}_y} \kappa(y) = \mathscr{O}_x / \mathfrak{m}_y \mathscr{O}_x$$

is the local ring of x in the prescheme $f^{-1}(y)$ and therefore has dimension 0.

We shall now obtain a formula more precise than (5.5.2.1) when f is assumed to be of finite type. **IV-2 | 95**

Proposition (5.5.3). — *Let A be a Noetherian ring, let T be an indeterminate, and let $\mathfrak{p}$ be a prime ideal of A. Then*

$$\mathfrak{p}' = \mathfrak{p}A[T]$$

is a prime ideal of $B = A[T]$, and $\mathfrak{p}' \cap A = \mathfrak{p}$. There are infinitely many prime ideals of B, distinct from $\mathfrak{p}'$, whose intersection with A is $\mathfrak{p}$; these prime ideals are pairwise incomparable. Moreover, if $\mathfrak{q}$ is any such ideal, then

(5.5.3.1) $$\dim(B_{\mathfrak{q}}) = \dim(B_{\mathfrak{p}'}) + 1 = \dim(A_{\mathfrak{p}}) + 1.$$

Proof. For the first assertions, replacing A by $A/\mathfrak{p}$ and using

$$A[T]/\mathfrak{p}A[T] = (A/\mathfrak{p})[T]$$

reduces us immediately to the case $\mathfrak{p} = 0$. The prime ideals of $B = A[T]$ whose intersection with A is 0 are exactly those disjoint from the multiplicative set $S = A - \{0\}$ of the domain A. There is an inclusion-preserving bijection from this set of prime ideals to the prime ideals of

$$S^{-1}A[T] = K[T],$$

where K is the fraction field of A (Bourbaki, *Algèbre commutative*, chap. II, § 2, n° 5, prop. 11). The assertions follow.

Furthermore, by (5.5.1.1),[10]

$$\dim(B_{\mathfrak{q}}) \leqslant \dim(A_{\mathfrak{p}}) + \dim(B_{\mathfrak{q}}/\mathfrak{p}B_{\mathfrak{q}}).$$

Let k be the fraction field of $A/\mathfrak{p}$. The ring $B_{\mathfrak{q}}/\mathfrak{p}B_{\mathfrak{q}}$ is canonically identified with

$$(k[T])_{\overline{\mathfrak{q}}},$$

where $\overline{\mathfrak{q}}$ is a nonzero prime ideal of $k[T]$. It is therefore a discrete valuation ring and has dimension 1. Thus

$$\dim(B_{\mathfrak{q}}) \leqslant \dim(A_{\mathfrak{p}}) + 1.$$

Let

$$\mathfrak{p} = \mathfrak{p}_0 \supset \mathfrak{p}_1 \supset \cdots \supset \mathfrak{p}_m$$

be a chain of prime ideals of A of maximum length. The ideals $\mathfrak{p}_j B$ $(0 \leqslant j \leqslant m)$ are prime in B, pairwise distinct, and contained in $\mathfrak{q}$. Hence

$$\dim(B_{\mathfrak{q}}) \geqslant m + 1 = \dim(A_{\mathfrak{p}}) + 1.$$

It follows that

$$\operatorname{ht}(\mathfrak{q}) = \operatorname{ht}(\mathfrak{p}) + 1.$$

Since $\mathfrak{q} \neq \mathfrak{p}'$, we also have

$$\operatorname{ht}(\mathfrak{q}) \geqslant \operatorname{ht}(\mathfrak{p}') + 1 \geqslant \operatorname{ht}(\mathfrak{p}) + 1.$$

All these inequalities are equalities, and (5.5.3.1) follows. □

Corollary (5.5.4). — *For every Noetherian ring A,*

(5.5.4.1) $$\dim(A[T_1, \dots, T_r]) = \dim(A) + r,$$

where the T_i are indeterminates.

By contrast, there are examples of non-Noetherian local rings A such that

$$\dim(A) = 1 \qquad \text{and} \qquad \dim(A[T]) = 3$$

[30].

Corollary (5.5.5). — *For every locally Noetherian prescheme X, the dimension of*

$$X[T_1, \dots, T_r] = X \otimes_{\mathbf{Z}} \mathbf{Z}[T_1, \dots, T_r],$$

where the T_i are indeterminates, is $\dim(X) + r$.

Proof. This follows from (5.5.4) and (**0**, 14.1.7). □

Corollary (5.5.6). — *Under the hypotheses of (5.5.3), let $\mathfrak{q}$ be a prime ideal of $B = A[T]$ such that $\mathfrak{q} \cap A = \mathfrak{p}$. If k and k' are the residue fields of $A_{\mathfrak{p}}$ and $B_{\mathfrak{q}}$, respectively, then*

(5.5.6.1) $$\dim(A_{\mathfrak{p}}) + 1 = \dim(B_{\mathfrak{q}}) + \operatorname{tr.deg}_k k'.$$

[10] The printed French text cites *(5.5.1.2)*, which does not exist. The displayed inequality used here is *(5.5.1.1)*.

Proof. **IV-2** | 96

If $\mathfrak{q} = \mathfrak{p}B$, then

$$\dim(B_{\mathfrak{q}}) = \dim(A_{\mathfrak{p}})$$

by (5.5.3.1), while $k' = k(T)$. Thus (5.5.6.1) holds. If $\mathfrak{q} \neq \mathfrak{p}B$, then

$$\dim(B_{\mathfrak{q}}) = \dim(A_{\mathfrak{p}}) + 1,$$

and $\mathfrak{q}$ corresponds to a nonzero prime ideal of $k[T]$. Consequently k' is algebraic over k, and (5.5.6.1) again holds. □

Lemma (5.5.7). — *Let A be a Noetherian local domain, let $\mathfrak{m}$ be its maximal ideal, and let k be its residue field.*

(i) *Let B be a domain containing A such that $B = A[x]$ for some $x \in B$, and let $\mathfrak{q}$ be a prime ideal of B such that $\mathfrak{q} \cap A = \mathfrak{m}$. Then*

(5.5.7.1)
$$\dim(A) + \operatorname{tr.deg}_A B \geqslant \dim(B_{\mathfrak{q}}) + \operatorname{tr.deg}_k k',$$

where k' is the residue field of $B_{\mathfrak{q}}$ and $\operatorname{tr.deg}_A B$ denotes the transcendence degree of the fraction field of B over that of A.

(ii) *Suppose that for every maximal ideal $\mathfrak{n}$ of $A[T]$ such that $\mathfrak{n} \cap A = \mathfrak{m}$, the ring $(A[T])_{\mathfrak{n}}$ is catenary. Then the two sides of (5.5.7.1) are equal.*

Proof. (i) If x is transcendental over the fraction field of A, then $\operatorname{tr.deg}_A B = 1$, and the two sides of (5.5.7.1) are equal by (5.5.6).

Suppose instead that x is algebraic over the fraction field of A. Then

$$B = A[T]/\mathfrak{p},$$

where $\mathfrak{p}$ is a nonzero prime ideal of $A[T]$ such that $\mathfrak{p} \cap A = 0$, because B contains A. Thus

$$\operatorname{ht}(\mathfrak{p}) = 1$$

by (5.5.3). The ideal $\mathfrak{q}$ is of the form $\mathfrak{n}/\mathfrak{p}$, where $\mathfrak{n} \supset \mathfrak{p}$ is a prime ideal of $A[T]$ satisfying $\mathfrak{n} \cap A = \mathfrak{m}$, and

$$B_{\mathfrak{q}} = (A[T])_{\mathfrak{n}}/\mathfrak{p}(A[T])_{\mathfrak{n}}.$$

Formula (**0**, 16.1.4.1), applied to

$$X = \operatorname{Spec}((A[T])_{\mathfrak{n}}) \quad \text{and} \quad Y = \operatorname{Spec}(B_{\mathfrak{q}}),$$

gives

(5.5.7.2)
$$\begin{aligned}\dim((A[T])_{\mathfrak{n}}) &\geqslant \operatorname{ht}\big(\mathfrak{p}(A[T])_{\mathfrak{n}}\big) + \dim(B_{\mathfrak{q}})\\ &= 1 + \dim(B_{\mathfrak{q}}).\end{aligned}$$

Indeed,

$$\operatorname{ht}\big(\mathfrak{p}(A[T])_{\mathfrak{n}}\big) = \operatorname{ht}(\mathfrak{p}) = 1$$

by the bijection between prime ideals of $A[T]$ contained in $\mathfrak{n}$ and prime ideals of $(A[T])_{\mathfrak{n}}$. Finally, (5.5.6.1) gives

(5.5.7.3)
$$\dim((A[T])_{\mathfrak{n}}) = \dim(A) + 1 - \operatorname{tr.deg}_k k',$$

because $B_{\mathfrak{q}}$ and $(A[T])_{\mathfrak{n}}$ have the same residue field. Here $\operatorname{tr.deg}_A B = 0$, and (5.5.7.1) follows.

(ii) If $(A[T])_{\mathfrak{n}}$ is catenary, the two sides of (5.5.7.2) are equal (**0**, 16.1.4); hence the two sides of (5.5.7.1) are equal as well.

□

Theorem (5.5.8 (dimension formula)). — *Let A be a Noetherian local domain, let B be a domain containing A and finitely generated as an A-algebra, and let $\mathfrak{q}$ be a prime ideal of B such that $\mathfrak{q} \cap A$ is the maximal ideal $\mathfrak{m}$ of A. Let k and k' be the residue fields of A and $B_{\mathfrak{q}}$, respectively. Then*

(5.5.8.1)
$$\dim(A) + \operatorname{tr.deg}_A B \geqslant \dim(B_{\mathfrak{q}}) + \operatorname{tr.deg}_k k'.$$

Moreover, the two sides are equal if, for every finitely generated A-subalgebra A' of $B[T]$ and every maximal ideal $\mathfrak{m}'$ of A' such that $\mathfrak{m}' \cap A = \mathfrak{m}$, the local ring $A'_{\mathfrak{m}'}$ is catenary.

Proof. IV-2 | 97

Write
$$B = A[x_1, \dots, x_n]$$
and argue by induction on n. Put
$$C = A[x_1, \dots, x_{n-1}], \qquad \mathfrak{r} = \mathfrak{q} \cap C.$$
The ring $C_{\mathfrak{r}}$ is a Noetherian local domain. Let
$$S = C - \mathfrak{r}, \qquad B' = S^{-1}B, \qquad \mathfrak{q}' = S^{-1}\mathfrak{q}.$$
Then
$$B_{\mathfrak{q}} = B'_{\mathfrak{q}'}, \qquad B' = C_{\mathfrak{r}}[x_n], \qquad \mathfrak{q}' \cap C_{\mathfrak{r}} = \mathfrak{r}C_{\mathfrak{r}}.$$
Moreover, the fraction fields of B' and $C_{\mathfrak{r}}$ are those of B and C, respectively. If k_1 is the residue field of $C_{\mathfrak{r}}$, then (5.5.7.1) gives

(5.5.8.2) $$\dim(C_{\mathfrak{r}}) + \operatorname{tr.deg}_C B \geqslant \dim(B_{\mathfrak{q}}) + \operatorname{tr.deg}_{k_1} k'.$$

The induction hypothesis gives

(5.5.8.3) $$\dim(A) + \operatorname{tr.deg}_A C \geqslant \dim(C_{\mathfrak{r}}) + \operatorname{tr.deg}_k k_1.$$

Adding (5.5.8.2) and (5.5.8.3) term by term yields (5.5.8.1).

For the second assertion, first note that every finitely generated A-subalgebra of $C[T]$ is also a finitely generated A-subalgebra of $B[T]$. By induction on n, we may therefore suppose that the two sides of (5.5.8.3) are equal.

By (5.5.7), to prove equality in (5.5.8.2), it is enough to show that whenever $\mathfrak{n}$ is a maximal ideal of $C_{\mathfrak{r}}[T]$ satisfying
$$\mathfrak{n} \cap C_{\mathfrak{r}} = \mathfrak{r}C_{\mathfrak{r}},$$
the ring $(C_{\mathfrak{r}}[T])_{\mathfrak{n}}$ is catenary. We have
$$C_{\mathfrak{r}}[T] = S^{-1}C[T].$$
Thus $\mathfrak{n} = S^{-1}\mathfrak{n}'$ for a prime ideal $\mathfrak{n}'$ of $C[T]$ such that $\mathfrak{n}' \cap C = \mathfrak{r}$, and
$$(C_{\mathfrak{r}}[T])_{\mathfrak{n}} = (C[T])_{\mathfrak{n}'}.$$
Choose a maximal ideal $\mathfrak{m}'$ of $C[T]$ containing $\mathfrak{n}'$. Then $\mathfrak{m}' \cap A = \mathfrak{m}$, and $(C[T])_{\mathfrak{m}'}$ is catenary by hypothesis. Since $(C[T])_{\mathfrak{n}'}$ is a localization of this ring, it too is catenary (**0**, 16.1.4). □

5.6. Dimension formula and universally catenary rings IV-2 | 97

Proposition (5.6.1). — *Let A be a Noetherian ring. The following properties are equivalent:*

(a) *Every polynomial ring $A[T_1, \dots, T_n]$ is catenary.*
(b) *Every A-algebra of finite type is catenary.*
(c) *The ring A is catenary, and the following dimension formula holds. Let B' be any integral local A-algebra essentially of finite type (1.3.8); let $\mathfrak{q}$ be its maximal ideal and $\mathfrak{p}$ the inverse image of $\mathfrak{q}$ in A; let A' be the image of $A_{\mathfrak{p}}$ in B'; and let k and k' be the residue fields of A' and B', respectively. Then*

(5.6.1.1) $$\dim(A') + \operatorname{tr.deg}_{A'} B' = \dim(B') + \operatorname{tr.deg}_k k'.$$

Proof. Suppose first that condition (b) holds. Then B' is a local A'-algebra essentially of finite type (1.3.10); hence
$$B' = B''_{\mathfrak{q}''},$$
where B'' is a finitely generated A'-subalgebra of B' and $\mathfrak{q}''$ is a prime ideal of B'' lying over the maximal ideal of A'. Moreover, B' and B'' have the same fraction field, so
$$\operatorname{tr.deg}_{A'} B' = \operatorname{tr.deg}_{A'} B''.$$
To prove (5.6.1.1), it is enough to show that every finitely generated A'-subalgebra A_1 of $B'[T]$ is catenary. Indeed, the two sides of (5.5.8.1), applied to A', B'', and $\mathfrak{q}''$, are then equal. But Condition (b) implies that every A-algebra essentially of finite type is catenary (**0**, 16.1.4), and A_1 is such an A-algebra (1.3.9). Thus (b) implies (c).

It is immediate that (b) implies (a). Conversely, (a) implies (b), because every A-algebra of finite type is a quotient of a polynomial algebra (**0**, 16.1.4).

It remains to prove that (c) implies (b). Since every quotient by a prime ideal of an A-algebra of finite type is an integral A-algebra of finite type, it is enough to prove the following. Let B be an integral A-algebra of finite type, and let $\mathfrak{q}' \subset \mathfrak{q}$ be prime ideals of B. Then

(5.6.1.2) $$\dim(B_{\mathfrak{q}}/\mathfrak{q}'B_{\mathfrak{q}}) + \dim(B_{\mathfrak{q}'}) = \dim(B_{\mathfrak{q}}).$$

By (**0**, 16.1.4.2), this is precisely the required catenarity condition.

Let $\mathfrak{p}$ and $\mathfrak{p}'$ be the inverse images in A of $\mathfrak{q}$ and $\mathfrak{q}'$, respectively, and let $\mathfrak{n}$ be the kernel of **IV-2** | 98

$$A_{\mathfrak{p}} \longrightarrow B_{\mathfrak{q}}.$$

The image of $A_{\mathfrak{p}}$ in $B_{\mathfrak{q}}$ is isomorphic to $A_{\mathfrak{p}}/\mathfrak{n}$. Applying (5.6.1.1) to this image and to $B_{\mathfrak{q}}$ gives

(5.6.1.3) $$\begin{aligned}\dim(A_{\mathfrak{p}}/\mathfrak{n}) + \operatorname{tr.deg}_{A_{\mathfrak{p}}/\mathfrak{n}} B_{\mathfrak{q}} \\ = \dim(B_{\mathfrak{q}}) + \operatorname{tr.deg}_{\kappa(\mathfrak{p})} \kappa(\mathfrak{q}).\end{aligned}$$

The kernel of $A_{\mathfrak{p}'} \to B_{\mathfrak{q}'}$ is $\mathfrak{n}A_{\mathfrak{p}'}$. Applying (5.6.1.1) again gives

(5.6.1.4) $$\begin{aligned}\dim(A_{\mathfrak{p}'}/\mathfrak{n}A_{\mathfrak{p}'}) + \operatorname{tr.deg}_{A_{\mathfrak{p}'}/\mathfrak{n}A_{\mathfrak{p}'}} B_{\mathfrak{q}'} \\ = \dim(B_{\mathfrak{q}'}) + \operatorname{tr.deg}_{\kappa(\mathfrak{p}')} \kappa(\mathfrak{q}').\end{aligned}$$

Finally, $B/\mathfrak{q}'$ is an integral A-algebra of finite type. The inverse image of $\mathfrak{q}/\mathfrak{q}'$ in A is $\mathfrak{p}$, and the kernel of

$$A_{\mathfrak{p}} \longrightarrow B_{\mathfrak{q}}/\mathfrak{q}'B_{\mathfrak{q}}$$

is $\mathfrak{p}'A_{\mathfrak{p}}$. Hence

(5.6.1.5) $$\begin{aligned}\dim(A_{\mathfrak{p}}/\mathfrak{p}'A_{\mathfrak{p}}) + \operatorname{tr.deg}_{\kappa(\mathfrak{p}')}(B_{\mathfrak{q}}/\mathfrak{q}'B_{\mathfrak{q}}) \\ = \dim(B_{\mathfrak{q}}/\mathfrak{q}'B_{\mathfrak{q}}) + \operatorname{tr.deg}_{\kappa(\mathfrak{p})} \kappa(\mathfrak{q}).\end{aligned}$$

Add (5.6.1.4) and (5.6.1.5) term by term. The fields $\kappa(\mathfrak{p}')$ and $\kappa(\mathfrak{q}')$ are the fraction fields of $A_{\mathfrak{p}}/\mathfrak{p}'A_{\mathfrak{p}}$ and $B_{\mathfrak{q}}/\mathfrak{q}'B_{\mathfrak{q}}$, respectively. Furthermore, $A_{\mathfrak{p}'}/\mathfrak{n}A_{\mathfrak{p}'}$ and $A_{\mathfrak{p}}/\mathfrak{n}$ have the same fraction field, as do $B_{\mathfrak{q}'}$ and $B_{\mathfrak{q}}$. Since A is catenary, (**0**, 16.1.4.2) gives

$$\dim(A_{\mathfrak{p}}/\mathfrak{p}'A_{\mathfrak{p}}) + \dim(A_{\mathfrak{p}'}/\mathfrak{n}A_{\mathfrak{p}'}) = \dim(A_{\mathfrak{p}}/\mathfrak{n}).$$

Taking these observations and (5.6.1.3) into account yields (5.6.1.2). □

Definition (5.6.2). — A Noetherian ring is said to be *universally catenary* if it satisfies the equivalent conditions of (5.6.1).

Remarks (5.6.3). — (i) If A is universally catenary, then so is $S^{-1}A$ for every multiplicative subset S of A. This follows at once from 5.6.1(a) and the fact that every ring of fractions of a catenary ring is catenary.

Conversely, suppose that $A_{\mathfrak{p}}$ is universally catenary for every prime ideal $\mathfrak{p}$ of A. Then A is universally catenary. Indeed, apply 5.6.1(c); if $S = A - \mathfrak{p}$, then $S^{-1}B$ is an $A_{\mathfrak{p}}$-algebra of finite type and

$$B_{\mathfrak{q}} = (S^{-1}B)_{S^{-1}\mathfrak{q}}.$$

(ii) A locally Noetherian prescheme X is said to be *universally catenary* if $\mathscr{O}_x$ is universally catenary for every $x \in X$. By (i), a Noetherian ring A is universally catenary if and only if $\operatorname{Spec}(A)$ is universally catenary.

(iii) The criterion 5.6.1(c) involves only the images of A in integral A-algebras of finite type, hence only integral quotient rings of A.

It follows that if $\mathfrak{p}_i$ $(1 \leqslant i \leqslant n)$ are the minimal prime ideals of A, then A is universally catenary if and only if every $A/\mathfrak{p}_i$ is universally catenary. Likewise, a locally Noetherian prescheme X is universally catenary if and only if X_{red} is universally catenary. **IV-2** | 99

(iv) The criterion 5.6.1(b) and (i) show that every A-algebra essentially of finite type over a universally catenary ring A is universally catenary (1.3.8).

Proposition (5.6.4). — *Every quotient ring of a regular ring is universally catenary.*

Proof. By 5.6.3(iv), it is enough to show that every regular ring A is universally catenary. Each polynomial ring $A[T_1,\ldots,T_n]$ is regular (**0**, 17.3.7), hence catenary (**0**, 16.5.12), and the assertion follows from 5.6.1(a). □

In particular, Cohen's theorem (**0**, 19.8.8) implies that every complete Noetherian local ring is universally catenary. Likewise, every algebra of finite type over a field is universally catenary, and every prescheme locally of finite type over a field is universally catenary.

We shall see in (6.3.7) that "regular ring" may be replaced by "Cohen–Macaulay ring" in (5.6.4).

Proposition (5.6.5). — *Let Y be an irreducible locally Noetherian prescheme, let X be an irreducible prescheme, and let $f : X \to Y$ be a dominant morphism locally of finite type. Let ξ and η be the generic points of X and Y, respectively, and put*

$$e = \dim(f^{-1}(\eta)) = \operatorname{tr.deg}_{\kappa(\eta)} \kappa(\xi),$$

the dimension of the generic fibre (**0**, 2.1.8), (4.1.1)*. For every $x \in X$, with $y = f(x)$, one has*

$$e + \dim(\mathscr{O}_y) \geqslant \operatorname{tr.deg}_{\kappa(y)} \kappa(x) + \dim(\mathscr{O}_x) \tag{5.6.5.1}$$

and

$$\dim(\mathscr{O}_x) \leqslant \dim(\mathscr{O}_y) + \dim(\mathscr{O}_x \otimes_{\mathscr{O}_y} \kappa(y)) - \delta(x), \tag{5.6.5.2}$$

where

$$\delta(x) = \dim_x(f^{-1}(y)) - e.$$

If Y is universally catenary, equality holds in (5.6.5.1) *and* (5.6.5.2)*. If, in addition, x is closed in $f^{-1}(y)$, then*

$$\dim(\mathscr{O}_x) = \dim(\mathscr{O}_y) + e. \tag{5.6.5.3}$$

Proof. We may restrict to the case in which X and Y are affine, and hence f is of finite type, and then replace both preschemes by their reductions (1.5.4). Thus X and Y may be assumed integral.

Since f is dominant, $\mathscr{O}_y$ identifies with a subring of $\mathscr{O}_x$, and their fraction fields are $\kappa(\eta)$ and $\kappa(\xi)$, respectively (**I**, 8.2.7). Moreover, $\mathscr{O}_x$ is the localization at a prime ideal $\mathfrak{q}$ of an integral $\mathscr{O}_y$-algebra B of finite type (**I**, 3.6.5). Applying (5.5.8.1) to $A = \mathscr{O}_y$, B, and $\mathfrak{q}$ gives (5.6.5.1).

Furthermore,

$$\mathscr{O}_x \otimes_{\mathscr{O}_y} \kappa(y) = \mathscr{O}_x / \mathfrak{m}_y \mathscr{O}_x$$

is the local ring of the fibre $f^{-1}(y)$ at x (**I**, 3.6.1). Since the fibre is of finite type over $\kappa(y)$, (5.2.3.1) gives

$$\dim(\mathscr{O}_x \otimes_{\mathscr{O}_y} \kappa(y)) = \dim_x(f^{-1}(y)) - \operatorname{tr.deg}_{\kappa(y)} \kappa(x).$$

Thus (5.6.5.2) is simply another form of (5.6.5.1).

When Y is universally catenary, equality in (5.6.5.1) is exactly (5.6.1.1), applied to $A = \mathscr{O}_y$ and **IV-2** | 100
$B' = \mathscr{O}_x$. Finally, if x is closed in the fibre, then in general

$$\operatorname{tr.deg}_{\kappa(y)} \kappa(x) = \dim(\overline{\{x\}} \cap f^{-1}(y));$$

this follows from (5.2.1), applied to the reduced closed sub-prescheme of $f^{-1}(y)$ whose underlying space is the displayed subspace. Equation (5.6.5.3) follows. □

We shall prove in (13.1.1) that under the hypotheses of (5.6.5) one always has $\delta(x) \geqslant 0$. Thus in this case (5.6.5.2) sharpens (5.5.2.1).

Corollary (5.6.6). — *Under the general hypotheses of* (5.6.5),

$$\dim(X) \leqslant \dim(Y) + e. \tag{5.6.6.1}$$

If Y is universally catenary, equality holds in (5.6.6.1) *if and only if*

$$\dim(Y) = \sup_{y \in f(X)} \dim(\mathscr{O}_y). \tag{5.6.6.2}$$

In particular, equality holds in (5.6.6.1) *when Y is locally of finite type over a field.*

Proof. Apply (5.6.5.1) at a closed point x of X, and use (5.1.4.2) and (5.1.11); this gives (5.6.6.1). Conversely, every nonempty fibre $f^{-1}(y)$ contains a point closed in that fibre (5.1.11). If Y is universally catenary, (5.6.5.3) holds at such a point. Taking suprema in (5.6.5.3) as x ranges over X, and observing that every point closed in X is *a fortiori* closed in $f^{-1}(f(x))$, yields the second assertion by (5.1.4.1) and (5.1.4.2).

For the last assertion, choose an affine open neighbourhood U of the generic point of X such that $f|_U$ is of finite type. Then $f(U)$ is constructible (1.8.5) and dense in Y, and therefore contains a nonempty open, hence dense, subset of Y (**0**, 9.2.2). Since Y is locally of finite type over a field, it is universally catenary (5.6.4); moreover, the two sides of (5.6.6.2) are equal by (5.2.2) and (4.1.1.3).

Condition (5.6.6.2) is trivially satisfied when f is surjective. □

Corollary (5.6.7). — *Let Y be a locally Noetherian prescheme, let $f : X \to Y$ be a morphism locally of finite type, and let n be an integer. If*

$$\dim(f^{-1}(y)) \leqslant n$$

for every $y \in Y$, then

$$\dim(X) \leqslant \dim(Y) + n. \tag{5.6.7.1}$$

Proof. By (**0**, 14.1.7) and (1.5.4), we may assume that X and Y are affine and reduced, so that f is of finite type. Let X_i $(1 \leqslant i \leqslant m)$ be the integral closed sub-preschemes whose underlying spaces are the irreducible components of X. Then

$$\dim(X) = \sup_i \dim(X_i).$$

Let Z_i be the reduced closed sub-prescheme of Y whose underlying space is $\overline{f(X_i)}$. It is integral (**0**, 2.1.5), and the restriction of f factors as

$$X_i \xrightarrow{g_i} Z_i \xrightarrow{j_i} Y,$$

where j_i is the canonical injection (**I**, 5.2.2), and g_i is dominant and of finite type (1.5.4).

We have $\dim(Z_i) \leqslant \dim(Y)$. If ζ_i is the generic point of Z_i, then **IV-2** | 101

$$\dim(g_i^{-1}(\zeta_i)) \leqslant n$$

by hypothesis. Thus it is enough to show

$$\dim(X_i) \leqslant \dim(Z_i) + n$$

for every i, and this is (5.6.6.1). □

Corollary (5.6.8). — *Let Y be a locally Noetherian prescheme, let X be irreducible, let $f : X \to Y$ be a morphism locally of finite type, and let $n \geqslant 0$ be an integer. Suppose that Y is universally catenary and that*

$$\dim(f^{-1}(y)) \geqslant n \quad \textit{for every } y \in Y.$$

Then

$$\dim(X) \geqslant \dim(Y) + n. \tag{5.6.8.1}$$

If instead every fibre has dimension exactly n, then

$$\dim(X) = \dim(Y) + n. \tag{5.6.8.2}$$

Proof. Since $n \geqslant 0$, either hypothesis implies that f is surjective, and therefore Y is irreducible. If η is the generic point of Y, then $\dim(f^{-1}(\eta)) \geqslant n$, respectively $\dim(f^{-1}(\eta)) = n$. The conclusion follows from (5.6.6). □

Remarks (5.6.9). — (i) Even if Y is regular, X is irreducible, and $f : X \to Y$ is dominant and of finite type, the two sides of (5.6.6.1) need not be equal. Take $Y = \operatorname{Spec}(A)$ for a discrete valuation ring A, take $X = \operatorname{Spec}(K)$ for its fraction field K, and let f be the canonical morphism.

(ii) Example 5.4.3(i) shows that the hypothesis that X is irreducible cannot be omitted from (5.6.6) or (5.6.8), even when all the other hypotheses hold. We shall see in (10.6.1) that such phenomena cannot occur under additional hypotheses on Y, satisfied for example when Y is locally of finite type over a field or over a Dedekind ring having infinitely many prime ideals.

Proposition (5.6.10). — *Let A be an integral universally catenary Noetherian local ring, and let B be an integral finite A-algebra containing A. For every maximal ideal $\mathfrak{n}$ of B,*

$$\dim(B_{\mathfrak{n}}) = \dim(A).$$

Proof. We have $\operatorname{tr.deg}_A B = 0$, and the residue field of $B_{\mathfrak{n}}$ is algebraic over the residue field of A.[11] Every maximal ideal of B lies over the maximal ideal of A, so the assertion follows from (5.6.1.1). □

Example (5.6.11). — Let A be an integral, integrally closed Noetherian local ring. Then (**0**, 16.1.6) shows that the conclusion of (5.6.10) holds for every integral finite A-algebra B containing A. We now construct, by contrast, an integral catenary Noetherian local ring A for which that conclusion fails.

Use the construction of 5.2.5(i). Let k_0 be a field, let

$$k = k_0(S_i)_{i\in\mathbf{N}}$$

be a purely transcendental extension of infinite transcendence degree, and let $V = k[S]_{(S)}$ be the discrete valuation ring obtained by localizing $k[S]$ at (S). Put $E = V[T]$. In E, the maximal ideal

$$\mathfrak{m} = (S) + (T)$$

has height 2, whereas the maximal ideal

$$\mathfrak{m}' = (ST - 1)$$

has height 1.

The corresponding residue fields are **IV-2 | 102**

$$\kappa(\mathfrak{m}) = k, \qquad \kappa(\mathfrak{m}') = k(S),$$

the latter being the fraction field of V. By the choice of k, these fields are isomorphic. Let

$$\varepsilon : E \longrightarrow E/\mathfrak{m}, \qquad \varepsilon' : E \longrightarrow E/\mathfrak{m}'$$

be the canonical homomorphisms, choose an isomorphism

$$\sigma : \kappa(\mathfrak{m}) \xrightarrow{\sim} \kappa(\mathfrak{m}'),$$

and let C be the subring of E formed by the elements x such that

$$\varepsilon'(x) = \sigma(\varepsilon(x)).$$

This is a special case of the "gluing procedures" to be studied systematically in Chapter V.

It is immediate that

$$\mathfrak{n} = \mathfrak{m}\mathfrak{m}' = \mathfrak{m} \cap \mathfrak{m}'$$

is a maximal ideal of C, and that $C/\mathfrak{n}$ identifies with the subfield of $(E/\mathfrak{m}) \times (E/\mathfrak{m}')$ formed by the pairs $(z, \sigma(z))$. Moreover,

$$E = C + C(ST - 1),$$

so E is a finite C-algebra; it is plainly the integral closure of C. We next prove that C is Noetherian.

Lemma (5.6.11.1). — *Let R be a ring, let S be a subring, and let*

$$\mathfrak{K} = \operatorname{Ann}_S(R/S)$$

be the conductor of S in R, that is, the largest ideal of S which is also an ideal of R.

(i) *For every ideal $\mathfrak{J} \subset \mathfrak{K}$ of R, there is a strictly increasing map from the set of ideals $\mathfrak{a}$ of S such that $R\mathfrak{a} = \mathfrak{J}$ to the set of $(S/\mathfrak{K})$-submodules of $\mathfrak{J}/\mathfrak{K}\mathfrak{J}$.*

[11] The printed French text says "the fraction field of A". Here the field required by the dimension formula is the residue field of A.

(ii) *If $S/\mathfrak{K}$ and R are Noetherian and R is a finite S-module, then every increasing sequence of ideals of S contained in $\mathfrak{K}$ is stationary.*

Proof. For (i), if $R\mathfrak{a} = \mathfrak{J}$, then

$$\mathfrak{K}\mathfrak{J} = \mathfrak{K}(R\mathfrak{a}) = \mathfrak{K}\mathfrak{a} \subset \mathfrak{a}.$$

Thus $\mathfrak{a} \mapsto \mathfrak{a}/\mathfrak{K}\mathfrak{J}$ gives the asserted strictly increasing map.

For (ii), let $(\mathfrak{L}_r)$ be an increasing sequence of ideals of S contained in $\mathfrak{K}$. Since R is Noetherian, the sequence $(R\mathfrak{L}_r)$ is stationary; after discarding finitely many terms, suppose that all its members are the same ideal $\mathfrak{J}$ of R. The module $\mathfrak{J}/\mathfrak{K}\mathfrak{J}$ is finite over R, hence over S, and therefore finite over the Noetherian ring $S/\mathfrak{K}$. It is consequently Noetherian, and (i) shows that $(\mathfrak{L}_r)$ is stationary. □

Apply the lemma with $R = E$ and $S = C$. The ideal $\mathfrak{n}$ is the conductor of C in E. For every ideal $\mathfrak{a}$ of C,

$$\mathfrak{a}/(\mathfrak{n} \cap \mathfrak{a}) \simeq (\mathfrak{a} + \mathfrak{n})/\mathfrak{n}$$

is a submodule of the simple C-module $C/\mathfrak{n}$. It is therefore enough to prove that every ideal $\mathfrak{a} \cap \mathfrak{n}$ is finitely generated; this follows from (5.6.11.1). Thus C is Noetherian.

By (**0**, 16.1.5),

$$\dim(C) = \dim(E) = 2.$$

Set $A = C_{\mathfrak{n}}$ and $U = C - \mathfrak{n}$. Then

$$B = U^{-1}E$$

is the integral closure of A and is a finite A-module. The ideals $\mathfrak{m}$ and $\mathfrak{m}'$ are the only prime ideals of E containing $\mathfrak{n}$. Hence B is semilocal, and its local rings at its two maximal ideals are isomorphic to $E_{\mathfrak{m}}$ and $E_{\mathfrak{m}'}$, of dimensions 2 and 1, respectively. Thus $\dim(B) = 2$ and, by (**0**, 16.1.5), $\dim(A) = 2$.

Since A is an integral local ring of dimension 2, it is catenary: every prime ideal other than 0 and the maximal ideal has height 1. Nevertheless it does not satisfy the conclusion of (5.6.10), and therefore is not universally catenary.

The ideal $\mathfrak{n}$ has height 2 in C. If $\mathfrak{p}$ is a height-1 prime ideal of C, there is a unique prime ideal $\mathfrak{p}'$ of E above $\mathfrak{p}$; it has height 1, and

$$C_{\mathfrak{p}} = E_{\mathfrak{p}'}.$$

Existence follows from integrality, and the Cohen–Seidenberg theorem shows that every prime ideal of E above $\mathfrak{p}$ has height 1.

Moreover, E is a finite C-algebra and $C_{\mathfrak{p}}$ is integrally closed (Bourbaki, *Algèbre commutative*, chap. V, § 1, n° 5, cor. 5 of prop. 16). This proves uniqueness and the displayed equality. **IV-2** | 103

It would be interesting to know whether every integral Noetherian local ring satisfying the conclusion of (5.6.10) is universally catenary. Nagata asserted this [33], but his proof does not appear to be complete.

5.7. Depth and property (S_k) **IV-2** | 103

Definition (5.7.1). — Let X be a locally Noetherian prescheme and let $\mathscr{F}$ be a coherent $\mathscr{O}_X$-module. The *depth* (respectively, *codepth*) of $\mathscr{F}$ at a point $x \in X$ is the number $\operatorname{prof}(\mathscr{F}_x)$ (respectively, $\operatorname{coprof}(\mathscr{F}_x)$) (**0**, 16.4.5), (**0**, 16.4.9). The *codepth* of $\mathscr{F}$ is the number

(5.7.1.1) $$\operatorname{coprof}(\mathscr{F}) = \sup_{x \in X} \operatorname{coprof}(\mathscr{F}_x).$$

The module $\mathscr{F}$ is said to be a *Cohen–Macaulay $\mathscr{O}_X$-module at x* if $\mathscr{F}_x$ is a Cohen–Macaulay $\mathscr{O}_x$-module, that is (**0**, 16.5.1), if $\operatorname{coprof}(\mathscr{F}_x) = 0$. It is said to be a *Cohen–Macaulay $\mathscr{O}_X$-module* if it is so at every point, or equivalently if $\operatorname{coprof}(\mathscr{F}) = 0$. A point $x \in X$ such that $\mathscr{O}_x$ is a Cohen–Macaulay ring is also called a *Cohen–Macaulay point* of X.

The *codepth of* X, denoted by $\operatorname{coprof}(X)$, is the number $\operatorname{coprof}(\mathscr{O}_X)$. The prescheme X is said to be *Cohen–Macaulay* if $\mathscr{O}_X$ is a Cohen–Macaulay $\mathscr{O}_X$-module, or equivalently if $\operatorname{coprof}(X) = 0$. Every locally Noetherian prescheme of dimension 0 is evidently Cohen–Macaulay. To say that $\operatorname{Spec}(A)$ is Cohen–Macaulay means that A is a Cohen–Macaulay ring (**0**, 16.5.13).

Definition (5.7.2). — Let X be a locally Noetherian prescheme, let $\mathscr{F}$ be a coherent $\mathscr{O}_X$-module, and let k be an integer, positive or negative. The module $\mathscr{F}$ is said to satisfy property (S_k) if, for every $x \in X$,

(5.7.2.1)
$$\operatorname{prof}(\mathscr{F}_x) \geqslant \inf\{k, \dim(\mathscr{F}_x)\}.$$

It is said to satisfy property (S_k) *at a point* $x \in X$ if, for every generization x' of x in X,

(5.7.2.2)
$$\operatorname{prof}(\mathscr{F}_{x'}) \geqslant \inf\{k, \dim(\mathscr{F}_{x'})\}.$$

The prescheme X is said to satisfy property (S_k) (respectively, property (S_k) at x) if $\mathscr{O}_X$ does so (respectively, does so at x).

The module $\mathscr{F}$ satisfies (S_k) if and only if it satisfies (S_k) at every point of X. If U is an open subset of X and $\mathscr{F}$ satisfies (S_k), then $\mathscr{F}|U$ satisfies (S_k). Conversely, if (U_α) is an open covering of X and $\mathscr{F}|U_\alpha$ satisfies (S_k) for every α, then $\mathscr{F}$ satisfies (S_k).

Remarks (5.7.3). — (i) Recall that $\operatorname{prof}(\mathscr{F}_x) \leqslant \dim(\mathscr{F}_x)$ (**0**, 16.4.5.1) whenever $\mathscr{F}_x \neq 0$. Thus $\mathscr{F}$ satisfies (S_k) precisely when $\operatorname{prof}(\mathscr{F}_x) \geqslant k$ except at points x for which $\dim(\mathscr{F}_x) < k$, while at those latter points

$$\dim(\mathscr{F}_x) = \operatorname{prof}(\mathscr{F}_x).$$

Equivalently (**0**, 16.5.1), $\mathscr{F}$ is Cohen–Macaulay at those points. At points where $\dim(\mathscr{F}_x) = k$, one likewise has $\operatorname{prof}(\mathscr{F}_x) = k$.

Hence $\mathscr{F}$ is also Cohen–Macaulay at those points. To say that $\mathscr{F}$ satisfies (S_k) for every k is therefore the same as to say that $\mathscr{F}$ is a Cohen–Macaulay $\mathscr{O}_X$-module. If $k' \geqslant k$, then $(S_{k'})$ implies (S_k); if $k \leqslant 0$, every coherent $\mathscr{O}_X$-module satisfies (S_k). **IV-2** | 104

(ii) To verify (5.7.2.1), it is enough to consider $x \in \operatorname{Supp}(\mathscr{F})$; otherwise $\dim(\mathscr{F}_x) = -\infty$ (**0**, 14.1.2).

(iii) If $X = \operatorname{Spec}(A)$, where A is Noetherian, and $\mathscr{F} = \widetilde{M}$, where M is a finite A-module, then M is said to satisfy (S_k) when $\mathscr{F}$ does.

For an arbitrary locally Noetherian prescheme X, saying that $\mathscr{F}$ satisfies (S_k) at x means the following. Put $Y = \operatorname{Spec}(\mathscr{O}_x)$; then the $\mathscr{O}_Y$-module $\widetilde{\mathscr{F}_x}$ satisfies (S_k). Notice that (5.7.2.1) does not in general imply (5.7.2.2) for every generization x' of x, since there is no general inequality between $\operatorname{prof}(\mathscr{F}_x)$ and $\operatorname{prof}(\mathscr{F}_{x'})$ (**0**, 16.4.6).

(iv) It follows immediately from the definition that if $\mathscr{F}$ satisfies (S_k) at x, then it also satisfies (S_k) at every generization of x.

(v) Property (S_k) is especially important for $k = 1$ and $k = 2$. Serre introduced it for $k = 2$ in order to express his normality criterion; see (5.8.6).[12]

(vi) Let Y be a closed sub-prescheme of X, let $j : Y \to X$ be the canonical immersion, and let $\mathscr{G}$ be a coherent $\mathscr{O}_Y$-module. For every $x \in Y$,

$$\dim(\mathscr{G}_x) = \dim((j_*\mathscr{G})_x), \qquad \operatorname{prof}(\mathscr{G}_x) = \operatorname{prof}((j_*\mathscr{G})_x),$$

and consequently

$$\operatorname{coprof}(\mathscr{G}_x) = \operatorname{coprof}((j_*\mathscr{G})_x).$$

Thus $\mathscr{G}$ satisfies (S_k) if and only if $j_*\mathscr{G}$ does.

Proposition (5.7.4). — *Let X be a locally Noetherian prescheme and let $\mathscr{F}$ be a coherent $\mathscr{O}_X$-module. Put $S = \operatorname{Supp}(\mathscr{F})$, and for every $n \geqslant 0$ let Z_n be the set of points $z \in X$ such that $\operatorname{coprof}(\mathscr{F}_z) > n$; thus $Z_n \subset S$.*

(i) *The module $\mathscr{F}$ satisfies (S_k) if and only if, for every $n \geqslant 0$,*

(5.7.4.1)
$$\operatorname{codim}(Z_n, S) > n + k.$$

(ii) *Suppose in addition that every Z_n is closed in X. Then $\mathscr{F}$ satisfies (S_k) at a point $x \in S$ if and only if, for every $n \geqslant 0$,*

(5.7.4.2)
$$\operatorname{codim}_x(Z_n, S) > n + k.$$

[12] The printed French text points to (5.8.5); Serre's normality criterion is Theorem (5.8.6).

Proof. (i) By definition (5.1.3),

$$\operatorname{codim}(Z_n, S) = \inf_{z \in Z_n} \dim(\mathscr{O}_{S,z}),$$

and (5.7.4.1) therefore says (5.1.12.2) that, for every $z \in X$ and every $n \geqslant 0$,

$$\dim(\mathscr{F}_z) - \operatorname{prof}(\mathscr{F}_z) \geqslant n + 1$$

implies

$$\dim(\mathscr{F}_z) \geqslant n + k + 1.$$

If $a = \dim(\mathscr{F}_z)$ and $b = \operatorname{prof}(\mathscr{F}_z)$, then $b \leqslant a$; requiring, for every $n \geqslant 0$, that $b \leqslant a - n - 1$ imply $k \leqslant a - n - 1$ is equivalent to $b \geqslant \inf\{k, a\}$. This proves (i).

IV-2 | 105

(ii) The argument is the same as in (i), except that one restricts to the points z which are generizations of x and uses (5.1.3.2).

□

Proposition (5.7.5). — *Let X be a locally Noetherian prescheme and let $\mathscr{F}$ be a coherent $\mathscr{O}_X$-module. The module $\mathscr{F}$ satisfies (S_k), where $k \geqslant 1$, if and only if the following condition holds: for every integer r with $0 \leqslant r < k$, every open subset U of X, and every $(\mathscr{F}|U)$-regular sequence $(f_i)_{1 \leqslant i \leqslant r}$ of sections of $\mathscr{O}_X$ over U, the module*

$$(\mathscr{F}|U) \Big/ \Big(\sum_{i=1}^{r} f_i(\mathscr{F}|U) \Big)$$

has no embedded associated prime cycle.

Proof. For $k = 1$, the assertion says that $\mathscr{F}$ satisfies (S_1) if and only if $\mathscr{F}$ has no embedded associated prime cycle. Indeed, (S_1) says that $\operatorname{prof}(\mathscr{F}_x) \geqslant 1$ at precisely the points $x \in \operatorname{Supp}(\mathscr{F})$ for which $\dim(\mathscr{F}_x) > 0$; at the other points of the support, $\dim(\mathscr{F}_x) = \operatorname{prof}(\mathscr{F}_x) = 0$. Now $\operatorname{prof}(\mathscr{F}_x) \geqslant 1$ means that the maximal ideal $\mathfrak{m}_x$ is not associated to $\mathscr{F}_x$ (0, 16.4.6(i)), or equivalently that x is not associated to $\mathscr{F}$ (3.1.1). If S' is a sub-prescheme of X whose underlying space is $\operatorname{Supp}(\mathscr{F})$, then

$$\dim(\mathscr{F}_x) = \dim(\mathscr{O}_{S',x})$$

(5.1.12.1); saying that this dimension is positive is the same as saying that x is not a maximal point of $\operatorname{Supp}(\mathscr{F})$ (5.1.2). This proves the assertion for $k = 1$.

Let $k > 1$, and first suppose that $\mathscr{F}$ satisfies (S_k). By induction on k and the case just proved, it is enough to show that if f is an $\mathscr{F}$-regular section of $\mathscr{O}_X$, then $\mathscr{F}/f\mathscr{F}$ satisfies (S_{k-1}). At each $x \in X$, the element f_x is $\mathscr{F}_x$-regular. If it is invertible, the quotient stalk is zero. Otherwise $f_x \in \mathfrak{m}_x$, and

$$\operatorname{prof}(\mathscr{F}_x/f_x\mathscr{F}_x) = \operatorname{prof}(\mathscr{F}_x) - 1, \qquad \dim(\mathscr{F}_x/f_x\mathscr{F}_x) = \dim(\mathscr{F}_x) - 1$$

(0, 16.4.6(i)), (**0**, 16.3.4); the assertion follows. Thus the condition is necessary.

Conversely, suppose the stated condition holds. We argue by induction on k. Let $x \in X$, and first suppose that $\dim(\mathscr{F}_x) \geqslant k$. The induction hypothesis gives (S_{k-1}), so $\operatorname{prof}(\mathscr{F}_x) \geqslant k - 1$. By (**0**, 15.2.4), after replacing X by an open neighbourhood U of x, there is an $(\mathscr{F}|U)$-regular sequence $(f_i)_{1 \leqslant i \leqslant k-1}$ with $(f_i)_x \in \mathfrak{m}_x$. Put

$$\mathscr{G} = (\mathscr{F}|U) \Big/ \Big(\sum_{i=1}^{k-1} f_i(\mathscr{F}|U) \Big).$$

By hypothesis $\mathscr{G}$ has no embedded associated prime cycle, while

$$\dim(\mathscr{G}_x) = \dim(\mathscr{F}_x) - (k-1) \geqslant 1$$

(**0**, 16.3.4). Hence x is not associated to $\mathscr{G}$, so $\operatorname{prof}(\mathscr{G}_x) \geqslant 1$ (**0**, 16.4.6); since

$$\operatorname{prof}(\mathscr{G}_x) = \operatorname{prof}(\mathscr{F}_x) - (k-1),$$

we obtain $\operatorname{prof}(\mathscr{F}_x) \geqslant k$.

If instead $\dim(\mathscr{F}_x) = r < k$, the induction hypothesis gives

$$\operatorname{prof}(\mathscr{F}_x) \geqslant \inf\{k-1, r\} = r.$$

Thus $\mathscr{F}$ satisfies (S_k), completing the proof. □

Corollary (5.7.6). — *Suppose that $\mathscr{F}$ satisfies (S_k), where $k \geqslant 1$. If $(f_i)_{1\leqslant i\leqslant r}$ is an $\mathscr{F}$-regular sequence of sections of $\mathscr{O}_X$ over X and $r < k$, then*

$$\mathscr{F} \Big/ \Big(\sum_{i=1}^{r} f_i \mathscr{F} \Big)$$

satisfies (S_{k-r}).

Proof. This follows immediately from (5.7.5). □

Corollary (5.7.7). — *The module $\mathscr{F}$ satisfies (S_2) if and only if $\mathscr{F}$ has no embedded associated prime cycle and, for every open subset U of X and every $(\mathscr{F}|U)$-regular section f of $\mathscr{O}_X$ over U, the module $(\mathscr{F}|U)/f(\mathscr{F}|U)$ has no embedded associated prime cycle.*

Proof. This follows immediately from (5.7.5). □

IV-2 | 106

Remarks (5.7.8). — Let X be a locally Noetherian prescheme of dimension 1. The following conditions are equivalent: X is Cohen–Macaulay; X satisfies (S_1); X satisfies (S_n) for some $n \geqslant 1$. This follows from Definitions (5.7.1) and (5.7.2). By (5.7.5), these conditions are also equivalent to the absence of an embedded associated prime cycle. In particular, every reduced locally Noetherian prescheme of dimension 1 is Cohen–Macaulay.

Proposition (5.7.9). — *Let A and B be Noetherian rings, let $\rho : A \to B$ be a ring homomorphism, and let M be a B-module such that the A-module $M_{[\rho]}$ is finite. Let $\mathfrak{p}$ be a prime ideal of A. The prime ideals of B lying over $\mathfrak{p}$ and belonging to* Supp(M) *are finite in number. If $(\mathfrak{q}_i)_{1\leqslant i\leqslant n}$ is the family of these ideals, then*

$$\dim_{A_\mathfrak{p}}(M_\mathfrak{p}) = \sup_i \dim_{B_{\mathfrak{q}_i}}(M_{\mathfrak{q}_i}), \tag{5.7.9.1}$$

$$\operatorname{prof}_{A_\mathfrak{p}}(M_\mathfrak{p}) = \inf_i \operatorname{prof}_{B_{\mathfrak{q}_i}}(M_{\mathfrak{q}_i}). \tag{5.7.9.2}$$

Proof. Let $\mathfrak{b}$ be the annihilator of M. The ring $B/\mathfrak{b}$ identifies with an A-submodule of $\operatorname{End}_A(M_{[\rho]})$, and is therefore finite over A. Hence only finitely many prime ideals of B lie over $\mathfrak{p}$ and contain $\mathfrak{b}$; these are precisely the ones belonging to $\operatorname{Supp}(M)$.

Replacing B by $B/\mathfrak{b}$ does not change the right-hand sides of (5.7.9.1) and (5.7.9.2) (**0**, 16.1.9), (**0**, 16.4.8); we may therefore suppose that B is finite over A. Put $S = A - \mathfrak{p}$ and $B' = S^{-1}B$. Then B' is a Noetherian semilocal ring whose maximal ideals are $S^{-1}\mathfrak{q}_i$, and

$$\dim_{A_\mathfrak{p}}(M_\mathfrak{p}) = \dim_{B'}(M_\mathfrak{p})$$

(**0**, 16.1.9). Formula (5.7.9.1) is now the semilocal dimension formula (**0**, 16.1.7.4).

For (5.7.9.2), as in (**0**, 16.4.8), it is enough to treat the case $\operatorname{prof}_{A_\mathfrak{p}}(M_\mathfrak{p}) = 0$. The same argument shows that $M_\mathfrak{p}$ contains a B'-submodule of finite length, and hence a simple B'-submodule. Such a module is isomorphic to the residue field of one of the local rings $B_{\mathfrak{q}_i}$. Thus

$$\operatorname{prof}_{B_{\mathfrak{q}_i}}(M_{\mathfrak{q}_i}) = 0$$

for at least one i (**0**, 16.4.6), proving the formula. □

Corollary (5.7.10). — *Assume the hypotheses of (5.7.9), and suppose in addition that A is local. The A-module $M_{[\rho]}$ is Cohen–Macaulay if and only if every $M_{\mathfrak{q}_i}$, for $\mathfrak{q}_i$ lying over the maximal ideal of A, is a Cohen–Macaulay $B_{\mathfrak{q}_i}$-module and all the numbers $\dim_{B_{\mathfrak{q}_i}}(M_{\mathfrak{q}_i})$ are equal.*

Proof. By (5.7.9.1) and (5.7.9.2), these conditions are equivalent to

$$\dim_A(M_{[\rho]}) = \operatorname{prof}_A(M_{[\rho]}).$$

□

Corollary (5.7.11). — *Assume the hypotheses of (5.7.9).*

(i) *If $M_{[\rho]}$ satisfies (S_k), then M satisfies (S_k).*

(ii) *Suppose that for every pair of prime ideals $\mathfrak{q}, \mathfrak{q}'$ of B satisfying $\rho^{-1}(\mathfrak{q}) = \rho^{-1}(\mathfrak{q}')$, one has*

$$\dim_{B_{\mathfrak{q}}}(M_{\mathfrak{q}}) = \dim_{B_{\mathfrak{q}'}}(M_{\mathfrak{q}'}).$$

If M satisfies (S_k), then $M_{[\rho]}$ satisfies (S_k).

IV-2 | 107

Proof. This follows immediately from (5.7.9.1), (5.7.9.2), and the definition of (S_k). □

(5.7.12). In accordance with (5.7.1), if A is any Noetherian ring and M is a finite A-module, define

$$\operatorname{coprof}_A(M) = \operatorname{coprof}(\widetilde{M}) = \sup_{x \in X} \operatorname{coprof}_{A_x}(M_x), \qquad X = \operatorname{Spec}(A).$$

We shall see in (6.11.5) that this definition agrees with that of (**0**, 16.4.9) when A is a Noetherian local ring.

Corollary (5.7.13). — *Let A and B be Noetherian rings, let $\rho : A \to B$ be a ring homomorphism, and let M be a B-module such that $M_{[\rho]}$ is a finite A-module. Then*

(5.7.13.1) $$\operatorname{coprof}_A(M_{[\rho]}) \geqslant \operatorname{coprof}_B(M).$$

Proof. This follows from (5.7.12) and (5.7.9.1), (5.7.9.2). □

5.8. Regular preschemes and property (R_k). Serre's normality criterion

(5.8.1). Recall (**0**, 4.1.4) that a ringed space $(X, \mathscr{O}_X)$ is said to be *regular* at a point $x \in X$ if $\mathscr{O}_x$ is a regular local ring. When dealing with preschemes, we shall use this terminology in this chapter only when X is locally Noetherian.

Definition (5.8.2). — A locally Noetherian prescheme X is said to be *regular in codimension* $\leqslant k$, or to satisfy property (R_k), if the set of points where X is not regular has codimension $> k$. In other words (5.1.3), for every $x \in X$,

$$\dim(\mathscr{O}_x) \leqslant k \quad \Longrightarrow \quad \mathscr{O}_x \text{ is regular.}$$

To say that X is regular means that X satisfies (R_k) for every k.

If $X = \operatorname{Spec}(A)$, where A is a Noetherian ring, we say that A satisfies (R_k) if X does; to say that X is regular is to say that the ring A is regular (**0**, 17.3.6). For an arbitrary locally Noetherian prescheme X, we say that X satisfies (R_k) *at a point* $x \in X$ if the local ring $\mathscr{O}_x$ satisfies (R_k). Thus, for every generization x' of x in X, the relation $\dim(\mathscr{O}_{x'}) \leqslant k$ must imply that $\mathscr{O}_{x'}$ is a regular local ring. By (**0**, 17.3.6), saying that X is regular at x is equivalent to saying that X satisfies (R_n) at x for every $n \geqslant 0$.

Proposition (5.8.3). — *Let k be a field and let X be a prescheme locally of finite type over k. For every $x \in X$, there is an open neighbourhood of x in X which is isomorphic to a subscheme of a regular k-scheme.*

Proof. There is an affine open neighbourhood U of x isomorphic to a k-scheme $\operatorname{Spec}(A)$, where A is a k-algebra of finite type. The algebra A is therefore isomorphic to a quotient of a polynomial algebra $k[T_1, \ldots, T_n]$, and the latter is a regular ring (**0**, 17.3.7). □

(5.8.4). By (5.8.2), saying that X satisfies (R_0) means that, at every maximal point x of X, the ring $\mathscr{O}_x$ is a field (**0**, 17.1.4); in other words, X is reduced at x. The set U of points where X is reduced is open, because the nilradical of X is a coherent $\mathscr{O}_X$-module (**I**, 6.1.1), (**0**, 5.2.2). Consequently, saying that X satisfies (R_0) is equivalent to saying that U is everywhere dense.

IV-2 | 108

Proposition (5.8.5). — *A locally Noetherian prescheme X is reduced if and only if it satisfies* (S_1) *and* (R_0).

Proof. Taking (5.7.5) into account, this follows from the preceding remark and (3.2.1). □

Theorem (5.8.6). — (Serre's criterion). *Let X be a locally Noetherian prescheme. Then X is normal if and only if it satisfies* (S_2) *and* (R_1). *Equivalently, for every $x \in X$, the following conditions hold:*

(i) *If $\dim(\mathscr{O}_x) \leqslant 1$, then $\mathscr{O}_x$ is regular; that is, it is a field or a discrete valuation ring* (**0**, 17.1.4).
(ii) *If $\dim(\mathscr{O}_x) \geqslant 2$, then $\operatorname{prof}(\mathscr{O}_x) \geqslant 2$.*

Proof. The conditions are necessary. Indeed, saying that X is normal means that, for every $x \in X$, the ring $\mathscr{O}_x$ is an integrally closed Noetherian local ring. If $\dim(\mathscr{O}_x) = 0$, then $\mathscr{O}_x$ is a field because it is a domain; if $\dim(\mathscr{O}_x) = 1$, then $\mathscr{O}_x$ is a discrete valuation ring by (**II**, 7.1.6). Furthermore, for every nonzero element $f_x \in \mathscr{O}_x$, the associated prime ideals of $\mathscr{O}_x / f_x \mathscr{O}_x$ are non-embedded (Bourbaki, *Alg. comm.*, chap. VII, § 1, no. 4, prop. 8). Hence $\mathscr{O}_x$ satisfies (S_2) by (5.7.7).

Conversely, suppose that the two conditions hold. It follows first from (5.8.5) that X is reduced. Since the question is local, we may suppose that $X = \operatorname{Spec}(A)$, where A is a reduced Noetherian ring (**I**, 5.1.4). If R is the total ring of fractions of A, then R is a direct product of finitely many fields; taking (**II**, 6.3.6) into account, it is enough to prove that A is integrally closed in R.

Let $h = f/g \in R$ be integral over A, where $f, g \in A$ and g is a non-zero-divisor. There is a relation

$$f^n + \sum_{i=1}^{n} a_i f^{n-i} g^i = 0, \qquad a_i \in A \quad (1 \leqslant i \leqslant n). \tag{5.8.6.1}$$

Let $\mathfrak{p}$ be a prime ideal of A such that $\dim(A_\mathfrak{p}) = 1$, and write $f_\mathfrak{p}$ and $g_\mathfrak{p}$ for the images of f and g in $A_\mathfrak{p}$. It follows from (5.8.6.1) that $f_\mathfrak{p}/g_\mathfrak{p}$ is integral over $A_\mathfrak{p}$. This quotient belongs to the total ring of fractions of $A_\mathfrak{p}$, since flatness implies that $g_\mathfrak{p}$ is still a non-zero-divisor (**0**, 5.3.1). But $A_\mathfrak{p}$ is regular and hence integrally closed, so $f_\mathfrak{p}/g_\mathfrak{p} \in A_\mathfrak{p}$. Equivalently,

$$(fA)_\mathfrak{p} \subset (gA)_\mathfrak{p}.$$

Since g is a non-zero-divisor in A, condition (S_2) and (5.7.7) imply that A/gA has only non-embedded associated prime ideals $\mathfrak{p}_i$ $(1 \leqslant i \leqslant n)$. The ideal gA is therefore an intersection of primary ideals $\mathfrak{q}_i$ corresponding to the $\mathfrak{p}_i$; moreover, each $\mathfrak{q}_i$ is the inverse image in A, under $A \to A_{\mathfrak{p}_i}$, of $(gA)_{\mathfrak{p}_i}$ (Bourbaki, *Alg. comm.*, chap. IV, § 2, no. 3, prop. 5). By the Hauptidealsatz (**0**, 16.3.2), $\dim(A_{\mathfrak{p}_i}) = 1$ for every i, so the preceding argument gives

$$(fA)_{\mathfrak{p}_i} \subset (gA)_{\mathfrak{p}_i} \qquad (1 \leqslant i \leqslant n).$$

Now fA is contained in the intersection of the inverse images of the $(fA)_{\mathfrak{p}_i}$. It is therefore contained in the intersection of the inverse images of the $(gA)_{\mathfrak{p}_i}$, which is gA. Thus $fA \subset gA$, and hence $f/g \in A$. □

IV-2 | 109

5.9. ***Z*-pure and *Z*-closed modules** Some of the notions and results in this section and the next are special cases of notions and results developed in Chapter III in the theory of local cohomology. For the reader's convenience, we give an independent account here.

(5.9.1). Let X be a locally Noetherian prescheme and let Z be a subset of X *stable under specialization*. This means that the closure of every finite subset M of Z is contained in Z. It follows that Z is the union of a filtered increasing family (Z_α) of closed subsets of X; conversely, such a union is plainly stable under specialization.

Put $U_\alpha = X - Z_\alpha$. Then $X - Z$ is the intersection of the filtered decreasing family of open subsets U_α. Let $i_\alpha : U_\alpha \to X$ be the canonical injection, and, whenever $U_\alpha \supset U_\beta$, let $i_{\alpha\beta} : U_\beta \to U_\alpha$ be the canonical injection, so that $i_\beta = i_\alpha \circ i_{\alpha\beta}$.

Let $\mathscr{F}$ be an $\mathscr{O}_X$-module, not necessarily quasi-coherent. We have

$$(i_\beta)_*(\mathscr{F}|U_\beta) = (i_\alpha)_*((i_{\alpha\beta})_*(\mathscr{F}|U_\beta)).$$

The canonical homomorphism (**0**, 4.4.3.2)

$$\mathscr{F}|U_\alpha \longrightarrow (i_{\alpha\beta})_*(\mathscr{F}|U_\beta)$$

therefore gives, after applying $(i_\alpha)_*$, a homomorphism

$$\rho_{\beta\alpha} : (i_\alpha)_*(\mathscr{F}|U_\alpha) \longrightarrow (i_\beta)_*(\mathscr{F}|U_\beta).$$

For $U_\alpha \supset U_\beta \supset U_\gamma$, one immediately checks that $\rho_{\gamma\alpha} = \rho_{\gamma\beta} \circ \rho_{\beta\alpha}$. Thus the modules $(i_\alpha)_*(\mathscr{F}|U_\alpha)$ form an inductive system under the homomorphisms $\rho_{\beta\alpha}$. We put

(5.9.1.1) $$\mathscr{H}^0_{X/Z}(\mathscr{F}) = \varinjlim_{\alpha} (i_\alpha)_*(\mathscr{F}|U_\alpha).$$

This $\mathscr{O}_X$-module does not depend on the increasing family (Z_α) of closed subsets having union Z. Indeed, let V be a Noetherian open subset of X. In the category of $\mathscr{O}_V$-modules, the functor $\mathscr{G} \mapsto \Gamma(V, \mathscr{G})$ commutes with inductive limits (**G**, II.3.10.1); hence (5.9.1.1) gives

(5.9.1.2) $$\Gamma(V, \mathscr{H}^0_{X/Z}(\mathscr{F})) = \varinjlim_{\alpha} \Gamma(V \cap U_\alpha, \mathscr{F}).$$

Let (Z'_λ) be another filtered increasing family of closed subsets of X with union Z. For fixed α, the set $V \cap Z_\alpha$ is the union of the $V \cap Z_\alpha \cap Z'_\lambda$. Now $V \cap Z_\alpha$ is locally closed in X, and every closed irreducible subset of it has a generic point. Since the $V \cap Z_\alpha \cap Z'_\lambda$ form a filtered increasing family of closed subsets of $V \cap Z_\alpha$, there is a λ such that

$$V \cap Z_\alpha \cap Z'_\lambda = V \cap Z_\alpha \qquad (\mathbf{0}, 9.2.4).$$

Equivalently, $V \cap Z_\alpha \subset V \cap Z'_\lambda$. The two filtered decreasing families $V \cap U_\alpha$ and $V \cap U'_\lambda$, where $U'_\lambda = X - Z'_\lambda$, are therefore cofinal. The asserted independence follows from (5.9.1.2).

The subset Z need not be constructible. For example, take $X = \operatorname{Spec}(A)$, where A is a Noetherian domain having infinitely many maximal ideals, and let Z be the complement of the generic point of X. **IV-2** | 110

If Z is closed and $i : X - Z \to X$ is the canonical injection, then

(5.9.1.3) $$\mathscr{H}^0_{X/Z}(\mathscr{F}) = i_*(\mathscr{F}|X - Z).$$

In particular, when $Z = \varnothing$, $\mathscr{H}^0_{X/Z}(\mathscr{F}) = \mathscr{F}$.

Proposition (5.9.2). — (i) *The functor $\mathscr{F} \mapsto \mathscr{H}^0_{X/Z}(\mathscr{F})$ is left exact.*

(ii) *If $\mathscr{F}$ is quasi-coherent, so is $\mathscr{H}^0_{X/Z}(\mathscr{F})$.*

Proof. Assertion (i) follows from (5.9.1.1), from the left exactness of $(i_\alpha)_*$, and from the fact that inductive limits preserve exactness in the category of $\mathscr{O}_X$-modules. Assertion (ii) follows from (**I**, 9.2.2) and from the fact that an inductive limit of quasi-coherent $\mathscr{O}_X$-modules is quasi-coherent (**I**, 1.3.9). ☐

Remark (5.9.3). — If $\mathscr{F}$ is an $\mathscr{O}_X$-algebra, then $\mathscr{H}^0_{X/Z}(\mathscr{F})$ is one as well (**0**, 4.2.4). In particular, $\mathscr{H}^0_{X/Z}(\mathscr{O}_X)$ is a quasi-coherent $\mathscr{O}_X$-algebra, and, for every $\mathscr{O}_X$-module $\mathscr{F}$, $\mathscr{H}^0_{X/Z}(\mathscr{F})$ is a module over that algebra; it is quasi-coherent when $\mathscr{F}$ is quasi-coherent (**I**, 9.6.1).

More specifically, suppose that $X = \operatorname{Spec}(A)$, where A is a Noetherian domain. Then $\mathscr{H}^0_{X/Z}(\mathscr{O}_X)$ is the $\mathscr{O}_X$-algebra $\widetilde{B}$, where

(5.9.3.1) $$B = \bigcap_{\mathfrak{p} \in X - Z} A_{\mathfrak{p}}.$$

This follows at once from (5.9.1.2) and (**I**, 8.2.1.1).

Proposition (5.9.4). — *Let X be a locally Noetherian prescheme, let $Z \subset X$ be stable under specialization, let X' be a locally Noetherian prescheme, and let $f : X' \to X$ be flat. Then $Z' = f^{-1}(Z)$ is stable under specialization, and, for every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$, there is a canonical isomorphism*

(5.9.4.1) $$f^*(\mathscr{H}^0_{X/Z}(\mathscr{F})) \xrightarrow{\sim} \mathscr{H}^0_{X'/Z'}(f^*\mathscr{F}).$$

Proof. With the notation of (5.9.1), $Z'_\alpha = f^{-1}(Z_\alpha)$ is closed in X', and Z' is the union of the Z'_α. The base change of i_α to X' is the canonical injection $i'_\alpha : U'_\alpha \to X'$, where $U'_\alpha = X' - Z'_\alpha = f^{-1}(U_\alpha)$. Since f is flat, the canonical homomorphism

$$f^*((i_\alpha)_*(\mathscr{F}|U_\alpha)) \longrightarrow (i'_\alpha)_*(f^*\mathscr{F}|U'_\alpha)$$

is bijective (2.3.1). For $\alpha \leqslant \beta$, the diagram

$$\begin{tikzcd} f^*((i_\alpha)_*(\mathscr{F}|U_\alpha)) \arrow[r, "\sim"] \arrow[d] & (i'_\alpha)_*(f^*\mathscr{F}|U'_\alpha) \arrow[d] \\ f^*((i_\beta)_*(\mathscr{F}|U_\beta)) \arrow[r, "\sim"] & (i'_\beta)_*(f^*\mathscr{F}|U'_\beta) \end{tikzcd}$$

is commutative. Passing to the limit gives a canonical isomorphism

$$\varinjlim_\alpha f^*((i_\alpha)_*(\mathscr{F}|U_\alpha)) \xrightarrow{\sim} \mathscr{H}^0_{X'/Z'}(f^*\mathscr{F}).$$

Since f^* commutes with inductive limits (**0**, 4.3.2), this is precisely (5.9.4.1). □ **IV-2** | 111

Corollary (5.9.5). — *Under the hypotheses of (5.9.4), if $\mathscr{H}^0_{X/Z}(\mathscr{F})$ is coherent, then $\mathscr{H}^0_{X'/Z'}(f^*\mathscr{F})$ is coherent. The converse holds when f is faithfully flat and quasi-compact.*

Proof. The first assertion follows from (5.9.4.1) and (**0**, 5.3.11). The second amounts to saying that if $\mathscr{H}^0_{X'/Z'}(f^*\mathscr{F})$ is of finite type, then so is $\mathscr{H}^0_{X/Z}(\mathscr{F})$; this follows from (5.9.4.1) and (2.5.2). □

Corollary (5.9.6). — *Let X be a locally Noetherian prescheme, let $Z \subset X$ be stable under specialization, and let $\mathscr{F}$ be a quasi-coherent $\mathscr{O}_X$-module. For every $x \in X$, put $X_x = \operatorname{Spec}(\mathscr{O}_x)$ and $Z_x = Z \cap X_x$. There is a functorial isomorphism*

(5.9.6.1) $$(\mathscr{H}^0_{X/Z}(\mathscr{F}))_x \xrightarrow{\sim} \mathscr{H}^0_{X_x/Z_x}(\widetilde{\mathscr{F}_x}).$$

Proof. Apply (5.9.4) to the canonical flat morphism $X_x \to X$ and use (**I**, 1.6.5). □

(5.9.7). With the notation of (5.9.1), for every α there is a canonical functorial homomorphism

$$\mathscr{F} \longrightarrow (i_\alpha)_*(\mathscr{F}|U_\alpha) \qquad (\mathbf{0}, 4.4.3.2).$$

These homomorphisms form an inductive system, and passage to the limit gives a canonical functorial homomorphism

(5.9.7.1) $$\rho_{X/Z} : \mathscr{F} \longrightarrow \mathscr{H}^0_{X/Z}(\mathscr{F}).$$

Proposition (5.9.8). — *Let X be a locally Noetherian prescheme, let $Z \subset X$ be stable under specialization, and let $\mathscr{F}$ be an $\mathscr{O}_X$-module. The following conditions are equivalent:*

a) *The homomorphism $\rho_{X/Z}$ in (5.9.7.1) is injective (respectively bijective).*
b) *For every Noetherian open subset V of X, the homomorphism*

$$(\rho_{X/Z})_V : \Gamma(V, \mathscr{F}) \longrightarrow \varinjlim_\alpha \Gamma(V \cap U_\alpha, \mathscr{F})$$

is injective (respectively bijective).

They are also equivalent to:

a') *For every closed subset $T \subset Z$ of X, the canonical homomorphism (**0**, 4.4.3.2)*

$$\mathscr{F} \longrightarrow i_*(\mathscr{F}|X - T),$$

where $i : X - T \to X$ is the canonical injection, is injective (respectively bijective).

b') *For every closed subset $T \subset Z$ and every Noetherian open subset $V \subset X$, the restriction homomorphism*

$$\Gamma(V, \mathscr{F}) \longrightarrow \Gamma(V \cap (X - T), \mathscr{F})$$

is injective (respectively bijective).

Proof. Taking (5.9.1.2) into account, the equivalence of a) and b), and likewise that of a') and b'), follows from the definition of the functor Γ and its left exactness.

For every closed subset $T \subset Z$, the homomorphism $(\rho_{X/Z})_V$ is the composite

(5.9.8.1) $$\Gamma(V, \mathscr{F}) \longrightarrow \Gamma(V \cap (X - T), \mathscr{F}) \longrightarrow \varinjlim_\alpha \Gamma(V \cap U_\alpha, \mathscr{F}).$$

Thus b) implies b') in the injective case, while b') implies b) directly from the definition of an inductive limit.

It remains to show that, if $\rho_{X/Z}$ is bijective, then so is $\Gamma(V, \mathscr{F}) \to \Gamma(V \cap (X-T), \mathscr{F})$. By (5.9.8.1), it is enough to observe that whenever $U' \subset U$ are open subsets of V containing $V \cap (X-Z)$, the restriction homomorphism $\Gamma(U, \mathscr{F}) \to \Gamma(U', \mathscr{F})$ is injective. This follows from the injectivity of $\rho_{X/Z}$ by replacing V with U and $V \cap (X-T)$ with U'. □ **IV-2** | 112

Definition (5.9.9). — Under the hypotheses of (5.9.8), the module $\mathscr{F}$ is called *Z-pure* (respectively *Z-closed*) if $\rho_{X/Z}$ is injective (respectively bijective).

If $X = \operatorname{Spec}(A)$ is affine and $\mathscr{F} = \widetilde{M}$, where M is an A-module, we call M Z-pure (respectively Z-closed) when $\mathscr{F}$ is.

We say that $\mathscr{F}$ is *Z-pure* (respectively *Z-closed*) *at a point* $x \in X$ if, with the notation of (5.9.6), $\widetilde{\mathscr{F}_x}$ is Z_x-pure (respectively Z_x-closed). By (5.9.6), this is equivalent to saying that

$$\mathscr{F}_x \longrightarrow (\mathscr{H}^0_{X/Z}(\mathscr{F}))_x$$

is injective (respectively bijective). At every point $x \in X - Z$, $\mathscr{F}$ is Z-closed by (5.9.8).

Corollary (5.9.10). — (i) *Let (V_λ) be an open covering of X. Then $\mathscr{F}$ is Z-pure (respectively Z-closed) if and only if, for every λ, $\mathscr{F}|V_\lambda$ is $(Z \cap V_\lambda)$-pure (respectively $(Z \cap V_\lambda)$-closed).*

(ii) *Let $Z' \subset Z$ be stable under specialization. If $\mathscr{F}$ is Z-pure (respectively Z-closed), then it is Z'-pure (respectively Z'-closed).*

Proof. This follows immediately from condition b') of (5.9.8). □

Proposition (5.9.11). — *Under the hypotheses of (5.9.8), the supports of $\ker(\rho_{X/Z})$ and $\operatorname{coker}(\rho_{X/Z})$ are contained in Z, and $\mathscr{H}^0_{X/Z}(\mathscr{F})$ is Z-closed.*

Furthermore, if $u : \mathscr{F} \to \mathscr{F}'$ is an $\mathscr{O}_X$-module homomorphism and $\mathscr{F}'$ is Z-closed, then u factors uniquely as

$$\mathscr{F} \xrightarrow{\rho_{X/Z}} \mathscr{H}^0_{X/Z}(\mathscr{F}) \xrightarrow{v} \mathscr{F}'.$$

If, in addition, the supports of $\ker(u)$ and $\operatorname{coker}(u)$ are contained in Z, then v is an isomorphism.

Proof. The first assertion says that, for every $x \in X - Z$,

$$\ker(\rho_{X/Z})_x = \operatorname{coker}(\rho_{X/Z})_x = 0.$$

Equivalently, $(\rho_{X/Z})_x$ is bijective, or $\mathscr{F}$ is Z-closed at x, as noted after (5.9.9).

To prove that $\mathscr{H}^0_{X/Z}(\mathscr{F})$ is Z-closed, it is enough to show, for every Noetherian open $V \subset X$, that

$$\varinjlim_\beta \Gamma(V \cap U_\beta, \mathscr{H}^0_{X/Z}(\mathscr{F})) = \Gamma(V, \mathscr{H}^0_{X/Z}(\mathscr{F})).$$

By definition,

$$\Gamma(V \cap U_\beta, \mathscr{H}^0_{X/Z}(\mathscr{F})) = \varinjlim_\alpha \Gamma(V \cap U_\alpha \cap U_\beta, \mathscr{F}).$$

The double family $(U_\alpha \cap U_\beta)$ is filtered decreasing, so the assertion follows from (5.9.1) and the theorem on double inductive limits.

We now prove the second part. For every α, $(i_\alpha)_*(u)$ is the unique homomorphism making the diagram **IV-2** | 113

$$\begin{tikzcd}
\mathscr{F} \arrow[r, "u"] \arrow[d] & \mathscr{F}' \arrow[d] \\
(i_\alpha)_*(\mathscr{F}|U_\alpha) \arrow[r, "(i_\alpha)_*(u)"'] & (i_\alpha)_*(\mathscr{F}'|U_\alpha)
\end{tikzcd}$$

commute. Hence there is a unique homomorphism w making all diagrams

$$\begin{tikzcd}
(i_\alpha)_*(\mathscr{F}|U_\alpha) \arrow[r, "(i_\alpha)_*(u)"] \arrow[d] & (i_\alpha)_*(\mathscr{F}'|U_\alpha) \arrow[d] \\
\mathscr{H}^0_{X/Z}(\mathscr{F}) \arrow[r, "w"'] & \mathscr{H}^0_{X/Z}(\mathscr{F}')
\end{tikzcd}$$

commute. Since $\mathscr{F}'$ is Z-closed, it identifies canonically with $\mathscr{H}^0_{X/Z}(\mathscr{F}')$. This proves existence and uniqueness of v.

Suppose finally that the supports of $\ker(u)$ and $\operatorname{coker}(u)$ are contained in Z. We show that, for every Noetherian open $V \subset X$, the homomorphism

$$\Gamma(V, \mathscr{H}^0_{X/Z}(\mathscr{F})) \longrightarrow \Gamma(V, \mathscr{F}')$$

is an isomorphism. If a section $t \in \Gamma(V, \mathscr{H}^0_{X/Z}(\mathscr{F}))$ maps to zero, then, for some α, it is represented by a section on $V \cap U_\alpha$. By the hypothesis on u, its germ vanishes at every point of $V \cap (X - Z)$. It therefore vanishes on an open neighbourhood of $V \cap (X - Z)$, and so represents zero in $\Gamma(V, \mathscr{H}^0_{X/Z}(\mathscr{F}))$.

Conversely, let $s' \in \Gamma(V, \mathscr{F}')$. For every $x \in V \cap (X - Z)$, there is an open neighbourhood $W^{(x)}$ of x and a section $s^{(x)}$ of $\mathscr{F}$ on $W^{(x)}$ whose image under u is $s'|W^{(x)}$. Hence $s'|W^{(x)}$ is also the image under v of a section $t^{(x)}$ of $\mathscr{H}^0_{X/Z}(\mathscr{F})$. Since v is injective, these sections agree on overlaps. They therefore glue to a section t over an open subset $U \subset V$ containing $V \cap (X - Z)$. As $\mathscr{H}^0_{X/Z}(\mathscr{F})$ is Z-closed, t extends uniquely over V; its image under v agrees with s' on U, and hence on V by the same argument.

The module $\mathscr{H}^0_{X/Z}(\mathscr{F})$ is called the *Z-closure* of $\mathscr{F}$. □

IV-2 | 114

Remarks (5.9.12). — (i) Let $\mathscr{C}(X)$ be the category of $\mathscr{O}_X$-modules, and let $\mathscr{C}_Z(X)$ be its full subcategory of modules whose support is contained in Z. This is a localizing subcategory in the sense of Gabriel, and $\mathscr{H}^0_{X/Z}$ is precisely Gabriel's localization functor (cf. [27]); this gives another proof of (5.9.11). When Z is closed, the functor $i^* : \mathscr{C}(X) \to \mathscr{C}(X - Z)$, where $i : X - Z \to X$, defines an equivalence

$$\mathscr{C}(X)/\mathscr{C}_Z(X) \simeq \mathscr{C}(X - Z).$$

(ii) By (5.9.11), $\mathscr{H}^0_{X/Z}(\mathscr{F}) = 0$ if and only if $\operatorname{Supp}(\mathscr{F}) \subset Z$. Indeed, the vanishing implies that $\ker(\rho_{X/Z}) = \mathscr{F}$. Conversely, if $\operatorname{Supp}(\mathscr{F}) \subset Z$, apply the second part of (5.9.11) to the unique map $u : \mathscr{F} \to 0$; the corresponding map $v : \mathscr{H}^0_{X/Z}(\mathscr{F}) \to 0$ is an isomorphism.

(iii) The preceding constructions make sense for every locally Noetherian ringed space in which every closed irreducible subset has a unique generic point. In particular, on a locally Noetherian prescheme they apply to arbitrary sheaves of abelian groups, regarded as modules over the sheaf associated with the constant presheaf **Z**. For every $x \in X$ one still has the canonical isomorphism (5.9.6.1), in which $\widetilde{\mathscr{F}_x}$ denotes the sheaf induced by $\mathscr{F}$ on the subspace X_x of X. A direct proof follows from (5.9.1.2) and the theorem on double inductive limits.

5.10. Property (S_2) and Z-closure

(5.10.1). Let X be a locally Noetherian prescheme and let $\mathscr{F}$ be a coherent $\mathscr{O}_X$-module. For every subset T of X, put

(5.10.1.1) $$\operatorname{prof}_T(\mathscr{F}) = \inf_{z \in T} \operatorname{prof}(\mathscr{F}_z).$$

Proposition (5.10.2). — *Let X be a locally Noetherian prescheme, let Z be a subset of X stable under specialization, and let $\mathscr{F}$ be a quasi-coherent $\mathscr{O}_X$-module. The following conditions are equivalent:*

a) *$\mathscr{F}$ is Z-pure.*
b) *$\operatorname{Ass}(\mathscr{F})$ does not meet Z.*

If, in addition, $\mathscr{F}$ is coherent, these conditions are also equivalent to:

c) $\operatorname{prof}_Z(\mathscr{F}) \geqslant 1$.

Proof. To say that $\mathscr{F}$ is Z-pure means that, for every Noetherian open subset V of X and every open subset $U \supset X - Z$, the restriction homomorphism

$$\Gamma(V, \mathscr{F}) \longrightarrow \Gamma(V \cap U, \mathscr{F})$$

is injective (5.9.8). By (3.1.8), this is equivalent to $V \cap \mathrm{Ass}(\mathscr{F}) \subset U$, which proves the equivalence of a) and b). Further, to say that $x \in \mathrm{Ass}(\mathscr{F})$ means that no element of $\mathfrak{m}_x$ is $\mathscr{F}_x$-regular (3.1.2); when $\mathscr{F}$ is coherent, this is equivalent to $\mathrm{prof}(\mathscr{F}_x) = 0$. The equivalence of b) and c) follows immediately. □

Corollary (5.10.3). — *Let*

$$0 \longrightarrow \mathscr{F}' \longrightarrow \mathscr{F} \longrightarrow \mathscr{F}'' \longrightarrow 0$$

be an exact sequence of quasi-coherent $\mathscr{O}_X$-modules. If $\mathscr{F}$ is Z-pure, then so is $\mathscr{F}'$. Conversely, if $\mathscr{F}'$ and $\mathscr{F}''$ are Z-pure, then so is $\mathscr{F}$.

IV-2 | 115

Proof. This follows from the form (5.10.2), b), of the condition for a quasi-coherent $\mathscr{O}_X$-module to be Z-pure, and from (3.1.7). □

Corollary (5.10.4). — *Suppose that $\mathscr{F}$ is coherent. For $\mathscr{F}$ to be Z-pure at a point $x \in X$, it is necessary and sufficient that*

$$\mathrm{prof}_{Z_x}(\widetilde{\mathscr{F}_x}) \geqslant 1,$$

with the notation of (5.9.6).

Proof. This follows immediately from (5.10.2) and (5.9.6). □

Theorem (5.10.5). — *Let X be a locally Noetherian prescheme, let Z be a subset of X stable under specialization, and let $\mathscr{F}$ be a coherent $\mathscr{O}_X$-module. For $\mathscr{F}$ to be Z-closed, it is necessary and sufficient that*

$$\mathrm{prof}_Z(\mathscr{F}) \geqslant 2.$$

Proof. By (5.10.2), we may restrict ourselves to the case in which $\mathscr{F}$ is Z-pure and $\mathrm{prof}_Z(\mathscr{F}) \geqslant 1$. Moreover, to say that $\mathrm{prof}_Z(\mathscr{F}) \geqslant 2$ is equivalent to saying that

$$\mathrm{prof}_{Z_\alpha}(\mathscr{F}) \geqslant 2$$

for every closed subset Z_α of Z; similarly, by (5.9.8), to say that $\mathscr{F}$ is Z-closed is equivalent to saying that it is Z_α-closed for every α. We may therefore first reduce to the case in which Z is closed.

The question is local. For each $x \in Z$, it is enough to prove the theorem for $\mathscr{F}|U$, where U is an affine open neighbourhood of x; we may thus suppose that $X = U$ is affine. Then $\mathrm{Ass}(\mathscr{F})$ is finite (3.1.6), and, since $\mathrm{Ass}(\mathscr{F}) \subset X - Z$, there is a section f of $\mathscr{O}_X$ over X such that

$$\mathrm{Ass}(\mathscr{F}) \subset X_f \subset X - Z \qquad \text{(II, 4.5.4)}.$$

It follows that f is $\mathscr{F}$-regular (3.1.9), and for every $y \in Z$ one has $f_y \in \mathfrak{m}_y$, hence

$$\mathrm{prof}(\mathscr{F}_y) = 1 + \mathrm{prof}(\mathscr{F}_y / f_y \mathscr{F}_y) \qquad \text{(0, 16.4.6)}.$$

Thus $\mathrm{prof}_Z(\mathscr{F}) \geqslant 2$ is equivalent to $\mathrm{prof}_Z(\mathscr{F}/f\mathscr{F}) \geqslant 1$, or, by (5.10.2), to $\mathscr{F}/f\mathscr{F}$ being Z-pure. It remains to show that this last property is equivalent to $\mathscr{F}$ being Z-closed.

Consider the exact sequence

$$0 \longrightarrow \mathscr{F} \xrightarrow{f} \mathscr{F} \longrightarrow \mathscr{F}/f\mathscr{F} \longrightarrow 0,$$

where multiplication by f is injective by hypothesis. Put $W = X - Z$. We have the commutative diagram

$$\begin{tikzcd}
0 \arrow[r] & \Gamma(X,\mathscr{F}) \arrow[r, "f"] \arrow[d] & \Gamma(X,\mathscr{F}) \arrow[r] \arrow[d] & \Gamma(X,\mathscr{F}/f\mathscr{F}) \arrow[r] \arrow[d] & 0 \\
0 \arrow[r] & \Gamma(W,\mathscr{F}) \arrow[r, "f"] & \Gamma(W,\mathscr{F}) \arrow[r] & \Gamma(W,\mathscr{F}/f\mathscr{F}) &
\end{tikzcd}$$

whose two rows are exact, since X is affine. If the restriction homomorphism

$$\Gamma(X,\mathscr{F}) \longrightarrow \Gamma(W,\mathscr{F})$$

is bijective, the diagram shows that

$$\Gamma(X,\mathscr{F}/f\mathscr{F}) \longrightarrow \Gamma(W,\mathscr{F}/f\mathscr{F})$$

is injective; hence $\mathscr{F}/f\mathscr{F}$ is Z-pure (5.9.8).

Conversely, suppose that $\mathscr{F}/f\mathscr{F}$ is Z-pure, and let s be a section of $\mathscr{F}$ over W. Since $X_f \subset W$, there is an integer $n > 0$ such that $f^n(s|X_f)$ extends to a section t of $\mathscr{F}$ over X (**I**, 1.4.1). The restrictions of t and $f^n s$ to X_f are equal; the relation $\operatorname{Ass}(\mathscr{F}) \subset X_f$ therefore implies, by (5.10.2), that $t|W = f^n s$. Since f is $\mathscr{F}$-regular, it is enough to show that $t = f^n t'$ for some $t' \in \Gamma(X, \mathscr{F})$.

This is equivalent to the image of t in $\Gamma(X, \mathscr{F}/f^n\mathscr{F})$ being zero. For every k, $f^k\mathscr{F}/f^{k+1}\mathscr{F}$ is IV-2 | 116
isomorphic to $\mathscr{F}/f\mathscr{F}$, hence is Z-pure. By induction on n, using (5.10.3), it follows that $\mathscr{F}/f^n\mathscr{F}$ is Z-pure. But the image of $t|W = f^n s$ in $\Gamma(W, \mathscr{F}/f^n\mathscr{F})$ is zero; the assertion follows from Z-purity. □

Corollary (5.10.6). — *Let $\mathscr{F}$ be a coherent $\mathscr{O}_X$-module. For $\mathscr{F}$ to be Z-closed at a point x, it is necessary and sufficient that*

$$\operatorname{prof}_{Z_x}(\widetilde{\mathscr{F}_x}) \geqslant 2.$$

Proof. This follows from (5.9.6) and (5.10.5). □

Theorem (5.10.7). — (Hartshorne). *Let X be a locally Noetherian prescheme and let Y be a closed subset of X. Suppose that* $\operatorname{prof}(\mathscr{O}_{X,y}) \geqslant 2$ *for every $y \in Y$. Then, for every connected component C of X, $C - (C \cap Y)$ is connected.*

Proof. We may restrict ourselves to the case in which X is connected. By (5.10.5), the canonical homomorphism

$$\mathscr{O}_X \longrightarrow i_*(\mathscr{O}_X|X - Y),$$

where $i : X - Y \to X$ is the canonical injection, is bijective. Consequently the restriction homomorphism

$$\Gamma(X, \mathscr{O}_X) \longrightarrow \Gamma(X - Y, \mathscr{O}_X)$$

is also bijective. It remains to apply (**III**, 7.8.6.1). □

Corollary (5.10.8). — *Let X be a locally Noetherian prescheme and let d be an integer such that, for every $x \in X$,*

$$\dim(\mathscr{O}_x) \geqslant d \quad\Longrightarrow\quad \operatorname{prof}(\mathscr{O}_x) \geqslant 2.$$

Suppose that X is connected. If X' and X'' are two distinct irreducible components of X, there is a sequence $(X_i)_{0 \leqslant i \leqslant n}$ of irreducible components of X such that $X_0 = X'$, $X_n = X''$, and

$$\operatorname{codim}(X_{i-1} \cap X_i, X) \leqslant d - 1 \qquad (1 \leqslant i \leqslant n).$$

In this case one says that X is connected in codimension $\leqslant d - 1$.

Proof. If Y is a closed subset of X such that $\operatorname{codim}(Y, X) \geqslant d$, then $\dim(\mathscr{O}_{X,y}) \geqslant d$ for every $y \in Y$ (5.1.3); hence $\operatorname{prof}(\mathscr{O}_{X,y}) \geqslant 2$ for every $y \in Y$, and (5.10.7) shows that $X - Y$ is connected.

For $\operatorname{codim}(Y, X) \geqslant d$, it is necessary and sufficient that, for every $y \in Y$, there be an open neighbourhood V of y such that $\operatorname{codim}(Y \cap V, V) \geqslant d$ (**0**, 14.2.3). Let $\mathfrak{Y}$ be the set of closed subsets Y of X of codimension at least d. The union of two members of $\mathfrak{Y}$ belongs to $\mathfrak{Y}$ (**0**, 14.2.5), and every closed subset of a member of $\mathfrak{Y}$ also belongs to $\mathfrak{Y}$. In other words, $\mathfrak{Y}$ is an *antifilter* of closed subsets of X. The corollary now follows from the following topological lemma. □

Lemma (5.10.8.1). — *Let X be a connected locally Noetherian topological space and let $\mathfrak{Y}$ be an antifilter of closed subsets of X. Suppose that a closed subset Y belongs to $\mathfrak{Y}$ whenever, for every $y \in Y$, there exist an open neighbourhood V of y in X and a $Y_y \in \mathfrak{Y}$ such that $V \cap Y = V \cap Y_y$. The following conditions are equivalent:*

a) *For every $Y \in \mathfrak{Y}$, the space $X - Y$ is connected.*
b) *If X' and X'' are two distinct irreducible components of X, there is a sequence $(X_i)_{0 \leqslant i \leqslant n}$ of irreducible components of X such that $X_0 = X'$, $X_n = X''$, and*

$$X_{i-1} \cap X_i \notin \mathfrak{Y} \qquad (1 \leqslant i \leqslant n).$$

Proof. Suppose b) holds and let $Y \in \mathfrak{Y}$. Put $U = X - Y$. If U' and U'' are two distinct irreducible components of U, there are irreducible components X' and X'' of X such that $X' \cap U = U'$ and $X'' \cap U = U''$ (**0**, 2.1.6).

Choose a sequence (X_i) with the property in b), and put $U_i = X_i \cap U$ for $0 \leqslant i \leqslant n$. Each U_i is an IV-2 | 117
irreducible component of U (**0**, 2.1.6), and $U_i \cap U_{i-1} \neq \varnothing$ for $1 \leqslant i \leqslant n$: otherwise $X_i \cap X_{i-1} \subset Y$, so $X_i \cap X_{i-1} \in \mathfrak{Y}$, contrary to the choice of the X_i. Thus U is connected.

Conversely, suppose a) holds. Let Y be the union of the sets $X_\alpha \cap X_\beta$, where (X_α, X_β) ranges over the pairs of distinct irreducible components of X for which $X_\alpha \cap X_\beta \in \mathfrak{Y}$. Every $y \in Y$ has an open neighbourhood V meeting only finitely many irreducible components of X. It follows both that Y is closed and that $V \cap Y$ is the intersection of V with a member of $\mathfrak{Y}$. By hypothesis, $Y \in \mathfrak{Y}$; hence $U = X - Y$ is connected. Moreover, Y is nowhere dense in X.

Let X' and X'' be distinct irreducible components of X, and let U' and U'' be their respective traces on U. They are distinct irreducible components of U (**0**, 2.1.6). The union of those irreducible components W of U for which there is a sequence $(U_i)_{0 \leqslant i \leqslant n}$ of irreducible components of U satisfying

$$U_0 = U', \qquad U_{i-1} \cap U_i \neq \varnothing \ (1 \leqslant i \leqslant n), \qquad U_n = W,$$

is both open and closed in U, because U is locally Noetherian and its irreducible components form a locally finite family of closed subsets. Since U is connected, there is such a sequence ending at U''. Let X_i be the irreducible component of X such that $X_i \cap U = U_i$ (**0**, 2.1.6). Since $U_{i-1} \neq U_i$, one has $X_{i-1} \neq X_i$. If $X_{i-1} \cap X_i \in \mathfrak{Y}$ for some i, then $X_{i-1} \cap X_i \subset Y$, contrary to $U_{i-1} \cap U_i \neq \varnothing$. This proves b). □

The hypothesis on X in (5.10.8) is satisfied when X is a Cohen–Macaulay prescheme and $d \geqslant 2$.

Corollary (5.10.9). — *If a Noetherian local ring A satisfies* (S_2) *and is catenary, then it is equidimensional.*

Proof. The hypothesis of (5.10.8) is satisfied by $X = \operatorname{Spec}(A)$ with $d = 2$. By that corollary, to show that all irreducible components of X have the same dimension, it is enough to consider two such components X' and X'' with

$$\operatorname{codim}(X' \cap X'', X) = 1.$$

There is then an irreducible component Z of $X' \cap X''$ such that $\operatorname{codim}(Z, X) = 1$. Since

$$1 = \operatorname{codim}(Z, X) \geqslant \operatorname{codim}(Z, X') \geqslant 1,$$

one has $\operatorname{codim}(Z, X') = 1$; similarly $\operatorname{codim}(Z, X'') = 1$. Since X is catenary, this implies $\dim(X') = \dim(X'')$. □

Proposition (5.10.10). — *Let X be a locally Noetherian prescheme, let Z be a subset of X stable under specialization, and let $\mathscr{F}$ be a coherent $\mathscr{O}_X$-module. Suppose that the $\mathscr{O}_X$-module $\mathscr{H}^0_{X/Z}(\mathscr{F})$ is coherent. Then:*

(i)
$$\operatorname{prof}_Z\big(\mathscr{H}^0_{X/Z}(\mathscr{F})\big) \geqslant 2.$$

(ii) *For every $x \in \operatorname{Ass}(\mathscr{F}) \cap (X - Z)$,*
$$\operatorname{codim}\big(Z \cap \overline{\{x\}}, \overline{\{x\}}\big) \geqslant 2.$$

(iii) *The set U of points $x \in X$ such that*
$$\operatorname{prof}_{Z_x}(\widetilde{\mathscr{F}}_x) \geqslant 2$$
(with the notation of (5.9.6)) is open in X; moreover, $X - U \subset Z$, and U is the largest open subset of X such that $\mathscr{F}|U$ is $(Z \cap U)$-closed.

IV-2 | 118

Proof. Put, for brevity,

$$\mathscr{F}' = \mathscr{H}^0_{X/Z}(\mathscr{F}).$$

By (5.9.11), $\mathscr{F}'$ is Z-closed, so assertion (i) follows from (5.10.5).

Let $x \in \operatorname{Ass}(\mathscr{F}) \cap (X - Z)$. The restrictions of $\mathscr{F}$ and $\mathscr{F}'$ to $X - Z$ are canonically isomorphic (5.9.11); hence $x \in \operatorname{Ass}(\mathscr{F}')$. For $y \in Z \cap \overline{\{x\}}$, let $\mathfrak{p}$ be the prime ideal of $\mathscr{O}_y$ corresponding to x. It is associated to the $\mathscr{O}_y$-module $\mathscr{F}'_y$. Consequently, by (i) and (**0**, 16.4.6.2),

$$2 \leqslant \operatorname{prof}(\mathscr{F}'_y) \leqslant \dim(\mathscr{O}_y/\mathfrak{p}) = \operatorname{codim}\big(\overline{\{y\}}, \overline{\{x\}}\big),$$

which proves (ii).

Finally, by (5.10.5), U is the set of points x for which $\widetilde{\mathscr{F}}_x$ is Z_x-closed; by (5.9.6), it is equivalently the set of points at which the canonical homomorphism

$$\mathscr{F}_x \longrightarrow \mathscr{F}'_x$$

is bijective. Thus $X - U$ is the union of the supports of $\operatorname{Ker}(\rho_{X/Z})$ and $\operatorname{Coker}(\rho_{X/Z})$. These are coherent $\mathscr{O}_X$-modules by the hypothesis and (**0**, 5.3.4), so their supports are closed (**0**, 5.2.2). Hence U is open. It is plainly the largest open subset on which $\mathscr{F}$ is $(Z \cap U)$-closed, and $X - U \subset Z$ follows from (5.9.11). □

We shall see in (5.11.1) that, in the most important cases, assertion (ii) conversely implies that $\mathscr{H}^0_{X/Z}(\mathscr{F})$ is coherent.

(5.10.11). Let X be a locally Noetherian prescheme and let Z be a subset of X stable under specialization. We saw in (5.9.3) that

$$\mathscr{A} = \mathscr{H}^0_{X/Z}(\mathscr{O}_X)$$

is a quasi-coherent $\mathscr{O}_X$-algebra. The X-scheme

$$X' = \operatorname{Spec}(\mathscr{A})$$

(**II**, 1.3.1) is called the *Z-closure* of X.

For every $\mathscr{O}_X$-module $\mathscr{F}$, $\mathscr{H}^0_{X/Z}(\mathscr{F})$ is an $\mathscr{A}$-module, and it is quasi-coherent when $\mathscr{F}$ is quasi-coherent. In that case there is a unique quasi-coherent $\mathscr{O}_{X'}$-module $\mathscr{F}'$ such that, if $g : X' \to X$ denotes the structural morphism, then

$$\mathscr{H}^0_{X/Z}(\mathscr{F}) = g_*(\mathscr{F}'). \tag{5.10.11.1}$$

Proposition (5.10.12). — *Use the notation of* (5.10.11).

(i) *Let $x \in X$. The morphism obtained from g by localization,*

$$X' \times_X X_x \longrightarrow X_x = \operatorname{Spec}(\mathscr{O}_{X,x}),$$

is an isomorphism if and only if $\mathscr{O}_X$ is Z-closed at x. This condition holds for every $x \in X - Z$.

(ii) *Put $Z' = g^{-1}(Z)$ and suppose that X' is locally Noetherian. Then $\mathscr{F}'$ is Z'-closed. If, in addition, $\mathscr{F}'$ is a coherent $\mathscr{O}_{X'}$-module, then*

$$\operatorname{prof}_{Z'}(\mathscr{F}') \geqslant 2.$$

(iii) *Suppose that both $\mathscr{H}^0_{X/Z}(\mathscr{O}_X)$ and $\mathscr{H}^0_{X/Z}(\mathscr{F})$ are coherent. Then $g : X' \to X$ is finite. The set U of points $x \in X$ such that*

$$\operatorname{prof}_{Z_x}(\widetilde{\mathscr{O}}_x) \geqslant 2 \quad \textit{and} \quad \operatorname{prof}_{Z_x}(\widetilde{\mathscr{F}}_x) \geqslant 2$$

is open in X and satisfies $X - U \subset Z$. Moreover, U is the largest open subset of X such that $g^{-1}(U) \to U$ is an isomorphism and the restriction to U of the canonical g-morphism from $\mathscr{F}$ to $\mathscr{F}'$ is an isomorphism.

Proof. Assertion (i) follows from the definitions, and (iii) is an immediate consequence of (5.10.10), (iii).

For (ii), let V be an open subset of X containing $X - Z$, put $V' = g^{-1}(V)$, and let $i : V \to X$ and $i' : V' \to X'$ be the canonical injections.

The canonical homomorphism **IV-2** | 119

$$\rho_{X'/Z'} : \mathscr{F}' \longrightarrow i'_*(\mathscr{F}'|V')$$

has the property that $g_*(\rho_{X'/Z'})$ is the canonical homomorphism

$$\rho_{X/Z} : \mathscr{H}^0_{X/Z}(\mathscr{F}) \longrightarrow i_*(\mathscr{H}^0_{X/Z}(\mathscr{F})|V),$$

by (**II**, 1.4.2) and (5.10.11.1). Since $\mathscr{H}^0_{X/Z}(\mathscr{F})$ is Z-closed (5.9.11), $\rho_{X/Z}$ is an isomorphism, and therefore so is $\rho_{X'/Z'}$. The open subset $X' - Z'$ is the intersection of the filtered family of inverse images $g^{-1}(V)$, as V ranges over the open subsets of X containing $X - Z$. Since X' is locally Noetherian, (5.9.1) now shows that $\mathscr{F}'$ is Z'-closed. The final assertion follows from (5.10.5). □

(5.10.13). We shall now apply the preceding results when Z is one of the sets $\mathrm{Z}^{(n)}(X)$ (or simply $\mathrm{Z}^{(n)}$), defined as the set of points $x \in X$ such that

$$\dim(\mathscr{O}_x) \geqslant n.$$

It is clear that $\mathrm{Z}^{(n)}$ is stable under specialization. A closed subset T of X is contained in $\mathrm{Z}^{(n)}$ if and only if

$$\operatorname{codim}(T, X) \geqslant n.$$

We shall be concerned here with the case $n = 2$.

Proposition (5.10.14). — *Let X be a locally Noetherian prescheme, and let $\mathscr{F}$ be a coherent $\mathscr{O}_X$-module whose support is X.*

(i) *The module $\mathscr{F}$ satisfies (S_1) if and only if it is $\mathrm{Z}^{(1)}$-pure.*

(ii) *The module $\mathscr{F}$ satisfies (S_2) if and only if it is $\mathrm{Z}^{(2)}$-closed and $\mathrm{Z}^{(1)}$-pure, or equivalently, if it is $\mathrm{Z}^{(2)}$-closed and has no associated prime cycle of codimension 1.*

Proof. To say that $\mathscr{F}$ has property (S_1) means that it has no embedded associated prime cycle (5.7.5), or equivalently that

$$\dim(\mathscr{F}_x) = 0 \qquad \text{for every } x \in \operatorname{Ass}(\mathscr{F})$$

(3.1.4). Since $\operatorname{Supp}(\mathscr{F}) = X$, this is equivalent to $\dim(\mathscr{O}_x) = 0$ (5.1.12.1); in other words, $\operatorname{Ass}(\mathscr{F})$ does not meet $\mathrm{Z}^{(1)}$. Assertion (i) therefore follows from (5.10.2).

To say that $\mathscr{F}$ is $\mathrm{Z}^{(2)}$-closed means that

$$\operatorname{prof}_{\mathrm{Z}^{(2)}}(\mathscr{F}) \geqslant 2,$$

or equivalently that, for every $x \in X$,

$$\dim(\mathscr{O}_x) \geqslant 2 \quad \Longrightarrow \quad \operatorname{prof}(\mathscr{F}_x) \geqslant 2.$$

Thus (S_2) implies that $\mathscr{F}$ is $\mathrm{Z}^{(2)}$-closed. It also implies (S_1), so $\mathscr{F}$ has no embedded associated prime cycle (5.7.5); since its support is X, this says that all its associated prime cycles have codimension 0.

Conversely, suppose that $\mathscr{F}$ is $\mathrm{Z}^{(2)}$-closed and has no associated prime cycle of codimension 1. It remains only to consider a point x for which $\dim(\mathscr{O}_x) = 1$. By hypothesis $x \notin \operatorname{Ass}(\mathscr{F})$, and hence $\operatorname{prof}(\mathscr{F}_x) > 0$. Since $\dim(\mathscr{F}_x) = \dim(\mathscr{O}_x) = 1$, it follows that $\operatorname{prof}(\mathscr{F}_x) = 1$. Therefore $\mathscr{F}$ satisfies (S_2). Finally, if $\mathscr{F}$ is $\mathrm{Z}^{(1)}$-pure, it satisfies (S_1) by (i); as observed above, all its associated prime cycles then have codimension 0, so the same argument applies.

Notice that a module may be $\mathrm{Z}^{(2)}$-closed without satisfying (S_1). For example, if $\dim X = 1$, then $\mathrm{Z}^{(2)} = \varnothing$ and every $\mathscr{O}_X$-module is $\mathrm{Z}^{(2)}$-closed, even though a module may have embedded associated prime cycles.

We recall that Chapter III gives, by means of local cohomology, a characterization of (S_n) for every $n \geqslant 1$ that generalizes (5.10.14). □

Corollary (5.10.15). — *Let X be a locally Noetherian prescheme, and let $\mathscr{F}$ be a coherent $\mathscr{O}_X$-module with support X. Suppose that $\mathscr{F}$ has no associated prime cycle of codimension 1 and that*

$$\mathscr{F}' = \mathscr{H}^0_{X/\mathrm{Z}^{(2)}}(\mathscr{F})$$

is coherent. Then:

(i) *$\mathscr{F}'$ satisfies (S_2).* **IV-2** | 120

(ii) *The set U of points $x \in X$ at which $\mathscr{F}$ satisfies (S_2) (5.7.2) is open in X, and*

$$\operatorname{codim}(X - U, X) \geqslant 2.$$

Proof. By (5.9.11), $\mathscr{F}'$ is $\mathrm{Z}^{(2)}$-closed. Moreover, $\operatorname{Supp}(\mathscr{F}') = X$: every maximal point of X lies outside $\mathrm{Z}^{(2)}$, and at such a point $\mathscr{F}'_x = \mathscr{F}_x \neq 0$. Thus the support of $\mathscr{F}'$ is dense in X; it is also closed because $\mathscr{F}'$ is coherent, and hence it is all of X.

It remains to see that $\mathscr{F}'$ has no associated prime cycle of codimension 1. If $x \in \operatorname{Ass}(\mathscr{F}')$ and

$$\dim(\mathscr{F}'_x) = \dim(\mathscr{O}_x) = 1,$$

then $x \notin Z^{(2)}$, so $\mathscr{F}'_x = \mathscr{F}_x$ and consequently $x \in \mathrm{Ass}(\mathscr{F})$, contrary to the hypothesis. Assertion (i) now follows from (5.10.14).

For (ii), one has

$$Z^{(n)}(X_x) = Z^{(n)}(X) \cap X_x$$

with the notation of (5.9.6), by (**I**, 2.4.2). The absence of associated prime cycles of codimension 1 for $\mathscr{F}$ implies the same property for $\widetilde{\mathscr{F}}_x$. By (5.10.14), $\widetilde{\mathscr{F}}_x$ satisfies (S_2) if and only if it is $Z^{(2)}(X_x)$-closed. The assertion therefore follows from (5.10.6) and (5.10.10), (iii). □

Proposition (5.10.16). — *Let X be a locally Noetherian prescheme, let*

$$X' = \mathrm{Spec}\big(\mathscr{H}^0_{X/Z^{(2)}}(\mathscr{O}_X)\big)$$

be its $Z^{(2)}$-closure, and let $g : X' \to X$ be the structural morphism. Suppose that X has no associated prime cycle of codimension 1.

(i) *At a point $x \in X$, the prescheme X satisfies (S_2) if and only if the morphism*

$$X'_x \longrightarrow X_x$$

deduced from g (with the notation of (5.10.12)) is an isomorphism. This condition always holds if

$$\mathrm{codim}\big(\overline{\{x\}}, X\big) \leqslant 1.$$

(ii) *Suppose in addition that g is finite (see (5.11.2) for sufficient conditions). Then the set U of points at which X satisfies (S_2) is open,*

$$\mathrm{codim}(X - U, X) \geqslant 2,$$

and U is the largest open subset of X for which $g^{-1}(U) \to U$ is an isomorphism.

(iii) *Under the hypotheses of* (ii), *X' satisfies (S_2). Moreover, for every $x' \in X'$ such that*

$$\mathrm{codim}\big(\overline{\{x'\}}, X'\big) \leqslant 1,$$

the point $x = g(x')$ satisfies

$$\mathrm{codim}\big(\overline{\{x\}}, X\big) = \mathrm{codim}\big(\overline{\{x'\}}, X'\big).$$

(iv) *Under the hypotheses of* (ii), *let $\mathscr{F}$ be a coherent $\mathscr{O}_X$-module with support X, and suppose that $\mathscr{H}^0_{X/Z^{(2)}}(\mathscr{F})$ is coherent. The $\mathscr{O}_{X'}$-module $\mathscr{F}'$ defined by*

$$g_*(\mathscr{F}') = \mathscr{H}^0_{X/Z^{(2)}}(\mathscr{F})$$

is coherent and satisfies (S_2), and its support is a union of irreducible components of X'.

Proof. Assertions (i) and (ii) have already been proved in substance: (i) follows from (5.10.12), (i), and (5.10.14), while (ii) is the special case of (5.10.15), (ii), obtained by taking $\mathscr{F} = \mathscr{O}_X$.

We prove (iii). Put $x = g(x')$. Since g is finite, so is $X'_x \to X_x$, and therefore

$$\dim(\mathscr{O}_{X',x'}) \leqslant \dim(X'_x) \leqslant \dim(X_x) = \dim(\mathscr{O}_{X,x})$$

by (5.4.1). Suppose first that $\dim(\mathscr{O}_{X',x'}) \leqslant 1$. Then $\dim(\mathscr{O}_{X,x}) \leqslant 1$ as well: otherwise $x \in Z^{(2)}$ and (5.10.12), (ii), applied to $\mathscr{O}_X$, would give

$$\mathrm{prof}(\mathscr{O}_{X',x'}) \geqslant 2,$$

which is impossible. Hence $x \notin Z^{(2)}$, and (5.10.12), (i), gives an isomorphism

$$\mathscr{O}_{X,x} \simeq \mathscr{O}_{X',x'}.$$

In particular their dimensions are equal. Since X has no associated prime cycle of codimension 1, the equality $\dim(\mathscr{O}_{X,x}) = 1$ implies $x \notin \mathrm{Ass}(\mathscr{O}_X)$, so

$$\mathrm{prof}(\mathscr{O}_{X,x}) = \mathrm{prof}(\mathscr{O}_{X',x'}) = 1.$$

If instead $\dim(\mathscr{O}_{X',x'}) \geqslant 2$, then $\dim(\mathscr{O}_{X,x}) \geqslant 2$, so $x \in Z^{(2)}$ and (5.10.12), (ii), gives

$$\mathrm{prof}(\mathscr{O}_{X',x'}) \geqslant 2.$$

This proves all the assertions in (iii).

For (iv), replace $\mathscr{O}_X$ by $\mathscr{F}$ in the preceding argument. Since g is finite and $g_*(\mathscr{F}')$ is coherent, $\mathscr{F}'$ is coherent. The same argument proves that $\mathscr{F}'$ satisfies (S_2) and that, if $\dim(\mathscr{F}'_{x'}) \leqslant 1$, then $\mathscr{F}_x$ and $\mathscr{F}'_{x'}$ are di-isomorphic. In particular,

$$\dim(\mathscr{F}'_{x'}) = 0 \quad\Longrightarrow\quad \dim(\mathscr{F}_x) = 0 \quad\Longrightarrow\quad \dim(\mathscr{O}_{X,x}) = 0,$$

because $\mathrm{Supp}(\mathscr{F}) = X$, and hence also $\dim(\mathscr{O}_{X',x'}) = 0$. Every irreducible component of $\mathrm{Supp}(\mathscr{F}')$ is therefore an irreducible component of X'. Finally, $\mathrm{Supp}(\mathscr{F}')$ is closed because $\mathscr{F}'$ is coherent. □

Proposition (5.10.17). — *Let A be a Noetherian integral domain, and denote by $A^{(1)}$ the intersection of the local rings $A_\mathfrak{p}$, where $\mathfrak{p}$ ranges over the prime ideals of A of height 1. Suppose that $A^{(1)}$ is a finite A-algebra. Then:*

(i) *The ring $A^{(1)}$ satisfies (S_2).*

(ii) *The set U of primes $\mathfrak{p} \in \mathrm{Spec}(A)$ for which the canonical homomorphism*

$$A_\mathfrak{p} \longrightarrow (A^{(1)})_\mathfrak{p}$$

is bijective is precisely the set of primes for which $A_\mathfrak{p}$ satisfies (S_2). The set U is open in $X = \mathrm{Spec}(A)$ and

$$\mathrm{codim}(X - U, X) \geqslant 2.$$

(iii) *For every multiplicative subset S of A, $(S^{-1}A)^{(1)}$ is a finite $S^{-1}A$-algebra.*

(iv) *Let B be a finite integral A-algebra that is an integral domain and contains A. Then $B^{(1)}$ is a finite B-algebra. Moreover, if $\mathfrak{q}$ is a prime ideal of B of height 1, then $\mathfrak{q} \cap A$ has height 1 in A.*

Proof. Formula (5.9.3.1) shows that

$$X' = \mathrm{Spec}(A^{(1)})$$

is the $Z^{(2)}$-closure of $X = \mathrm{Spec}(A)$. Since A has no embedded associated prime ideals, assertions (i) and (ii) are special cases of (5.10.16), (i)–(iii).

For (iii), observe that

$$(S^{-1}A)^{(1)} = S^{-1}A^{(1)},$$

which is a special case of (5.9.4). Indeed, $S^{-1}A$ is flat over A, its prime ideals are the ideals $S^{-1}\mathfrak{p}$ with $\mathfrak{p} \in \mathrm{Spec}(A)$ disjoint from S, and

$$\mathrm{ht}(S^{-1}\mathfrak{p}) = \mathrm{ht}(\mathfrak{p}).$$

Since $A^{(1)}$ is finite over A, its localization $S^{-1}A^{(1)}$ is finite over $S^{-1}A$.

To prove (iv), put $Y = \mathrm{Spec}(B)$ and let $f : Y \to X$ be the structural morphism. Since f is finite, (5.4.1) gives, for every $y \in Y$,

$$\dim(\mathscr{O}_{Y,y}) \leqslant \dim(\mathscr{O}_{X,f(y)}).$$

Consequently, if

$$T = f^{-1}(Z^{(2)}(X)),$$

then $T \supset Z^{(2)}(Y)$.

We claim that

$$\mathscr{G} = \mathscr{H}^0_{X/Z^{(2)}(X)}(f_*(\mathscr{O}_Y))$$

is coherent. The module $f_*(\mathscr{O}_Y)$ corresponds to B viewed as an A-module. Since B is a finite integral A-algebra and an integral domain, its field of fractions is finite over the field of fractions of A; hence B is contained in a finite free A-module. By (5.9.2), (i), $\mathscr{G}$ is therefore a quasi-coherent $\mathscr{O}_X$-submodule of

$$\left(\mathscr{H}^0_{X/Z^{(2)}(X)}(\mathscr{O}_X)\right)^n$$

for a suitable n. The latter module is coherent by hypothesis, and hence so is $\mathscr{G}$.

By the definition (5.9.1.2), there is an isomorphism

$$\mathscr{G} \simeq f_*(\mathscr{H}^0_{Y/T}(\mathscr{O}_Y)).$$

It follows, in particular, that $\mathscr{H}^0_{Y/T}(\mathscr{O}_Y)$ is a coherent $\mathscr{O}_Y$-module. Applying (5.10.10), (ii), to $\mathscr{O}_Y$ and the generic point of Y, we obtain

$$\mathrm{codim}(T, Y) \geqslant 2,$$

that is, $T \subset Z^{(2)}(Y)$. Thus $T = Z^{(2)}(Y)$. Formula (5.9.3.1) now identifies the corresponding algebra with $B^{(1)}$, proving that $B^{(1)}$ is finite over B. Finally, if $\mathfrak{q}$ has height 1, then $\mathfrak{q} \notin T$, so $\mathfrak{q} \cap A \notin Z^{(2)}(X)$. Incomparability for the integral extension $A \subset B$ excludes $\mathfrak{q} \cap A = (0)$; hence

$$\mathrm{ht}(\mathfrak{q} \cap A) = 1.$$

$\square$

IV-2 | 122

5.11. Coherence criteria for the modules $\mathscr{H}^0_{X/Z}(\mathscr{F})$

Proposition (5.11.1). — *Let X be a locally Noetherian prescheme, let Z be a subset of X stable under specialization, and let $\mathscr{F}$ be a coherent $\mathscr{O}_X$-module. Denote by (x_α) the family of points of*

$$\mathrm{Ass}(\mathscr{F}) \cap (X - Z),$$

and, for every α, let Y_α be the reduced closed subprescheme of X whose underlying space is $\overline{\{x_\alpha\}}$, and put $Z_\alpha = Z \cap \overline{\{x_\alpha\}}$. The following two conditions are equivalent:

a) *$\mathscr{H}^0_{X/Z}(\mathscr{F})$ is a coherent $\mathscr{O}_X$-module.*

b) *For every α, $\mathscr{H}^0_{Y_\alpha/Z_\alpha}(\mathscr{O}_{Y_\alpha})$ is a coherent $\mathscr{O}_{Y_\alpha}$-module.*

These conditions imply:

c) *For every α,* $\mathrm{codim}(Z_\alpha, Y_\alpha) \geqslant 2$.

Moreover, conditions a), b), *and* c) *are equivalent if, in addition, either of the following properties holds:*

(i) *Every point of X has an open neighbourhood isomorphic to a subscheme of a regular scheme; one also says in this case that X is* locally immersible in a regular scheme.

(ii) *For every α, Y_α is universally catenary* (5.6.2), *and its normalization $\widetilde{Y}_\alpha$* (**II**, 6.3.8) *is finite over Y_α.*

Proof. All the properties under consideration are local on X. We may therefore restrict ourselves to the case in which $X = \mathrm{Spec}(A)$ is affine, A is Noetherian, and $\mathscr{F} = \widetilde{M}$, where M is a finite A-module. For every α, let $h_\alpha : Y_\alpha \to X$ be the canonical injection. Then

$$(h_\alpha)_*(\mathscr{O}_{Y_\alpha}) = \mathscr{G}_\alpha$$

is the $\mathscr{O}_X$-module corresponding to the quotient $A/\mathfrak{j}_{x_\alpha}$; by the definition of $\mathrm{Ass}(\mathscr{F})$, this quotient is isomorphic to an A-submodule of M. Since $\mathscr{H}^0_{X/Z}(\mathscr{G}_\alpha)$ is a quasi-coherent $\mathscr{O}_X$-submodule of $\mathscr{H}^0_{X/Z}(\mathscr{F})$ (5.9.2), condition a) implies that it is coherent. On the other hand, the definition (5.9.1.2) gives

$$\mathscr{H}^0_{X/Z}(\mathscr{G}_\alpha) \simeq (h_\alpha)_*\big(\mathscr{H}^0_{Y_\alpha/Z_\alpha}(\mathscr{O}_{Y_\alpha})\big).$$

Thus a) implies b).

To prove the converse, it is enough to find a finite filtration $(\mathscr{F}_i)_{0 \leqslant i \leqslant n}$ by coherent $\mathscr{O}_X$-modules, with $\mathscr{F}_0 = \mathscr{F}$ and $\mathscr{F}_n = 0$, such that

$$\mathscr{H}^0_{X/Z}(\mathscr{F}_i/\mathscr{F}_{i+1})$$

is coherent for every i. Indeed, the assertion then follows by descending induction from the exact sequences

$$0 \longrightarrow \mathscr{F}_{i+1} \longrightarrow \mathscr{F}_i \longrightarrow \mathscr{F}_i/\mathscr{F}_{i+1},$$

the left exactness of $\mathscr{H}^0_{X/Z}$ (5.9.2), and (**0I**, 5.3.3) and (**I**, 6.1.1). In view of (3.2.8), it is therefore enough to treat the case in which $\mathscr{F}$ is irredundant, that is, $\mathrm{Ass}(M) = \{\mathfrak{p}\}$ consists of one element. We use the following lemma.

Lemma (5.11.1.1). — *Let A be a Noetherian ring and let M be a finite A-module such that* $\mathrm{Ass}(M) = \{\mathfrak{p}\}$. *There is a finite filtration $(M_i)_{0 \leqslant i \leqslant r}$ of M, with $M_0 = M$ and $M_r = 0$, such that every quotient M_i/M_{i+1} is isomorphic to a submodule of $A/\mathfrak{p}$.*

Proof. The canonical homomorphism $M \to M_\mathfrak{p} = N$ is injective (Bourbaki, *Algèbre commutative*, Chapter IV, §1, no. 2, Proposition 6). Put

$$B = A_\mathfrak{p}, \qquad \mathfrak{m} = \mathfrak{p}A_\mathfrak{p}.$$

Then $\mathfrak{m}$ is the maximal ideal of B and $\mathrm{Ass}(N) = \{\mathfrak{m}\}$ (*loc. cit.*, Proposition 5).

Since N is a finite B-module, there is an integer s such that $\mathfrak{m}^s N = 0$. The filtration by the powers $\mathfrak{m}^j N$ may be refined to a finite filtration (N_i) of N whose successive quotients are isomorphic to **IV-2 | 123**

$$B/\mathfrak{m} = \mathrm{Frac}(A/\mathfrak{p}).$$

Intersecting it with M gives $M_i = M \cap N_i$. Each quotient M_i/M_{i+1} is then isomorphic to a finite $(A/\mathfrak{p})$-submodule of $\mathrm{Frac}(A/\mathfrak{p})$, and every such module is isomorphic to a submodule of $A/\mathfrak{p}$. □

Completion of the proof of Proposition 5.11.1. The lemma and the preceding filtration argument reduce the proof, under condition b), to showing that $\mathscr{H}^0_{X/Z}(\mathscr{G})$ is coherent when

$$\mathscr{G} = (A/\mathfrak{p})^\sim$$

and $\mathfrak{p}$ is an associated prime of M. If $\mathfrak{p} = \mathfrak{j}_y$ with $y \in Z$, the support of $\mathscr{G}$ is a closed subset contained in Z, because Z is stable under specialization. Hence $\mathscr{H}^0_{X/Z}(\mathscr{G}) = 0$ by (5.9.1.2). Otherwise, $\mathfrak{p} = \mathfrak{j}_{x_\alpha}$ for some α, and

$$\mathscr{G} = (h_\alpha)_*(\mathscr{O}_{Y_\alpha}).$$

The displayed isomorphism above and condition b) then show that $\mathscr{H}^0_{X/Z}(\mathscr{G})$ is coherent. This proves the equivalence of a) and b).

Condition a) implies c) by (5.10.10, ii). It remains to prove, under either hypothesis (i) or (ii), that c) implies b). If X satisfies (i), each Y_α does as well. Consequently, in view of (5.9.3.1), the required assertion follows from Corollary 5.11.2 below. □

Corollary (5.11.2). — *Let A be a Noetherian domain satisfying either of the following hypotheses:*

(i) *A is a quotient of a regular Noetherian ring.*

(ii) *A is universally catenary, and its integral closure A' is a finite A-algebra.*

Then

$$A^{(1)} = \bigcap_{\substack{\mathfrak{p} \in \mathrm{Spec}(A) \\ \mathrm{ht}(\mathfrak{p}) = 1}} A_\mathfrak{p}$$

is a finite A-algebra.

Proof. Suppose first that (i) holds, and put $X = \mathrm{Spec}(A)$. The set U of points at which X satisfies (S_2) is open by (6.11.2).[13] Put $Z = X - U$. Then $\mathrm{codim}(Z, X) \geqslant 2$. Indeed, if $x \in X$ and $\dim(\mathscr{O}_x) \leqslant 1$, then $\dim(\mathscr{O}_{x'}) \leqslant 1$ for every generization x' of x. Since $\mathscr{O}_{x'}$ is a domain, it has positive depth whenever its dimension is positive, and therefore X satisfies (S_2) at x.

Thus $Z \subset Z^{(2)}(X)$. If $j : U \to X$ is the canonical injection, (5.9.1.2) gives

$$\mathscr{H}^0_{X/Z^{(2)}(X)}(\mathscr{O}_X) \simeq j_*\big(\mathscr{H}^0_{U/Z^{(2)}(U)}(\mathscr{O}_U)\big).$$

The prescheme U satisfies (S_2), so (5.10.14) identifies the module inside the parentheses with $\mathscr{O}_U$. Since $\mathrm{codim}(Z, X) \geqslant 2$, Chapter III, §9 shows that $j_*(\mathscr{O}_U)$ is coherent. Finally, (5.9.3.1) identifies the corresponding A-module with $A^{(1)}$, proving the assertion under (i).

Now suppose that (ii) holds. The ring A' is a Noetherian normal domain, hence it is the intersection of its local rings $A'_{\mathfrak{p}'}$ as $\mathfrak{p}'$ ranges over the height-one prime ideals of A' (Bourbaki, *Algèbre commutative*, Chapter VII, §1, no. 6, Theorem 4). For such a prime $\mathfrak{p}'$, put

$$\mathfrak{p} = \mathfrak{p}' \cap A, \qquad S = A - \mathfrak{p}.$$

The ring $A'_{\mathfrak{p}'}$ is the localization of the finite $A_\mathfrak{p}$-algebra $S^{-1}A'$ at $S^{-1}\mathfrak{p}'$. The latter prime lies above the maximal ideal $\mathfrak{p}A_\mathfrak{p}$ and is therefore maximal. Moreover, $A_\mathfrak{p}$ is universally catenary by (5.6.3, i). Formula (5.6.10) consequently gives **IV-2 | 124**

$$\dim(A_\mathfrak{p}) = \dim(A'_{\mathfrak{p}'}) = 1.$$

It follows that $A^{(1)} \subset A'$. Since A' is a finite A-module and A is Noetherian, its submodule $A^{(1)}$ is finite as well. □

[13] The reader may verify that Corollary 5.11.2 is not used in the proof of (6.11.2).

Remark (5.11.3). — The conclusion that $A^{(1)}$ is a finite A-algebra need no longer hold if, in hypothesis (ii) of (5.11.2), one assumes only that A is catenary.

Indeed, consider the catenary local ring A constructed in (5.6.11); its integral closure A' (denoted there by B) is a finite A-algebra. If $A^{(1)}$ were also finite over A, then, being contained in the fraction field of A, it would be contained in A'. On the other hand, in the notation of (5.6.11), every height-one prime ideal of A is of the form $\mathfrak{p}A$, where $\mathfrak{p}$ is a height-one prime of C, and

$$A_{\mathfrak{p}A} = C_{\mathfrak{p}}.$$

Moreover, $C_{\mathfrak{p}} = E_{\mathfrak{p}'}$, where $\mathfrak{p}'$ is the unique prime of E above $\mathfrak{p}$. Thus $A_{\mathfrak{p}A}$ is integrally closed and consequently contains A'. By definition this gives $A' \subset A^{(1)}$, so finiteness of $A^{(1)}$ would force $A^{(1)} = A'$. This is impossible: one of the two prime ideals of A' above the maximal ideal $\mathfrak{n}A$ of A has height 1, whereas $\mathfrak{n}A$ has height 2, contradicting (5.10.17, iv).

Corollary (5.11.4). — *Let X be a locally Noetherian prescheme, let Z be a closed subset of X, put $U = X - Z$, and let $i : U \to X$ be the canonical injection. Let $\mathscr{F}$ be a coherent $\mathscr{O}_U$-module. A necessary condition for $i_*(\mathscr{F})$ to be a coherent $\mathscr{O}_X$-module is that*

$$\operatorname{codim}\big(\overline{\{x\}} \cap Z, \overline{\{x\}}\big) \geqslant 2 \qquad \textit{for every } x \in \operatorname{Ass}(\mathscr{F}).$$

This condition is sufficient in either of the following cases:

(i) *X is locally immersible in a regular scheme.*

(ii) *X is universally catenary and universally Japanese; by definition, the latter means that every point $x \in X$ has an affine open neighbourhood whose ring is universally Japanese* (**0**, 23.1.1).

Proof. By (**I**, 9.4.7), there is a coherent $\mathscr{O}_X$-submodule $\mathscr{G}$ of $i_*(\mathscr{F})$ such that $\mathscr{G}|U = \mathscr{F}$. Plainly,

$$\operatorname{Ass}(\mathscr{G}) \subset \operatorname{Ass}(\mathscr{F}) \subset \operatorname{Ass}\big(i_*(\mathscr{F})\big),$$

and

$$\operatorname{Ass}\big(i_*(\mathscr{F})\big) = \operatorname{Ass}(\mathscr{F})$$

by (3.1.13). Hence $\operatorname{Ass}(\mathscr{G}) = \operatorname{Ass}(\mathscr{F})$. It remains to apply (5.11.1) to $\mathscr{G}$, observing that

$$i_*(\mathscr{F}) = \mathscr{H}^0_{X/Z}(\mathscr{G}),$$

and that, when X is universally catenary and universally Japanese, hypothesis (ii) of (5.11.1) holds by definition. □

Corollary (5.11.5). — *Let X be a locally Noetherian prescheme, let Z be a subset of X stable under specialization, and let $\mathscr{F}$ be a coherent $\mathscr{O}_X$-module such that $\operatorname{Ass}(\mathscr{F}) \subset X - Z$. Consider the conditions:*

a) *$\mathscr{H}^0_{X/Z}(\mathscr{F})$ is a coherent $\mathscr{O}_X$-module.*

d) *For every subset T of Z closed in X, $i_*(\mathscr{F}|X - T)$ is coherent, where $i : X - T \to X$ is the canonical injection. It is enough here*
to consider an increasing filtered family of such closed subsets whose union is Z. **IV-2** | 125

Then a) *implies* d). *If X satisfies either hypothesis* (i) *or* (ii) *of* (5.11.1), *the two conditions are equivalent.*

Proof. The hypothesis and (3.1.13) give

$$\operatorname{Ass}\big(i_*(\mathscr{F}|X - T)\big) = \operatorname{Ass}(\mathscr{F}).$$

It follows from (5.10.2) that the canonical maps

$$i_*(\mathscr{F}|X - T) \longrightarrow \mathscr{H}^0_{X/Z}(\mathscr{F})$$

are injective. Condition a) therefore implies d).

Conversely, condition d) and (5.11.1) imply, in the notation of that proposition, that

$$\operatorname{codim}(T \cap Y_\alpha, Y_\alpha) \geqslant 2.$$

Since Z is the union of its subsets closed in X, it follows that

$$\operatorname{codim}(Z \cap Y_\alpha, Y_\alpha) \geqslant 2.$$

The last assertion now follows from (5.11.1). □

Corollary (5.11.6). — *Let A be a Noetherian ring and put $X = \operatorname{Spec}(A)$. Consider the following properties:*

a) *For every quotient domain B of A, the ring $B^{(1)}$ (5.11.2) is a finite B-algebra.*
b) *For every coherent $\mathscr{O}_X$-module $\mathscr{F}$ and every subset Z of X stable under specialization such that*

$$\operatorname{codim}\left(\overline{\{x\}} \cap Z, \overline{\{x\}}\right) \geqslant 2$$

for every $x \in \operatorname{Ass}(\mathscr{F}) \cap (X - Z)$, the module $\mathscr{H}^0_{X/Z}(\mathscr{F})$ is coherent.
c) *For every closed subset T of X and every coherent $\mathscr{O}_U$-module $\mathscr{G}$, where $U = X - T$, such that*

$$\operatorname{codim}\left(\overline{\{x\}} \cap T, \overline{\{x\}}\right) \geqslant 2 \qquad (x \in \operatorname{Ass}(\mathscr{G})),$$

the module $i_*(\mathscr{G})$ is coherent, where $i : U \to X$ is the canonical injection.
d) *For every quotient domain B of A and every ideal $\mathfrak{J}$ of B of height at least 2, the ring*

$$\bigcap_{\mathfrak{p} \not\supseteq \mathfrak{J}} B_{\mathfrak{p}}$$

is a finite B-algebra.

Then

$$\text{a)} \iff \text{b)} \implies \text{c)} \iff \text{d)}.$$

Moreover, all four properties hold in either of the following cases:
(i) *A is a quotient of a regular ring.*
(ii) *A is universally catenary and universally Japanese.*

Proof. Let $B = A/\mathfrak{q}$, where $\mathfrak{q}$ is a prime ideal of A, so that $Y = \operatorname{Spec}(B) = V(\mathfrak{q})$ is a closed subset of X. Put $Z = Z^{(2)}(Y)$, viewed as a subset of X stable under specialization. Since B is a domain, $\operatorname{Ass}(A/\mathfrak{q})$ consists only of the generic point $\mathfrak{q}$ of Y. If b) holds, apply it to

$$\mathscr{F} = (A/\mathfrak{q})^\sim$$

and to Z. Formula (5.9.3.1) then shows that $B^{(1)}$ is a finite A-module, and hence a finite B-module. Thus b) implies a).

Conversely, suppose a) holds. Let $\mathscr{F}$ and Z satisfy the assumptions in b), and use the notation of (5.11.1). Each $Y_\alpha = \operatorname{Spec}(B_\alpha)$, where B_α is a quotient domain of A. Since $Z_\alpha \subset Z^{(2)}(Y_\alpha)$, condition a), (5.10.2), and the fact that $\operatorname{Ass}(\mathscr{O}_{Y_\alpha})$ consists of the generic point show that

$$\mathscr{H}^0_{Y_\alpha/Z_\alpha}(\mathscr{O}_{Y_\alpha})$$

is coherent. Property b) follows from (5.11.1).

To prove that c) implies d), argue as above with $\mathscr{G} = (A/\mathfrak{q})^\sim|U$ and $T = V(\mathfrak{J})$. Conversely, **IV-2** | 126
d) implies c) by applying the same componentwise argument and (5.11.1). Property c) is plainly a special case of b). Finally, (5.11.2), together with the definitions of universally catenary and universally Japanese rings, proves all four properties under either hypothesis (i) or (ii). □

Remarks (5.11.7). — (i) It is not known whether condition d) in (5.11.5) implies condition a) without an additional hypothesis on X. We shall see in (7.2.4) that it does when X is a local scheme. Likewise, when A is a Noetherian local ring, the four properties a), b), c), and d) of (5.11.6) are equivalent (7.2.4). It is not known whether this result extends to every Noetherian ring.

(ii) If A satisfies property a) of (5.11.6), then so does every localization $S^{-1}A$ and every finite A-algebra C. Indeed, every quotient domain of $S^{-1}A$ has the form

$$S^{-1}(A/\mathfrak{q}),$$

where $\mathfrak{q}$ is a prime ideal of A disjoint from S. On the other hand, if $\mathfrak{r}$ is a prime ideal of C and $\mathfrak{p}$ is its inverse image in A, then $C/\mathfrak{r}$ is a finite integral $(A/\mathfrak{p})$-algebra containing $A/\mathfrak{p}$. The assertions therefore follow from (5.10.17, iii) and (5.10.17, iv).

5.12. Relations between the properties of a Noetherian local ring A and of a quotient ring A/tA We have already seen in (3.4) relations between the properties of A and those of A/tA concerning associated prime ideals, as well as the properties of being a domain or being reduced. In this subsection we give further relations between the properties of these rings, involving the notions of dimension and depth.

Proposition (5.12.1). — *Let A be a Noetherian local ring, put $X = \mathrm{Spec}(A)$, and let t be an element of A belonging to a system of parameters (**0**, 16.3.6). Let X_0 be the closed subspace $V(t)$ of X, and let $X_1 = X - X_0$. Let Z be a subset of X stable under specialization. Suppose that X is biequidimensional (as is the case when A is equidimensional and is a quotient of a regular local ring (**0**, 16.5.12)). If $Z_0 = Z \cap X_0$ and $Z_1 = Z \cap X_1$, then*

$$\text{(5.12.1.1)} \qquad \mathrm{codim}(Z_0, X_0) \leqslant \mathrm{codim}(Z, X) \leqslant \mathrm{codim}(Z_1, X_1).$$

Proof. The second inequality follows from the definition (5.1.3). For the first, it is enough to treat the case in which Z is closed. Indeed, by hypothesis Z is a union of closed subsets Z_α, and inequalities

$$\mathrm{codim}(X_0 \cap Z_\alpha, X_0) \leqslant \mathrm{codim}(Z_\alpha, X)$$

for all α give

$$\begin{aligned}\mathrm{codim}(Z_0, X_0) &= \inf_\alpha \mathrm{codim}(X_0 \cap Z_\alpha, X_0)\\ &\leqslant \inf_\alpha \mathrm{codim}(Z_\alpha, X) = \mathrm{codim}(Z, X).\end{aligned}$$

Suppose therefore that Z is closed. Then

$$\mathrm{codim}(Z, X) = \dim(X) - \dim(Z)$$

by (**0**, 14.3.5.1).

Moreover, X_0 is catenary and equidimensional, and $\dim(X_0) = \dim(X) - 1$ by (**0**, 16.3.4); hence **IV-2** | 127

$$\mathrm{codim}(Z_0, X_0) = \dim(X) - 1 - \dim(Z_0).$$

Since $\dim(Z_0) \geqslant \dim(Z) - 1$ (**0**, 16.3.4), the first inequality in (5.12.1.1) follows. □

Proposition (5.12.2). — *Let A be a catenary Noetherian local ring, let M be a finite A-module, let t be an M-regular element belonging to the maximal ideal $\mathfrak{m}$ of A, and let $k \geqslant 1$. If M/tM is equidimensional and satisfies (S_k), then the same is true of M.*

Proof. In view of $(\mathbf{Err}_{\mathrm{III}}, 30)$ and (5.7.3, vi), we may reduce to the case

$$\mathrm{Supp}(M) = \mathrm{Spec}(A) = X.$$

Put $X_0 = V(t) = \mathrm{Spec}(A/tA)$. Since M/tM satisfies (S_1), it has no embedded associated prime ideals (5.7.5). Applying (3.4.4) at the closed point of X (and of every closed subprescheme of X), we see that the irreducible components of $\mathrm{Supp}(M/tM)$ are exactly the irreducible components of $Y_i \cap X_0$, where Y_i $(1 \leqslant i \leqslant r)$ are the irreducible components of X.

Because t is M-regular, $V(t)$ contains no maximal point of X (3.1.8). Every irreducible component of $Y_i \cap X_0$ therefore has codimension 1 in Y_i (5.1.8). Since X is catenary and all irreducible components of $\mathrm{Supp}(M/tM)$ have the same dimension, the Y_i all have the same dimension. Thus X is equidimensional, and hence biequidimensional because A is local and catenary.

It remains to prove (S_k). By the criterion (5.7.4), with its notation, we must show that

$$\mathrm{codim}(Z_n, X) > n + k$$

for every integer $n \geqslant 0$. The hypothesis on M/tM and the same criterion give

$$\mathrm{codim}(Z_n \cap X_0, X_0) > n + k.$$

Every specialization of a point of Z_n again belongs to Z_n, as will be proved in (6.11.5).[14] Finally, t belongs to a system of parameters for M (**0**, 16.4.1), and hence also to one for A, because the annihilator of M is nilpotent under the hypothesis $\mathrm{Supp}(M) = \mathrm{Spec}(A)$. The required inequality now follows from (5.12.1). □

[14] The reader may verify that Proposition 5.12.2 is not used in the proof of (6.11.5).

Remark (5.12.3). — If in Proposition 5.12.2 one assumes only that M/tM is equidimensional, it need not follow that M is equidimensional. For example, let k be a field, let $B = k[T, U, V]$, let C be the local ring of B at the maximal ideal $BT + BU + BV$, and put

$$\mathfrak{p} = CU, \qquad \mathfrak{q} = CV + C(T + U), \qquad A = C/\mathfrak{p}\mathfrak{q}.$$

Geometrically, A is the local ring, at their intersection point x, of the closed subscheme of affine 3-space formed by a plane and a line meeting that plane at x. Let t, u, v be the images of T, U, V in A. The element t is not a zero divisor in A, and

$$A/tA \simeq C_0/\mathfrak{p}_0\mathfrak{q}_0,$$

where C_0 is the local ring of $B_0 = k[U, V]$ at the maximal ideal $B_0U + B_0V$, while

$$\mathfrak{p}_0 = C_0U, \qquad \mathfrak{q}_0 = C_0U + C_0V.$$

Thus $\mathfrak{q}_0$ is the maximal ideal of C_0.

It is immediate that $\operatorname{Spec}(A/tA)$ is irreducible of dimension 1, that A/tA does not satisfy (S_1), **IV-2** | 128
and that $\operatorname{Spec}(A)$ is not equidimensional.

Corollary (5.12.4). — *Let A be a catenary Noetherian local ring, let t be a regular element belonging to the maximal ideal of A, and let $k \geqslant 1$. If A/tA satisfies (S_k), then so does A.*

Proof. For $k = 1$ this follows from (3.4.4), in view of the interpretation of (S_1) in (5.7.5). For $k \geqslant 2$, Hartshorne's criterion (5.10.9) shows that A/tA is equidimensional, and Proposition 5.12.2 applies. □

Proposition (5.12.5). — *Let A be a catenary Noetherian local ring, let t be a regular element of A belonging to its maximal ideal, and let $k \geqslant 0$. If A/tA is reduced and equidimensional and satisfies (R_k), then A has these same three properties.*

Proof. We already know from (3.4.6) that A is reduced, and Proposition 5.12.2, applied with $k = 1$, shows that A is equidimensional. Put

$$X = \operatorname{Spec}(A), \qquad X_0 = V(t) = \operatorname{Spec}(A/tA),$$

and let Z be the set of points at which X is not regular. Every specialization of a point of Z belongs to Z (**0**, 17.3.2). On the other hand, if $x \in X_0$ and X_0 is regular at x, then X is regular at x (**0**, 17.1.8). Consequently the nonregular locus Z_0' of X_0 contains $Z_0 = Z \cap X_0$. The hypothesis gives

$$k < \operatorname{codim}(Z_0', X_0) \leqslant \operatorname{codim}(Z_0, X_0).$$

Since A is equidimensional and catenary, Proposition 5.12.1 gives

$$\operatorname{codim}(Z_0, X_0) \leqslant \operatorname{codim}(Z, X).$$

Thus X satisfies (R_k). □

Remark (5.12.6). — If in Proposition 5.12.5 one assumes only that A/tA is reduced and satisfies (R_k), it need not follow that A satisfies (R_k). For example, let k be a field and let $P(U, V) \in k[U, V]$ be irreducible, with the curve Γ defined by (P) in $\operatorname{Spec}(k[U, V])$ singular at the maximal ideal $(U) + (V)$. One may take, for example,

$$P(U, V) = U(U^2 + V^2) + (U^2 - V^2),$$

which defines a cubic with a double point. Let $B = k[T, U, V, W]$, let C be the local ring of B at the maximal ideal $BT + BU + BV + BW$, and put

$$\mathfrak{p} = CW + CP(U - T, V), \qquad \mathfrak{q} = CU.$$

Consider the local ring $A = C/\mathfrak{p}\mathfrak{q}$. Geometrically, the corresponding closed subscheme X of affine 4-space is the union of a hyperplane H and a 2-dimensional "cylinder" L with base Γ; the "singular line" Y of L is not contained in H, and A is the local ring of X at the point $x = Y \cap H$.

Let t be the image of T in A. The scheme $\operatorname{Spec}(A/tA)$ has x as its only singular point; its local ring there is A/tA, which is reduced and has dimension 2. By contrast, the generic point y of Y, defined by the image in A of

$$C(U - T) + CV + CW,$$

is a singular point of X, and $\mathscr{O}_{X,y}$ has dimension 1. Thus A/tA is reduced and satisfies (R_1), whereas A does not satisfy (R_1).

IV-2 | 129

Corollary (5.12.7). — *Let A be a catenary Noetherian local ring and let t be a regular element of A belonging to its maximal ideal. If A/tA is a domain and is integrally closed, then so is A.*

Proof. By Serre's criterion (5.8.6) and the fact that A is local, it is enough to prove that $\mathrm{Spec}(A)$ satisfies (S_2) and (R_1). The hypothesis on A/tA implies (R_1) for A by Proposition 5.12.5 and (S_2) for A by Corollary 5.12.4. □

Proposition (5.12.8). — (Hironaka's lemma). *Let A be a reduced, equidimensional, catenary Noetherian local ring. Suppose in addition that, for every minimal prime ideal $\mathfrak{q}_i$ of A, the ring $B_i = A/\mathfrak{q}_i$ has the property that $B_i^{(1)}$ (notation of (5.10.17)) is a finite B_i-algebra. This last condition holds, for example, when A has either property* (i) *or property* (ii) *of (5.11.6).*

Let $t \in A$ be a non-zero-divisor satisfying the following conditions:

(i) *The A-module A/tA has a unique nonembedded associated prime ideal $\mathfrak{p}$. (It necessarily has height* 1 *by the Hauptidealsatz (**0**, 16.3.2), but it is not assumed to be the only associated prime of A/tA.)*
(ii) *The ideal $\mathfrak{p}A_\mathfrak{p}$ is generated by $t/1$.*
(iii) *The ring $A/\mathfrak{p}$ is integrally closed.*

Then A is a domain and is integrally closed, and $\mathfrak{p} = tA$.

Proof. Put $X = \mathrm{Spec}(A)$ and $Z = V(tA)$. Condition (i) says that Z is irreducible, with generic point corresponding to $\mathfrak{p}$. By (ii), the maximal ideal of the Noetherian local ring $A_\mathfrak{p}$ is generated by one element. Thus $A_\mathfrak{p}$ is a discrete valuation ring with uniformizer $t/1$ (Bourbaki, *Algèbre commutative*, chap. VI, §3, no. 6, prop. 9), and $A_\mathfrak{p}/tA_\mathfrak{p}$, its residue field, has length 1 as an $A_\mathfrak{p}$-module.

It follows from (3.4.2) that Z is contained in only one irreducible component, say X_i, of X. For every other irreducible component X_j one consequently has

$$\dim(X_j \cap Z) < \dim(Z) = \dim(X_i \cap Z).$$

Since t is not a zero divisor, it belongs to none of the minimal prime ideals $\mathfrak{q}_j$, and hence

$$\mathrm{codim}(X_i \cap Z, X_i) = \mathrm{codim}(X_j \cap Z, X_j) = 1$$

for every $j \neq i$ (5.1.8). But A is biequidimensional; the displayed strict inequality would therefore force $\dim(X_i) \neq \dim(X_j)$ (**0**, 14.3.3.1), a contradiction. Hence A has only one minimal prime. Since it is reduced, A is a domain.

Let $A^{(1)}$ have the meaning of (5.10.17). It is a finite A-algebra and therefore a Noetherian semilocal ring. Every nonembedded associated prime $\mathfrak{r}$ of $A^{(1)}/tA^{(1)}$ has height 1 by the Hauptidealsatz. Its contraction $\mathfrak{r} \cap A$ also has height 1 (5.10.17, iv), and, since it contains tA, condition (i) forces

$$\mathfrak{r} \cap A = \mathfrak{p}.$$

Let A' be the integral closure of A and put $S = A - \mathfrak{p}$. The integral closure of $A_\mathfrak{p}$ is $S^{-1}A'$ (Bourbaki, *Algèbre commutative*, chap. V, §1, no. 5, prop. 17); it equals $A_\mathfrak{p}$ because this ring is a discrete valuation ring. Consequently there is only one prime $\mathfrak{p}'$ of A' above $\mathfrak{p}$ (*loc. cit.*, §2, no. 1, lemma 1), and therefore only one prime $\mathfrak{p}^{(1)}$ of $A^{(1)}$ above $\mathfrak{p}$. Moreover,

$$A_\mathfrak{p} = A'_{\mathfrak{p}'} = A^{(1)}_{\mathfrak{p}^{(1)}}.$$

The ring $A^{(1)}$ satisfies (S_2) (5.10.17, i). Since t is a non-zero-divisor on $A^{(1)}$, the quotient **IV-2** | 130

$$A^{(1)}/tA^{(1)}$$

has no embedded associated primes (5.7.7). Thus $\mathfrak{p}^{(1)}$ is its only associated prime, so $tA^{(1)}$ is $\mathfrak{p}^{(1)}$-primary. Equivalently, $tA^{(1)}$ is the inverse image in $A^{(1)}$ of

$$tA^{(1)}_{\mathfrak{p}^{(1)}} = tA_\mathfrak{p},$$

which is the maximal ideal of $A_\mathfrak{p}$ by (ii). It follows that

$$tA^{(1)} = \mathfrak{p}^{(1)}$$

is prime in $A^{(1)}$.

The domain $A^{(1)}/\mathfrak{p}^{(1)}$ is finite over $A/\mathfrak{p}$ and has the same fraction field, namely the residue field of $A^{(1)}_{\mathfrak{p}^{(1)}} = A_{\mathfrak{p}}$. Condition (iii) therefore gives

$$A^{(1)}/\mathfrak{p}^{(1)} = A/\mathfrak{p}.$$

Hence

$$A^{(1)} = A + \mathfrak{p}^{(1)} = A + tA^{(1)}.$$

Since t lies in the Jacobson radical of the Noetherian semilocal ring $A^{(1)}$, Nakayama's lemma yields $A^{(1)} = A$. Thus

$$\mathfrak{p}^{(1)} = \mathfrak{p} = tA.$$

Finally, A is catenary and $A/tA = A/\mathfrak{p}$ is a domain and integrally closed by (iii). Corollary 5.12.7 shows that A is integrally closed. □

Remark (5.12.9). — The conclusion of Hironaka's lemma fails without the hypothesis that A is equidimensional. Let k be a field, put

$$B = k[X, Y, Z], \qquad \mathfrak{r}_1 = BZ, \qquad \mathfrak{r}_2 = BX + BY, \qquad C = B/\mathfrak{r}_1\mathfrak{r}_2.$$

Let $\mathfrak{m} = BX + BY + BZ$, let $\mathfrak{n} = \mathfrak{m}/\mathfrak{r}_1\mathfrak{r}_2$ be its image in C, and let $A = C_{\mathfrak{n}}$. Finally, let t_0 be the image of $Y + Z$ in C, and let t be its image in A. Thus $\operatorname{Spec}(C)$ is the union of a plane P and a line D not contained in P, while $\operatorname{Spec}(C/t_0C)$ is a line D' contained in P and passing through $D \cap P$.

The ring A is reduced and catenary, since it is a quotient of a regular ring, and its minimal prime ideals $\mathfrak{q}_1$ and $\mathfrak{q}_2$ are the images of $\mathfrak{r}_1$ and $\mathfrak{r}_2$. The A-module A/tA has a unique nonembedded associated prime $\mathfrak{p}$, the image of $BY + BZ$; the ideal $\mathfrak{p}A_{\mathfrak{p}}$ is generated by $t/1$, and $A/\mathfrak{p} \simeq k[X]$. Nevertheless, A is not a domain.

Corollary (5.12.10). — *Let A be a Noetherian local domain satisfying one of the following hypotheses:*

a) *A is a quotient of a regular ring;*
b) *A is universally catenary and universally Japanese.*

Let $(x_i)_{1\leqslant i\leqslant n}$ be a sequence of n elements of A, and put

$$\mathfrak{J} = x_1A + \cdots + x_nA.$$

Suppose that:

(i) *$A/\mathfrak{J}$ has a unique nonembedded associated prime $\mathfrak{p}$, and $\mathfrak{p}$ has height n;*
(ii) *the maximal ideal $\mathfrak{p}A_{\mathfrak{p}}$ is generated by the $x_i/1$ (so $A_{\mathfrak{p}}$ is a regular local ring of dimension n);*
(iii) *$A/\mathfrak{p}$ is integrally closed.*

Then, for every i with $0 \leqslant i \leqslant n$, the quotient

$$A/(x_1A + \cdots + x_iA)$$

is integrally closed and has dimension $\dim(A) - i$. In particular, $\mathfrak{J}$ is prime and equals $\mathfrak{p}$, the ring A is integrally closed, and $(x_i)_{1\leqslant i\leqslant n}$ is an A-regular sequence.

Proof. We argue by induction on n. The assertion is trivial for $n = 0$ and is Hironaka's lemma for $n = 1$, so suppose $n \geqslant 2$. Put

$$\mathfrak{J}' = x_1A + \cdots + x_{n-1}A,$$

and let $\mathfrak{q}$ be a prime minimal among those containing $\mathfrak{J}'$. Then $\operatorname{ht}(\mathfrak{q}) \leqslant n - 1$ (**0**, 16.3.1). We first show that $\mathfrak{q} \subset \mathfrak{p}$. If $\mathfrak{p}'$ is minimal among the primes containing $\mathfrak{q} + x_nA$, then $\mathfrak{p}'/\mathfrak{q}$ has height at most 1 by the Hauptidealsatz (**0**, 16.3.2); because A is catenary, $\operatorname{ht}(\mathfrak{p}') \leqslant n$. But $\mathfrak{p}'$ contains $\mathfrak{J}$, and the unique minimal prime of $A/\mathfrak{J}$ is $\mathfrak{p}$. Hence $\mathfrak{p}' = \mathfrak{p}$, and $\mathfrak{q} \subset \mathfrak{p}$.

The prime $\mathfrak{q}$ is therefore induced from a prime of $A_{\mathfrak{p}}$ minimal over $\mathfrak{J}'A_{\mathfrak{p}}$. By (ii) and (**0**, 17.1.7), **IV-2** | 131
the ideal $\mathfrak{J}'A_{\mathfrak{p}}$ is prime. Consequently

$$\mathfrak{q} = A \cap \mathfrak{J}'A_{\mathfrak{p}}$$

is the unique nonembedded associated prime of $A/\mathfrak{J}'$, and has height $n - 1$. Moreover,

$$\mathfrak{q}A_{\mathfrak{q}} = \mathfrak{J}'A_{\mathfrak{q}},$$

and, since $A_{\mathfrak{q}} = (A_{\mathfrak{p}})_{\mathfrak{q}A_{\mathfrak{p}}}$, the maximal ideal of $A_{\mathfrak{q}}$ is generated by the images of $x_1, \ldots, x_{n-1}$. Thus the shortened sequence already satisfies conditions (i) and (ii).

We verify condition (iii) for it. Put $B = A/\mathfrak{q}$, let $\mathfrak{n} = \mathfrak{p}/\mathfrak{q}$, and let t be the image of x_n in B. Property a) (respectively b)) passes from A to B (5.6.3, iv), and $t \neq 0$ because $x_n \notin \mathfrak{q}$. A prime of B minimal over t comes from a prime of A minimal over $\mathfrak{q} + x_n A$; the only such prime is $\mathfrak{p}$. Hence $\mathfrak{n}$ is the unique nonembedded associated prime of B/tB. Furthermore,

$$B_{\mathfrak{n}} = A_{\mathfrak{p}}/\mathfrak{q}A_{\mathfrak{p}}, \qquad \mathfrak{n}B_{\mathfrak{n}} = \mathfrak{p}A_{\mathfrak{p}}/\mathfrak{q}A_{\mathfrak{p}}.$$

Since $\mathfrak{q}A_{\mathfrak{p}} = \mathfrak{J}'A_{\mathfrak{p}}$ and $\mathfrak{p}A_{\mathfrak{p}}$ is generated by $x_1, \ldots, x_n$, the ideal $\mathfrak{n}B_{\mathfrak{n}}$ is generated by t. Finally, $B/\mathfrak{n} = A/\mathfrak{p}$ is integrally closed. Hironaka's lemma therefore gives

$$B = A/\mathfrak{q} \text{ integrally closed}, \qquad \mathfrak{p} = \mathfrak{q} + x_n A.$$

The induction hypothesis applied to $x_1, \ldots, x_{n-1}$ now shows that $A/(x_1A + \cdots + x_iA)$ is integrally closed and has dimension $\dim(A) - i$ for $0 \leqslant i \leqslant n-1$, and that $\mathfrak{q} = \mathfrak{J}'$. Hence

$$\mathfrak{p} = \mathfrak{J}' + x_n A = \mathfrak{J},$$

so $A/\mathfrak{J} = A/\mathfrak{p}$ is integrally closed. Finally, $\dim(A_{\mathfrak{p}}) = n$, and biequidimensionality of A gives

$$\dim(A/\mathfrak{p}) = \dim(A) - \dim(A_{\mathfrak{p}}) = \dim(A) - n.$$

This completes the induction. □

5.13. Properties preserved under passage to a direct limit Throughout this subsection, $(A_\alpha, \varphi_{\beta\alpha})$ denotes a direct system of rings whose index set is filtered and preordered. We put **IV-2 | 131**

$$A = \varinjlim_{\alpha} A_\alpha$$

and denote by $\varphi_\alpha : A_\alpha \to A$ the canonical homomorphism.

Proposition (5.13.1). — (i) *For every index α, let $\mathfrak{a}_\alpha$ be an ideal of A_α such that*

$$\varphi_{\beta\alpha}(\mathfrak{a}_\alpha) \subset \mathfrak{a}_\beta \qquad (\alpha \leqslant \beta).$$

Then the $\mathfrak{a}_\alpha$, with the restrictions of the $\varphi_{\beta\alpha}$, form a direct system; $\mathfrak{a} = \varinjlim \mathfrak{a}_\alpha$ is canonically identified with an ideal of A, and

$$A/\mathfrak{a} \simeq \varinjlim_{\alpha} (A_\alpha/\mathfrak{a}_\alpha).$$

If, in addition,

$$\mathfrak{a}_\alpha = \varphi_{\beta\alpha}^{-1}(\mathfrak{a}_\beta) \qquad (\alpha \leqslant \beta),$$

then

$$\mathfrak{a}_\alpha = \varphi_\alpha^{-1}(\mathfrak{a}) \qquad \textit{for every } \alpha.$$

(ii) *Conversely, for every ideal $\mathfrak{a}$ of A, if*

$$\mathfrak{a}_\alpha = \varphi_\alpha^{-1}(\mathfrak{a}) \qquad \textit{for every } \alpha,$$

then the $\mathfrak{a}_\alpha$ form a direct system and

$$\mathfrak{a} = \varinjlim_{\alpha} \mathfrak{a}_\alpha.$$

Proof. Assertion (ii) is plainly a special case of (i). In (i), the canonical identification of $\mathfrak{a}$ with an ideal of A, and that of $A/\mathfrak{a}$ with $\varinjlim(A_\alpha/\mathfrak{a}_\alpha)$, follow from the exactness of the direct-limit functor in the category of abelian groups.

Moreover, $\mathfrak{a}$ is the union of the increasing family of images $\varphi_\alpha(\mathfrak{a}_\alpha)$. Thus, if $x_\alpha \in A_\alpha$ and $\varphi_\alpha(x_\alpha) \in \mathfrak{a}$, there are $\beta \geqslant \alpha$ and $y_\beta \in \mathfrak{a}_\beta$ such that

$$\varphi_\alpha(x_\alpha) = \varphi_\beta(y_\beta).$$

For some $\gamma \geqslant \beta$ one then has

$$\varphi_{\gamma\alpha}(x_\alpha) = \varphi_{\gamma\beta}(y_\beta) \in \mathfrak{a}_\gamma.$$

Under the additional inverse-image hypothesis this implies $x_\alpha \in \mathfrak{a}_\alpha$, and proves the last assertion of (i). □

Corollary (5.13.2). — *Let $\mathfrak{N}_\alpha$ be the nilradical of A_α. The nilradical of A is canonically identified with $\varinjlim \mathfrak{N}_\alpha$, and*

$$A_{\text{red}} \simeq \varinjlim_\alpha (A_\alpha)_{\text{red}}.$$

In particular, if every A_α is reduced, then A is reduced.

IV-2 | 132

Proof. It is clear that

$$\varphi_{\beta\alpha}(\mathfrak{N}_\alpha) \subset \mathfrak{N}_\beta \qquad (\alpha \leqslant \beta),$$

and that $\varinjlim \mathfrak{N}_\alpha$ is a nil ideal of A, hence is contained in the nilradical $\mathfrak{N}$ of A. Conversely, if $x \in \mathfrak{N}$, then $x^h = 0$ for some integer h. Write $x = \varphi_\alpha(x_\alpha)$ with $x_\alpha \in A_\alpha$. The relation $\varphi_\alpha(x_\alpha^h) = 0$ implies that for some $\beta \geqslant \alpha$,

$$\varphi_{\beta\alpha}(x_\alpha^h) = 0.$$

Putting $x_\beta = \varphi_{\beta\alpha}(x_\alpha)$, we obtain $x_\beta^h = 0$, hence $x_\beta \in \mathfrak{N}_\beta$, while $x = \varphi_\beta(x_\beta)$. This proves the assertion, in view of (5.13.1). □

Proposition (5.13.3). — (i) *For every index α, let $\mathfrak{p}_\alpha$ be a prime ideal of A_α such that*

$$\varphi_{\beta\alpha}(\mathfrak{p}_\alpha) \subset \mathfrak{p}_\beta \qquad (\alpha \leqslant \beta).$$

Then $\mathfrak{p} = \varinjlim \mathfrak{p}_\alpha$ is a prime ideal of A. In particular, if all the A_α are domains, then A is a domain.

(ii) *If, in addition,*

$$\mathfrak{p}_\alpha = \varphi_{\beta\alpha}^{-1}(\mathfrak{p}_\beta) \qquad (\alpha \leqslant \beta),$$

then there is a canonical identification

$$A_\mathfrak{p} \simeq \varinjlim_\alpha (A_\alpha)_{\mathfrak{p}_\alpha}.$$

(iii) *Suppose that A is local, with maximal ideal $\mathfrak{p}$, and that the homomorphisms $\varphi_\alpha : A_\alpha \to A$ are injective. If $\mathfrak{p}_\alpha = \varphi_\alpha^{-1}(\mathfrak{p})$, then*

$$A \simeq \varinjlim_\alpha (A_\alpha)_{\mathfrak{p}_\alpha},$$

and every canonical homomorphism $(A_\alpha)_{\mathfrak{p}_\alpha} \to A$ is injective.

Proof. The two assertions in (i) are equivalent, since

$$A/\mathfrak{p} \simeq \varinjlim_\alpha (A_\alpha/\mathfrak{p}_\alpha).$$

Suppose therefore that all the A_α are domains, and let $x, y \in A$ satisfy $xy = 0$. For some α one may write

$$x = \varphi_\alpha(x_\alpha), \qquad y = \varphi_\alpha(y_\alpha),$$

with $x_\alpha, y_\alpha \in A_\alpha$ and $\varphi_\alpha(x_\alpha y_\alpha) = 0$. Hence there is $\beta \geqslant \alpha$ such that, on putting

$$x_\beta = \varphi_{\beta\alpha}(x_\alpha), \qquad y_\beta = \varphi_{\beta\alpha}(y_\alpha),$$

one has $x_\beta y_\beta = 0$. Since A_β is a domain, $x_\beta = 0$ or $y_\beta = 0$, and therefore $x = 0$ or $y = 0$.

For (ii), the hypothesis says that the multiplicative subsets $A_\alpha - \mathfrak{p}_\alpha$ form a direct system whose direct limit is $A - \mathfrak{p}$. The local rings $(A_\alpha)_{\mathfrak{p}_\alpha}$ therefore form a direct system with local transition maps, and the canonical homomorphisms to $A_\mathfrak{p}$ induce a surjection

$$\psi : \varinjlim_\alpha (A_\alpha)_{\mathfrak{p}_\alpha} \longrightarrow A_\mathfrak{p}.$$

To prove injectivity, let $x_\alpha \in A_\alpha$ and $s_\alpha \in A_\alpha - \mathfrak{p}_\alpha$, and suppose that

$$\frac{\varphi_\alpha(x_\alpha)}{\varphi_\alpha(s_\alpha)} = 0 \quad \text{in } A_\mathfrak{p}.$$

There is $s' \in A - \mathfrak{p}$ such that $s'\varphi_\alpha(x_\alpha) = 0$. After replacing α by a larger index, we may write $s' = \varphi_\alpha(s'_\alpha)$ with $s'_\alpha \in A_\alpha - \mathfrak{p}_\alpha$. Then $\varphi_\alpha(s'_\alpha x_\alpha) = 0$, so for some $\beta \geqslant \alpha$,

$$\varphi_{\beta\alpha}(s'_\alpha x_\alpha) = 0 \quad \text{in } A_\beta.$$

It follows that the image of x_α/s_α in the direct limit is zero.

Finally, the first assertion of (iii) follows from (ii) and $A_{\mathfrak{p}} = A$. Every element of $A_\alpha - \mathfrak{p}_\alpha$ maps to a unit of A, and the injectivity of $(A_\alpha)_{\mathfrak{p}_\alpha} \to A$ follows from that of φ_α. □

Corollary (5.13.4). — *Suppose that all the A_α are domains and that all the transition homomorphisms $\varphi_{\beta\alpha}$ are injective. If A'_α denotes the integral closure of A_α, then*

$$A' = \varinjlim_\alpha A'_\alpha$$

is the integral closure of A. In particular, if every A_α is integrally closed, then A is integrally closed.

*If the A_α are unibranch local rings (respectively, geometrically unibranch local rings) (**0**, 23.2.1), and the $\varphi_{\beta\alpha}$ are injective local homomorphisms, then A is unibranch (respectively, geometrically unibranch).*

Proof. Let K_α be the fraction field of A_α. By (5.13.3, ii), applied to $\mathfrak{p}_\alpha = (0)$,

$$K = \varinjlim_\alpha K_\alpha$$

is the fraction field of A. Thus $A' = \varinjlim A'_\alpha$ is identified with a subring of K which is plainly integral over A. **IV-2** | 133

Conversely, let $z \in K$ satisfy an equation of integral dependence

$$z^n + \sum_{i=1}^{n} c_i z^{n-i} = 0, \qquad c_i \in A.$$

There are an index α, an element $z_\alpha \in K_\alpha$, and elements $c_{i\alpha} \in A_\alpha$ whose images are z and the c_i, respectively, and such that the same equation holds in K_α. Hence $z_\alpha \in A'_\alpha$, so $z \in A'$. This also proves at once that a direct limit of the integrally closed rings occurring here is integrally closed.

Suppose now that the A_α are local and that the transition maps are local. Then A is local and, if k_α denotes the residue field of A_α,

$$k = \varinjlim_\alpha k_\alpha$$

is the residue field of A (**0**, 10.3.1.3). If every A'_α is local, then A' is local, and hence A is unibranch. If, moreover, the residue field k'_α of A'_α is a radicial extension of k_α for every α, then

$$k' = \varinjlim_\alpha k'_\alpha,$$

the residue field of A', is a radicial extension of k. Thus A is geometrically unibranch. □

(5.13.5). A ring A is called *normal* if $\operatorname{Spec}(A)$ is normal; in other words, if for every prime ideal $\mathfrak{p}$ of A, the ring $A_{\mathfrak{p}}$ is a domain and is integrally closed.

This implies that A is reduced and that $\mathfrak{p}$ can contain only one minimal prime ideal $\mathfrak{q}$ of A; in other words, $\mathfrak{p}$ belongs to only one irreducible component of $\operatorname{Spec}(A)$. Moreover, $\mathfrak{q}$ is the inverse image of (0) under the canonical homomorphism $A \to A_{\mathfrak{p}}$, and hence

$$A_{\mathfrak{p}} \simeq (A/\mathfrak{q})_{\mathfrak{p}/\mathfrak{q}}.$$

It follows that the domain $A/\mathfrak{q}$ is integrally closed, being the intersection of integrally closed rings (**I**, 8.2.1.1).

If A is Noetherian and normal, it is the direct product of finitely many integrally closed domains (**I**, 5.1.4).

Corollary (5.13.6). — *Suppose that all the A_α are normal and that, for $\alpha \leqslant \beta$, every irreducible component of* $\operatorname{Spec}(A_\beta)$ *dominates an irreducible component of* $\operatorname{Spec}(A_\alpha)$. *Then*

$$A = \varinjlim_\alpha A_\alpha$$

is normal.

Proof. Let $\mathfrak{p}$ be a prime ideal of A, and put

$$\mathfrak{p}_\alpha = \varphi_\alpha^{-1}(\mathfrak{p})$$

for every α. By hypothesis, $\mathfrak{p}_\alpha$ contains a unique minimal prime ideal $\mathfrak{q}_\alpha$ of A_α. If $\alpha \leqslant \beta$, then $\varphi_{\beta\alpha}^{-1}(\mathfrak{q}_\beta)$ is a minimal prime ideal of A_α contained in $\mathfrak{p}_\alpha$, hence equals $\mathfrak{q}_\alpha$.

Put
$$B_\alpha = A_\alpha/\mathfrak{q}_\alpha.$$
The domains B_α form a direct system under the injective homomorphisms
$$\varphi'_{\beta\alpha} : B_\alpha \longrightarrow B_\beta$$
induced by the $\varphi_{\beta\alpha}$. Each B_α is integrally closed, so
$$B = \varinjlim_\alpha B_\alpha$$
is integrally closed by (5.13.4). If
$$\mathfrak{p}'_\alpha = \mathfrak{p}_\alpha/\mathfrak{q}_\alpha,$$
then
$$(B_\alpha)_{\mathfrak{p}'_\alpha} = (A_\alpha)_{\mathfrak{p}_\alpha}.$$
Consequently,
$$\varinjlim_\alpha (B_\alpha)_{\mathfrak{p}'_\alpha} = \varinjlim_\alpha (A_\alpha)_{\mathfrak{p}_\alpha} = A_\mathfrak{p}$$
is a localization of B at a prime ideal (5.13.3). It is therefore a domain and is integrally closed, proving the corollary. □

Proposition (5.13.7). — *Suppose that every A_α is regular and that, for $\alpha \leqslant \beta$, the homomorphism $\varphi_{\beta\alpha}$ makes A_β a flat A_α-module. Suppose in addition that*
$$A = \varinjlim_\alpha A_\alpha$$
is Noetherian. Then A is regular.

Proof. By definition, it is enough to prove that the Noetherian local ring $A_\mathfrak{p}$ is regular for every prime ideal $\mathfrak{p}$ of A. Put
$$\mathfrak{p}_\alpha = \varphi_\alpha^{-1}(\mathfrak{p}).$$
By (5.13.3),
$$\mathfrak{p} = \varinjlim_\alpha \mathfrak{p}_\alpha, \qquad A_\mathfrak{p} = \varinjlim_\alpha (A_\alpha)_{\mathfrak{p}_\alpha}.$$
The rings $(A_\alpha)_{\mathfrak{p}_\alpha}$ are regular, and for $\alpha \leqslant \beta$ the ring $(A_\beta)_{\mathfrak{p}_\beta}$ is flat over $(A_\alpha)_{\mathfrak{p}_\alpha}$ (**0**, 6.3.2). We are therefore reduced to the case in which all the A_α, as well as A, are local.

To prove that A is regular, it is enough to show that for any two finite A-modules M and N, there is an integer i_0 such that

IV-2 | 134
$$\operatorname{Tor}_i^A(M,N) = 0 \qquad (i \geqslant i_0)$$
(**0**, 17.3.1) and (**0**, 17.2.6). We use the following lemma, in which the rings A_α are again arbitrary. □

Lemma (5.13.7.1). — *For every finitely presented A-module M, there are an index α and a finitely presented A_α-module M_α such that*
$$M \simeq M_\alpha \otimes_{A_\alpha} A.$$

Proof. We may write $M = A^r/P$, where P is a finitely generated A-submodule of A^r. Since
$$A^r = \varinjlim_\alpha A_\alpha^r$$
and P is finitely generated, there are an index α and a finitely generated A_α-submodule $P_\alpha \subset A_\alpha^r$ whose canonical image generates P. Right exactness of the tensor product then gives
$$M \simeq (A_\alpha^r/P_\alpha) \otimes_{A_\alpha} A.$$
□

Completion of the proof of Proposition 5.13.7. Since A is Noetherian, the finite modules M and N are finitely presented. After increasing α if necessary, the lemma gives

$$M = M_\alpha \otimes_{A_\alpha} A, \qquad N = N_\alpha \otimes_{A_\alpha} A.$$

The A_α-module A is flat (**0**, 6.1.2), and base change for Tor gives

$$\mathrm{Tor}_i^A(M, N) \simeq \mathrm{Tor}_i^{A_\alpha}(M_\alpha, N_\alpha) \otimes_{A_\alpha} A$$

(**III**, 6.3.9). Since A_α is regular, the right-hand side vanishes for all sufficiently large i. This proves the proposition. □

Corollary (5.13.8). — *Let $k \geqslant 0$. Suppose that the A_α are Noetherian and satisfy (R_k). Suppose also that, for $\alpha \leqslant \beta$, the homomorphism $\varphi_{\beta\alpha}$ makes A_β a flat A_α-module, that $A = \varinjlim A_\alpha$ is Noetherian, and that for every α the induced map*

$$^a\varphi_\alpha : \mathrm{Spec}(A) \longrightarrow \mathrm{Spec}(A_\alpha)$$

is a homeomorphism. Then A satisfies (R_k).

Proof. Let $\mathfrak{p}$ be a prime ideal of A, and put

$$\mathfrak{p}_\alpha = \varphi_\alpha^{-1}(\mathfrak{p}).$$

Then

$$\mathfrak{p} = \varinjlim_\alpha \mathfrak{p}_\alpha, \qquad A_\mathfrak{p} = \varinjlim_\alpha (A_\alpha)_{\mathfrak{p}_\alpha}$$

by (5.13.3). It follows from (**I**, 2.4.2) and the hypothesis that

$$\mathrm{Spec}(A_\mathfrak{p}) \longrightarrow \mathrm{Spec}\big((A_\alpha)_{\mathfrak{p}_\alpha}\big)$$

is a surjective homeomorphism for every α. Hence

$$\dim(A_\mathfrak{p}) = \dim\big((A_\alpha)_{\mathfrak{p}_\alpha}\big) \qquad \text{for every } \alpha.$$

If $\dim(A_\mathfrak{p}) \leqslant k$, then each $(A_\alpha)_{\mathfrak{p}_\alpha}$ is regular. Moreover, for $\alpha \leqslant \beta$, $(A_\beta)_{\mathfrak{p}_\beta}$ is flat over $(A_\alpha)_{\mathfrak{p}_\alpha}$ (**0**, 6.3.2). Proposition (5.13.7) therefore shows that $A_\mathfrak{p}$ is regular. Thus A satisfies (R_k). □

§6. Flat morphisms of locally Noetherian preschemes

Let X, Y be two locally Noetherian preschemes, $f : X \to Y$ a morphism. For every $y \in Y$, the fibre $f^{-1}(y) = X \times_Y \mathrm{Spec}(\boldsymbol{k}(y))$ is also a locally Noetherian prescheme, since it suffices to see this when $Y = \mathrm{Spec}(\mathrm{A})$ and $X = \mathrm{Spec}(\mathrm{B})$ are spectra of Noetherian rings, and then $\mathrm{B} \otimes_\mathrm{A} \boldsymbol{k}(y)$ is a ring of fractions of the quotient ring $\mathrm{B}/\mathfrak{J}_y\mathrm{B}$, hence is Noetherian. We propose first of all in this paragraph to relate the properties of X, of Y, and of the fibres $f^{-1}(y)$ (where y ranges over Y), under the hypothesis that the morphism f is *flat*. The questions treated will reduce to the study of relations between the Noetherian local rings $\mathcal{O}_y$, $\mathcal{O}_x$, and $\mathcal{O}_x \otimes_{\mathcal{O}_y} \boldsymbol{k}(y)$, the homomorphism $\mathcal{O}_y \to \mathcal{O}_x$ being local and making $\mathcal{O}_x$ a flat $\mathcal{O}_y$-module. In n^os^ 6.11 to 6.13 (rather separate from the rest of the paragraph, by their "absolute" rather than "relative" nature), we apply certain preceding results to find criteria allowing us to affirm that the *singular locus* (or certain analogous sets) of certain preschemes are closed sets; these criteria will play an important role in §7.

IV-2 | 134 **IV-2** | 135

6.1. Flatness and dimension

Proposition (6.1.1). — *Let* A, B *be two local Noetherian rings,* $\mathfrak{m}$ *the maximal ideal of* A, $k = \mathrm{A}/\mathfrak{m}$ *its residue field,* $\varphi : \mathrm{A} \to \mathrm{B}$ *a local homomorphism. Suppose that for every prime ideal* $\mathfrak{p}$ *of* A*, distinct from* $\mathfrak{m}$*, and for every minimal element* $\mathfrak{q}$ *of the set of prime ideals of* B *containing* $\mathfrak{p}\mathrm{B}$, $\varphi^{-1}(\mathfrak{q})$ *is distinct from* $\mathfrak{m}$ *(in other words, no irreducible component of* $\mathrm{Spec}(\mathrm{B}/\mathfrak{p}\mathrm{B})$ *is contained in the inverse image of the closed point* $\mathfrak{m}$ *of* $\mathrm{Spec}(\mathrm{A})$ *in* $\mathrm{Spec}(\mathrm{B})$*). Then we have*

$$\dim(\mathrm{B}) = \dim(\mathrm{A}) + \dim(\mathrm{B} \otimes_{\mathrm{A}} k). \tag{6.1.1.1}$$

Proof. We argue by induction on $n = \dim(\mathrm{A})$; the assertion is trivial for $n = 0$, $\mathfrak{m}\mathrm{B}$ being then contained in the nilradical of B. We may therefore suppose $n > 0$. Let $\mathfrak{q}_i$ ($1 \leqslant i \leqslant m$) be the minimal prime ideals of B, and let $\mathfrak{p}_i = \varphi^{-1}(\mathfrak{q}_i)$; for every i, we have $\mathfrak{p}_i \neq \mathfrak{m}$; otherwise (since $n > 0$) there would exist a prime ideal $\mathfrak{p} \neq \mathfrak{m}$ contained in $\mathfrak{p}_i$ and as $\mathfrak{q}_i$ is minimal among the prime ideals of B containing $\mathfrak{p}\mathrm{B}$, we would arrive at a contradiction with the hypothesis. Therefore $\mathfrak{m}$ is distinct from the union of the $\mathfrak{p}_i$ and of the minimal prime ideals $\mathfrak{p}'_j$ ($1 \leqslant j \leqslant r$) of A (Bourbaki, *Alg. comm.*, chap. II, § 1, n° 1, prop. 2) and there exists an $a \in \mathfrak{m}$ not belonging to any of the $\mathfrak{p}_i$ nor any of the $\mathfrak{p}'_j$. Set $\mathrm{A}' = \mathrm{A}/a\mathrm{A}$, $\mathrm{B}' = \mathrm{B}/a\mathrm{B}$; we have (**0**, 16.3.4)

$$\dim(\mathrm{A}') = \dim(\mathrm{A}) - 1, \quad \dim(\mathrm{B}') = \dim(\mathrm{B}) - 1$$

by construction of a, and on the other hand $\mathrm{B}' \otimes_{\mathrm{A}'} k = \mathrm{B} \otimes_{\mathrm{A}} k$, hence

$$\dim(\mathrm{B}' \otimes_{\mathrm{A}'} k) = \dim(\mathrm{B} \otimes_{\mathrm{A}} k)$$

and it suffices to prove (6.1.1) for A′ and B′; now, by virtue of the bijective correspondence between ideals of A (resp. B) containing a and ideals of A′ (resp. B′), the hypotheses of the statement are also valid for A′ and B′; we may therefore apply the induction hypothesis, which completes the proof. □

Corollary (6.1.2). — *Let* A, B *be two local Noetherian rings,* k *the residue field of* A, $\varphi : \mathrm{A} \to \mathrm{B}$ *a local homomorphism,* $\mathrm{M} \neq 0$ *an* A*-module of finite type,* $\mathrm{N} \neq 0$ *a* B*-module of finite type. If* N *is a flat* A*-module* (*resp. if* B *is a flat* A*-module*)*, then we have*

$$\dim_{\mathrm{B}}(\mathrm{M} \otimes_{\mathrm{A}} \mathrm{N}) = \dim_{\mathrm{A}}(\mathrm{M}) + \dim_{\mathrm{B}\otimes_{\mathrm{A}} k}(\mathrm{N} \otimes_{\mathrm{A}} k) \tag{6.1.2.1}$$

(*resp.* (6.1.1)).

Proof. It suffices to prove the assertion concerning N; on the other hand, if $\mathfrak{b}$ is the annihilator of N, we may replace B by $\mathrm{B}/\mathfrak{b}$, and therefore suppose that $\mathrm{Supp}(\mathrm{N}) = \mathrm{Spec}(\mathrm{B})$; the hypothesis then means that the morphism $f : \mathrm{Spec}(\mathrm{B}) \to \mathrm{Spec}(\mathrm{A})$ corresponding to φ is *quasi-flat* (2.3.3); we conclude (2.3.4) that for every prime ideal $\mathfrak{p} \neq \mathfrak{m}$ of A, every irreducible component of $f^{-1}(\mathrm{V}(\mathfrak{p}))$ **IV-2** | 136
dominates $\mathrm{V}(\mathfrak{p})$, and therefore the condition of (6.1.1) is satisfied, whence the conclusion. □

Corollary (6.1.3). — *Let* A, B *be two local Noetherian rings,* $\mathfrak{m}$ *the maximal ideal of* A, k *its residue field,* $\varphi : \mathrm{A} \to \mathrm{B}$ *a local homomorphism. Suppose that* $\dim(\mathrm{B} \otimes_{\mathrm{A}} k) = 0$ *(that is to say* (**0**, 16.2.1) *that* $\mathfrak{m}\mathrm{B}$ *is an* ideal of definition *of* B*). Then we have* $\dim(\mathrm{B}) \leqslant \dim(\mathrm{A})$*. If in addition there exists a* B*-module of finite type* N *that is a flat* A*-module and has support equal to* $\mathrm{Spec}(\mathrm{B})$ *(which holds in particular if* B *is a flat* A*-module), then* $\dim(\mathrm{B}) = \dim(\mathrm{A})$.

Proof. The first assertion follows from (5.5.1) and the second from (6.1.2). □

Corollary (6.1.4). — *Let* X, Y *be two locally Noetherian preschemes,* $f : X \to Y$ *a surjective morphism. For every closed subset* Z *of* Y*, we have*

$$\mathrm{codim}(f^{-1}(Z), X) \leqslant \mathrm{codim}(Z, Y) \tag{6.1.4.1}$$

Moreover, if f *is quasi-flat* (2.3.3)*, the two sides of* (6.1.4.1) *are equal.*

Proof. Indeed, if y is a maximal point of Z and x a maximal point of the fibre $f^{-1}(y)$, we have $\dim(\mathscr{O}_{X,x}) \leqslant \dim(\mathscr{O}_{Y,y})$ by virtue of (5.5.2); the inequality (6.1.4.1) then follows from (5.1.2.1) and from (5.1.3.1) and from the fact that f is surjective. If in addition f is quasi-flat, we know (2.3.4) that every irreducible component of $f^{-1}(Z)$ dominates an irreducible component of Z; the maximal points of $f^{-1}(Z)$ are therefore the maximal points of the fibres $f^{-1}(y)$, where y ranges over the set of maximal points of Z (**0**, 2.1.8), and for each of these maximal points x we have $\dim(\mathscr{O}_x \otimes_{\mathscr{O}_y} \boldsymbol{k}(y)) = 0$; as in addition $\mathscr{O}_x$ is a flat $\mathscr{O}_y$-module, we have $\dim(\mathscr{O}_x) = \dim(\mathscr{O}_y)$ by virtue of (6.1.1), whence the equality in (6.1.4.1), taking into account that f is surjective. □

The proposition (6.1.1) admits the following partial converse:

Proposition (6.1.5). — *Let* A, B *be two local Noetherian rings, k the residue field of* A, $\varphi : \mathrm{A} \to \mathrm{B}$ *a local homomorphism,* M *a* B*-module of finite type. Suppose that:*

1° A *is a regular ring.*
2° M *is a Cohen-Macaulay* B*-module.*
3° $\dim_{\mathrm{B}}(\mathrm{M}) = \dim(\mathrm{A}) + \dim_{\mathrm{B}\otimes_{\mathrm{A}} k}(\mathrm{M} \otimes_{\mathrm{A}} k)$.

Then M *is a flat* A*-module.*

Proof. We argue by induction on $n = \dim(\mathrm{A})$. If $n = 0$, A is a field since it is regular (**0**, 17.1.4) and the assertion is trivial. Suppose $n > 0$; let $\mathfrak{m}$ be the maximal ideal of A, and let $x \in \mathfrak{m}$ be an element not belonging to $\mathfrak{m}^2$; we know then (**0**, 17.1.8) that $\mathrm{A}' = \mathrm{A}/x\mathrm{A}$ is regular and $\dim(\mathrm{A}') = \dim(\mathrm{A}) - 1$. Set

$$\mathrm{B}' = \mathrm{B}/x\mathrm{B}, \quad \mathrm{M}' = \mathrm{M}/x\mathrm{M} = \mathrm{M} \otimes_{\mathrm{A}} \mathrm{A}';$$

then

$$\mathrm{B}' \otimes_{\mathrm{A}'} k = \mathrm{B} \otimes_{\mathrm{A}} k, \quad \mathrm{M}' \otimes_{\mathrm{A}'} k = \mathrm{M} \otimes_{\mathrm{A}} k$$

and by virtue of (**0**, 16.3.9.2) we have

$$\dim_{\mathrm{B}'}(\mathrm{M}') \leqslant \dim(\mathrm{A}') + \dim_{\mathrm{B}'\otimes_{\mathrm{A}'} k}(\mathrm{M}' \otimes_{\mathrm{A}'} k);$$

we conclude therefore from (**0**, 16.3.4) that we have **IV-2 | 137**

$$\dim_{\mathrm{B}}(\mathrm{M}) \leqslant \dim_{\mathrm{B}'}(\mathrm{M}') + 1 \leqslant (\dim(\mathrm{A}') + \dim_{\mathrm{B}\otimes_{\mathrm{A}} k}(\mathrm{M} \otimes_{\mathrm{A}} k)) + 1 = \dim(\mathrm{A}) + \dim_{\mathrm{B}\otimes_{\mathrm{A}} k}(\mathrm{M} \otimes_{\mathrm{A}} k).$$

Since by hypothesis the extreme terms of these inequalities are equal, we have necessarily: (i) $\dim_{\mathrm{B}'}(\mathrm{M}') = \dim_{\mathrm{B}}(\mathrm{M}) - 1$, and as M is by hypothesis a Cohen-Macaulay B-module, this means that x is M-*regular* (**0**, 16.1.9) and (**0**, 16.5.5); (ii) $\dim_{\mathrm{B}'}(\mathrm{M}') = \dim(\mathrm{A}') + \dim_{\mathrm{B}'\otimes_{\mathrm{A}'} k}(\mathrm{M}' \otimes_{\mathrm{A}'} k)$; as M′ is a Cohen-Macaulay B′-module by virtue of (i) and of (**0**, 16.1.9) and (**0**, 16.5.5) and A′ is regular, the induction hypothesis proves that M′ is a flat A′-module; we deduce then from (**0**, 10.2.7) that M is a flat A-module, since x is M-regular by (i). □

6.2. Flatness and projective dimension

Proposition (6.2.1). —

(i) *Let* A, B *be two rings, $\varphi : \mathrm{A} \to \mathrm{B}$ a homomorphism such that* B *is a flat* A*-module. Then, for every* A*-module* M*, we have*

$$\dim.\mathrm{proj}_{\mathrm{B}}(\mathrm{M} \otimes_{\mathrm{A}} \mathrm{B}) \leqslant \dim.\mathrm{proj}_{\mathrm{A}}(\mathrm{M}). \tag{6.2.1.1}$$

(ii) *Suppose in addition that* A *is a Noetherian ring,* B *a faithfully flat* A*-module, and* M *an* A*-module of finite type; then*

$$\dim.\mathrm{proj}_{\mathrm{B}}(\mathrm{M} \otimes_{\mathrm{A}} \mathrm{B}) = \dim.\mathrm{proj}_{\mathrm{A}}(\mathrm{M}). \tag{6.2.1.2}$$

Proof.

(i) We may restrict to the case where $n = \dim.\mathrm{proj}_{\mathrm{A}}(\mathrm{M})$ is finite; there therefore exists a left resolution

$$0 \longrightarrow \mathrm{P}_n \longrightarrow \mathrm{P}_{n-1} \longrightarrow \ldots \longrightarrow \mathrm{P}_0 \longrightarrow \mathrm{M} \longrightarrow 0$$

of M by projective A-modules; as B is a flat A-module, the sequence

$$0 \longrightarrow \mathrm{P}_n \otimes_{\mathrm{A}} \mathrm{B} \longrightarrow \mathrm{P}_{n-1} \otimes_{\mathrm{A}} \mathrm{B} \longrightarrow \ldots \longrightarrow \mathrm{P}_0 \otimes_{\mathrm{A}} \mathrm{B} \longrightarrow \mathrm{M} \otimes_{\mathrm{A}} \mathrm{B} \longrightarrow 0$$

is exact; on the other hand, the $\mathrm{P}_i \otimes_{\mathrm{A}} \mathrm{B}$ are projective B-modules; whence the conclusion.

(ii) Suppose that $\dim . \mathrm{proj}_{\mathrm{B}}(\mathrm{M} \otimes_{\mathrm{A}} \mathrm{B}) = m$, and consider an exact sequence

$$0 \longrightarrow \mathrm{R} \longrightarrow \mathrm{P}_{m-1} \longrightarrow \mathrm{P}_{m-2} \longrightarrow \ldots \longrightarrow \mathrm{P}_0 \longrightarrow \mathrm{M} \longrightarrow 0$$

where the P_i $(0 \leqslant i \leqslant m-1)$ are projective A-modules of finite type; as A is Noetherian, R is also an A-module of finite type. As B is a flat A-module, we also have an exact sequence

$$0 \longrightarrow \mathrm{R} \otimes_{\mathrm{A}} \mathrm{B} \longrightarrow \mathrm{P}_{m-1} \otimes_{\mathrm{A}} \mathrm{B} \longrightarrow \ldots \longrightarrow \mathrm{P}_0 \otimes_{\mathrm{A}} \mathrm{B} \longrightarrow \mathrm{M} \otimes_{\mathrm{A}} \mathrm{B} \longrightarrow 0$$

and the hypothesis on $\mathrm{M} \otimes_{\mathrm{A}} \mathrm{B}$ implies that $\mathrm{R} \otimes_{\mathrm{A}} \mathrm{B}$ is a projective B-module (**0**, 17.2.1). As B is a faithfully flat A-module, we conclude that R is a projective A-module (Bourbaki, *Alg. comm.*, chap. I$^{\text{er}}$, § 3, n$^{\text{o}}$ 6, prop. 12); hence $\dim . \mathrm{proj}_{\mathrm{A}}(\mathrm{M}) \leqslant m$, which completes the proof. □

Corollary (6.2.2). — *Let $f : X \to Y$ be a flat morphism of preschemes, $\mathscr{E}$ a quasi-coherent $\mathscr{O}_Y$-Module. If* $\dim . \mathrm{proj}(\mathscr{E}) \leqslant n$ (**0**, 17.2.14), *then* $\dim . \mathrm{proj}(f^*(\mathscr{E})) \leqslant n$.

IV-2 | 138

Proposition (6.2.3). — *Let* A, B *be two local Noetherian rings, k the residue field of* A, $\varphi : \mathrm{A} \to \mathrm{B}$ *a local homomorphism,* N *a* B*-module of finite type. Suppose that* B *and* N *are flat* A*-modules. Then we have*

(6.2.3.1) $$\dim . \mathrm{proj}_{\mathrm{B}}(\mathrm{N}) = \dim . \mathrm{proj}_{\mathrm{B} \otimes_{\mathrm{A}} k}(\mathrm{N} \otimes_{\mathrm{A}} k).$$

Proof. Consider a left resolution of N by free B-modules of finite type

$$\ldots \longrightarrow \mathrm{L}_i \longrightarrow \mathrm{L}_{i-1} \longrightarrow \ldots \longrightarrow \mathrm{L}_0 \longrightarrow \mathrm{N} \longrightarrow 0$$

As the L_i and N are flat A-modules (B being a flat A-module) it follows from (2.1.10) that the $\mathrm{Z}_i(\mathrm{L}_\bullet)$ are flat A-modules, that $\mathrm{L}_\bullet \otimes_{\mathrm{A}} k$ is a resolution of $\mathrm{N} \otimes_{\mathrm{A}} k$ and that $\mathrm{Z}_i(\mathrm{L}_\bullet \otimes_{\mathrm{A}} k) = \mathrm{Z}_i(\mathrm{L}_\bullet) \otimes_{\mathrm{A}} k$ for all i. Note that since B is Noetherian, the $\mathrm{Z}_i(\mathrm{L}_\bullet)$ are B-modules of finite type, hence the $\mathrm{Z}_i(\mathrm{L}_\bullet \otimes_{\mathrm{A}} k)$ are $(\mathrm{B} \otimes_{\mathrm{A}} k)$-modules of finite type. Now, to say that a B-module (resp. a $(\mathrm{B} \otimes_{\mathrm{A}} k)$-module) of finite type is flat is equivalent to saying that it is *free* or even *projective* (**0**, 10.1.3). As the $\mathrm{Z}_i(\mathrm{L}_\bullet)$ are flat A-modules, it follows on the other hand from (**0**, 10.2.5) (where we set $\mathrm{C} = \mathrm{B}$) that, for $\mathrm{Z}_i(\mathrm{L}_\bullet)$ to be a flat B-module, it is necessary and sufficient that $\mathrm{Z}_i(\mathrm{L}_\bullet) \otimes_{\mathrm{A}} k$ be a $(\mathrm{B} \otimes_{\mathrm{A}} k)$-module that is flat. The smallest integer n such that $\mathrm{Z}_{n-1}(\mathrm{L}_\bullet)$ is a free B-module is therefore also the smallest integer n such that $\mathrm{Z}_{n-1}(\mathrm{L}_\bullet \otimes_{\mathrm{A}} k)$ is a free $(\mathrm{B} \otimes_{\mathrm{A}} k)$-module, which proves the proposition (**0**, 17.2.1). □

6.3. Flatness and depth

Proposition (6.3.1). — *Let* A, B *be two local Noetherian rings, k the residue field of* A, $\varphi : \mathrm{A} \to \mathrm{B}$ *a local homomorphism,* M *an* A*-module of finite type,* N *a* B*-module of finite type. If* N *is a flat* A*-module* $\neq 0$, *then we have*

(6.3.1.1) $$\mathrm{prof}_{\mathrm{B}}(\mathrm{M} \otimes_{\mathrm{A}} \mathrm{N}) = \mathrm{prof}_{\mathrm{A}}(\mathrm{M}) + \mathrm{prof}_{\mathrm{B} \otimes_{\mathrm{A}} k}(\mathrm{N} \otimes_{\mathrm{A}} k).$$

Proof. We may restrict to the case where $\mathrm{M} \neq 0$, without which both sides of (6.3.1) are all equal to $+\infty$. We will argue by induction on the integer n equal to the second member of (6.3.1.1) (which is finite by virtue of the hypotheses, of (**0**, 16.4.6.2) and of the lemma of Nakayama applied to N). Suppose first $n = 0$; then, if $\mathfrak{m}$ and $\mathfrak{n}$ denote the maximal ideals of A and B respectively, $\mathfrak{m}$ is a prime ideal associated to M and $\mathfrak{n}/\mathfrak{m}\mathrm{B}$ a prime ideal of $\mathrm{B}/\mathfrak{m}\mathrm{B} = \mathrm{B} \otimes_{\mathrm{A}} k$ associated to $\mathrm{N} \otimes_{\mathrm{A}} k$. We conclude then from (3.3.1) that $\mathfrak{n}$ is a prime ideal associated to $\mathrm{M} \otimes_{\mathrm{A}} \mathrm{N}$; hence, by (**0**, 16.4.6), (i), $\mathrm{prof}_{\mathrm{B}}(\mathrm{M} \otimes_{\mathrm{A}} \mathrm{N}) = 0$. Suppose therefore $n > 0$, and distinguish two cases:

a) Suppose $\mathrm{prof}_{\mathrm{A}}(\mathrm{M}) > 0$. Let $x \in \mathfrak{m}$ be an M-regular element, and set

$$\mathrm{A}' = \mathrm{A}/x\mathrm{A}, \quad \mathrm{B}' = \mathrm{B}/x\mathrm{B}, \quad \mathrm{M}' = \mathrm{M}/x\mathrm{M}, \quad \mathrm{N}' = \mathrm{N}/x\mathrm{N};$$

then

$$\mathrm{B}' \otimes_{\mathrm{A}'} k = \mathrm{B} \otimes_{\mathrm{A}} k, \quad \mathrm{N}' \otimes_{\mathrm{A}'} k = \mathrm{N} \otimes_{\mathrm{A}} k$$

since $x \in \mathfrak{m}$, and

$$\mathrm{M}' \otimes_{\mathrm{A}'} \mathrm{N}' = (\mathrm{M} \otimes_{\mathrm{A}} \mathrm{N})/x(\mathrm{M} \otimes_{\mathrm{A}} \mathrm{N});$$

in addition, as N is a flat A-module, the hypothesis that x is M-regular implies that x is also $(\mathrm{M} \otimes_{\mathrm{A}} \mathrm{N})$-regular. We thus have (**0**, 16.4.6), (ii), and (**0**, 16.4.8) **IV-2 | 139**

$$\mathrm{prof}_{\mathrm{A}'}(\mathrm{M}') = \mathrm{prof}_{\mathrm{A}}(\mathrm{M}) - 1, \quad \mathrm{prof}_{\mathrm{B}'}(\mathrm{M}' \otimes_{\mathrm{A}'} \mathrm{N}') = \mathrm{prof}_{\mathrm{B}}(\mathrm{M} \otimes_{\mathrm{A}} \mathrm{N}) - 1$$

and

$$\mathrm{prof}_{\mathrm{B}'\otimes_{\mathrm{A}'}k}(\mathrm{N}'\otimes_{\mathrm{A}'}k)=\mathrm{prof}_{\mathrm{B}\otimes_{\mathrm{A}}k}(\mathrm{N}\otimes_{\mathrm{A}}k).$$

The equality (6.3.1.1) is therefore a consequence of the same relation for A', B', M' and N'; but as N is a flat A-module, $\mathrm{N}'=\mathrm{N}\otimes_{\mathrm{A}}\mathrm{A}'$ is a flat A'-module (**0**, 6.2.1); we may therefore apply the induction hypothesis, which proves (6.3.1.1) in this case.

b) Suppose $\mathrm{prof}_{\mathrm{B}\otimes_{\mathrm{A}}k}(\mathrm{N}\otimes_{\mathrm{A}}k)>0$. Consider an element $y\in\mathfrak{n}$ which is $(\mathrm{N}\otimes_{\mathrm{A}}k)$-regular; it follows from (**0**, 10.2.4) that y is N-regular and that we then have

$$\mathrm{N}'=\mathrm{N}/y\mathrm{N}$$

is a flat A-module, since N is supposed to be a flat A-module. Applying (**0**, 6.1.2) to the exact sequence of A-modules

$$0\longrightarrow\mathrm{N}\xrightarrow{y}\mathrm{N}\longrightarrow\mathrm{N}'\longrightarrow 0$$

we conclude that we have isomorphisms

$$(\mathrm{M}\otimes_{\mathrm{A}}\mathrm{N})/y(\mathrm{M}\otimes_{\mathrm{A}}\mathrm{N})\xrightarrow{\sim}\mathrm{M}\otimes_{\mathrm{A}}\mathrm{N}'\quad\text{and}\quad\mathrm{N}'\otimes_{\mathrm{A}}k\xrightarrow{\sim}(\mathrm{N}\otimes_{\mathrm{A}}k)/y(\mathrm{N}\otimes_{\mathrm{A}}k)$$

and in addition that y is $(\mathrm{M}\otimes_{\mathrm{A}}\mathrm{N})$-regular. We thus have

$$\mathrm{prof}_{\mathrm{B}\otimes_{\mathrm{A}}k}(\mathrm{N}'\otimes_{\mathrm{A}}k)=\mathrm{prof}_{\mathrm{B}\otimes_{\mathrm{A}}k}(\mathrm{N}\otimes_{\mathrm{A}}k)-1$$

and

$$\mathrm{prof}_{\mathrm{B}}(\mathrm{M}\otimes_{\mathrm{A}}\mathrm{N}')=\mathrm{prof}_{\mathrm{B}}(\mathrm{M}\otimes_{\mathrm{A}}\mathrm{N})-1;$$

the induction hypothesis shows that the relation (6.3.1.1) is valid for A, B, M and N', and from what precedes, we deduce (6.3.1.1) for A, B, M and N. ☐

Corollary (6.3.2). — *Under the hypotheses of* (6.3.1), *suppose in addition* $\mathrm{M}\neq 0$ *and* $\mathrm{N}\neq 0$; *then we have*

(6.3.2.1) $$\mathrm{coprof}_{\mathrm{B}}(\mathrm{M}\otimes_{\mathrm{A}}\mathrm{N})=\mathrm{coprof}_{\mathrm{A}}(\mathrm{M})+\mathrm{coprof}_{\mathrm{B}\otimes_{\mathrm{A}}k}(\mathrm{N}\otimes_{\mathrm{A}}k).$$

Proof. This follows immediately from (6.3.1.1) and (6.1.2) and from the definition of the codepth (**0**, 16.4.9). ☐

Corollary (6.3.3). — *Under the hypotheses of* (6.3.1), *suppose in addition* $\mathrm{M}\neq 0$ *and* $\mathrm{N}\neq 0$; *for* $\mathrm{M}\otimes_{\mathrm{A}}\mathrm{N}$ *to be a Cohen-Macaulay* B*-module, it is necessary and sufficient that* M *be a Cohen-Macaulay* A*-module and that* $\mathrm{N}\otimes_{\mathrm{A}}k$ *be a* $(\mathrm{B}\otimes_{\mathrm{A}}k)$*-module of Cohen-Macaulay.*

Proof. This follows from the corollary (6.3.2) and from the definition of Cohen-Macaulay modules by the fact that their codepth is zero (**0**, 16.5.1), taking into account that the condition $\mathrm{N}\neq 0$ is equivalent to $\mathrm{N}\otimes_{\mathrm{A}}k\neq 0$ by virtue of the lemma of Nakayama. ☐

Corollary (6.3.4). — *Under the hypotheses of* (6.3.1), *suppose in addition that* $\mathrm{N}\otimes_{\mathrm{A}}k$ *is a* B*-module of finite length; then we have*

(6.3.4.1) $$\mathrm{prof}_{\mathrm{B}}(\mathrm{M}\otimes_{\mathrm{A}}\mathrm{N})=\mathrm{prof}_{\mathrm{A}}(\mathrm{M}).$$

If in addition $\mathrm{M}\neq 0$ *and* $\mathrm{N}\neq 0$, *then we have* **IV-2 | 140**

(6.3.4.2) $$\mathrm{coprof}_{\mathrm{B}}(\mathrm{M}\otimes_{\mathrm{A}}\mathrm{N})=\mathrm{coprof}_{\mathrm{A}}(\mathrm{M}).$$

Proof. It amounts to the same to say that $\mathrm{N}\otimes_{\mathrm{A}}k$ is a B-module of finite length or a $(\mathrm{B}\otimes_{\mathrm{A}}k)$-module of finite length, and we know (**0**, 16.2.3) that modules of finite length $\neq 0$ are of dimension 0 and depth 0.

The corollary (6.3.4) is applicable in particular when $\mathrm{B}\otimes_{\mathrm{A}}k$ is an Artinian ring, that is to say when $\mathfrak{m}\mathrm{B}$ is an *ideal of definition* of the ring B. ☐

Corollary (6.3.5). — *Let* X, Y *be two locally Noetherian preschemes,* $f: X\to Y$ *a flat morphism.*

(i) *If, at a point* $x\in X$, $\mathrm{coprof}(\mathscr{O}_x)\leqslant n$, *then, setting* $y=f(x)$, *we have* $\mathrm{coprof}(\mathscr{O}_y)\leqslant n$ *and* $\mathrm{coprof}(\mathscr{O}_x\otimes_{\mathscr{O}_y}\boldsymbol{k}(y))\leqslant n$; *in particular, if* $\mathscr{O}_x$ *is a Cohen-Macaulay ring, the same is true of* $\mathscr{O}_y$ *and of* $\mathscr{O}_x\otimes_{\mathscr{O}_y}\boldsymbol{k}(y)$.

(ii) *Conversely, suppose that* $\mathscr{O}_x\otimes_{\mathscr{O}_y}\boldsymbol{k}(y)$ *is a Cohen-Macaulay ring. Then, if* $\mathrm{coprof}(\mathscr{O}_y)\leqslant n$ *(resp. if* $\mathscr{O}_y$ *is a Cohen-Macaulay ring), we have* $\mathrm{coprof}(\mathscr{O}_x)\leqslant n$ *(resp.* $\mathscr{O}_x$ *is a Cohen-Macaulay ring).*

Proof. It suffices to apply (6.3.2) for $\mathrm{M} = \mathscr{O}_y$ and $\mathrm{N} = \mathrm{B} = \mathscr{O}_x$. □

Corollary (6.3.6). — *Let* A *be a Cohen-Macaulay ring. Then* $\mathrm{A}' = \mathrm{A}[\mathrm{T}_1, \ldots, \mathrm{T}_n]$ *(T_i indeterminates) is a Cohen-Macaulay ring.*

Proof. Indeed, if we set $Y = \mathrm{Spec}(\mathrm{A})$, $X = \mathrm{Spec}(\mathrm{A}')$ and if $f : X \to Y$ is the canonical morphism, f is *flat* (since A' is a free A-module (2.1.2)) and for every $y \in Y$, $\boldsymbol{k}(y)[\mathrm{T}_1, \ldots, \mathrm{T}_n]$ is a regular ring (**0**, 17.3.7), hence *a fortiori* a Cohen-Macaulay ring; it therefore suffices to apply (6.3.5). □

Corollary (6.3.7). — *Every quotient ring of a Cohen-Macaulay ring is universally catenary.*

Proof. This follows from (6.3.6), from (5.6.1) and from (**0**, 16.5.12). □

Proposition (6.3.8). — *Let* A *be a local Noetherian ring; suppose that there exists a Cohen-Macaulay* A*-module* M *of finite type whose support is equal to* Spec(A)*. Let* B *be a quotient ring of* A*, and let* $f : \mathrm{Spec}(\widehat{\mathrm{B}}) \to \mathrm{Spec}(\mathrm{B})$ *be the canonical morphism; then, for every* $x \in \mathrm{Spec}(\mathrm{B})$, $f^{-1}(x)$ *is a Cohen-Macaulay prescheme.*

Proof. As B is an A-module of finite type, one has $\widehat{\mathrm{B}} = \mathrm{B} \otimes_{\mathrm{A}} \widehat{\mathrm{A}}$ (**0**, 7.3.3); hence f is the restriction to $\mathrm{Spec}(\widehat{\mathrm{B}})$ of the canonical morphism $\mathrm{Spec}(\widehat{\mathrm{A}}) \to \mathrm{Spec}(\mathrm{A})$, and the fibres of these two morphisms at a point of Spec(B) are the same. We are therefore reduced to proving the proposition when B = A. Let $\mathfrak{p} = \mathfrak{j}_x$ be a prime ideal of A. Since $\mathfrak{p} \in \mathrm{Supp}(\mathrm{M})$ by hypothesis, there exists (**0**, 16.5.6) a M-regular sequence $(t_i)_{1 \leqslant i \leqslant r}$ of elements of $\mathfrak{p}$ such that

$$\mathrm{N} = \mathrm{M}/\Big(\sum_{i=1}^{r} t_i \mathrm{M}\Big)$$

is a Cohen–Macaulay A-module, $\mathfrak{p}$ is a minimal associated prime ideal of N, and

$$\dim(\mathrm{N}) = \dim(\mathrm{M}/\mathfrak{p}\mathrm{M}) = \dim(\mathrm{A}/\mathfrak{p})$$

(**0**, 16.5.9). The same argument as at the beginning shows that one may replace M by N and A by $\mathrm{A}/(\sum_{i=1}^{r} t_i \mathrm{A})$; consequently one may suppose that $\mathfrak{p}$ is a minimal prime ideal of A. Set, to simplify, **IV-2** | 141
$\mathrm{A}' = \widehat{\mathrm{A}}$, $\mathrm{M}' = \widehat{\mathrm{M}} = \mathrm{M} \otimes_{\mathrm{A}} \mathrm{A}'$ (**0**, 7.3.3); we know (**0**, 16.5.2) that M' is a Cohen-Macaulay A'-module, which implies that for every prime ideal $\mathfrak{p}'$ of A', $\mathrm{M}'_{\mathfrak{p}'}$ is a Cohen-Macaulay $\mathrm{A}'_{\mathfrak{p}'}$-module (**0**, 16.5.10). Taking into account (**I**, 3.6.5), one sees that if we set $\mathrm{A}'' = \mathrm{A}' \otimes_{\mathrm{A}} \mathrm{A}_{\mathfrak{p}}$ and $\mathrm{M}'' = \mathrm{M}' \otimes_{\mathrm{A}} \mathrm{A}_{\mathfrak{p}}$, M'' is a Cohen-Macaulay A''-module. For every prime ideal $\mathfrak{p}''$ of A'' above $\mathfrak{p}$, $\mathrm{M}''_{\mathfrak{p}''} = \mathrm{M}_{\mathfrak{p}} \otimes_{\mathrm{A}_{\mathfrak{p}}} \mathrm{A}''_{\mathfrak{p}''}$ is a Cohen-Macaulay $\mathrm{A}''_{\mathfrak{p}''}$-module (**0**, 16.5.10); on the other hand, $\mathrm{M}_{\mathfrak{p}}$ is by hypothesis a Cohen-Macaulay $\mathrm{A}_{\mathfrak{p}}$-module and $\mathrm{A}''_{\mathfrak{p}''}$ is a flat $\mathrm{A}_{\mathfrak{p}}$-module since A' is a flat A-module (**0**, 7.3.3) and (6.3.2). We conclude from (6.3.3) that, if k is the residue field of $\mathrm{A}_{\mathfrak{p}}$, $k \otimes_{\mathrm{A}_{\mathfrak{p}}} \mathrm{A}''_{\mathfrak{p}''}$ is a Cohen-Macaulay ring. But since $\mathrm{A}_{\mathfrak{p}}$ is of dimension 0, the prime ideals of A' correspond bijectively to those of $k \otimes_{\mathrm{A}_{\mathfrak{p}}} \mathrm{A}''$ (**I**, 3.5.7), and if $\mathfrak{q}''$ is the prime ideal of $k \otimes_{\mathrm{A}_{\mathfrak{p}}} \mathrm{A}''$ corresponding to $\mathfrak{p}''$, the local rings $(k \otimes_{\mathrm{A}_{\mathfrak{p}}} \mathrm{A}'')_{\mathfrak{q}''}$ and $k \otimes_{\mathrm{A}_{\mathfrak{p}}} \mathrm{A}''_{\mathfrak{p}''}$ are isomorphic. Therefore (**0**, 16.5.13), the ring $k \otimes_{\mathrm{A}_{\mathfrak{p}}} \mathrm{A}''$ is a Cohen-Macaulay ring. □

6.4. Flatness and property (S_k)

Proposition (6.4.1). — *Let X, Y be two locally Noetherian preschemes, $f : X \to Y$ a morphism, $\mathscr{E}$ a coherent $\mathscr{O}_Y$-Module, $\mathscr{F}$ a coherent $\mathscr{O}_X$-Module and f-flat.*

(i) *Let $x \in \mathrm{Supp}(\mathscr{F})$ be such that $\mathscr{E} \otimes_{\mathscr{O}_Y} \mathscr{F}$ has property (S_k) at the point x; then $\mathscr{E}$ has property (S_k) at the point $y = f(x)$.*

(ii) *Suppose that for every $y \in f(\mathrm{Supp}(\mathscr{F}))$, $\mathscr{F}_y = \mathscr{F} \otimes_{\mathscr{O}_y} \boldsymbol{k}(y)$ has property (S_k); then, if for a point $y \in f(\mathrm{Supp}(\mathscr{F}))$, $\mathscr{E}$ has property (S_k) at the point y, $\mathscr{E} \otimes_{\mathscr{O}_Y} \mathscr{F}$ has property (S_k) at every point of $f^{-1}(y)$.*

Proof.

(i) We know (**Err**$_{\mathbf{III}}$, 30) that there exists a closed sub-prescheme X' of X having for underlying space $\mathrm{Supp}(\mathscr{F})$ and a coherent $\mathscr{O}_{X'}$-Module $\mathscr{F}'$ such that $\mathscr{F} = j_*(\mathscr{F}')$, where j is the canonical injection $X' \hookrightarrow X$; we may replace X by X' and $\mathscr{F}$ by $\mathscr{F}'$, in other words suppose that $\mathrm{Supp}(\mathscr{F}) = X$. Let y' be a generization of y in Y; we know (2.3.4) that there is a generization x' of x in X such that $y' = f(x')$; we may in addition suppose that x' is the generic point of an irreducible component of $f^{-1}(y')$; we then have $\dim(\mathscr{F}_{x'} \otimes_{\mathscr{O}_{y'}} \boldsymbol{k}(y')) = 0$. By virtue of (6.1.2), we then have, setting $\mathscr{G} = \mathscr{E} \otimes_{\mathscr{O}_Y} \mathscr{F}$,

$$\dim(\mathscr{G}_{x'}) = \dim(\mathscr{E}_{y'})$$

and by virtue of (6.3.1)

$$\mathrm{prof}(\mathscr{G}_{x'}) = \mathrm{prof}(\mathscr{E}_{y'})$$

taking into account that the depth is always at most equal to the dimension. By hypothesis, we have

$$\mathrm{prof}(\mathscr{G}_{x'}) \geqslant \inf(k, \dim(\mathscr{G}_{x'}))$$

hence

$$\mathrm{prof}(\mathscr{E}_{y'}) \geqslant \inf(k, \dim(\mathscr{E}_{y'}))$$

which proves the first assertion.

IV-2 | 142

(ii) As for every generization x' of $x \in f^{-1}(y)$, $y' = f(x')$ is a generization of y, we may restrict to verifying that if $x \in \mathrm{Supp}(\mathscr{G})$ and $f(x) = y$, we have $\mathrm{prof}(\mathscr{G}_x) \geqslant \inf(k, \dim(\mathscr{G}_x))$; it follows from (6.1.2) and (6.3.1) that we have

$$\dim(\mathscr{G}_x) = \dim(\mathscr{E}_y) + \dim(\mathscr{F}_x \otimes_{\mathscr{O}_y} \boldsymbol{k}(y))$$

$$\mathrm{prof}(\mathscr{G}_x) = \mathrm{prof}(\mathscr{E}_y) + \mathrm{prof}(\mathscr{F}_x \otimes_{\mathscr{O}_y} \boldsymbol{k}(y)).$$

By hypothesis, we have

$$\mathrm{prof}(\mathscr{E}_y) \geqslant \inf(k, \dim(\mathscr{E}_y))$$

$$\mathrm{prof}(\mathscr{F}_x \otimes_{\mathscr{O}_y} \boldsymbol{k}(y)) \geqslant \inf(k, \dim(\mathscr{F}_x \otimes_{\mathscr{O}_y} \boldsymbol{k}(y)))$$

whence, adding term by term,

$$\mathrm{prof}(\mathscr{G}_x) \geqslant \inf(k, \dim(\mathscr{E}_y)) + \inf(k, \dim(\mathscr{F}_x \otimes_{\mathscr{O}_y} \boldsymbol{k}(y))) \geqslant$$
$$\geqslant \inf(k, \dim(\mathscr{E}_y) + \dim(\mathscr{F}_x \otimes_{\mathscr{O}_y} \boldsymbol{k}(y))) = \inf(k, \dim(\mathscr{G}_x))$$

which proves (ii).

□

Corollary (6.4.2). — *Let X, Y be two locally Noetherian preschemes, $f : X \to Y$ a flat morphism, $\mathscr{E}$ a coherent $\mathscr{O}_Y$-Module. Suppose that for every $y \in Y$, the prescheme $f^{-1}(y)$ has property (S_k). Then, for $f^*(\mathscr{E})$ to have property (S_k) at a point x, it is necessary and sufficient that $\mathscr{E}$ have property (S_k) at the point $f(x)$.*

Remark (6.4.3). — Let A, B be two local Noetherian rings, k the residue field of A, $\varphi : \mathrm{A} \to \mathrm{B}$ a local homomorphism, M a B-module of finite type that is a flat A-module, and suppose in addition that the A-module A and the $(\mathrm{B} \otimes_{\mathrm{A}} k)$-module $\mathrm{M} \otimes_{\mathrm{A}} k$ have property (S_n); can one then conclude that the B-module M has property (S_n)? We do not know even when $n = 1$, $\mathrm{M} = \mathrm{B}$ and $\mathrm{B} = \widehat{\mathrm{A}}$, which is to say we do not know whether in general the *completion* of a local Noetherian ring satisfying (S_n) also satisfies (S_n), even for $n = 1$. Setting $Y = \mathrm{Spec}(\mathrm{A})$, $X = \mathrm{Spec}(\mathrm{B})$ and $\mathscr{F} = \widetilde{\mathrm{M}}$, it would suffice, by virtue of (6.4.1), (ii), to show that for *every* $y \in Y$, $\mathscr{F}_y$ has property (S_k) (and not only when y is the closed point of Y); it would also suffice to show that the set U of $x \in X$ such that $\mathscr{F}_x \otimes_{\mathscr{O}_{f(x)}} \boldsymbol{k}(f(x))$ satisfies (S_k) is *open* in X (since it contains the closed point of X by hypothesis). We will show further on (12.1.4) that U is open when B is a local ring of a finite type A-algebra and $\mathrm{M} = \mathrm{B}$. On the other hand, for $\mathrm{B} = \widehat{\mathrm{A}}$ and $\mathrm{M} = \mathrm{B}$, we have seen in (6.3.8) that the preschemes $f^{-1}(y)$ are Cohen-Macaulay preschemes (in other words, satisfy (S_n) for *every* n) when A is a quotient of a local Cohen-Macaulay ring. We conclude that when A is a quotient of a local Cohen-Macaulay ring (or, more generally, of a local ring satisfying the hypotheses of (6.3.8)), *for* A *to satisfy* (S_n), *it is necessary and sufficient that its completion* $\widehat{\mathrm{A}}$ *satisfy* (S_n). It would remain to see whether this property holds without restriction on A.

6.5. Flatness and property (R_k) **IV-2 | 143**

Proposition (6.5.1). — *Let* A, B *be two local Noetherian rings, k the residue field of* A, $\varphi : \mathrm{A} \to \mathrm{B}$ *a local homomorphism, for which* B *is a flat* A*-module. Then:*

(i) If B *is regular,* A *is regular.*
(ii) If A *and* $\mathrm{B} \otimes_{\mathrm{A}} k$ *are regular,* B *is regular.*

This proposition is given here for the record, having already been proved in (**0**, 17.3.3).

Corollary (6.5.2). — *Let X, Y be two locally Noetherian preschemes, $f : X \to Y$ a flat morphism.*

(i) If X is regular at a point x, Y is regular at the point $f(x)$.
(ii) If for a $y \in f(X)$, Y is regular at the point y and if $f^{-1}(y)$ is a regular prescheme at a point x, then X is regular at the point x.

Proposition (6.5.3). — *Let X, Y be two locally Noetherian preschemes, $f : X \to Y$ a flat morphism.*

(i) If X has property (R_k) at a point x (resp. has property (R_k)), Y has property (R_k) at the point $f(x)$ (resp. Y has property (R_k) at all points of $f(X)$).
(ii) Suppose that for every $y \in f(X)$, the prescheme $f^{-1}(y)$ has property (R_k); then, if for a point $y \in f(X)$, Y has property (R_k) at the point y, X has property (R_k) at every point of $f^{-1}(y)$.

Proof.

(i) Set $y = f(x)$ and let y' be a generization of y; as in the proof of (6.4.1), there is a generic point x' of an irreducible component of $f^{-1}(y')$ which is a generization of x; hence $\dim(\mathscr{O}_{x'} \otimes_{\mathscr{O}_{y'}} \boldsymbol{k}(y')) = 0$ and by virtue of the hypothesis and of (6.1.2), $\dim(\mathscr{O}_{x'}) = \dim(\mathscr{O}_{y'})$. The hypothesis implies, provided that $\dim(\mathscr{O}_{x'}) > k$, that $\mathscr{O}_{x'}$ is a regular ring, and then $\mathscr{O}_{y'}$ is regular by virtue of (6.5.1).

(ii) As for every generization x' of $x \in f^{-1}(y)$, $y' = f(x')$ is a generization of y, we may restrict to verifying that if $\dim(\mathscr{O}_x) \leqslant k$, then $\mathscr{O}_x$ is a regular ring. Now, by virtue of (6.1.2)

$$\dim(\mathscr{O}_x) = \dim(\mathscr{O}_y) + \dim(\mathscr{O}_x \otimes_{\mathscr{O}_y} \boldsymbol{k}(y))$$

hence if $\dim(\mathscr{O}_x) \leqslant k$, we have *a fortiori* $\dim(\mathscr{O}_y) \leqslant k$ and $\dim(\mathscr{O}_x \otimes_{\mathscr{O}_y} \boldsymbol{k}(y)) \leqslant k$ and the hypothesis implies that $\mathscr{O}_y$ and $\mathscr{O}_x \otimes_{\mathscr{O}_y} \boldsymbol{k}(y)$ are regular rings. We conclude then from (6.5.1) that $\mathscr{O}_x$ is a regular ring.

□

Corollary (6.5.4). — *Let X, Y be two locally Noetherian preschemes, $f : X \to Y$ a flat morphism.*

(i) If X is normal at a point x, Y is normal at the point $f(x)$.
(ii) If, for every $y \in f(X)$, $f^{-1}(y)$ is a normal prescheme and if Y is normal at a point $y \in f(X)$, then X is a normal prescheme at every point of $f^{-1}(y)$.

Proof. This follows immediately from the normality criterion of Serre (5.8.6) and from (6.4.1) applied for $k = 2$ and (6.5.3) applied for $k = 1$. □

Remarks (6.5.5). — **IV-2 | 144**

(i) Let A, B be two local Noetherian rings, $\varphi : \mathrm{A} \to \mathrm{B}$ a local homomorphism such that B is a flat A-module. Let k be the residue field of A, and suppose that the two rings A and $\mathrm{B} \otimes_{\mathrm{A}} k$ satisfy property (R_i) (5.8.2); then *it does not necessarily follow* that B satisfies (R_i), even in the particular case where $i = 0$ or $i = 1$ and where B is the *completion* $\widehat{\mathrm{A}}$ of A. Nagata has in fact given an example where A is *normal* (hence satisfies (R_1)) but where $\widehat{\mathrm{A}}$ is not even reduced (hence does not satisfy (R_0)) [30]. We cannot apply the proposition (6.5.3) to this case because the fibres $f^{-1}(y)$ do not necessarily satisfy property (R_i) at the points distinct from the closed point of $Y = \mathrm{Spec}(\mathrm{A})$. We will show further on (7.8.3), (v)) that such phenomena do not arise for the local Noetherian rings that one encounters most often in applications.

(ii) The property for a prescheme of being *integral* does not at all behave like the properties we have just examined and the preceding ones: it can happen that $f : X \to Y$ is a flat morphism of finite type, that all the fibres $f^{-1}(y)$ are geometrically regular (and even geometrically regular (6.7.6)) and that Y is integral, without X being even locally integral. For example, let k be an algebraically closed field of characteristic 0, and let A be the integral ring $k[\mathrm{U}, \mathrm{V}]/(\mathrm{UV} - (\mathrm{U}+\mathrm{V})^3)$ (whose spectrum is therefore a "cubic with a double point"); A is not integrally closed, and if u, v are the canonical images of U, V in A, the integral closure of A is the ring $\mathrm{C} = \mathrm{A}[t]$, with $t = (u-v)/(u+v)$, which satisfies the equation $t^2 = 1 + u + v$, whence $u = \frac{1}{2}(t^3 + t^2 - t)$, $v = \frac{1}{2}(-t^3 + t^2 + t)$ and therefore $\mathrm{C} = k[t]$, isomorphic to a polynomial ring in one indeterminate over k. If $\mathfrak{m} = \mathrm{A}u + \mathrm{A}v$, the maximal ideal of A (corresponding to the "double point" of the cubic), there are two maximal ideals $\mathfrak{n}_1$, $\mathfrak{n}_2$ of C, generated respectively by $t-1$ and $t+1$. Let B be the subring of the product $\mathrm{C} \times \mathrm{C}$ formed by the pairs of polynomials (f, g) such that $f(1) = g(-1)$ and $f(-1) = g(1)$ ($\mathrm{Spec}(\mathrm{B})$ is the prescheme obtained by "gluing" two copies of $\mathrm{Spec}(\mathrm{C})$, the point $\mathfrak{n}_1$ (resp. $\mathfrak{n}_2$) of one of the two copies being "glued" to the point $\mathfrak{n}_2$ (resp. $\mathfrak{n}_1$) of the other; cf. chap. V, where this operation will be discussed in a general way). There are therefore two maximal ideals $\mathfrak{r}_1$, $\mathfrak{r}_2$ of B above the maximal ideal $\mathfrak{m}$ of A. Moreover, as the "gluing" process commutes with localisation and completion, one easily verifies that the canonical homomorphisms $\widehat{\mathrm{A}}_{\mathfrak{m}} \to \widehat{\mathrm{B}}_{\mathfrak{r}_1}$ and $\widehat{\mathrm{A}}_{\mathfrak{m}} \to \widehat{\mathrm{B}}_{\mathfrak{r}_2}$ are bijective; consequently $\mathrm{B}_{\mathfrak{r}_1}$ and $\mathrm{B}_{\mathfrak{r}_2}$ are flat $\mathrm{A}_{\mathfrak{m}}$-modules (Bourbaki, *Alg. comm.*, chap. III, § 3, n° 5, prop. 10). For every other maximal ideal $\mathfrak{p}$ of A, there are two maximal ideals $\mathfrak{q}_1$, $\mathfrak{q}_2$ of B above $\mathfrak{p}$, and the homomorphisms $\mathrm{A}_{\mathfrak{p}} \to \mathrm{B}_{\mathfrak{q}_1}$ and $\mathrm{A}_{\mathfrak{p}} \to \mathrm{B}_{\mathfrak{q}_2}$ are bijective. We see thus that the morphism $\mathrm{Spec}(\mathrm{B}) \to \mathrm{Spec}(\mathrm{A})$ is flat and finite, and that all its fibres are geometrically regular (it is even *étale*, as we will see later (17.6.3)); however it is immediate that B is not integral.

6.6. Properties of transitivity

IV-2 | 145

Proposition (6.6.1). — *For a locally Noetherian prescheme* Z, *let us denote by* $\boldsymbol{P}(\mathrm{Z})$ *any one of the following properties:*

a) Z *is a Cohen-Macaulay prescheme.*
b) Z *satisfies* (S_n).
c) Z *is regular.*
d) Z *satisfies* (R_n).
e) Z *is normal.*
f) Z *is reduced.*

Let then X, Y, Z *be three locally Noetherian preschemes,* $f : \mathrm{X} \to \mathrm{Y}$, $g : \mathrm{Y} \to \mathrm{Z}$ *two morphisms.*

(i) Suppose that f *and* g *are flat and that for every* $y \in f(\mathrm{X})$ *(resp. every* $z \in g(\mathrm{Y})$*), the prescheme* $f^{-1}(y)$ *(resp.* $g^{-1}(z)$*) satisfies* $\boldsymbol{P}$. *Then* $h = g \circ f$ *is flat and, for every* $z \in h(\mathrm{X})$, $h^{-1}(z)$ *satisfies* $\boldsymbol{P}$.

(ii) Suppose the following conditions are satisfied: f *is faithfully flat,* $h = g \circ f$ *is flat, for every* $y \in \mathrm{Y}$, *the prescheme* $f^{-1}(y)$ *satisfies* $\boldsymbol{P}$, *and for every* $z \in g(\mathrm{Y})$, *the prescheme* $h^{-1}(z)$ *satisfies* $\boldsymbol{P}$. *Then* g *is flat, and for every* $z \in g(\mathrm{Y})$, $g^{-1}(z)$ *satisfies* $\boldsymbol{P}$.

Proof. (i) We already know (**0**, 2.1.6) that h is flat; furthermore, for every $z \in \mathrm{Z}$, $f_z = f \otimes \mathbf{1}_{\boldsymbol{k}(z)} : h^{-1}(z) \to g^{-1}(z)$ is flat (**0**, 2.1.4), and for every $y \in g^{-1}(z)$, $f_z^{-1}(y)$ is isomorphic to $f^{-1}(y)$ (**I**, 3.6.4). The conclusion follows then respectively from (6.3.5), (ii), (6.4.2), (6.5.2), (ii), (6.5.3), (ii), (6.5.4), (ii) and (3.3.5), (ii).

(ii) We already know that g is flat (2.2.13); in addition, for every $z \in \mathrm{Z}$, f_z is faithfully flat (2.2.13). The conclusion follows then respectively from (6.3.5), (i), (6.4.2), (6.5.2), (i), (6.5.3), (i), (6.5.4), (ii) and (2.1.13). ∎

Remark (6.6.2). — Suppose h flat, f faithfully flat, and suppose that for every $z \in \mathrm{Z}$, $h^{-1}(z)$ is of coprofundity $\leqslant n$ (5.7.1); then it follows from the reasoning of (6.6.1), (ii) and (6.3.2) that $g^{-1}(z)$ is of coprofundity $\leqslant n$ for every $z \in g(\mathrm{Y})$ and that for every $y \in \mathrm{Y}$, $f^{-1}(y)$ is of coprofundity $\leqslant n$.

6.7. Application to base changes in algebraic preschemes

Proposition (6.7.1). — *Let k be a field, X a k-prescheme locally Noetherian, $\mathscr{F}$ an $\mathscr{O}_{\mathrm{X}}$-Module coherent. Let k' be an extension of k; set $\mathrm{X}' = \mathrm{X} \otimes_k k'$, $\mathscr{F}' = \mathscr{F} \otimes_k k'$ and let $p : \mathrm{X}' \to \mathrm{X}$ be the canonical projection. We suppose either that X is locally of finite type over k, or that k' is an extension of finite type of k, so that in both cases X' is locally Noetherian. Let x' be a point of X', $x = p(x')$. Then:*

(i) We have $\operatorname{coprof}(\mathscr{F}_x) = \operatorname{coprof}(\mathscr{F}'_{x'})$; in particular, for $\mathscr{F}_x$ to be an $\mathscr{O}_x$-module of Cohen-Macaulay, it is necessary and sufficient that $\mathscr{F}'_{x'}$ be an $\mathscr{O}_{x'}$-module of Cohen-Macaulay.

(ii) For $\mathscr{F}$ to satisfy the property (S_n) at the point x, it is necessary and sufficient that $\mathscr{F}'$ satisfy (S_n) at the point x'.

Proof. We know that p is faithfully flat (2.2.13); the two assertions are then consequences respectively of (6.3.2) and (6.4.2), provided that one proves that $p^{-1}(x) = \operatorname{Spec}(\boldsymbol{k}(x) \otimes_k k')$ is a Cohen-Macaulay prescheme; as one of the two fields $\boldsymbol{k}(x)$, k' is an extension of finite type of k by hypothesis, we are reduced to proving the following: □ **IV-2 | 146**

Lemma (6.7.1.1). — *Let K, L be two extensions of a field k, one of which is of finite type (so that the ring $\mathrm{K} \otimes_k \mathrm{L}$ is Noetherian). Then $\mathrm{K} \otimes_k \mathrm{L}$ is a Cohen-Macaulay ring.*

Proof. Suppose for example that L is an extension of finite type of k, so that L is extension of a pure extension $k(\mathbf{t})$ of k ($\mathbf{t}$ being a system $(t_i)_{1 \leqslant i \leqslant m}$ of indeterminates). We then set $\mathrm{A} = \mathrm{K} \otimes_k k(\mathbf{t})$, $\mathrm{B} = \mathrm{K} \otimes_k \mathrm{L}$, B is an A-module flat (**0**, 6.2.1) and of finite type; the morphism $h : \operatorname{Spec}(\mathrm{B}) \to \operatorname{Spec}(\mathrm{A})$ is finite, and as every Artinian prescheme is of Cohen-Macaulay, to prove that B is a Cohen-Macaulay ring, it suffices to prove that A is a Cohen-Macaulay ring (6.3.5). Now, if S is the set of nonzero elements of $k[\mathbf{t}]$, then $\mathrm{A} = \mathrm{S}^{-1}\mathrm{A}'$, where $\mathrm{A}' = \mathrm{K} \otimes_k k[\mathbf{t}] = \mathrm{K}[\mathbf{t}]$; by (**0**, 16.5.13), it suffices to prove that A' is regular (**0**, 17.3.7). □

Corollary (6.7.2). — *For $\mathscr{O}_x$ to be a Cohen–Macaulay ring (resp. for X to satisfy (S_n) at the point x), it is necessary and sufficient that $\mathscr{O}_{x'}$ be a Cohen–Macaulay ring (resp. that X' satisfy (S_n) at the point x').*

Corollary (6.7.3). — *Let X and Y be two locally Noetherian k-preschemes, at least one of which is locally of finite type over k. Let $\mathscr{F}$ (resp. $\mathscr{G}$) be a coherent $\mathscr{O}_{\mathrm{X}}$-Module (resp. a coherent $\mathscr{O}_{\mathrm{Y}}$-Module). If $\mathscr{F}$ and $\mathscr{G}$ satisfy property (S_n), then so does $\mathscr{F} \otimes_k \mathscr{G}$.*

Proof. The hypothesis implies that $\mathrm{X} \times_k \mathrm{Y}$ is locally Noetherian; let $p : \mathrm{X} \times_k \mathrm{Y} \to \mathrm{X}$ and $q : \mathrm{X} \times_k \mathrm{Y} \to \mathrm{Y}$ be the canonical projections, which are flat morphisms. Suppose, for example, that X is locally of finite type over k; we may write $\mathscr{F} \otimes_k \mathscr{G} = p^*(\mathscr{F}) \otimes_k \mathscr{G}$, and since $\mathscr{F}$ is flat relative to the structural morphism $\mathrm{X} \to \operatorname{Spec}(k)$, $p^*(\mathscr{F})$ is q-flat (2.1.4). Applying the criterion (6.4.1), (ii) to the morphism q, it suffices to see that, for every $y \in \mathrm{Y}$, $p^*(\mathscr{F}) \otimes_{\mathscr{O}_{\mathrm{Y}}} \boldsymbol{k}(y)$ has property (S_n); but $p^*(\mathscr{F}) \otimes_{\mathscr{O}_{\mathrm{Y}}} \boldsymbol{k}(y) = \mathscr{F} \otimes_k \boldsymbol{k}(y)$, and since X is locally of finite type over k, the conclusion follows from (6.7.1), (ii). □

Proposition (6.7.4). — *For a locally Noetherian prescheme Z and a point $z \in \mathrm{Z}$, let $\boldsymbol{P}(\mathrm{Z}, z)$ be one of the following properties:*

a) Z is regular at the point z.

b) Z satisfies (R_n) at the point z.

c) Z is normal at the point z.

d) Z is reduced at the point z.

Under the hypotheses and with the notation of (6.7.1), if $\boldsymbol{P}(\mathrm{X}', x')$ is true, then $\boldsymbol{P}(\mathrm{X}, x)$ is true. The converse is true if k' is a separable extension of k.

Proof. The case where $\boldsymbol{P}$ is property d) has been included only for the record, having already been treated in (2.1.13) and (4.6.1). The same reasoning as at the beginning of the proof of (6.7.1) shows that the first assertion follows respectively from (6.5.2), (i), (6.5.3), (i), and (6.5.4), (i); similarly, the second assertion follows from (6.5.2), (ii), (6.5.3), (ii), and (6.5.4), (ii),

provided that one proves that $p^{-1}(x)$ is a regular prescheme; in other words, we are reduced to proving the following lemma. □ **IV-2 | 147**

Lemma (6.7.4.1). — *Let* K *and* L *be two extensions of a field* k*, one of which is of finite type. If* L *is a separable extension of* k*, then the ring* $K \otimes_k L$ *is regular.*

Proof. We distinguish two cases.

A) L is an extension of finite type of k. With the notation of (6.7.1.1), we may then suppose that L is a finite separable extension of $k(\mathbf{t})$. For every $s \in \operatorname{Spec}(A)$, the ring $\boldsymbol{k}(s) \otimes_{k(\mathbf{t})} L$ is a direct sum of finitely many fields, finite separable extensions of $\boldsymbol{k}(s)$, and is therefore regular; it follows from (6.5.2), (ii) that it suffices to prove that A is regular. Since $A = S^{-1}A'$, it suffices to prove that A' is regular (**0**, 17.3.6), and this was proved in the proof of (6.7.1.1).

B) Let (L_λ) be the filtered family of subextensions of L that are of finite type over k. By A), each ring $C_\lambda = K \otimes_k L_\lambda$ is regular; moreover, if $L_\lambda \subset L_\mu$, then L_μ is a flat L_λ-module, so C_μ is a flat C_λ-module (**0**, 6.2.1). Since $C = K \otimes_k L = \varinjlim (K \otimes_k L_\lambda)$ is Noetherian, we may apply (5.13.7), and C is therefore regular. ☐

Remarks (6.7.5). — (i) In the proof of the fact that $\boldsymbol{P}(X, x)$ implies $\boldsymbol{P}(X', x')$, one cannot dispense with the hypothesis that k' is a *separable* extension of k. We have indeed already seen (4.6.1) when $\boldsymbol{P}$ is the property d); but even when X is *geometrically integral* (4.6.2), it can happen that X is *regular* without X' being *normal*.

Take, for example, for X a normal algebraic curve over k (**II**, 7.4.2). Since the local rings of X are integrally closed and of dimension 1, they are discrete valuation rings and hence regular (**II**, 7.1.6); consequently X is a regular k-scheme (and *a fortiori* satisfies (R_n) for every $n \geqslant 0$). To say that X is geometrically integral then means that its field K of rational functions is a separable and primary extension of k (4.6.3).

Now let k be a nonperfect field of characteristic $p > 2$, and let $a \in k$ be an element not belonging to k^p. Let $B = k[S, T]$ be the polynomial ring in two indeterminates. The polynomial

$$P(S, T) = T^2 - S^p + a$$

is irreducible in B, since one checks at once that $S^p - a$ is not a square in $k[S]$; hence $X = \operatorname{Spec}(A)$, where $A = B/PB$, is an irreducible affine curve over k. To see that X is regular, it suffices to show that it is normal (**II**, 7.4.5). But $A = k[S][t]$, where t is a root of P considered as a polynomial in T over $k[S]$, so the field $K = R(X)$ of rational functions of X is the field of fractions $k(S)[T]/(P)$ of A, a quadratic extension of $k(S)$, hence separable over $k(S)$ and *a fortiori* over k. Since 2 is invertible in k, one checks at once that A is the integral closure of $k[S]$ in K; thus A is integrally closed, and X is regular. Moreover, if an element $f + tg$ of K (with $f, g \in k(S)$) is algebraic over k, then so are its norm and trace over $k(S)$; since $k(S)$ is a purely transcendental extension of k, it follows readily that $f \in k$ and $g = 0$. Thus k is algebraically closed in K, and *a fortiori* K is a primary extension of k (4.3.1). Nevertheless, if $k' = k(a^{1/p})$, then $X' = X \otimes_k k'$ is not normal: in $k'[S]$ one has **IV-2** | 148

$$S^p - a = (S - a^{1/p})^p,$$

and X' is therefore isomorphic to $\operatorname{Spec}(A')$, where $A' = k'[S][t']$ and t' is a root of $T^2 - S^p$. The ring A' is not integrally closed: the element $t'' = t'/S$ of its field of fractions $K' = k'(S)[t']$ satisfies the integral-dependence equation

$$(t'')^2 - S^{p-2} = 0$$

over A', but does not belong to A'. In classical terminology, the "genus" over k' of the field K' of rational functions of X' is *strictly smaller* than that of K over k.

(ii) As recalled in (i), it follows from (4.6.1) that when X is not a geometrically reduced algebraic prescheme over k, there exist finite radicial extensions k' of k such that $X' = X \otimes_k k'$ is not reduced. It is interesting to give an example where X is a regular scheme over k, such that k is *algebraically closed* in the field K of rational functions of X. Let k be a field of characteristic $p > 0$, in which there exist two elements a, b forming a p-free family over k^p. Denoting again by B the ring $k[S, T]$, consider this time the polynomial $P(S, T) = T^p - aS^p - b$; as $aS^p + b$ is not a p-th power in $k(S)$, P is irreducible as a polynomial of $k(S)[T]$, and the scheme $X_0 = \operatorname{Spec}(B/PB)$ is therefore an integral affine curve over k, whose field of rational functions is $K = k(S)[t]$, where t is a root of P; let us show that k is *algebraically closed* in K. Suppose indeed that K contains an element z algebraic over k and not in k; one would then also have $z \notin k(S)$, so $[k(S)[z] : k(S)] > 1$; as $[K : k(S)] = p$, and as K is radicial over $k(S)$, one would have $z^p \in k(S)$, so $c = z^p \in k$ since z is algebraic over k; but then one would have $t^p = aS^p + b \in k^p(S^p)(c)$ hence a and b would belong to $k^p(c)$, which is absurd. So X is the normalisation of the curve X_0 in K, which is therefore a normal curve (and hence *regular*) over k. If $k' = k(a^{1/p}, b^{1/p})$, it is clear that $aS^p + b$ is a p-th power in $k'(S)$, hence $K \otimes_k k'$ is *not reduced*, nor *a fortiori* the scheme $X \otimes_k k'$.

Definition (6.7.6). — Let k be a field, X a k-prescheme locally Noetherian. We say that X is *geometrically regular* at a point x (resp. has the property (R_n) *geometric*) at a point x, resp. is geometrically normal at a point x) if, *for every* finite extension k' of k, $X' = X_{(k')} = X \otimes_k k'$ is regular (resp. has the property (R_n), resp. is normal) at every point x' of X' whose projection in X is x. We say that X is *geometrically regular* (resp. has the property (R_n) *geometric*, or equivalently is geometrically regular in codimension $\leqslant n$), resp. is *geometrically normal*) if X is geometrically regular (resp. has the property (R_n) geometric, resp. is geometrically normal) at every point.

We say that an algebra A over k is a *geometrically regular ring* (resp. geometrically normal, resp. geometrically reduced, resp. having the property (R_n) geometric) if Spec(A) has the same property.

If $X = \operatorname{Spec}(K)$, where K is an extension of k, then saying that X is geometrically regular, or geometrically normal, or *geometrically reduced*, amounts to saying that K is a *separable* extension of k: this follows from (4.6.1) and the fact that if K is a separable extension of k and k' a finite extension of k, $K \otimes_k k'$ is composed of a direct product of a finite number of fields (Bourbaki, *Alg.*, chap. VIII, § 7, no 3, cor. 1 of th. 1).

IV-2 | 149

Proposition (6.7.7). — *Let k be a field, X a k-prescheme locally Noetherian, x a point of X; denote by $Q(k')$ the relation "k' is an extension of k, and $\boldsymbol{P}(X_{(k')}, x')$ is true for every point x' of $X_{(k')}$ whose projection in X is x", where $\boldsymbol{P}(Z, z)$ is one of the properties* a), b), c) *of the statement* (6.7.4). *Then the following properties are equivalent:*

a) *$Q(k')$ is true for every finite extension k' of k.*
b) *$Q(k')$ is true for every finite radicial extension k' of k.*
c) *$Q(k')$ is true for every extension of finite type k' of k.*

Suppose in addition that X is locally of finite type over k; then the three preceding properties are also equivalent to the following:

d) *$Q(k')$ is true for every extension k' of k.*
e) *$Q(k')$ is true for a perfect extension k' of k.*
f) *$Q(k')$ is true for every extension $k' = k^{p^{-s}}$, where p is the characteristic exponent of k, and $s > 0$.*

Proof. To prove the equivalence of a), b) and c), it clearly suffices to show that b) implies c). Let K be an extension of finite type of k, which is then the field of fractions of a k-algebra of finite type A; set $Y = \operatorname{Spec}(A)$. We know (4.6.6) that there exists a finite and radicial extension k' of k such that $Y' = (Y \otimes_k k')_{\text{red}}$ is separable over k'; if η' is the generic point of Y', $K' = \boldsymbol{k}(\eta')$ is a separable extension of k' by (4.6.1). This being so, $\boldsymbol{P}(X_{(k')}, x')$ is true by hypothesis for every point x' of $X_{(k')}$ above x, so it follows from (6.7.4) that $\boldsymbol{P}(X_{(K')}, x'')$ is true for every point x'' of $X_{(K')}$ above x, since $X_{(K')} = (X_{(k')})_{(K')}$, x'' is above a point x' of $X_{(k')}$, itself above x, and K′ is separable over k'. But we also have $X_{(K')} = (X_{(K)})_{(K')}$ and for every $x_0 \in X_{(K)}$ above x, there exists $x'' \in X_{(K')}$ above x_0; it therefore follows from (6.7.4) that $\boldsymbol{P}(X_{(K)}, x_0)$ is true.

Suppose now that X is locally of finite type over k, so that for *every* extension K of k, $X_{(K)}$ is locally Noetherian. As a radicial extension of k is isomorphic to a sub-extension of a perfect extension of k, it follows immediately from (6.7.4) that e) implies f); also, every finite radicial extension of k is contained in an extension $k^{p^{-s}} \subset k^{p^{-\infty}}$, so f) implies b); d) trivially implies e), and finally e) implies d). Indeed, if K is any extension *whatever* of k, there exists an extension K′ of k containing (up to k-isomorphisms) k' and K; since K′ is a separable extension of k', one deduces from (6.7.4) that $Q(k')$ is true, then that $Q(K)$ is true, reasoning as in the first part of the proof. It therefore suffices to prove that b) *implies* e). We shall take $k' = k^{p^{-\infty}}$ in e).

The question being local on X, one can furthermore limit oneself to the case where X is affine and of finite type over k, by replacing X by a neighbourhood of x; let then $X = \operatorname{Spec}(B)$, where B is a k-algebra of finite type; furthermore, by definition of the property $\boldsymbol{P}$ in the cases considered, one can also replace X by the local scheme of X at the point x, hence suppose that B is a *local* Noetherian ring. Set $\mathrm{B}' = \mathrm{B} \otimes_k k'$; k' is the inductive limit of its finite sub-extensions k'_λ and if one sets $\mathrm{B}'_\lambda = \mathrm{B} \otimes_k k'_\lambda$, the morphism $f_\lambda : \mathrm{Spec}(\mathrm{B}') \to \mathrm{Spec}(\mathrm{B}'_\lambda)$ is a *homeomorphism* of $\mathrm{Spec}(\mathrm{B}')$ onto $\mathrm{Spec}(\mathrm{B}'_\lambda)$ for every λ; indeed f_λ is bijective by virtue of (**I**, 3.5.2), (3.5.7) and (3.5.8); on the other hand, it is closed by (**II**, 6.1.10). One can now apply (5.13.6) which proves (by virtue of the hypothesis b)) that b) implies e) when $\boldsymbol{P}(\mathrm{Z}, z)$ is the property (R_n) at the point z. The case where $\boldsymbol{P}$ is the property of being regular (i.e. of having the property (R_n) for every n) follows trivially. Finally, taking into account Serre's normality criterion (5.8.6), b) implies e) further when $\boldsymbol{P}(\mathrm{Z}, z)$ is the property of being normal at the point z, since this is equivalent to saying that Z has at the point z the properties (S_2) and (R_1): one applies what precedes for $n = 1$, and (6.7.2), (ii) for $n = 2$. ☐ **IV-2 | 150**

Corollary (6.7.8). — *Let k be a field; for a k-prescheme locally Noetherian* X *and a point $x \in \mathrm{X}$, denote by $\boldsymbol{P}(\mathrm{X}, x)$ any of the following properties:*

(i) $\mathrm{coprof}(\mathscr{O}_x) \leqslant n$.
(ii) $\mathscr{O}_x$ *is a Cohen-Macaulay ring.*
(iii) X *satisfies the property* (S_n) *at the point* x.
(iv) X *is geometrically regular at the point* x.
(v) X *has the property* (R_n) *geometric at the point* x.
(vi) X *is geometrically normal at the point* x.
(vii) X *is geometrically reduced (i.e. separable) at the point* x.

Let k' be an extension of k; one supposes either that k' is of finite type, or that X *is locally of finite type over k, so that $\mathrm{X}' = \mathrm{X} \otimes_k k'$ is locally Noetherian. Let x' be a point of* X′ *whose projection in* X *is x. Then, for $\boldsymbol{P}(\mathrm{X}, x)$ to be true, it is necessary and sufficient that $\boldsymbol{P}(\mathrm{X}', x')$ be so.*

Proof. This has already been seen for property (vii) (4.6.11), and for properties (i), (ii), and (iii) (6.7.1). For (iv), (v), and (vi), this follows from (6.7.7): the necessity follows from the equivalence of criteria a) and c), and from the equivalence of c) and d) when X is locally of finite type over k. To prove sufficiency, let k'' be a finite radicial extension of k; one may regard k' and k'' as subextensions of an extension K of k. Set $\mathrm{X}'' = \mathrm{X} \otimes_k k''$ and $\mathrm{X}_0 = \mathrm{X} \otimes_k \mathrm{K}$, and note that, since k'' is radicial over k, there is only *one* point x'' of X″ above x (**I**, 3.5.7) and (3.5.8). Let x_0 be any point of X_0 above x'. If $\boldsymbol{P}(\mathrm{X}', x')$ is true, then so is $\boldsymbol{P}(\mathrm{X}_0, x_0)$ by (6.7.7), c) and d) (if k' is of finite type over k, one may suppose the same of K; if X is locally of finite type over k, then X′ is locally of finite type over k'). It follows from (6.7.4) that $Q(k'')$ is true (with the notation of (6.7.7)), and hence $\boldsymbol{P}(\mathrm{X}, x)$ is true by (6.7.7), b). ☐

6.8. Regular, normal, reduced, smooth morphisms

Definition (6.8.1). — Let X, Y be two preschemes, $f : \mathrm{X} \to \mathrm{Y}$ a morphism such that the fibre $f^{-1}(y)$ is a locally Noetherian prescheme for every $y \in \mathrm{Y}$, x a point of X. We say that f is respectively a morphism:

(i) of coprofundity $\leqslant n$ at the point x;
(ii) of Cohen-Macaulay at the point x; **IV-2 | 151**
(iii) (S_n) at the point x;
(iv) regular at the point x;
(v) (R_n) at the point x;
(vi) normal at the point x;
(vii) reduced at the point x;

if f is flat at the point x, and if in addition the corresponding property $\boldsymbol{P}(f^{-1}(f(x)), x)$ (notation of (6.7.8)) is true.

We say that f is *smooth* at the point x if it is locally of finite presentation in a neighbourhood of x and if it is regular at the point x. We say respectively that f is a morphism: of coprofundity $\leqslant n$, of Cohen-Macaulay, (S_n), regular, (R_n), normal, reduced, smooth, if it has the corresponding property at every point of X.

Proposition (6.8.2). — *Let* X, Y *be two locally Noetherian preschemes, $f : \mathrm{X} \to \mathrm{Y}$ a morphism, x a point of* X. *Denote by $\boldsymbol{M}(f, x)$ one of the properties (i) to (vii) of the definition (6.8.1), or the property of being smooth at the point x. Let* Y′ *be a locally Noetherian prescheme, $g : \mathrm{Y}' \to \mathrm{Y}$ a morphism, $\mathrm{X}' = \mathrm{X} \times_\mathrm{Y} \mathrm{Y}'$,*

$f' = f_{(Y')} : X' \to Y'$. *Suppose that f or g is locally of finite type. Then, for every $x' \in X'$ above x, the property $\boldsymbol{M}(f, x)$ implies $\boldsymbol{M}(f', x')$.*

Proof. Set $y = f(x)$, $y' = f'(x')$; by transitivity of fibres (**I**, 3.6.4), we have $f'^{-1}(y') = f^{-1}(y) \otimes_{\boldsymbol{k}(y)} \boldsymbol{k}(y')$. Since either $f^{-1}(y)$ is locally of finite type over $\boldsymbol{k}(y)$, or $\boldsymbol{k}(y')$ is of finite type over $\boldsymbol{k}(y)$ (**I**, 6.4.11), it follows from (6.7.8) that the properties $\boldsymbol{P}(f^{-1}(y), x)$ and $\boldsymbol{P}(f'^{-1}(y'), x')$ are equivalent; furthermore, if f is flat at the point x, f' is flat at the point x' (2.1.4), which proves the proposition, taking into account (1.4.3), (iii). □

Proposition (6.8.3). — *For a morphism f of locally Noetherian preschemes, let $\boldsymbol{M}(f)$ be one of the following properties: being Cohen-Macaulay, (S_n), regular, (R_n), normal, reduced.*

- *(i) Let X, Y, Z be three locally Noetherian preschemes, $f : X \to Y$, $g : Y \to Z$ two morphisms. If $\boldsymbol{M}(f)$ and $\boldsymbol{M}(g)$ are true, $\boldsymbol{M}(g \circ f)$ is true.*
- *(ii) Conversely, if f is surjective and if $\boldsymbol{M}(f)$ and $\boldsymbol{M}(g \circ f)$ are true, then $\boldsymbol{M}(g)$ is true.*
- *(iii) Let X, Y, Y′ be three locally Noetherian preschemes, $f : X \to Y$, $h : Y' \to Y$ two morphisms; set $X' = X \times_Y Y'$, $f' = f_{(Y')} : X' \to Y'$. Suppose that f or h is locally of finite type. If $\boldsymbol{M}(f)$ is true, then so is $\boldsymbol{M}(f')$; the converse is true when h is faithfully flat.*

The conclusions of (i) and (iii) are also true when $\boldsymbol{M}$ is the property of being smooth and (in (iii)) h is quasi-compact.

Proof. (i) We already know that if f and g are flat, so is $u = g \circ f$, and that if f and $g \circ f$ are flat and f is surjective, then g is flat (2.1.6) and (2.2.13). On the other hand, for every $z \in Z$, the morphism $f_z = f \otimes \mathbf{1}_{\boldsymbol{k}(z)} : u^{-1}(z) \to g^{-1}(z)$ is flat (resp. faithfully flat if f is) and for every $y \in g^{-1}(z)$, $f_z^{-1}(y)$ is isomorphic to $f^{-1}(y)$ (**I**, 3.6.4). If $\boldsymbol{M}(f)$ and $\boldsymbol{M}(g)$ are true, $\boldsymbol{M}(g \circ f)$ is then true for the cases where $\boldsymbol{M}$ is the property of being Cohen-Macaulay or (S_n), by virtue of (6.6.1). On the other hand, let k' be a finite extension of $\boldsymbol{k}(z)$; setting $Y'_z = g^{-1}(z) \otimes_{\boldsymbol{k}(z)} k'$, $X'_z = u^{-1}(z) \otimes_{\boldsymbol{k}(z)} k'$, and $f'_z = f_z \otimes \mathbf{1}_{k'} : X'_z \to Y'_z$; the morphism f'_z
is flat (resp. faithfully flat) and for every $y' \in Y'_z$, the fibre $f_z'^{-1}(y')$ is isomorphic to $f^{-1}(y) \otimes_{\boldsymbol{k}(y)}$ **IV-2** | 152
$\boldsymbol{k}(y')$, denoting by y the image of y' in $g^{-1}(z)$ (**I**, 3.6.4). When $\boldsymbol{M}$ is the property of being regular, (R_n), normal or reduced, the hypothesis that $\boldsymbol{M}(f)$ and $\boldsymbol{M}(g)$ are true implies that Y'_z and each of the fibres $f_z'^{-1}(y')$ for $y' \in Y'_z$ have the corresponding property among the properties $c)$, $d)$, $e)$, $f)$ of (6.6.1); one deduces from (6.6.1), (i) that X'_z has the same property, hence $\boldsymbol{M}(g \circ f)$ is true.

(ii) Conversely, the hypothesis that $\boldsymbol{M}(g \circ f)$ and $\boldsymbol{M}(f)$ are true and that f is surjective implies that Y'_z has the corresponding property by virtue of (6.6.1), (ii), since f'_z is surjective for every z; hence $\boldsymbol{M}(g)$ is true.

(iii) The first assertion follows immediately from (6.8.2). On the other hand, if h is faithfully flat and f' flat, f is flat (2.4.1); since, with the notations of (6.8.2), the properties $\boldsymbol{P}(f^{-1}(y), x)$ and $\boldsymbol{P}(f'^{-1}(y'), x')$ are equivalent (6.7.8), one sees that $\boldsymbol{M}(f)$ and $\boldsymbol{M}(f')$ are then equivalent.

Finally, the last assertion of the proposition follows from (1.4.3), (iii) and (2.7.1), (iv). □

Remarks (6.8.4). — (i) If f is faithfully flat, g flat and if $g \circ f$ is of coprofundity $\leqslant n$, then g is of coprofundity $\leqslant n$, as follows from the reasoning of (6.6.2).

(ii) When, in (6.8.1), one takes for Y the spectrum of a field k, the notions (iv), (v) and (vi) reduce to those defined in (6.7.5). It is clear that these latter are relative to the base field k. The definition (6.8.1) thus leads to saying that a prescheme X is "regular (resp. (R_n), resp. normal) over k" instead of saying that it is "geometrically regular (resp. (R_n), resp. normal) relative to k"; one will avoid confusing this notion with the property of being regular (resp. (R_n), resp. normal) which is independent of k. One can make in this connection the same remarks as in (4.5.12).

Proposition (6.8.5). — *Let k be a field, X, Y two k-preschemes locally Noetherian, at least one of which is locally of finite type over k. For a k-prescheme Z, denote by $\boldsymbol{P}(Z)$ one of the properties $c)$ to $f)$ of (6.6.1); the property "$\boldsymbol{P}(Z)$ geometric" is then defined in (6.7.6) (resp. (4.6.1)). Then:*

- *(i) If X has the property $\boldsymbol{P}$, and Y the property $\boldsymbol{P}$ geometric, $X \times_k Y$ has the property $\boldsymbol{P}$.*
- *(ii) If X and Y have the property $\boldsymbol{P}$ geometric, so does $X \times_k Y$.*

Proof. Indeed, let $f : X \times_k Y \to X$, $g : X \to \operatorname{Spec}(k)$ be the structural morphisms, which are faithfully flat (2.2.13). The hypothesis that Y has the property $\boldsymbol{P}$ geometric implies by virtue of (6.8.2) that

$\boldsymbol{M}(f)$ is true, $\boldsymbol{M}$ being the property (6.8.3) which corresponds to $\boldsymbol{P}$; under the hypothesis (ii), $\boldsymbol{M}(g)$ is also true, hence the assertion (ii) follows from (6.8.3), (i). As for the assertion (i), it follows directly from (6.6.1), (i). □

Theorem (6.8.6). — *Let* X, Y *be two locally Noetherian preschemes,* $f : \mathrm{X} \to \mathrm{Y}$ *a morphism locally of finite type,* x *a point of* X, $y = f(x)$*. The following properties are equivalent:*

a) f *is smooth at the point* x.
b) f *is regular at the point* x. IV-2 | 153
c) $\mathscr{O}_x$ *is a formally smooth* $\mathscr{O}_y$*-algebra* (**0**, 19.3.1) *for the adic topologies on* $\mathscr{O}_x$ *and* $\mathscr{O}_y$.
c′) $\mathscr{O}_x$ *is a formally smooth* $\mathscr{O}_y$*-algebra* (**0**, 19.3.1) *for the discrete topologies on* $\mathscr{O}_x$ *and* $\mathscr{O}_y$.

Proof. The equivalence of a) and b) follows from the definitions (6.8.1) and from the fact that for locally Noetherian preschemes, morphisms locally of finite type are locally of finite presentation (1.4.2).

Secondly, for $\mathscr{O}_x$ to be a formally smooth $\mathscr{O}_y$-algebra for the adic topologies, it is necessary and sufficient that $\mathscr{O}_x$ be flat over $\mathscr{O}_y$ and that $\mathscr{O}_x \otimes_{\mathscr{O}_y} \boldsymbol{k}(y)$ be formally smooth over $\boldsymbol{k}(y)$ for its adic topology (**0**, 19.7.1). The latter condition is equivalent to geometric regularity over $\boldsymbol{k}(y)$ (**0**, 19.6.6); this proves the equivalence of b) and c). Finally, to prove the equivalence of c) and c'), one may reduce to the affine case $\mathrm{Y} = \mathrm{Spec}(\mathrm{A})$, $\mathrm{X} = \mathrm{Spec}(\mathrm{C})$, where A is Noetherian and C is a finite-type Noetherian A-algebra, say $\mathrm{C} = \mathrm{A}[\mathrm{T}_1, \ldots, \mathrm{T}_n]/\mathfrak{J}$. Since $\mathfrak{J}/\mathfrak{J}^2$ is a finitely presented C-module, the equivalence follows from (**0**, 22.6.4). □

Corollary (6.8.7). — *Let* X, Y *be two locally Noetherian preschemes,* $f : \mathrm{X} \to \mathrm{Y}$ *a morphism locally of finite type. Then the set of points* $x \in \mathrm{X}$ *where* f *is smooth* (*or regular*) *is open in* X.

Proof. Indeed it follows from (**0**, 22.6.5) that the set of $x \in \mathrm{X}$ satisfying the condition c') of (6.8.6) is open in X, and we conclude by (6.8.6). □

Remark (6.8.8). — In (17.5.1), we shall show that the equivalence of b) and c') in (6.8.6), as well as the corollary (6.8.7), remain valid without the Noetherian hypothesis on X and Y, provided that one restricts to morphisms *locally of finite presentation*.

6.9. The theorem of generic flatness

Theorem (6.9.1). — *Let* Y *be a locally Noetherian and integral prescheme,* $u : \mathrm{X} \to \mathrm{Y}$ *a morphism of finite type,* $\mathscr{F}$ *a coherent* $\mathscr{O}_\mathrm{X}$*-Module. There then exists a non-empty open subset* U *of* Y *such that* $\mathscr{F}|u^{-1}(\mathrm{U})$ *is flat over* U.

Proof. One can clearly limit oneself to the case where $\mathrm{Y} = \mathrm{Spec}(\mathrm{A})$ is affine; then X is a finite union of affine opens X_i of finite type over Y; if, for each i, there exists a non-empty open U_i in Y such that $\mathscr{F}|(\mathrm{X}_i \cap u^{-1}(\mathrm{U}_i))$ is flat over U_i, it is clear that taking for U the intersection of the U_i, we shall have answered the question; one can therefore suppose that $\mathrm{X} = \mathrm{Spec}(\mathrm{B})$, where B is an A-algebra of finite type. We then have $\mathscr{F} = \widetilde{\mathrm{M}}$, where M is a B-module of finite type; the theorem will follow from the following: □

Lemma (6.9.2). — *Let* A *be an integral Noetherian ring,* B *a finite-type* A*-algebra, and* M *a finite* B*-module. Then there exists* $f \neq 0$ *in* A *such that* M_f *is a free* A_f*-module.*

Proof. Denote by K the field of fractions of A; then $\mathrm{B} \otimes_\mathrm{A} \mathrm{K}$ is an algebra of finite type over K and IV-2 | 154
$\mathrm{M} \otimes_\mathrm{A} \mathrm{K}$ is a $(\mathrm{B} \otimes_\mathrm{A} \mathrm{K})$-module of finite type. We shall reason by induction on the *dimension* n of the support of $\mathrm{M} \otimes_\mathrm{A} \mathrm{K}$, which is either $-\infty$ or finite and $\geqslant 0$. Suppose first $n = -\infty$, i.e. $\mathrm{M} \otimes_\mathrm{A} \mathrm{K} = 0$; if $(m_i)_{1 \leqslant i \leqslant r}$ is a system of generators of the B-module M, there therefore exists $f \neq 0$ in A such that $f m_i = 0$ for $1 \leqslant i \leqslant r$; hence $\mathrm{M}_f = 0$ and the lemma is true in this case.

Suppose now $n \geqslant 0$. We know that there exists a composition series $\mathrm{M} = \mathrm{M}_1 \supset \mathrm{M}_2 \supset \ldots \supset \mathrm{M}_q = 0$ of the B-module M such that each quotient $\mathrm{N}_i = \mathrm{M}_i/\mathrm{M}_{i+1}$ is isomorphic to a B-module of the form $\mathrm{B}/\mathfrak{p}_i$, where $\mathfrak{p}_i$ is a prime ideal of B (Bourbaki, *Alg. comm.*, chap. IV, § 1, no 4, th. 1). If the theorem is true for each N_i, there exists for each i an $f_i \neq 0$ in A such that $(\mathrm{N}_i)_{f_i}$ is free over A_{f_i}; setting $f = f_1 f_2 \cdots f_{q-1}$, it follows that $(\mathrm{N}_i)_f$ is a free A_f-module for $1 \leqslant i \leqslant q-1$. But

$(\mathrm{N}_i)_f = (\mathrm{M}_i)_f/(\mathrm{M}_{i+1})_f$ (0, 1.3.2), and since an extension of free modules is free, we deduce that M_f is a free A_f-module.

Replacing B by $\mathrm{B}/\mathfrak{p}$, where $\mathfrak{p}$ is a prime ideal of B, one can therefore reduce to the case $\mathrm{M} = \mathrm{B}$ with B integral. We then know (Bourbaki, *Alg. comm.*, chap. V, § 3, no 1, cor. 1 of th. 1) that there exist $g \neq 0$ in A and elements t_i $(1 \leqslant i \leqslant m)$ of B, algebraically independent over A, such that B_g is integral over $\mathrm{A}_g[t_1, \ldots, t_m]$. One can replace A by A_g, B by B_g and suppose that B is integral over $\mathrm{C} = \mathrm{A}[t_1, \ldots, t_m]$, hence a C-module of finite type and *without torsion*. We know furthermore (4.1.2) that the dimension of $\mathrm{Spec}(\mathrm{B} \otimes_{\mathrm{A}} \mathrm{K})$ is equal to m, hence $m = n$.

This being so, if h is the rank of the C-module without torsion B, there exists a short exact sequence of C-modules

$$0 \longrightarrow \mathrm{C}^h \longrightarrow \mathrm{B} \longrightarrow \mathrm{M}' \longrightarrow 0$$

where M' is a torsion C-module of finite type; the support of M' does not therefore contain the generic point of $\mathrm{Spec}(\mathrm{C})$ (I, 7.4.6) and hence the support of $\mathrm{M}' \otimes_{\mathrm{A}} \mathrm{K}$ does not contain the generic point of $\mathrm{Spec}(\mathrm{C} \otimes_{\mathrm{A}} \mathrm{K})$ (I, 9.1.13.1); one concludes (4.1.2.1) that its dimension is $< n$. By the induction hypothesis, there exists $f \neq 0$ in A such that M'_f is a free A_f-module; moreover C^h_f is a free A_f-module, and therefore so is B_f, which by (0, 1.3.2) is an extension of free modules. □

Corollary (6.9.3). — *Let* S *be a Noetherian prescheme,* $u : \mathrm{X} \to \mathrm{S}$ *a morphism of finite type,* $\mathscr{F}$ *a coherent* $\mathscr{O}_{\mathrm{X}}$*-Module. There then exists a partition* $(\mathrm{S}_i)_{1 \leqslant i \leqslant n}$ *of* S *into a finite number of locally closed subsets of* S*, such that, if one still denotes by* S_i *the reduced sub-prescheme having* S_i *for underlying space, and if one sets* $\mathrm{X}_i = \mathrm{X} \times_{\mathrm{S}} \mathrm{S}_i$*, the* $\mathscr{O}_{\mathrm{X}_i}$*-Module* $\mathscr{F}_i = \mathscr{F} \otimes_{\mathscr{O}_{\mathrm{S}}} \mathscr{O}_{\mathrm{S}_i}$ *is flat over* S_i*.*

Proof. We proceed by Noetherian induction (0, 2.2.2) on the set of closed subsets T of S such that the reduced closed sub-prescheme with underlying space T satisfies the conclusion of (6.9.3). One can therefore limit oneself to proving the corollary for S by supposing that it is true for every reduced closed sub-prescheme whose underlying space is a closed subset distinct from S. Since the morphism $\mathrm{S}_{\mathrm{red}} \to \mathrm{S}$ is of finite type and surjective, one can replace S by $\mathrm{S}_{\mathrm{red}}$, hence suppose S reduced and non-empty. Since S is Noetherian, the interior T of an irreducible component of S is non-empty, and the induced prescheme on T is integral; there therefore exists by virtue of (6.9.1) a non-empty open $\mathrm{U} \subset \mathrm{T}$

such that $\mathscr{F}|u^{-1}(\mathrm{U})$ is flat over U. If Y is then the reduced closed sub-prescheme of S with underlying space $\mathrm{S} - \mathrm{U}$, there exists by hypothesis a partition (Y_i) of Y into locally closed subsets of Y (hence of S) such that $\mathscr{F}_i = \mathscr{F} \otimes_{\mathscr{O}_{\mathrm{S}}} \mathscr{O}_{\mathrm{Y}_i}$ is flat over Y_i for every i; it is clear that the Y_i and U form a partition answering the question. □ **IV-2 | 155**

6.10. Dimension and depth of a module normally flat along a closed sub-prescheme

(6.10.1). Let X be a locally Noetherian prescheme, $\mathscr{J}$ a quasi-coherent Ideal of $\mathscr{O}_{\mathrm{X}}$, Y the closed sub-prescheme of X defined by $\mathscr{J}$, $j : \mathrm{Y} \to \mathrm{X}$ the canonical injection. For every integer $k \geqslant 0$, the $\mathscr{O}_{\mathrm{X}}$-Module $\mathscr{J}^k\mathscr{F}/\mathscr{J}^{k+1}\mathscr{F}$ is annihilated by $\mathscr{J}$, hence of the form $j_*(\mathscr{G}_k)$, where $\mathscr{G}_k = j^*(\mathscr{J}^k\mathscr{F}/\mathscr{J}^{k+1}\mathscr{F}) = j^*(\mathscr{J}^k\mathscr{F})$ is a coherent $\mathscr{O}_{\mathrm{Y}}$-Module. By abuse of language, we shall denote by $\mathrm{gr}^{\bullet}_{\mathscr{J}}(\mathscr{F})$ the graded $\mathscr{O}_{\mathrm{Y}}$-Module equal to the direct sum

$$\bigoplus_{k=0}^{\infty} \mathscr{G}_k = j^*\Big(\bigoplus_{k=0}^{\infty} \mathscr{J}^k\mathscr{F}/\mathscr{J}^{k+1}\mathscr{F}\Big);$$

in particular, we have $\mathrm{gr}^0_{\mathscr{J}}(\mathscr{F}) = \mathscr{G}_0 = \mathscr{F} \otimes_{\mathscr{O}_{\mathrm{X}}} \mathscr{O}_{\mathrm{Y}} = j^*(\mathscr{F})$. We shall say (following Hironaka) that $\mathscr{F}$ is *normally flat along* Y if $\mathrm{gr}^{\bullet}_{\mathscr{J}}(\mathscr{F})$ is a flat $\mathscr{O}_{\mathrm{Y}}$-Module. This amounts to the same (2.1.12) and (0, 6.1.2) as saying that each of the $\mathscr{O}_{\mathrm{Y}}$-Modules $\mathscr{G}_k = j^*(\mathscr{J}^k\mathscr{F})$ is *locally free*.

Proposition (6.10.2). — *Let* X *be a locally Noetherian prescheme,* Y *a closed integral sub-prescheme of* X*. For every coherent* $\mathscr{O}_{\mathrm{X}}$*-Module* $\mathscr{F}$*, there exists an open* U *of* X *such that* $\mathrm{Y} \cap \mathrm{U} \neq \varnothing$ *and that* $\mathscr{F}|\mathrm{U}$ *is normally flat along* $\mathrm{Y} \cap \mathrm{U}$*.*

Proof. Indeed, let $\mathscr{J}$ be the coherent ideal of $\mathscr{O}_{\mathrm{X}}$ defining Y. The $\mathscr{O}_{\mathrm{Y}}$-algebra $\mathscr{B} = \mathrm{gr}^{\bullet}_{\mathscr{J}}(\mathscr{O}_{\mathrm{X}})$ is quasi-coherent and *of finite type*, since it is generated by $\mathrm{gr}^1_{\mathscr{J}}(\mathscr{O}_{\mathrm{X}})$, the inverse image of $\mathscr{J}/\mathscr{J}^2$. Since $\mathrm{gr}^{\bullet}_{\mathscr{J}}(\mathscr{F})$ is a quasi-coherent $\mathscr{B}$-module generated by $\mathrm{gr}^0_{\mathscr{J}}(\mathscr{F})$, it is a $\mathscr{B}$-Module *of finite type*. If one sets $\mathrm{Z} = \mathrm{Spec}(\mathscr{B})$, the structural morphism $u : \mathrm{Z} \to \mathrm{Y}$ is of finite type, and if $\mathscr{H}$ is the coherent $\mathscr{O}_{\mathrm{Z}}$-Module such that $u_*(\mathscr{H}) = \mathrm{gr}^{\bullet}_{\mathscr{J}}(\mathscr{F})$, it suffices to apply to u and to $\mathscr{H}$ the theorem of generic flatness (6.9.1) to prove the proposition. □

Proposition (6.10.3). — *The notations being those of (6.10.1), suppose that $\mathscr{F}$ is normally flat along* Y. *Then:*

(i) $\mathrm{Y} \cap \mathrm{Supp}(\mathscr{F})$ *is a part both open and closed of* Y *(in other words, a union of connected components of* Y*).*

(ii) If $\mathscr{J}$ is locally nilpotent, $\mathrm{Supp}(\mathscr{F})$ *is an open and closed part of* X*, and for every $x \in \mathrm{Supp}(\mathscr{F})$, we have*

(6.10.3.1) $$\dim(\mathscr{F}_x) = \dim(\mathscr{O}_{\mathrm{Y},x})$$

(6.10.3.2) $$\mathrm{prof}(\mathscr{F}_x) = \mathrm{prof}(\mathscr{O}_{\mathrm{Y},x})$$

(6.10.3.3) $$\mathrm{coprof}(\mathscr{F}_x) = \mathrm{coprof}(\mathscr{O}_{\mathrm{Y},x}).$$

Proof. (i) With the notations of (6.10.1), we have $\mathrm{Y} \cap \mathrm{Supp}(\mathscr{F}) = \mathrm{Supp}(\mathscr{G}_0)$ (**I**, 9.1.13), and as by hypothesis $\mathscr{G}_0$ is a locally free $\mathscr{O}_{\mathrm{Y}}$-Module of finite type, its support is at the same time open and closed in Y.

(ii) The hypothesis that $\mathscr{J}$ is locally nilpotent implies that the underlying spaces of X and Y are the same, whence the two first assertions of (ii), taking into account (i); it remains to prove (6.10.3.2) and (6.10.3.3) by difference. Let $(f_i)_{1 \leqslant i \leqslant p}$ be a finite family of elements of the maximal ideal of $\mathscr{O}_{\mathrm{X},x}$ whose images in $\mathscr{O}_{\mathrm{Y},x} = \mathscr{O}_{\mathrm{X},x}/\mathscr{J}_x$ form a maximal $\mathscr{O}_{\mathrm{Y},x}$-regular sequence; the hypothesis on $\mathscr{F}$ and $\mathscr{J}$ implies that the $\mathscr{O}_{\mathrm{Y},x}$-module $\mathrm{gr}^{\bullet}_{\mathscr{J}_x}(\mathscr{F}_x)$ is free of finite type, hence the suite (f_i) is $\mathrm{gr}^{\bullet}_{\mathscr{J}_x}(\mathscr{F}_x)$-regular; one deduces that this suite is also $\mathscr{F}_x$-regular (**0**, 15.1.19). On the other hand, let n be the largest integer such that $\mathscr{F}_x^{(n)} = \mathscr{J}_x^n \mathscr{F}_x \neq 0$. The hypothesis implies also that $\mathrm{gr}^{\bullet}_{\mathscr{J}_x}(\mathscr{F}_x/\mathscr{F}_x^{(n)})$ is free of finite type, hence the suite (f_i) is also $(\mathscr{F}_x/\mathscr{F}_x^{(n)})$-regular (*loc. cit.*). Applying the lemma (3.4.1.4), one concludes by induction on i that there is an exact sequence **IV-2** | 156

$$0 \longrightarrow \mathscr{F}_x^{(n)} \Big/ \Big(\sum_{i=1}^{p} f_i \mathscr{F}_x^{(n)} \Big) \longrightarrow \mathscr{F}_x \Big/ \Big(\sum_{i=1}^{p} f_i \mathscr{F}_x \Big).$$

But the hypothesis implies that $\mathscr{F}_x^{(n)}$ is a free $\mathscr{O}_{\mathrm{Y},x}$-module of finite type and $\neq 0$, hence $\mathscr{F}_x^{(n)}/(\sum_{i=1}^{p} f_i \mathscr{F}_x^{(n)})$ is isomorphic to a module of the form $(\mathscr{O}_{\mathrm{Y},x}/(\sum_{i=1}^{p} f_i \mathscr{O}_{\mathrm{Y},x}))^m$ with $m > 0$; as $\mathrm{prof}(\mathscr{O}_{\mathrm{Y},x}/(\sum_{i=1}^{p} f_i \mathscr{O}_{\mathrm{Y},x})) = 0$ (**0**, 16.4.6) one also has, by the characterisation (**0**, 16.4.6), (i) of modules of zero depth, $\mathrm{prof}(\mathscr{F}_x^{(n)}/(\sum_{i=1}^{p} f_i \mathscr{F}_x^{(n)})) = 0$, then $\mathrm{prof}(\mathscr{F}_x/(\sum_{i=1}^{p} f_i \mathscr{F}_x)) = 0$; the $(f_i)_x$ belonging to the maximal ideal of $\mathscr{O}_{\mathrm{Y},x}$ and forming a maximal $\mathscr{F}_x$-regular suite, this shows that $\mathrm{prof}(\mathscr{F}_x) = p$ (**0**, 16.4.6), (ii). □

Corollary (6.10.4). — *Let $\mathrm{U}_{\mathrm{S}_n}(\mathscr{F})$ (resp. $\mathrm{U}_{\mathrm{C}_n}(\mathscr{F})$) be the set of $x \in \mathrm{X}$ such that $\mathscr{F}$ satisfies (S_n) (resp. such that $\mathrm{coprof}(\mathscr{F}_x) \leqslant n$). If $\mathscr{F}$ is normally flat along* Y*, if $\mathrm{Supp}(\mathscr{F}) = \mathrm{X}$, and if $\mathscr{J}$ is locally nilpotent, then $\mathrm{U}_{\mathrm{S}_n}(\mathscr{F}) = \mathrm{U}_{\mathrm{S}_n}(\mathscr{O}_{\mathrm{Y}})$ and $\mathrm{U}_{\mathrm{C}_n}(\mathscr{F}) = \mathrm{U}_{\mathrm{C}_n}(\mathscr{O}_{\mathrm{Y}})$.*

Proposition (6.10.5). — *The notations being those of (6.10.1), suppose that* Y *is connected and non-empty, and that $\mathscr{F}$ is normally flat along* Y*. For every integer $n \geqslant 0$, set*

(6.10.5.1) $$r(n) = \mathrm{rg}_{\mathscr{O}_{\mathrm{Y}}}(\mathrm{gr}^n_{\mathscr{J}}(\mathscr{F}))$$

(the locally free $\mathscr{O}_{\mathrm{Y}}$-Module $\mathrm{gr}^n_{\mathscr{J}}(\mathscr{F})$ being necessarily of constant rank). Then:

(i) There exists a polynomial $\mathrm{P} \in \mathbf{Q}[\mathrm{T}]$ such that $\mathrm{P}(n) = r(n)$ for all sufficiently large n.

(ii) We have $\mathrm{Y} \cap \mathrm{Supp}(\mathscr{F}) = \varnothing$ (in other words $\mathscr{F}/\mathscr{J}\mathscr{F} = 0$), or $\mathrm{Y} \cap \mathrm{Supp}(\mathscr{F}) = \mathrm{Y}$ (in other words $\mathrm{Y} \subset \mathrm{Supp}(\mathscr{F})$).

In the second case, denote $d - 1$ the degree of P*; for every maximal point y of* Y*, we have*

(6.10.5.2) $$\dim(\mathscr{F}_y) = d$$

and in particular

(6.10.5.3) $$\mathrm{codim}(\mathrm{Y}, \mathrm{Supp}(\mathscr{F})) = d.$$

(iii) Suppose $\mathrm{Y} \subset \mathrm{Supp}(\mathscr{F})$*. For every* $x \in \mathrm{Y}$*, we have*

$$\dim(\mathscr{F}_x) = \dim(\mathscr{O}_{\mathrm{Y},x}) + d. \tag{6.10.5.4}$$

More precisely, there exist in $\mathscr{J}_x$ *elements* f_i *(*$1 \leqslant i \leqslant d$*) forming part of a system of parameters for* $\mathscr{F}_x$ *(**0**, 16.3.6) and such that, in* $\mathrm{Spec}(\mathscr{O}_{\mathrm{X},x})$*, we have* $\mathrm{V}(\mathscr{J}_x) = \mathrm{V}(\sum_{i=1}^d f_i \mathscr{O}_{\mathrm{X},x}) \cap \mathrm{Supp}(\mathscr{F})$*.*

Proof. As Y is assumed connected, the first assertion of (ii) follows from (6.10.3), (i). If $\mathrm{Y} \cap \mathrm{Supp}(\mathscr{F}) = \varnothing$, assertion (i) is trivial with $\mathrm{P} = 0$. Suppose now that $\mathrm{Supp}(\mathscr{F}) \supset \mathrm{Y}$, and let y be a maximal point of Y. Since then $\mathrm{Y} = \mathrm{Supp}(\mathscr{F}/\mathscr{J}\mathscr{F})$, the module $\mathscr{F}_y/\mathscr{J}_y\mathscr{F}_y$ has finite length (3.1.4). Setting $s(n) = \mathrm{length}(\mathrm{gr}^n_{\mathscr{J}_y}(\mathscr{F}_y))$, we know that there exists a polynomial $\mathrm{R} \in \mathbf{Q}[\mathrm{T}]$ such that $s(n) = \mathrm{R}(n)$ for n large enough, namely $\mathrm{R}(n) = \mathrm{H}(n+1) - \mathrm{H}(n)$, where H is the Hilbert–Samuel polynomial of $\mathscr{F}_y$ for the $\mathscr{J}_y$-adic filtration (**0**, 16.2.1). Since the $\mathscr{O}_{\mathrm{Y},y}$-modules $\mathrm{gr}^n_{\mathscr{J}_y}(\mathscr{F}_y)$ are free by hypothesis, we have $r(n) = s(n)/m$, denoting by m the length of the $\mathscr{O}_{\mathrm{X},y}$-module $\mathscr{O}_{\mathrm{X},y}/\mathscr{J}_y$; thus (i) holds with $\mathrm{P} = \frac{1}{m}\mathrm{R}$. We know furthermore (**0**, 16.2.3) that $\deg(\mathrm{H}) = \dim(\mathscr{F}_y)$, whence the relation (6.10.5.2); the relation (6.10.5.3) follows from (5.1.12.2). IV-2 | 157

It remains to prove (iii) for any point $x \in \mathrm{Y}$. Set $\mathrm{A} = \mathscr{O}_{\mathrm{X},x}$, $\mathfrak{J} = \mathscr{J}_x$, and $\mathrm{M} = \mathscr{F}_x$, so that $\mathscr{O}_{\mathrm{Y},x} = \mathrm{A}/\mathfrak{J}$; let $\mathrm{S} = \mathrm{gr}^\bullet_{\mathfrak{J}}(\mathrm{A})$, which is a graded $(\mathrm{A}/\mathfrak{J})$-algebra of finite type, with positive degrees, such that $\mathrm{S}_0 = \mathrm{A}/\mathfrak{J}$, and generated by its homogeneous elements of degree 1; let finally $\mathrm{N} = \mathrm{gr}^\bullet_{\mathfrak{J}}(\mathrm{M})$, which is a graded S-module of finite type, each homogeneous component N_n being by hypothesis a free $(\mathrm{A}/\mathfrak{J})$-module of rank $r(n)$. Let $\mathfrak{m}$ be the maximal ideal of A, $k = \mathrm{A}/\mathfrak{m}$ its residue field; $\mathrm{B} = \mathrm{S} \otimes_{\mathrm{A}} k$ is a graded k-algebra of finite type, with positive degrees, generated by its homogeneous elements of degree 1 and such that $\mathrm{B}_0 = k$, so that $\mathfrak{q} = \mathrm{B}^+ = \bigoplus_{n \geqslant 1} \mathrm{B}_n$ is a maximal ideal of B; $\mathrm{E} = \mathrm{N} \otimes_{\mathrm{A}} k$ is a graded B-module of finite type such that $\mathrm{rg}_k(\mathrm{E}_n) = r(n)$. Applying (**0**, 16.2.7) to B and E, choose homogeneous elements $t_i \in \mathrm{B}_{n_i}$ $(1 \leqslant i \leqslant d)$, and lift each t_i to an element $f_i \in \mathfrak{J}^{n_i}$. For $n \geqslant \sup(n_i)$, consider the A-submodule $\sum_{i=1}^d f_i \mathfrak{J}^{n-n_i}\mathrm{M}$ of M; as the homogeneous component of degree n of the submodule $\sum_i t_i \mathrm{E}$ of E is equal to E_n as soon as n is large enough, one sees that, for n large enough, we have

$$\mathfrak{J}^n\mathrm{M} = \sum_{i=1}^d f_i \mathfrak{J}^{n-n_i}\mathrm{M} + \mathfrak{m}\mathfrak{J}^n\mathrm{M}$$

and as $\mathfrak{J}^n\mathrm{M}$ is an A-module of finite type, this implies, by Nakayama's lemma,

$$\mathfrak{J}^n\mathrm{M} = \sum_{i=1}^d f_i \mathfrak{J}^{n-n_i}\mathrm{M} \subset \sum_{i=1}^d f_i\mathrm{M}.$$

If $\mathfrak{a}$ is the annihilator of M, we have therefore (**0**, 1.7.5) in $\mathrm{Spec}(\mathrm{A})$

$$\mathrm{V}\Big(\sum_{i=1}^d f_i\mathrm{A}\Big) \cap \mathrm{V}(\mathfrak{a}) \subset \mathrm{V}(\mathfrak{J}^n) \cap \mathrm{V}(\mathfrak{a}) = \mathrm{V}(\mathfrak{J}) \cap \mathrm{V}(\mathfrak{a}) = \mathrm{V}(\mathfrak{J})$$

since by hypothesis $\mathrm{Y} \cap \mathrm{Spec}(\mathrm{A}) = \mathrm{V}(\mathfrak{J}) \cap \mathrm{Supp}(\mathrm{M}) = \mathrm{V}(\mathfrak{J})$. Since on the other hand the f_i belong to $\mathfrak{J}$, we have $\mathrm{V}(\mathfrak{J}) \subset \mathrm{V}(\sum_{i=1}^d f_i\mathrm{A})$, which proves the last relation of (iii). It remains to show that the f_i form part of a system of parameters for M. Replacing A by $\mathrm{A}/\mathfrak{a}$ and the f_i by their images in $\mathrm{A}/\mathfrak{a}$, one can limit oneself to the case where $\mathfrak{a} = 0$; we have just seen that

$$\dim(\mathrm{A}/\mathfrak{J}) = \dim\Big(\mathrm{A}/\Big(\sum_{i=1}^d f_i\mathrm{A}\Big)\Big),$$

and it remains therefore to prove (**0**, 16.3.7) that we have

$$\dim(\mathrm{A}) \geqslant \dim(\mathrm{A}/\mathfrak{J}) + d.$$

Now, let $\mathfrak{p}$ be a prime ideal of A containing $\mathfrak{J}$ and such that $\dim(\mathrm{A}/\mathfrak{J}) = \dim(\mathrm{A}/\mathfrak{p})$, so that $\mathfrak{p}$ is minimal among the prime ideals containing $\mathfrak{J}$. We have therefore $\mathfrak{p} = \mathfrak{i}_y$ where $y \in \mathrm{Spec}(\mathrm{A})$ is a maximal point of Y. But by virtue of (6.10.5.2) and the hypothesis $\mathrm{Spec}(\mathrm{A}) = \mathrm{Supp}(\mathrm{M})$, we have $\dim(\mathrm{A}_{\mathfrak{p}}) = d$; the inequality $\dim(\mathrm{A}/\mathfrak{p}) + \dim(\mathrm{A}_{\mathfrak{p}}) \leqslant \dim(\mathrm{A})$ (**0**, 16.1.4) completes the proof. □

Proposition (6.10.6). — *Let* X *be a locally Noetherian prescheme,* $\mathscr{F}$ *a coherent* $\mathscr{O}_X$*-Module,* Y *a closed irreducible sub-prescheme of* X*, of generic point* $y \in \mathrm{Supp}(\mathscr{F})$*. There then exists a neighbourhood* U *open and non-empty of* y *in* X *such that, for every* $x \in U \cap Y$*, we have*

$$\dim(\mathscr{F}_x) = \dim(\mathscr{F}_y) + \dim(\mathscr{O}_{Y,x}) \tag{6.10.6.1}$$

$$\mathrm{prof}(\mathscr{F}_x) = \mathrm{prof}(\mathscr{F}_y) + \mathrm{prof}(\mathscr{O}_{Y,x}) \tag{6.10.6.2}$$

$$\mathrm{coprof}(\mathscr{F}_x) = \mathrm{coprof}(\mathscr{F}_y) + \mathrm{coprof}(\mathscr{O}_{Y,x}). \tag{6.10.6.3}$$

Proof. Let $Y' = Y_{\mathrm{red}}$, which is a closed integral sub-prescheme of Y having the same underlying space, and defined by a locally nilpotent Ideal $\mathscr{J}$ of $\mathscr{O}_Y$ (**I**, 6.1.6). It follows that $\mathrm{gr}^\bullet_{\mathscr{J}}(\mathscr{O}_v)$ is a coherent $\mathscr{O}_{v'}$-Module, and as Y' is integral, there exists an open neighbourhood V of y in Y' such that $\mathrm{gr}^\bullet_{\mathscr{J}}(\mathscr{O}_v)|V$ is locally free (**0**, 5.2.7); otherwise said, replacing X by a neighbourhood of y, one can suppose that $\mathscr{O}_v$ is *normally flat* along Y'; one then deduces from (6.10.3) that we have **IV-2 | 158**

$$\dim(\mathscr{O}_{Y,x}) = \dim(\mathscr{O}_{Y',x}), \qquad \mathrm{prof}(\mathscr{O}_{Y,x}) = \mathrm{prof}(\mathscr{O}_{Y',x})$$

for every $x \in Y$; this allows us to limit ourselves to the case where the closed sub-prescheme Y is *integral*.

This being so, by virtue of (6.10.2), one can, replacing X by an open neighbourhood of y, suppose that $\mathscr{F}$ is *normally flat* along Y. Suppose now $p = \mathrm{prof}(\mathscr{F}_y)$; replacing at need X by an open neighbourhood of y, one can further suppose that there exist p sections f_i $(1 \leqslant i \leqslant p)$ of $\mathscr{O}_X$ above X, forming an $\mathscr{F}$-regular suite, such that the $(f_i)_y$ belong to the maximal ideal $\mathfrak{m}_y$ of $\mathscr{O}_X$ at the point y and that $\mathrm{prof}(\mathscr{F}_y/(\sum_{i=1}^p (f_i)_y \mathscr{F}_y)) = 0$ (**0**, 16.4.6). If $\mathfrak{J}$ is the Ideal of $\mathscr{O}_X$ defining Y, the hypothesis $\mathrm{prof}(\mathscr{G}_y) = 0$ implies that $\mathscr{G}_y$ contains a sub-module isomorphic to $\mathscr{O}_{X,y}/\mathfrak{m}_y$ (**0**, 16.4.6); reasoning as above (taking into account (**0**, 5.3.8) and (5.2.2)) shows that one can suppose that there exists a sub-$\mathscr{O}_X$-Module $\mathscr{G}'$ of $\mathscr{G}$ *isomorphic to* $\mathscr{O}_X/\mathfrak{J}$ so that $\mathscr{G}'_x = \mathscr{O}_{Y,x}$ for every $x \in Y$. Setting $\mathscr{G}'' = \mathscr{G}/\mathscr{G}'$; replacing X by an open neighbourhood of y, one can, by virtue of (6.10.2), suppose that $\mathscr{G}'$ and $\mathscr{G}''$ are *normally flat* along Y. Let then x be any point of Y, and set $q = \mathrm{prof}(\mathscr{O}_{Y,x}) = \mathrm{prof}(\mathscr{G}'_x)$; let $(g_i)_{1 \leqslant i \leqslant q}$ be a maximal $\mathscr{G}''_x$-regular suite of elements of the maximal ideal $\mathfrak{m}_x$ of $\mathscr{O}_{X,x}$. Each of the homogeneous components of $\mathrm{gr}^\bullet_{\mathscr{J}_x}(\mathscr{G}''_x)$ is a flat $\mathscr{O}_{Y,x}$-module of finite type by hypothesis, hence a free $\mathscr{O}_{Y,x}$-module, and it is therefore also $\mathrm{gr}^\bullet_{\mathscr{J}_x}(\mathscr{G}''_x)$-regular, hence it is also $\mathrm{gr}^\bullet_{\mathscr{J}_x}(\mathscr{G}''_x)$-regular, and whence the result $\mathrm{gr}^\bullet_{\mathscr{J}_x}(\mathscr{G}''_x)$ is $\mathscr{G}''_x$-regular (**0**, 15.1.19). Applying the lemma (**0**, 15.1.18) to the exact sequence

$$0 \longrightarrow \mathscr{G}'_x \longrightarrow \mathscr{G}_x \longrightarrow \mathscr{G}''_x \longrightarrow 0$$

by induction on j, one concludes an exact sequence

$$0 \longrightarrow \mathscr{G}'_x\Big/\Big(\sum_{j=1}^q g_j \mathscr{G}'_x\Big) \longrightarrow \mathscr{G}_x\Big/\Big(\sum_{j=1}^q g_j \mathscr{G}_x\Big).$$

But by hypothesis $\mathrm{prof}(\mathscr{G}'_x/(\sum_{j=1}^q g_j \mathscr{G}'_x)) = 0$ (**0**, 16.4.6); by the characterisation of modules of zero depth, one concludes that $\mathrm{prof}(\mathscr{G}_x/(\sum_{j=1}^q g_j \mathscr{G}_x)) = 0 = \mathrm{prof}(\mathscr{F}_x/(\sum_{i=1}^p f_i \mathscr{F}_x + \sum_{j=1}^q g_j \mathscr{F}_x))$; the suite (g_i) being $\mathscr{G}''_x$-regular and $\mathscr{G}''_x$ being $\mathscr{F}_x$-regular, the suite $((f_i)_x)$ is $\mathscr{F}_x$-regular by hypothesis and is formed of elements of the maximal ideal; one deduces (**0**, 16.4.6) that $\mathrm{prof}(\mathscr{F}_x) = p + q$, which completes the proof. □

6.11. Criteria for the sets $\mathrm{U}_{\mathrm{S}_n}(\mathscr{F})$ or $\mathrm{U}_{\mathrm{C}_n}(\mathscr{F})$ to be open

Lemma (6.11.1). — *Let* X *be a locally Noetherian prescheme,* $\mathscr{F}$ *an* $\mathscr{O}_{\mathrm{X}}$*-Module coherent; then the function* $x \mapsto \dim.\mathrm{proj}(\mathscr{F}_x)$ *is upper semi-continuous in* X.

Proof. One can restrict to the case where $\mathrm{X} = \mathrm{Spec}(\mathrm{A})$ is the spectrum of a Noetherian ring and $\mathscr{F} = \widetilde{\mathrm{M}}$, where M is an A-module of finite type. Suppose that for an $x \in \mathrm{X}$, we have $\dim.\mathrm{proj}(\mathrm{M}_x) = n < +\infty$ (if $n = +\infty$ there is nothing to prove); there exists a resolution

$$\mathrm{L}_{n-1} \longrightarrow \mathrm{L}_{n-2} \longrightarrow \cdots \longrightarrow \mathrm{L}_0 \longrightarrow \mathrm{M} \longrightarrow 0$$

where the L_i are free A-modules of *finite type* (A being Noetherian), whence an exact sequence **IV-2** | 159

$$0 \longrightarrow \mathrm{R} \longrightarrow \mathrm{L}_{n-1} \longrightarrow \mathrm{L}_{n-2} \longrightarrow \cdots \longrightarrow \mathrm{L}_0 \longrightarrow \mathrm{M} \longrightarrow 0$$

where R is an A-module of finite type; one deduces an exact sequence

$$0 \longrightarrow \mathrm{R}_x \longrightarrow (\mathrm{L}_{n-1})_x \longrightarrow \cdots \longrightarrow (\mathrm{L}_0)_x \longrightarrow \mathrm{M}_x \longrightarrow 0$$

where the $(\mathrm{L}_i)_x$ are free A_x-modules of finite type; as by hypothesis $\dim.\mathrm{proj}(\mathrm{M}_x) = n$, this implies that R_x is a projective A_x-module of finite type (**M**, VI, 2.1) and hence a free A_x-module of finite type ($\mathbf{0}_{\mathrm{III}}$, 10.1.3). We conclude that there exists an open neighbourhood U of x in X such that, for every $x' \in \mathrm{U}$, $\mathrm{R}_{x'}$ is a free $\mathrm{A}_{x'}$-module ($\mathbf{0}_{\mathrm{I}}$, 5.2.7), whence $\mathrm{M}_{x'}$ admits a projective resolution of length n, in other words $\dim.\mathrm{proj}(\mathrm{M}_{x'}) \leqslant n$, which proves the lemma. □

Proposition (6.11.2). — *Let* X *be a locally Noetherian prescheme and locally immersible in a regular scheme* (5.11.1)*; let* $\mathscr{F}$ *be an* $\mathscr{O}_{\mathrm{X}}$*-Module coherent. Then:*

- *(i)* (M. Auslander) *The function* $x \mapsto \mathrm{coprof}(\mathscr{F}_x)$ *is upper semi-continuous in* X *(in other words, for every integer* n*, the set* $\mathrm{U}_{\mathrm{C}_n}(\mathscr{F})$ *of* $x \in \mathrm{X}$ *such that* $\mathrm{coprof}(\mathscr{F}_x) \leqslant n$ *is* open*).*
- *(ii) For every integer* n*, the set* $\mathrm{U}_{\mathrm{S}_n}(\mathscr{F})$ *of* $x \in \mathrm{X}$ *such that* $\mathscr{F}$ *has the property* (S_n) *at the point* x *is open.*

Proof. (i) The question being local on X, one can, by virtue of the hypothesis, restrict to the case where X is a closed sub-prescheme of an affine regular scheme Y. If $j : \mathrm{X} \to \mathrm{Y}$ is the canonical injection, and $\mathscr{G} = j_*(\mathscr{F})$, one knows that one has then, for every $x \in \mathrm{X}$, $\dim(\mathscr{F}_x) = \dim(\mathscr{G}_x)$ and $\mathrm{prof}(\mathscr{F}_x) = \mathrm{prof}(\mathscr{G}_x)$, hence $\mathrm{coprof}(\mathscr{F}_x) = \mathrm{coprof}(\mathscr{G}_x)$, and as $\mathrm{coprof}(\mathscr{G}_x) = 0$ for $y \notin \mathrm{X}$—Y, one is reduced to proving the property for $\mathscr{G}$; in other words, one can restrict to the case where X is an affine *regular* scheme. One knows then (**0**, 17.3.4) that one has

$$\mathrm{prof}(\mathscr{F}_x) = \dim(\mathscr{O}_{\mathrm{X},x}) - \dim.\mathrm{proj}(\mathscr{F}_x).$$

On the other hand, if S is the unique closed sub-prescheme of X having for underlying space $\mathrm{Supp}(\mathscr{F})$, one has $\dim(\mathscr{F}_x) = \mathrm{codim}(\{x\}, \mathrm{S})$ (5.1.12.1), and, by virtue of (5.1.9)

$$\dim(\mathscr{F}_x) = \dim(\mathscr{O}_{\mathrm{X},x}) - \mathrm{codim}_x(\mathrm{S}, \mathrm{X})$$

since $\mathscr{O}_{\mathrm{X},x}$ is a regular ring, and *a fortiori* equidimensional (**0**, 16.5.12). We can therefore write

(6.11.2.1) $$\mathrm{coprof}(\mathscr{F}_x) = \dim.\mathrm{proj}(\mathscr{F}_x) - \mathrm{codim}_x(\mathrm{S}, \mathrm{X})$$

and the proposition follows then from (6.11.1) and from (**0**, 14.2.6).

(ii) As the $\mathrm{U}_{\mathrm{C}_n}(\mathscr{F})$ are open for every n by (i), the $\mathrm{Z}_n = \mathrm{X} - \mathrm{U}_{\mathrm{C}_n}(\mathscr{F})$ are closed in X; furthermore **IV-2** | 160 it is clear that $\mathrm{Z}_{n+1} \subset \mathrm{Z}_n$, and as $\dim(\mathscr{F}_x)$ is finite for every $x \in \mathrm{X}$ and $\mathrm{coprof}(\mathscr{F}_x) \leqslant \dim(\mathscr{F}_x)$, the intersection of the Z_n is *empty*; as one can restrict to the case where X is affine, hence quasi-compact, one can suppose that there exists an m such that $\mathrm{Z}_m = \varnothing$. Now, it follows from (5.7.4) that the relation $x \in \mathrm{U}_{\mathrm{S}_k}(\mathscr{F})$ is equivalent to the set of relations

(6.11.2.2) $$\mathrm{codim}_x(\mathrm{Z}_n, \mathrm{S}) > n + k$$

for every $n \geqslant 0$; but for $n \geqslant m$ this relation is automatically satisfied, hence one need only consider the relations (6.11.2.2) for $0 \leqslant n < m$. Now (**0**, 14.2.6) the set $\mathrm{V}_{n,k}$ of x satisfying (6.11.2.2) is open, and $\mathrm{U}_{\mathrm{S}_k}(\mathscr{F})$, intersection of the $\mathrm{V}_{n,k}$ for $0 \leqslant n < m$, is also open.

This completes the proof. □

Let us recall that the hypothesis that X is locally immersible in a regular scheme is always satisfied when X is a prescheme *locally of finite type over a field* k (5.8.3).

Corollary (6.11.3). — *Under the hypotheses of (6.11.2), the set* $\mathrm{CM}(\mathscr{F})$ *of points* $x \in \mathrm{X}$ *such that* $\mathscr{F}_x$ *is a Cohen-Macaulay module is open in* X.

Proof. Indeed, it is the set $\mathrm{U}_{\mathrm{C}_0}(\mathscr{F})$. □

Remarks (6.11.4). — (i) The reasoning of (6.11.2), (ii)) proves that (without any hypothesis on X) when $\mathrm{U}_{\mathrm{C}_n}(\mathscr{F})$ is open for *every* integer n, then $\mathrm{U}_{\mathrm{S}_n}(\mathscr{F})$ is open for every integer n.

(ii) We have $\mathrm{CM}(\mathscr{F}) = \bigcap \mathrm{U}_{\mathrm{S}_n}(\mathscr{F})$. If every point $x \in \mathrm{X}$ admits an open neighbourhood V of *finite* dimension, the sequence of intersections $\mathrm{V} \cap \mathrm{U}_{\mathrm{S}_n}(\mathscr{F})$ is *stationary* since there exists an m such that $\dim(\mathscr{F}_x) \leqslant m$ for every $x \in \mathrm{V}$; consequently, if the $\mathrm{U}_{\mathrm{S}_n}(\mathscr{F})$ are open in X, then $\mathrm{CM}(\mathscr{F})$ is also open in X.

(iii) We shall write $\mathrm{U}_{\mathrm{S}_n}(\mathrm{X})$, $\mathrm{U}_{\mathrm{C}_n}(\mathrm{X})$, $\mathrm{CM}(\mathrm{X})$ instead of $\mathrm{U}_{\mathrm{S}_n}(\mathscr{O}_\mathrm{X})$, $\mathrm{U}_{\mathrm{C}_n}(\mathscr{O}_\mathrm{X})$, $\mathrm{CM}(\mathscr{O}_\mathrm{X})$.

Proposition (6.11.5). — *Let* A *be a local Noetherian ring,* M *an* A*-module of finite type. For every prime ideal* $\mathfrak{p}$ *of* A*, we have*

$$\operatorname{coprof}_{\mathrm{A}_\mathfrak{p}}(\mathrm{M}_\mathfrak{p}) \leqslant \operatorname{coprof}_\mathrm{A}(\mathrm{M}). \tag{6.11.5.1}$$

Proof. One can restrict to the case where $\mathrm{M}_\mathfrak{p} \neq 0$. As $\widehat{\mathrm{A}}$ is a faithfully flat A-module ($\mathbf{0}_\mathrm{I}$, 7.3.5), there exists an ideal $\mathfrak{q}$ of $\widehat{\mathrm{A}}$ lying over $\mathfrak{p}$ ($\mathbf{0}_\mathrm{I}$, 6.5.1); as $\widehat{\mathrm{M}}_\mathfrak{q} = (\mathrm{M} \otimes_\mathrm{A} \widehat{\mathrm{A}})_\mathfrak{q} = \mathrm{M} \otimes_\mathrm{A} \widehat{\mathrm{A}}_\mathfrak{q}$ and $\widehat{\mathrm{A}}_\mathfrak{q}$ is a flat A-module, hence also a flat $\mathrm{A}_\mathfrak{p}$-module ($\mathbf{0}_\mathrm{I}$, 6.2.1), it follows from (6.3.2), applied to the local homomorphism $\mathrm{A}_\mathfrak{p} \to \widehat{\mathrm{A}}_\mathfrak{q}$, to $\mathrm{M}_\mathfrak{p}$ and $\widehat{\mathrm{M}}_\mathfrak{q}$, that $\operatorname{coprof}_{\mathrm{A}_\mathfrak{p}}(\mathrm{M}_\mathfrak{p}) \leqslant \operatorname{coprof}_{\widehat{\mathrm{A}}_\mathfrak{q}}(\widehat{\mathrm{M}}_\mathfrak{q})$. On the other part, $\mathrm{X} = \operatorname{Spec}(\widehat{\mathrm{A}})$ is isomorphic to a sub-prescheme of a regular scheme by virtue of the Cohen structure theorem ($\mathbf{0}$, 19.8.8, (i)). One deduces therefore from (6.11.2) that $\operatorname{coprof}_{\widehat{\mathrm{A}}_\mathfrak{q}}(\widehat{\mathrm{M}}_\mathfrak{q}) \leqslant \operatorname{coprof}_{\widehat{\mathrm{A}}}(\widehat{\mathrm{M}})$; finally, one knows that $\operatorname{coprof}_{\widehat{\mathrm{A}}}(\widehat{\mathrm{M}}) = \operatorname{coprof}_\mathrm{A}(\mathrm{M})$ ($\mathbf{0}$, 16.4.10), which finishes the proof of (6.11.5). This proposition justifies the definition of the coprofundity of an A-module when A is not a local ring, given in (5.7.12). □

Proposition (6.11.6). — *Let* X *be a locally Noetherian prescheme,* n *an integer* > 0*,* $\mathscr{F}$ *a coherent* $\mathscr{O}_\mathrm{X}$*-Module. Suppose that for every closed integral sub-prescheme* Y *of* X*, there exists an open non-empty part* W *of* Y *such that the sub-prescheme of* X *induced on* W *satisfies* (S_n)*. Then the set* $\mathrm{U}_{\mathrm{S}_n}(\mathscr{F})$ *is open in* X.

Proof. The question being local on X, one can restrict to the case where X is Noetherian. We shall reason by induction on n: for $n = 1$, the set $\mathrm{U}_{\mathrm{S}_1}(\mathscr{F})$ is open in X, for the set of $x \in \mathrm{X}$ where $\mathscr{F}$ does not satisfy (S_1) is the set of x such that $\mathscr{F}_x$ admits immersed associated prime ideals (5.7.5); if (Z_j) is the finite family of the prime cycles associated to $\mathscr{F}$ which are immersed, then $\mathrm{U}_{\mathrm{S}_1}(\mathscr{F}) = \mathrm{X} - \bigcup_j \mathrm{Z}_j$, whence our assertion since the Z_j are closed. We shall therefore suppose henceforth that $n > 1$. In the second place, one can restrict to the case where $\operatorname{Supp}(\mathscr{F}) = \mathrm{X}$, for there is a closed sub-prescheme T of X having $\operatorname{Supp}(\mathscr{F})$ as underlying space, and an $\mathscr{O}_\mathrm{T}$-Module coherent $\mathscr{G}$ such that $\mathscr{F} = j_*(\mathscr{G})$, $j : \mathrm{T} \to \mathrm{X}$ being the canonical injection ($\mathbf{Err}_\mathbf{III}$, 30); as it amounts to the same to prove that $\mathscr{F}$ or $\mathscr{G}$ satisfies (S_n) at a point $x \in \operatorname{Supp}(\mathscr{F})$, one can restrict to considering the case where $\mathrm{T} = \mathrm{X}$. Let us note finally that by definition (5.7.2), $\mathrm{U}_{\mathrm{S}_n}(\mathscr{F})$ is stable by generization. We shall now use the following lemma:

Lemma (6.11.6.1). — *Let* X *be a Noetherian space in which every irreducible closed subset admits a generic point. For* E *to be an open subset of* X*, it is necessary and it suffices that* E *be stable by generization, and that, for every open part* V *of* X *and every irreducible closed subset* Y *of* V*, such that* $\mathrm{V} - \mathrm{Y} \subset \mathrm{E}$ *and that the generic point of* Y *belongs to* E*,* $\mathrm{E} \cap \mathrm{Y}$ *contains an open non-empty part of* Y.

Proof. We observe that this criterion implies that of ($\mathbf{0}_\mathrm{III}$, 9.2.6) when every irreducible closed subset admits a generic point. There is obviously nothing other than to prove the sufficiency of the conditions stated.

Consider the interior U of E; the closed set $\mathrm{X} - \mathrm{U}$ is a union of its irreducible components, which are finite in number and closed in X. If $\mathrm{E} \neq \mathrm{U}$, the hypothesis that E is stable by generization would imply that the generic point z of one of the irreducible components of $\mathrm{X} - \mathrm{U}$ would belong to E. Now, z belongs to only one of the irreducible components of $\mathrm{X} - \mathrm{U}$; if T is the union of the other irreducible components of $\mathrm{X} - \mathrm{U}$, $\mathrm{V} = \mathrm{X} - \mathrm{T}$ is open in X, union of U and of the set $\mathrm{Y} = \overline{\{z\}} \cap \mathrm{V}$

closed in V and irreducible. By hypothesis $E \cap Y$ contains an open part W of Y; we conclude that $U \cup W$ is open *in* V, hence in X, which is absurd since U is supposed to be the interior of E.

By virtue of this lemma, one can suppose that there exists in X an integral sub-prescheme Y of generic point y such that $\mathscr{F}$ satisfies (S_n) at the point y and at every point of $X - Y$, and restrict to verifying that there exists in X an open neighbourhood of y such that $\mathscr{F}$ satisfies (S_n) in this neighbourhood. We distinguish two cases: **IV-2** | 161

1° y is a maximal point of X; as there exists an open neighbourhood of y meeting no irreducible component of X other than $\overline{\{y\}}$, one can suppose that X is irreducible, hence a *fortiori* has the same underlying space as Y, so that Y is defined by the Nilradical of $\mathscr{O}_X$, which is *nilpotent*. On the other hand, on can, replacing X by an open neighbourhood of y, suppose that $\mathscr{F}$ is *normally flat* along Y (6.9.1); it follows then from (6.10.4) that $U_{S_n}(\mathscr{F}) = U_{S_n}(\mathscr{O}_Y)$, and as the latter is by hypothesis an open neighbourhood of y in X, this proves the proposition in this case.

2° y is not a maximal point of X, in other words $\mathrm{Supp}(\mathscr{F}) = X$, $\dim(\mathscr{F}_y) \geqslant 1$, hence also $\mathrm{prof}(\mathscr{F}_y) \geqslant 1$ since $\mathscr{F}$ satisfies by hypothesis (S_n) (and *a fortiori* (S_1)) at the point y. Replacing X by an open neighbourhood of y if necessary, one can therefore suppose that there exists a section f of $\mathscr{O}_X$ over X, $\mathscr{F}$-regular and such that $f_y \in \mathfrak{m}_y$, or equivalently $f(y) = 0$ (**0**, 15.2.4); one has then also $f(x) = 0$ for every $x \in Y$ ($\mathbf{0}_{\mathrm{I}}$, 5.5.2). One knows that $\mathscr{F}/f\mathscr{F}$ satisfies (S_{n-1}) at the point y (5.7.6). Applying the induction hypothesis, and replacing X by an open neighbourhood of y, one can therefore suppose that $\mathscr{F}/f\mathscr{F}$ satisfies (S_{n-1}) at every point of X. But for every $x \in Y$, the relation $f(x) = 0$ implies that $\mathrm{prof}(\mathscr{F}_x|f_x\mathscr{F}_x) = \mathrm{prof}(\mathscr{F}_x) - 1$ and $\dim(\mathscr{F}_x|f_x\mathscr{F}_x) = \dim(\mathscr{F}_x) - 1$ (**0**, 16.3.4 and 16.4.6); the relation

$$\mathrm{prof}(\mathscr{F}_x|f_x\mathscr{F}_x) \geqslant \inf(n-1, \dim(\mathscr{F}_x|f_x\mathscr{F}_x))$$

is therefore equivalent to

$$\mathrm{prof}(\mathscr{F}_x) \geqslant \inf(n, \dim(\mathscr{F}_x)).$$

As we supposed that $\mathscr{F}$ satisfies (S_{n-1}) at every point of $X - Y$, this finishes the proof. ☐

Corollary (6.11.7). — *With the notations being those of (6.11.6):*

(i) *The set $U_{S_1}(\mathscr{F})$ is open in X.*

(ii) *For the set $U_{S_n}(\mathscr{F})$ to be open, it suffices that every maximal point x of $\mathrm{Supp}(\mathscr{F})$, belonging to $U_{S_n}(\mathscr{F})$, is interior to $U_{S_n}(\mathscr{F})$.*

Proof. Assertion (i) was proved in the course of the proof of (6.11.6); on the other hand, for $n = 2$ the case 2° of the proof of (6.11.6) is valid without any hypothesis on X, since (with the same notations) $U_{S_1}(\mathscr{F})$ and $U_{S_1}(\mathscr{F}/f\mathscr{F})$ are open in X. As for the case 1° of this proof, the hypothesis ensures precisely that it is unnecessary to consider it. ☐

IV-2 | 162

Proposition (6.11.8). — *Let X be a locally Noetherian prescheme satisfying the following property:*

(CMU) *Every closed integral sub-prescheme Y of X contains an open non-empty W such that the prescheme induced by X on W is a Cohen-Macaulay prescheme.*

Then, for every coherent $\mathscr{O}_X$-Module $\mathscr{F}$, the function $x \mapsto \mathrm{coprof}(\mathscr{F}_x)$ is locally constructible and upper semi-continuous; the sets $U_{C_n}(\mathscr{F})$ and $U_{S_n}(\mathscr{F})$ are open in X.

Proof. Indeed, let Y be a closed integral sub-prescheme of X, of generic point y; by virtue of (6.10.6), there is a neighbourhood V of y in Y such that, for every $x \in V \cap Y$, we have

$$\mathrm{coprof}(\mathscr{F}_x) = \mathrm{coprof}(\mathscr{F}_y) + \mathrm{coprof}(\mathscr{O}_{Y,x}). \tag{6.11.8.1}$$

But by hypothesis there exists an open non-empty W of Y such that, for $x \in V \cap W$, $\mathrm{coprof}(\mathscr{O}_{Y,x}) = 0$, hence $\mathrm{coprof}(\mathscr{F}_x)$ is constant in a neighbourhood of y in Y, which proves that the function $x \mapsto \mathrm{coprof}(\mathscr{F}_x)$ is locally constructible ($\mathbf{0}_{\mathrm{III}}$, 9.3.2); it follows furthermore from (6.11.5) and from ($\mathbf{0}_{\mathrm{III}}$, 9.3.4) that this function is upper semi-continuous. The last assertion follows from (6.11.4), (i), or from (6.11.6). ☐

Remarks (6.11.9). — (i) If X satisfies (CMU), then every prescheme X' locally of finite type over X also satisfies (CMU). Let Y' be a closed integral subprescheme of X', let y' be its generic point, put $y = u(y')$, and let Y be the integral closed subprescheme of X with underlying space $\overline{\{y\}}$. Then $u|_{Y'}$ factors as

$$Y' \xrightarrow{v} Y \xrightarrow{j} X,$$

where j is the canonical injection and v is locally of finite type.

Restricting to affine open neighbourhoods of y and y', we may suppose that $X = \mathrm{Spec}(A)$, where A is an integral Cohen–Macaulay ring, and $X' = \mathrm{Spec}(A')$, where A' is an integral finite-type A-algebra containing A. After replacing A by A_f for some $f \neq 0$, we may suppose that A' contains a polynomial ring $A[T_1, \ldots, T_n] = A''$ and is finite over A''. The ring A'' is Cohen–Macaulay (6.3.6); hence we may reduce to the case where A' is finite over A. After one further localisation, A' is a finite free A-module. It is therefore a Cohen–Macaulay A-module (**0**, 16.5.1); since it is finite over A, it is also a Cohen–Macaulay A'-module (**0**, 16.5.3), and hence a Cohen–Macaulay ring. **IV-2** | 163

(ii) Suppose that there exists a coherent $\mathscr{O}_X$-Module $\mathscr{F}$ such that $\mathrm{Supp}(\mathscr{F}) = X$ and that $\mathscr{F}$ is an $\mathscr{O}_X$-Module *of Cohen-Macaulay*. Then X satisfies the condition (CMU): indeed, with the notations of the proof of (6.11.8), the relation (6.11.8.1) shows that $\mathrm{coprof}(\mathscr{O}_{Y,x}) = 0$ in a neighbourhood (with respect to Y) of the generic point y of Y.

It is unknown whether there exist locally Noetherian preschemes of dimension $\geqslant 2$ that do not satisfy (CMU) (if $\dim(X) = 1$, it is immediate that every maximal point of X_{red} admits an open neighbourhood of dimension 1, hence a Cohen-Macaulay ring).

6.12. Nagata's criteria for Reg(X) to be open

(6.12.1). Given a locally Noetherian prescheme X, we call the *singular locus* of X and denote by $\mathrm{Sing}(X)$ the set of points $x \in X$ such that X is not regular at the point x (in other words, such that the local ring $\mathscr{O}_x$ is not regular); the complement $X - \mathrm{Sing}(X)$, set of $x \in X$ where X is regular, is denoted $\mathrm{Reg}(X)$. We propose in this subsection to give conditions ensuring that $\mathrm{Sing}(X)$ is *closed* (i.e. $\mathrm{Reg}(X)$ *open*).

Proposition (6.12.2). — *Let* X *be a locally Noetherian prescheme. The following conditions are equivalent:*

a) $\mathrm{Reg}(X)$ *is open in* X.

b) *For every* $x \in \mathrm{Reg}(X)$, *there exists an open non-empty part of* $\overline{\{x\}}$ *contained in* $\mathrm{Reg}(X)$.

Moreover, these conditions are implied by the following:

c) *For every* $x \in \mathrm{Reg}(X)$, *if we denote by* Y *the reduced closed sub-prescheme of* X *having* $\overline{\{x\}}$ *as underlying space,* $\mathrm{Reg}(Y)$ *is a neighbourhood of* x *in* Y.

Proof. The equivalence of a) and b) follows from the fact that $\mathrm{Reg}(X)$ is stable by generization (**0**, 17.3.2) and from ($\mathbf{0}_{\mathrm{III}}$, 9.2.6). To prove that c) implies b), one can restrict to the case where $X = \mathrm{Spec}(A)$ is the spectrum of an affine ring of x; if $(t_i)_{1 \leqslant i \leqslant n}$ is a regular system of parameters (**0**, 17.1.6) of the regular local ring A_x, one can suppose (replacing X by an open neighbourhood of x if necessary) that $t_i = (s_i)_x$ for every i, where $s_i \in A$ and where the family $(s_i)_{1 \leqslant i \leqslant n}$ is A-regular (**0**, 15.2.4). One has then $Y = \mathrm{Spec}(A/\mathfrak{p})$, where $\mathfrak{p} = \mathfrak{j}_x$; as the t_i generate the maximal ideal $\mathfrak{m} = \mathfrak{p}A_x$ of A_x, one can further suppose (replacing X by a smaller neighbourhood of x) that the s_i generate $\mathfrak{p}$. For every $y \in Y$, the $(s_i)_y$ generate therefore $\mathfrak{p}_y$; as they form a suite A_y-regular, they also form a suite $\mathrm{gr}^0_{\mathfrak{p}_y}(\mathscr{O}_y^Y)$-regular, so they form a $\mathrm{gr}_{\mathfrak{p}_y}(\mathscr{O}_y^Y)$-regular sequence and it is thus also $\mathscr{O}_y^Y$-regular, whence the conclusion. □

Corollary (6.12.3). — *Let* X *be a locally Noetherian prescheme. The following conditions are equivalent:*

a) *For every sub-prescheme* Y *of* X, $\mathrm{Reg}(Y)$ *is open in* Y. **IV-2** | 164

b) *For every closed integral sub-prescheme* Y *of* X, $\mathrm{Reg}(Y)$ *contains an open non-empty part of* Y.

Proof. It is clear that a) implies b). Conversely, to see that b) implies a), consider a closed integral sub-prescheme Z of Y with generic point z; if Y' is the integral closed sub-prescheme of X whose underlying space is the closure $Y' = \overline{\{z\}}$ of z in X, Z is open in Y' and the sub-prescheme Z of Y', being reduced, is induced by Y' on the open subset of Z in Y'. Now the hypothesis implies that $\mathrm{Reg}(Y')$ is a neighbourhood of z in Y', hence $\mathrm{Reg}(Z)$ is a neighbourhood of z in Z; it suffices then to apply (6.12.2) by replacing X by Y and Y by Z. □

Theorem (6.12.4). — (Nagata). — *Let* A *be a Noetherian ring,* $X = \mathrm{Spec}(A)$*. The following conditions are equivalent:*

a) *For every prescheme* X' *locally of finite type over* X, $\mathrm{Reg}(X')$ *is open in* X'*.*
b) *For every* A*-algebra* A' *finite and integral, there exists an open non-empty subset of* $X' = \mathrm{Spec}(A')$ *contained in* $\mathrm{Reg}(X')$*.*
c) *For every prime ideal* $\mathfrak{p}$ *of* A *and every finite radicial extension* K' *of the field of fractions* K *of* $A/\mathfrak{p}$*, there exists a sub-*A*-algebra* A' *of* K'*, finite over* A*, having* K' *as field of fractions, and such that there exists in* $X' = \mathrm{Spec}(A')$ *an open non-empty subset contained in* $\mathrm{Reg}(X')$*.*

Proof. It is clear that *a*) implies *b*). To see that *b*) implies *c*), it suffices to note that one can take as generators of the extension K' of K elements integral over $A/\mathfrak{p}$ (and *a fortiori* over A), and as these elements are finite in number, they generate a finite A-algebra A' whose field of fractions is K'; one can then apply *b*) to A'. It remains therefore to prove that *c*) implies *a*). The question being local on X', one can first suppose that $X' = \mathrm{Spec}(A')$, where A' is an A-algebra of finite type; in view of (6.12.2), it suffices to prove that for every closed integral sub-prescheme Y' of X', $\mathrm{Reg}(Y')$ contains an open non-empty part of Y'. In other words, one can restrict to proving that if A' is an A-algebra integral *of finite type* and $X' = \mathrm{Spec}(A')$, $\mathrm{Reg}(X')$ contains an open non-empty part. Let K' be the field of fractions of A'; if $\mathfrak{p}$ is the canonical image in X of the generic point of X', K' is an extension of the field of fractions K of $A/\mathfrak{p}$, and $A/\mathfrak{p}$ is identified with a subring of A', A' being a finite $(A/\mathfrak{p})$-algebra of finite type. One can obviously restrict in what follows to the proof when $\mathfrak{p} = 0$. We distinguish two cases:

I) K' *is a separable extension* of K. — One is then reduced to proving the

Lemma (6.12.4.1). — *Let* A *be a Noetherian integral ring,* A' *an* A*-algebra integral of finite type, such that the field of fractions* K' *of* A' *is a separable extension of the field of fractions* K *of* A*. If* $\mathrm{Spec}(A)$ *contains an open non-empty subset consisting of regular points, then so does* $\mathrm{Spec}(A')$*.*

Proof. Replacing A by a ring of fractions A_f, so that $D(f) \subset \mathrm{Reg}(\mathrm{Spec}(A))$, one can already suppose the ring A *regular*. By hypothesis there exists in K' a system $(t_i)_{1 \leqslant i \leqslant n}$ of elements algebraically independent over K and such that K' is a finite separable algebraic extension of $K(t_1, \ldots, t_n)$; considering a finite system of generators t'_j $(1 \leqslant j \leqslant m)$ of K' over $K(t_1, \ldots, t_n)$, which one can suppose to be integral over $A_1 = A[t_1, \ldots, t_n]$, one sees that $A'_1 = A_1[t'_1, \ldots, t'_m]$ is *finite* over A_1 and has K' as field of fractions. If one sets $X' = \mathrm{Spec}(A')$, $X'_1 = \mathrm{Spec}(A'_1)$, it follows from the fact that the fields of rational functions $R(X')$ and $R(X'_1)$ are both isomorphic to K' and from the fact that X' and X'_1 are A-preschemes of finite type, that there exists an open subset $U' \subset X'$ and an open $U'_1 \subset X'_1$ which are A-*isomorphic* (**I**, 6.5.5). One is therefore reduced to proving that $\mathrm{Reg}(X'_1)$ contains a non-empty open subset, in other words one can suppose that A' is an A_1-algebra *finite*. Now, one knows (**0**, 17.3.7) that A_1 is a regular ring, and one can therefore restrict to the case where A' is an A-algebra *finite* and K' an extension *separable* and *finite* of K. Let ξ be the generic point of X, $A'_\xi = K'$ is then a free module over $A_\xi = K$, hence (Bourbaki, *Alg.*, *comm.*, chap. II, § 5, no 1, cor. of prop. 2) one can, replacing A by a ring of fractions A_f, suppose that A' is a free A-module of finite type. Let then $(x_h)_{1 \leqslant h \leqslant r}$ be a basis of this A-module, and set IV-2 | 165

$$d = \det(\mathrm{Tr}_{A'/A}(x_h x_k)) = \det(\mathrm{Tr}_{K'/K}(x_h x_k)) \in A.$$

As K' is separable over K, one knows (Bourbaki, *Alg.*, chap. IX, § 2, prop. 5) that $d \neq 0$; replacing A by a ring of fractions A_z, one can therefore suppose *d invertible* in A. But then, for every $z \in \mathrm{Spec}(A)$, if one denotes by $\overline{x}_h$ $(1 \leqslant h \leqslant r)$ the canonical image of x_h in $A'(z) = A' \otimes_A \boldsymbol{k}(z)$, one has $\det(\mathrm{Tr}_{A'(z)/\boldsymbol{k}(z)}(\overline{x}_h\overline{x}_k)) = \overline{d}$, canonical image of d in $\boldsymbol{k}(z) = A_z/\mathfrak{m}_z$, and as $\overline{d}$ is invertible (hence $\neq 0$) in $\boldsymbol{k}(z)$, one knows (*loc. cit.*) that $A'(z)$ is a $\boldsymbol{k}(z)$-algebra *separable*, hence a direct product of finite separable field extensions of $\boldsymbol{k}(z)$. Since such an algebra is a *regular* ring, one sees that the morphism $g : X' \to X$ is *flat* and that its fibres $g^{-1}(z)$ are *regular* for every $z \in X$; one concludes then from (6.5.2, (ii)) that X' is *regular*, which finishes the proof in this case. □

II) *General case.* — As A' is an A-module without torsion, $A' \otimes_A K$ is identified with a subring of K', hence $X'' = \mathrm{Spec}(A' \otimes_A K)$ is an integral K-prescheme whose field of rational functions is K'. One knows (4.6.6) that there exists a finite radicial extension K_1 of K such that $X'_1 = \mathrm{Spec}(A' \otimes_A K_1) =$

$X'' \otimes_K K_1$, $(X'_1)_{red}$ is a K_1-prescheme *geometrically reduced* of finite type; furthermore, the morphism $\mathrm{Spec}(K_1) \to \mathrm{Spec}(K)$ being radicial, finite and surjective, it is a universal homeomorphism (2.4.5), hence X'_1 is homeomorphic to X'', and consequently $(X'_1)_{red}$ is integral; its field of rational functions K'_1 is a finite radicial extension of K' and a *separable* extension of finite type of K_1 (4.6.1). By virtue of hypothesis c) of the statement, there is a sub-A-algebra *finite* A_1 of K_1, having K_1 as field of fractions and such that if one sets $X_1 = \mathrm{Spec}(A_1)$, $\mathrm{Reg}(X_1)$ contains an open non-empty subset. Let A'_1 be the image of the canonical homomorphism $A' \otimes_A A_1 \to K'_1$ and let $X'_1 = \mathrm{Spec}(A'_1)$; A'_1 is an integral ring which is an A'-algebra *finite* and whose field of fractions is K'_1; furthermore, as the composite homomorphism $A' \to A' \otimes_A A_1 \to A'_1 \to K'_1$ is identical to $A' \to K' \to K'_1$, hence injective, the homomorphism $A' \to A'_1$ is injective; the morphism $g : X'_1 \to X'$ is therefore finite and surjective (**II**, 6.1.10). This being the hypothesis on A_1 and part I) of the proof imply that $\mathrm{Reg}(X'_1)$ contains an **IV-2** | 166 open non-empty V'_1; as g is closed (**II**, 6.1.10), one can suppose that $V'_1 = g^{-1}(V')$, where V' is an open affine of X'; replacing A' by the ring of V' and A'_1 by that of V'_1, one can therefore suppose that X'_1 is *regular*. Furthermore, the same reasoning as in I) applied to the generic point ξ' of X' allows (replacing X' by a neighbourhood of ξ') to suppose that A'_1 is an A'-module *free*, and hence that the morphism g is *flat*. But it follows then from (6.5.2, (i)) that X' is *regular*. □

Corollary (6.12.5). — (Zariski). — *Let k be a field; for every k-prescheme X locally of finite type over k, the set of $x \in X$ where X is regular (resp.* geometrically regular *over k) is open in X.*

Proof. The assertion of the corollary relative to the property of being regular follows from (6.12.4) by taking $A = k$. The assertion relative to the property of being geometrically regular follows already from (6.8.7); one can also deduce it from (6.12.4) in the following way: set $k' = k^{p^{-\infty}}$ (p being the characteristic exponent of k); as the morphism $\mathrm{Spec}(k') \to \mathrm{Spec}(k)$ is radicial, integral and surjective, it is a universal homeomorphism (2.4.5), hence the morphism projection $X \otimes_k k' \to X$ is a universal homeomorphism. The projection in X of $\mathrm{Reg}(X \otimes_k k')$ is the set of points of X where X is geometrically regular over k, by virtue of (6.7.7, e)); hence this set is open from what precedes. □

Corollary (6.12.6). — *Let A be a ring having one of the following properties:*

(i) A *is a Dedekind ring and its field of fractions* K *is of characteristic* 0.

(ii) A *is a semi-local Noetherian ring of dimension* $\leqslant 1$.

Then, for every prescheme X locally of finite type over A, $\mathrm{Reg}(X)$ is open in X.

Proof. Let us verify in both cases the condition c) of (6.12.4). In both cases, a prime ideal $\mathfrak{p}$ of A is maximal or minimal; if $\mathfrak{p}$ is maximal, an $(A/\mathfrak{p})$-algebra finite and integral is a field and the condition c) of (6.12.4) is trivially satisfied. Suppose therefore $\mathfrak{p}$ non-maximal, and distinguish the two cases of the statement.

(i) If K is of characteristic 0, there is no radicial extension of K other than K itself; as a Dedekind ring is regular (**0**, 17.1.4), the condition c) of (6.12.4) is trivially satisfied.

(ii) One can then suppose A integral (6.12.2), let K be its field of fractions; if K' is a finite radicial extension of K, A' a sub-A-algebra of K' generated by a finite system of generators of K' over K, integral over A, A' is a semi-local integral ring of dimension 1 (**0**, 16.1.5), and consequently, in $X' = \mathrm{Spec}(A')$, the reduced set at the generic point is open and evidently contained in $\mathrm{Reg}(X')$, which proves the condition c) of (6.12.4) in this case. □

This corollary applies notably when $A = \mathbf{Z}$.

Theorem (6.12.7). — (Nagata). — *Let A be a local Noetherian complete ring, $X = \mathrm{Spec}(A)$. Then $\mathrm{Reg}(X)$ is open in X.*

Proof. In view of (6.12.2), one is reduced to the case where moreover A is *integral*, and to proving that $\mathrm{Reg}(X)$ contains an open non-empty part of X. We distinguish two cases:

I) *The field of fractions K of A is of characteristic* 0. — One knows then (**0**, 19.8.8) that there exists a **IV-2** | 167 complete discrete valuation ring C and a subring B of A such that A is a B-algebra *finite* and that B is isomorphic to a formal power series ring $C[[T_1, \ldots, T_r]]$. As C is regular (**II**, 7.1.6), so is B (**0**, 17.3.8); furthermore, the field of fractions L of B being of characteristic 0, K is a *separable* extension finite of L, hence one can apply (6.12.4.1) to B, and this proves the proposition.

II) *The field of fractions* K *of* A *is of characteristic* $p > 0$. — Then A contains the prime field $\mathbf{F}_p$, and the theorem has been proved in this case (**0**, 22.7.6). □

Corollary (6.12.8). — *Let* A *be a local Noetherian complete ring. Then, for every prescheme* X *locally of finite type over* A, Reg(X) *is open in* X.

Proof. Let us verify the condition *c*) of (6.12.4). If $\mathfrak{p}$ is prime in A, $A/\mathfrak{p}$ is again a local Noetherian complete ring; if K' is a finite extension of the field of fractions K of $A/\mathfrak{p}$, K' is the field of fractions of a sub-A-algebra finite A' of K', generated by a finite system of generators of K' over K, integral over A. One knows then that A' is a semi-local complete ring (Bourbaki, *Alg. comm.*, chap. IV, § 2, no 5, cor. 3 of prop. 9), hence a product of local complete rings, and as A' is integral, it is a local complete ring; and by virtue of (6.12.7), if $X' = \mathrm{Spec}(A')$, $\mathrm{Reg}(X')$ is open and non-empty, whence the conclusion. □

Proposition (6.12.9). — *Let* X *be a locally Noetherian prescheme such that* Reg(X) *is open; then, for every* $n \geqslant 0$, *the set* $U_{R_n}(X)$ *of points* $x \in X$ *where* X *satisfies* (R_n) *is open.*

Proof. Indeed (5.8.2), $U_{R_n}(X)$ is the union of Reg(X) and of the set of $x \in \mathrm{Sing}(X)$ such that the generic points z_i of the irreducible components of Sing(X) containing x satisfy the relation $\dim(\mathscr{O}_{X,z_i}) \geqslant n+1$ (5.1.2); in other words, these points $x \in \mathrm{Sing}(X)$ are those for which $\mathrm{codim}_x(\mathrm{Sing}(X), X) \geqslant n+1$; as the function $x \mapsto \mathrm{codim}_x(\mathrm{Sing}(X), X)$ is lower semi-continuous (**0**, 14.2.6), the set of these points is open in Sing(X), which finishes the proof. □

Let us also note the following elementary result:

Proposition (6.12.10). — *Let* X *be a locally Noetherian prescheme. The set* $U_{R_0}(X)$ *is open in* X. *For* $U_{R_1}(X)$ *to be open in* X, *it is necessary and it suffices that every maximal* $x \in X$ *such that* $x \in U_{R_1}(X)$ *(which means that* X *is reduced at x) be interior to* $U_{R_1}(X)$.

Proof. By definition (5.8.2), $U_{R_0}(X)$ is the set $X - \bigcup_\alpha X'_\alpha$, where X'_α ranges over the set of irreducible components of X such that X is not reduced at their generic point; as the set of irreducible components of X is locally finite, $U_{R_0}(X)$ is open. As for $U_{R_1}(X)$, the stated condition is trivially necessary; let us prove that it is sufficient. Let X''_β be the irreducible components of X such that, at their generic point x''_β, the prescheme X is reduced; by hypothesis there exists an open $U \subset U_{R_1}(X)$ containing all the x''_β. Denote then by Z_λ the irreducible components of the closed set $Z = X - U$ whose generic point z_λ is such that $\dim(\mathscr{O}_{X,z_\lambda}) \leqslant 1$ and that $\mathscr{O}_{X,z_\lambda}$ is non-regular. No point belonging to one of the Z_λ can belong to $U_{R_1}(X)$; but conversely, if $x \in Z$ does not belong to any of the Z_λ, then, for every generization x' of x, either x' belongs to U, or $\dim(\mathscr{O}_{X,x'}) \geqslant 2$, or $\dim(\mathscr{O}_{X,x'}) = 1$, and as x' does not belong to any Z_λ, $\overline{\{x'\}}$ is necessarily one of the irreducible components of Z, of codimension 1 in X, distinct from the Z_λ, hence $\mathscr{O}_{X,x'}$ is regular by definition. One concludes that $U_{R_1}(X) = X - \bigcup_\lambda Z_\lambda$; as the set of Z_λ is locally finite in Z, $\bigcup_\lambda Z_\lambda$ is closed, which finishes the proof that $U_{R_1}(X)$ is open in X. □ **IV-2** | 168

6.13. Criteria for Nor(X) to be open

(6.13.1). Given a locally Noetherian prescheme X, we shall denote by Nor(X) the set of $x \in X$ where X is *normal*; this set contains Reg(X) and is contained in the (open) set of points x such that $\mathscr{O}_{X,x}$ is integral (i.e. the set of points x where X is reduced, and which belong to only one irreducible component of X).

Proposition (6.13.2). — *Let* X *be a locally Noetherian prescheme reduced,* X' *its normalization* (**II**, 6.3.8). *If the canonical morphism* $f : X' \to X$ *is finite,* Nor(X) *is open in* X.

Proof. Indeed, on $X' = \mathrm{Spec}(f_*(\mathscr{O}_{X'}))$ and $f_*(\mathscr{O}_{X'})$ is a coherent $\mathscr{O}_X$-Algebra by hypothesis (**II**, 6.1.3). To say that X is normal at a point x means that the canonical homomorphism $\mathscr{O}_x \to (f_*(\mathscr{O}_{X'}))_x$ is bijective (**II**, 6.3.4); but the set of these points is *open* since $\mathscr{O}_X$ and $f_*(\mathscr{O}_{X'})$ are coherent ($\mathbf{0}_\mathrm{I}$, 5.2.7). □

Corollary (6.13.3). — *If* A *is an integral Noetherian* Japanese *ring,* Nor(Spec(A)) *is open in* Spec(A).

Proposition (6.13.4). — *Let* X *be a locally Noetherian prescheme. For* $\mathrm{Nor}(X)$ *to be open, it is necessary and it suffices that every maximal point* x *of* X *such that* $x \in \mathrm{Nor}(X)$ *(which means that* X *is reduced at the point* x*) be interior to* $\mathrm{Nor}(X)$.

Proof. There is only to prove the sufficiency of the condition. By virtue of the remark made in (6.13.1), one can restrict (replacing X by an open of X in which X is reduced), i.e. to suppose that the maximal points of X belong to $U_{S_1}(X)$ and to $U_{R_1}(X)$; as $\mathrm{Nor}(X) = U_{S_1}(X) \cap U_{R_1}(X)$ by virtue of Serre's criterion (5.8.6), one deduces from (6.11.7) and (6.12.10) that these two sets are open; hence $\mathrm{Nor}(X)$ is open in X. □

Corollary (6.13.5). — *If* X *is such that* $\mathrm{Reg}(X)$ *is open in* X, *then* $\mathrm{Nor}(X)$ *is open in* X.

Proof. Indeed, every maximal point x where X is reduced (hence $\mathscr{O}_{X,x}$ is a field) belongs to $\mathrm{Reg}(X)$, hence is interior to $\mathrm{Reg}(X)$ by hypothesis, and *a fortiori* is interior to $\mathrm{Nor}(X)$. □

Proposition (6.13.6). — (Nagata). — *Let* A *be a Noetherian integral ring,* K *its field of fractions,* K′ *a finite extension of* K, A′ *the integral closure of* A *in* K′. *For* A′ *to be a finite* A*-algebra, it is necessary and it suffices that the two following conditions be satisfied:*

(i) There exists $f \neq 0$ *in* A *such that the integral closure* A'_f *of the ring of fractions* A_f *in* K′ *is a finite* A_f*-algebra.*

(ii) For every prime ideal $\mathfrak{p} \in \mathrm{Spec}(A)$, *the integral closure* $A'_{\mathfrak{p}}$ *of the local ring* $A_{\mathfrak{p}}$ *in* K′ *is a finite* $A_{\mathfrak{p}}$*-algebra.*

Proof. The conditions are necessary, for for every multiplicative subset S of A, $S^{-1}A'$ is the integral closure of $S^{-1}A$ in K′ and is by hypothesis a $S^{-1}A$-module of finite type. To see that the conditions are sufficient, consider the filtered increasing family (B_λ) of sub-A-algebras of K′ which are A-algebras finite and have K′ as field of fractions. Set $Y = \mathrm{Spec}(A)$, $X_\lambda = \mathrm{Spec}(B_\lambda)$, denote by u_λ the morphism $X_\lambda \to Y$ and let $S_\lambda = X_\lambda - \mathrm{Nor}(X_\lambda)$, $T_\lambda = u_\lambda(S_\lambda)$. One can restrict to the B_λ which contain a finite set whose image in A'_f is a system of generators of the A_f-module A'_f; this implies, by virtue of hypothesis (i), that $(B_\lambda)_f = A'_f$ for every λ, or equivalently that $u_\lambda^{-1}(D(f))$ is contained in $\mathrm{Nor}(X_\lambda)$. By virtue of (6.13.2), S_λ is therefore *closed* in Y. But for every $\mathfrak{p} \in \mathrm{Spec}(A)$, it exists by virtue of (ii) a λ such that $(B_\lambda)_{\mathfrak{p}} = A'_{\mathfrak{p}}$, and consequently all points of X_λ lying over $\mathfrak{p}$ belong to **IV-2** | 169 $\mathrm{Nor}(X_\lambda)$; in other words $\mathfrak{p} \notin T_\lambda$; as $\mathfrak{p} \in \mathrm{Spec}(A)$, it exists by virtue of (ii) a λ such that $(B_\lambda)_{\mathfrak{p}} = A'_{\mathfrak{p}}$, and consequently all points of X_λ lying over $\mathfrak{p}$ belong to $\mathrm{Nor}(X_\lambda)$; in other words $\mathfrak{p} \notin T_\lambda$; as Y is Noetherian and the T_λ are closed, there exists a λ_0 such that $T_{\lambda_0} = \varnothing$; hence B_{λ_0} is integrally closed, and as its field of fractions is K′, one has $B_{\lambda_0} = A'$. □

Proposition (6.13.7). — *Let* A *be a Noetherian ring,* $X = \mathrm{Spec}(A)$. *The following conditions are equivalent:*

a) *For every prescheme* X′ *locally of finite type over* X, $\mathrm{Nor}(X')$ *is open in* X′.

b) *For every* A*-algebra finite and integral* A′, $\mathrm{Nor}(\mathrm{Spec}(A'))$ *is open in* $\mathrm{Spec}(A')$.

c) *For every prime ideal* $\mathfrak{p}$ *of* A *and every finite radicial extension* K′ *of the field of fractions* K *of* $A/\mathfrak{p}$, *there exists a sub-*A*-algebra* A′ *of* K′, *finite over* A, *having* K′ *as field of fractions and such that* $\mathrm{Nor}(\mathrm{Spec}(A'))$ *is open in* $\mathrm{Spec}(A')$.

Proof. The fact that *a*) implies *b*) and that *b*) implies *c*) is proved as in (6.12.4). To show that *c*) implies *a*), one reduces as in (6.12.4) to proving that if A′ is an A-algebra integral and of finite type, the generic point of $\mathrm{Spec}(A')$ is interior to $\mathrm{Nor}(\mathrm{Spec}(A'))$. One distinguishes two cases as in (6.12.4) by proving first the

Lemma (6.13.7.1). — *Let* A *be a Noetherian integral ring,* A′ *an* A*-algebra integral of finite type, containing* A *and such that the field of fractions* K′ *of* A′ *is a separable extension of the field of fractions* K *of* A. *If* $\mathrm{Nor}(\mathrm{Spec}(A))$ *is open in* $\mathrm{Spec}(A)$, $\mathrm{Nor}(\mathrm{Spec}(A'))$ *is open in* $\mathrm{Spec}(A')$.

Proof. It suffices to prove (in view of (6.13.2)) that the generic point of $\mathrm{Spec}(A')$ is interior to $\mathrm{Nor}(\mathrm{Spec}(A'))$. The proof follows the same approach as that of (6.12.4.1), from which we conserve the notations. We note that when A is integrally closed, and then on takes $A_1 = A[t_1, \dots, t_n]$ and is integrally closed (Bourbaki, *Alg. comm.*, chap. V, § 1, no 3, cor. 2 of prop. 13); one reduces next to the case where A′ is a free A-module of *finite type*; the reasomment then applies (replacing A by an appropriate ring of fractions A_f with $f \neq 0$) the reasoning from case I) of (6.12.4) to see that the fibres $g^{-1}(z)$ of the morphism $g : X' \to X$ are regular and *a fortiori* normal. Furthermore g is flat and X is normal, hence (6.5.4, (ii)) X′ is normal. One then passes to the general case as in (6.12.4); II)), from which we conserve further the notations; applying hypothesis c), one sees this time that $\mathrm{Nor}(X'_1)$ is open and one reduces thus to the case where X'_1 is normal and $g : X' \to X'$ is flat and surjective; one concludes by applying (6.5.4, (i)). □

This lemma being proved, one passes to the general case as in (6.12.4; II)), from which we conserve the notations; applying hypothesis c), one sees this time that $\mathrm{Nor}(X'_1)$ is open and one reduces thus to the case where X'_1 is normal and $g : X' \to X'$ flat and surjective; one concludes by applying (6.5.4, (i)). □

6.14. Base change and integral closure

Proposition (6.14.1). — *Let* Y, Y′ *be two locally Noetherian preschemes,* $g : Y' \to Y$ *a normal morphism* (6.8.1). *Then, for every normal* Y*-prescheme* X*, the prescheme* $X' = X \times_Y Y'$ *is normal.*

Proof. We note that in this statement one *does not suppose* X locally Noetherian. □

Lemma (6.14.1.1). — *Let* R *be a ring that is a direct product of finitely many fields.*

(i) For a subring A *of* R *having* R *as total ring of fractions to be normal, it is necessary and it suffices that it be integrally closed in* R.

(ii) Let (A_λ) *be a family of normal subrings of* R*; if* $A = \bigcap_\lambda A_\lambda$ *admits* R *as total ring of fractions,* A *is normal.*

Proof. (i) As A is a subring of R, $A_\mathfrak{p}$ is a subring of $R_\mathfrak{p}$ for every prime ideal $\mathfrak{p}$ of A; furthermore $R_\mathfrak{p}$ is a ring of fractions of $A_\mathfrak{p}$; furthermore $R_\mathfrak{p}$ is necessarily a direct product of finitely many fields, hence every non-zero divisor of 0 in $R_\mathfrak{p}$ is invertible; this proves that $R_\mathfrak{p}$ is the total ring of fractions of $A_\mathfrak{p}$. If A is integrally closed in R, $A_\mathfrak{p}$ is therefore integrally closed in $R_\mathfrak{p}$; but if $R_\mathfrak{p}$ is a direct product of at least two rings, the integral closure of $A_\mathfrak{p}$ in $R_\mathfrak{p}$ is a direct product of at least two nonzero rings, which is absurd since $A_\mathfrak{p}$ is a local ring; hence $R_\mathfrak{p}$ is necessarily a field and $A_\mathfrak{p}$ is integral and integrally closed, which by definition means that A is normal. Conversely, if A is normal, $R_\mathfrak{p}$, total ring of fractions of an integral ring $A_\mathfrak{p}$, is a field and $A_\mathfrak{p}$ is integrally closed in $R_\mathfrak{p}$; hence R is an integral element over A, its image in each $R_\mathfrak{p}$ is integral over $A_\mathfrak{p}$, hence belongs to $A_\mathfrak{p}$; we conclude that $x \in A$ (Bourbaki, *Alg. comm.*, chap. II, § 3, no 3, cor. 1 of th. 1), and hence A is integrally closed in R.

(ii) As $A \subset A_\lambda \subset R$ for every λ, R is also the total ring of fractions of each A_λ. In view of the characterisation of normal rings having R as total ring of fractions, the assertion (ii) follows from Bourbaki, *Alg. comm.*, chap. V, § 1, no 3, prop. 12. □ **IV-2** | 170

This lemma being proved, the proof of (6.14.1) proceeds in several steps.

I) *Reduction to the case where* $Y = \mathrm{Spec}(A)$, $Y' = \mathrm{Spec}(A')$, $X = \mathrm{Spec}(B)$, A, A′ *being local Noetherian rings,* A integral, B the integral closure of A. — It suffices to prove that for every $x' \in X'$, the local ring $\mathscr{O}_{X',x'}$ is integral and integrally closed; let x, y, y' be the canonical images of x' in X, Y, Y′ respectively; if one sets $A = \mathscr{O}_{Y,y}$, $A' = \mathscr{O}_{Y',y'}$, $B = \mathscr{O}_{X,x}$, the rings $\mathscr{O}_{X,x}$, $\mathscr{O}_{Y,y}$, $\mathscr{O}_{Y',y'}$ for x, y, y' fixed, are the local rings at the prime ideals of the ring $B' = B \otimes_A A'$ (**I**, 3.6.5), and so it suffices to prove that B′ is a *normal* ring. Let us note on the other hand that $\mathrm{Spec}(A') \to \mathrm{Spec}(A)$ is a normal morphism by definition (6.8.1 and **I**, 3.6.5); one is reduced to the case where Y and Y′ are local schemes, that is to say to the case where A is an integral and integrally closed local ring ($\mathbf{0}_\mathrm{I}$, 6.8.1 and **I**, 3.6.5); one is reduced to the case where Y and Y′ are local schemes. Let us designate by (B_α) the family of *integral closures* of the sub-A-algebras *of finite type* of B; it is clear that B is the union of the filtered increasing family of the B_α. As $\varinjlim$ commutes with the tensor product, B′ is therefore also the union of the filtered increasing family $\overline{B'_\alpha} = B_\alpha \otimes_A A'$. To prove that B′ is normal, it suffices, by virtue of (5.13.6), to show that the rings B'_α are *normal* and that, for $\alpha \leqslant \beta$, every irreducible component of $\mathrm{Spec}(B'_\beta)$ *dominates* one irreducible component of $\mathrm{Spec}(B'_\alpha)$. But this last property follows from the hypothesis that A′ is an A-module flat and from (2.3.7, (ii)).

One can therefore restrict to proving that $B' = B \otimes_A A'$ is normal when B is the integral closure of a A-algebra integral *of finite type* C; in this case, if one sets $C' = C \otimes_A A'$, the morphism $\mathrm{Spec}(C') \to$

Spec(C) is normal (6.8.2); as $B' = B \otimes_C C'$, one sees that one can replace A and A′ by C and C′ respectively, hence suppose that A is integral and that B is the *integral closure* of A. Finally, the procedure from the beginning allows to restrict to the case where A is *local* (taking into account the fact that, if B is the integral closure of A, $B_{\mathfrak{p}}$ is the integral closure of $A_{\mathfrak{p}}$ for every prime ideal $\mathfrak{p}$ of A).

II) *Reduction to the case where* A *is a local integral ring of dimension* 1, B *a discrete valuation ring, integral closure of* A *and the morphism* $\operatorname{Spec}(B) \to \operatorname{Spec}(A)$ *radicial.* — Let K be the field of fractions of A. One knows (**0**, 23.2.7) that B is intersection of a family (V_λ) of discrete valuation rings such that, for every $x \in K$, one has $x \in V_\lambda$ except for a finite number of indices λ. One therefore has an exact sequence of A-modules

$$0 \longrightarrow B \longrightarrow K \longrightarrow \bigoplus_\lambda (K/V_\lambda).$$

Set $K' = K \otimes_A A'$, $V'_\lambda = V_\lambda \otimes_A A'$; by flatness, one deduces from the preceding exact sequence a new exact sequence

$$0 \longrightarrow B' \longrightarrow K' \longrightarrow \bigoplus (K'_\lambda/V'_\lambda)$$

and hence $B' = \bigcap_\lambda V'_\lambda$. Furthermore $\operatorname{Spec}(K')$ is the fibre of the morphism $\operatorname{Spec}(A') \to \operatorname{Spec}(A)$ at the generic point of Spec(A), hence K′ is a Noetherian ring, *normal*, and hence a direct product of finitely many integrally closed integral rings; the direct product L′ of the fields of fractions of these latter is the total ring of fractions of A′, hence also that of B′. One can therefore apply the lemma (6.14.1.1), and if one proves that each of the V'_λ is a *normal* ring, then so is B′. **IV-2** | 171

One knows on the other hand (**0**, 23.2.7) that one can take the V_λ such that there is a sub-A-algebra finite C of K such that V_λ is the integral closure of $C_{\mathfrak{p}_\lambda}$ where $\mathfrak{p}_\lambda$ is a prime ideal of height 1 in C. If one sets $C'_{\mathfrak{p}_\lambda} = C_{\mathfrak{p}_\lambda} \otimes_A A'$, the morphism $\operatorname{Spec}(C'_{\mathfrak{p}_\lambda}) \to \operatorname{Spec}(C_{\mathfrak{p}_\lambda})$ is normal (6.8.2) and one has $V'_\lambda = V_\lambda \otimes_{C_{\mathfrak{p}_\lambda}} C'_{\mathfrak{p}_\lambda}$; one can therefore replace B by V_λ and A by $C_{\mathfrak{p}_\lambda}$, hence suppose that A is local, integral and *of dimension* 1, B its integral closure and a discrete valuation ring. There is a sub-A-algebra *finite* A_1 of B such that the morphism $\operatorname{Spec}(B) \to \operatorname{Spec}(A_1)$ is radicial (**0**, 23.2.5), which implies in particular that A_1 is also a local ring (obviously of dimension 1); furthermore one can suppose that B and A_1 have the same residue field (*loc. cit.*). One can therefore by the same method replace A by A_1. Applying if necessary the procedure from the beginning of I), one can suppose finally that A′ is also a local ring and that the homomorphism $A \to A'$ is *local*.

III) *End of the proof.* — We shall first establish the following lemma: □

Lemma (6.14.1.2). — *Let* A *be a local Noetherian integral ring of dimension* 1, A′ *a local Noetherian integral ring,* $A \to A'$ *a local homomorphism such that the corresponding morphism* $\operatorname{Spec}(A') \to \operatorname{Spec}(A)$ *is* normal. *Let* K *be the field of fractions of* A, $\mathfrak{m}$ *the maximal ideal of* A, $\boldsymbol{k} = A/\mathfrak{m}$ *its residue field.*

(i) If $\mathfrak{q}'_j$ $(1 \leqslant j \leqslant r)$ are the minimal ideals of A′, $K' = K \otimes_A A'$ is a direct product of integral rings and integrally closed $K'_j \supset A'/\mathfrak{q}'_j$ $(1 \leqslant j \leqslant r)$, K'_j having as field of fractions the field of fractions L'_j of $A'/\mathfrak{q}'_j$, so that the total ring of fractions L′ of A′ is identified with the direct product of the L'_j and A′ is a subring of K′.

(ii) The ideal $\mathfrak{p}' = \mathfrak{m}A'$ of A′ is prime; the ring $A'_{\mathfrak{p}'}$ is of dimension 1 and is identified with a sub-product of the fields L'_j for the indices j such that $\mathfrak{q}'_j \subset \mathfrak{p}'$.

(iii) If $\overline{A'_{\mathfrak{p}'}}$ denotes the subring of L′, product of $A'_{\mathfrak{p}'}$ and of the L'_j such that $\mathfrak{q}'_j \not\subset \mathfrak{p}'$, one has

$$A' = K' \cap \overline{A'_{\mathfrak{p}'}}. \tag{6.14.1.3}$$

Proof. Assertion (i) has already been seen in the course of the proof, independent of the hypothesis on the dimension of A. The hypothesis that the morphism $\operatorname{Spec}(A') \to \operatorname{Spec}(A)$ is normal implies that $A' \otimes_A \boldsymbol{k} = A'/\mathfrak{m}A'$ is a normal local ring and *integral*, which shows already that $\mathfrak{p}' = \mathfrak{m}A'$ is prime. One has, by (6.1.2), $\dim(A'_{\mathfrak{p}'}) = \dim(A) + \dim(A'_{\mathfrak{p}'}/\mathfrak{m}A'_{\mathfrak{p}'})$. But $A'_{\mathfrak{p}'}/\mathfrak{m}A'_{\mathfrak{p}'} = A'_{\mathfrak{p}'}/\mathfrak{p}'A'_{\mathfrak{p}'}$ is the residue field of $A'_{\mathfrak{p}'}$, hence $\dim(A'_{\mathfrak{p}'}) = 1$. The fact that $A'_{\mathfrak{p}'}$ is contained in the composed direct of the L'_j for these indices j such that $\mathfrak{q}'_j \subset \mathfrak{p}'$, for these indices j are the minimal prime ideals of $A'_{\mathfrak{p}'}$. **IV-2** | 172

It remains to prove (6.14.1.3). Conversely, let y' be an element of this intersection; let a be a "parameter" for A, i.e. an element such that Aa is $\mathfrak{m}$-primary, and let a' be the image of a in A′; every element of K can be written x/a^n for $x \in A$ and $n > 0$ since Aa contains a power of $\mathfrak{m}$; hence one can write $y' = x'/a'^n$ with $x' \in A'$. Note now that $\mathfrak{p}'$ is the *only* prime ideal associated to $A'/a'^n A' = (A/a^n A) \otimes_A A'$: as A' is a flat A-module, this follows from (3.3.1), $\mathfrak{m}$ being the only prime ideal associated to $A/a^n A$ since A is integral. Hence, $a'^n A'$ is the inverse image in A' of $a'^n A'_{\mathfrak{p}'}$; as by hypothesis $y' \in \widehat{A'_{\mathfrak{p}'}}$, the image of x' in $A'_{\mathfrak{p}'}$ belongs to $a'^n A'_{\mathfrak{p}'}$; whence $x' \in a'^n A'$ and $y' \in A'$, which finishes the proof.

In the situation in which we have arrived at the end of II), B' is *radicial* over A' (**I**, 3.5.7) and is hence also a local ring; furthermore B' is integer over A', hence, if $\mathfrak{q}'$ is the unique prime ideal of B' lying over $\mathfrak{p}'$, $\mathfrak{q}'B'_{\mathfrak{p}'}$ is the unique maximal ideal of $B'_{\mathfrak{p}'}$ (Bourbaki, *Alg. comm.*, chap. V, § 2, no 1, prop. 1), hence $B'_{\mathfrak{q}'} = B'_{\mathfrak{p}'} = B \otimes_{A_\mathfrak{p}} A'_{\mathfrak{p}'}$. We shall first prove that $B'_{\mathfrak{p}'}$ is *Noetherian* and *normal*. $B'_{\mathfrak{p}'}$ contains $A'_{\mathfrak{p}'}$ and is contained in $K'_{\mathfrak{p}'}$, hence in the product L_1 of the L'_j such that $\mathfrak{q}'_j \subset \mathfrak{p}'$. The composed direct L'' of the fields of fractions of these latter is also the total ring of fractions of A', hence also that of $B'_{\mathfrak{p}'}$. For every index j such that $\mathfrak{q}'_j \subset \mathfrak{p}'$, let $\mathfrak{a}'_j$ be the product of the L'_h for these indices h such that $h \neq j$, so that $\mathfrak{a}'_j \cap A'_{\mathfrak{p}'} = \mathfrak{q}'_j A'_{\mathfrak{p}'}$; as every element of $A' - \mathfrak{p}'$ is regular in L_1, one has also

$$\mathfrak{a}'_j \cap A'_{\mathfrak{p}'} = \mathfrak{q}'_j A'_{\mathfrak{p}'}.$$

Let $\mathfrak{r}'_j = B'_{\mathfrak{p}'} \cap \mathfrak{a}'_j$, so that $B'_{\mathfrak{p}'}/\mathfrak{r}'_j$ is isomorphic to the projection of $B'_{\mathfrak{p}'}$ in L'_j; hence $B'_{\mathfrak{p}'}/\mathfrak{r}'_j$ contains the local integral ring of *dimension* 1, $A'_{\mathfrak{p}'}/\mathfrak{q}'_j A'_{\mathfrak{p}'}$, and is contained in its field of fractions L'_j; it is hence a Noetherian ring by virtue of the theorem of Krull-Akizuki (Bourbaki, *Alg. comm.*, chap. VII, § 2, no 5, prop. 5).

As the intersection of the $\mathfrak{r}'_j$ is reduced to 0, one deduces that $B'_{\mathfrak{p}'}$ itself is Noetherian, by virtue of **IV-2** | 173
the classical lemma:

Lemma (6.14.1.4). — *Let* R *be a ring,* $\mathfrak{a}$ *and* $\mathfrak{b}$ *two ideals of* R*; if* $R/\mathfrak{a}$ *and* $R/\mathfrak{b}$ *are Noetherian, so is* $R/(\mathfrak{a} \cap \mathfrak{b})$.

Proof. Indeed, let $\mathfrak{c}$ be an ideal of R such that $\mathfrak{a} \cap \mathfrak{b} \subset \mathfrak{c}$; one has therefore $\mathfrak{a} \cap \mathfrak{b} \subset \mathfrak{a} \cap \mathfrak{c} \subset \mathfrak{a}$; now $\mathfrak{c}/(\mathfrak{a} \cap \mathfrak{c})$ is an R-module isomorphic to $(\mathfrak{a} + \mathfrak{c})/\mathfrak{a}$, hence an ideal of $R/\mathfrak{a}$, and hence is of finite type; on the other hand $(\mathfrak{a} \cap \mathfrak{c})/(\mathfrak{a} \cap \mathfrak{b})$ is a sub-R-module of $\mathfrak{a}/(\mathfrak{a} \cap \mathfrak{b})$, and this latter is isomorphic to $(\mathfrak{a} + \mathfrak{b})/\mathfrak{b}$, hence is of finite type as an ideal of $R/\mathfrak{b}$; hence $(\mathfrak{a} \cap \mathfrak{c})/(\mathfrak{a} \cap \mathfrak{b})$ is also an R-module of finite type, and it follows finally that $\mathfrak{c}/(\mathfrak{a} \cap \mathfrak{b})$ is also an R-module of finite type. □

Let us note on the other hand that Spec(A) is made up of the closed point $\mathfrak{m}$ and of the generic point (o), of residue fields $\boldsymbol{k}$ and K respectively; as in the case where we are placed, the fields of fractions of B and its residue field are respectively isomorphic to K and $\boldsymbol{k}$, the fibres of the morphism $u : \operatorname{Spec}(B'_{\mathfrak{p}'}) \to \operatorname{Spec}(B)$ at the closed point and at the generic point of Spec(B) are respectively *isomorphic* to the fibres of the morphism $\operatorname{Spec}(A'_{\mathfrak{p}'}) \to \operatorname{Spec}(A)$ at the closed point and at the generic point of Spec(A) (**I**, 3.6.4), hence are *geometrically normal*; as on the other hand the morphism u is flat, we conclude that it is *normal* (6.8.1). But B and $B'_{\mathfrak{p}'}$ are Noetherian and B is normal, hence (6.5.4) $B'_{\mathfrak{p}'}$ is *normal*.

This being so, B is union of the filtered increasing family of its sub-A-algebras of finite type A_α; by flatness, B' is union of the filtered increasing family of the $A'_\alpha = A_\alpha \otimes_A A'$; if one sets $\mathfrak{p}'_\alpha = \mathfrak{q}' \cap A'_\alpha$, $B'_{\mathfrak{q}'}$ is also union of the filtered increasing family of the $(A'_\alpha)_{\mathfrak{p}'_\alpha}$ (5.13.3). Denote by L'' the direct product of the fields L'_j such that $\mathfrak{q}'_j \not\subset \mathfrak{p}'$; then for every α, $(A'_\alpha)_{\mathfrak{p}'_\alpha}$ is contained in $K'_{\mathfrak{p}'}$, and the ring $\overline{B'_{\mathfrak{q}'}} = L'' \times B'_{\mathfrak{q}'}$ is therefore union of the rings $L'' \times (A'_\alpha)_{\mathfrak{p}'_\alpha} = (\overline{A'_\alpha})_{\mathfrak{p}'_\alpha}$. But each of the A_α is local, Noetherian, integral and of dimension 1, and the morphism $\operatorname{Spec}(A'_\alpha) \to \operatorname{Spec}(A_\alpha)$ is normal (6.8.2), hence one can apply (6.14.1.2) and one has

$$A'_\alpha = K' \cap (\overline{A'_\alpha})_{\mathfrak{p}'_\alpha}$$

for every α; taking the inductive limit of each of the two members, it follows that

$$B' = K' \cap \overline{B'_{\mathfrak{q}'}}.$$

But $\overline{B'_{\mathfrak{q}'}}$, being the direct product of the normal rings L'' and $B'_{\mathfrak{q}'}$, is normal, and as it has the same total ring of fractions as K', the lemma (6.14.1.1) shows that B' is normal. □

Corollary (6.14.2). — *Let k be a field, X a k-prescheme normal (not necessarily locally Noetherian). Then, for every separable extension k' of k, $X_{(k')} = X \otimes_k k'$ is* normal.

Proof. One knows indeed (6.7.6) that the morphism $\operatorname{Spec}(k') \to \operatorname{Spec}(k)$ is then normal. □

Corollary (6.14.3). — *Let k be a field, X, Y two k-preschemes integral and normal, whose fields of rational functions $K = R(X)$, $L = R(Y)$ are separable extensions of k. Then the prescheme $X \times_k Y$ is* normal.

Proof. The question being local on X and Y, one can suppose that $X = \operatorname{Spec}(A)$, $Y = \operatorname{Spec}(B)$, where A and B are two integral rings and integrally closed, of fields of fractions K and L respectively; suppose first that A is a k-algebra of finite type, hence K is a finite type extension of k. By flatness, $A \otimes_k B$ is a sub-k-algebra of $K \otimes_k L$; now $K \otimes_k L$ is a Noetherian normal ring (by virtue of (6.7.1) or (6.14.2)), hence a direct product of finitely many integral rings C_i, so that if E_i is the field of fractions of C_i, the direct product E of the E_i is the total ring of fractions of $K \otimes_k L$; it is also the total ring of fractions of $A \otimes_k B$, since $K \otimes_k L$ is a ring of fractions of $A \otimes_k B$. This being so, one can write $A \otimes_k B = (A \otimes_k L) \cap (K \otimes_k B)$, and it follows from (6.14.2) that $A \otimes_k L$ and $K \otimes_k B$ are normal, hence $A \otimes_k B$ is normal by virtue of (6.14.1.1). **IV-2** | 174

Consider now the general case; A is then union of the filtered increasing family of its sub-k-algebras of finite type A_α, hence $A \otimes_k B$ is the inductive limit of the normal rings $A_\alpha \otimes_k B$. To prove that $A \otimes_k B$ is normal, it suffices hence (5.13.6) to prove that every irreducible component of $\operatorname{Spec}(A_\beta \otimes_k B)$ dominates one irreducible component of $\operatorname{Spec}(A_\alpha \otimes_k B)$ for $A_\alpha \subset A_\beta$, which follows immediately from the fact that B is a k-module flat, from (2.3.7, (ii)) and from the fact that A_α and A_β are integral rings. □

Proposition (6.14.4). — *Let A be a Noetherian ring, A′ a Noetherian A-algebra such that the morphism $\operatorname{Spec}(A') \to \operatorname{Spec}(A)$ is normal. Let B be an A-algebra, C the integral closure of A in B; set $B' = B \otimes_A A'$, $C' = C \otimes_A A'$, C′ being identified with a subring of B′; then C′ is the integral closure of A′ in B′.*

Proof. We shall proceed in several steps.

I) *Reduction to the case where B is reduced.* — Set $B_0 = B_{\text{red}} = B/\mathfrak{N}$ where $\mathfrak{N}$ is the nilradical of B, and let C_0 be the integral closure of A in B_0. One has the following lemma:

Lemma (6.14.4.1). — *Let A be a ring, B an A-algebra, $B_0 = B/\mathfrak{n}$ the quotient of B by a nilideal. If C_0 is the integral closure of A in B_0, the inverse image C of C_0 by the canonical homomorphism $\varphi : B \to B_0$ is the integral closure of A in B.*

Proof. Indeed, if $x \in B$ is such that $\varphi(x)$ satisfies an integral dependence equation over A, one deduces that x satisfies a relation of the form $x^n + a_1 x^{n-1} + \ldots + a_n \in \mathfrak{n}$ with $a_k \in A$, whence, by raising to a sufficiently large power, an integral dependence equation for x, with coefficients in A. □

One has therefore the exact sequence of A-modules

$$0 \longrightarrow C \longrightarrow B \longrightarrow B_0/C_0$$

whence, by flatness, the exact sequence

$$0 \longrightarrow C' \longrightarrow B' \longrightarrow B'_0/C'_0$$

where one has set $B'_0 = B_0 \otimes_A A'$, $C'_0 = C_0 \otimes_A A'$. If one proves that C'_0 is the integral closure of A′ in B'_0, the lemma (6.14.4.1) will prove that C′ is the integral closure of A′ in B′. One can therefore restrict to the case where B is an A-algebra of finite type; let $\mathfrak{q}_i$ $(1 \leqslant i \leqslant n)$ be its minimal prime ideals; as B is supposed *reduced*, it is identified with a *subring* of the product B_0 of the $B/\mathfrak{q}_i$; if C_0 is the integral closure of A in B_0, one has $C = B \cap C_0$; if one sets $B'_0 = B_0 \otimes_A A'$, $C'_0 = C_0 \otimes_A A'$, one has, by flatness, $C' = B' \cap C'_0$ ($\mathbf{0}_{\rm I}$, 6.1.3); it suffices therefore to prove that C'_0 is the integral closure of A′ in B'_0. But C_0 is the direct product of the C_i, integral closures of A in the $B_i = B/\mathfrak{q}_i$; hence C'_0 is the direct product of the $C'_i = C_i \otimes_A A'$ and it suffices to show that C'_i is the integral closure of A′ in $B'_i = B_i \otimes_A A'$. One is thus reduced to the case where B is integral and an A-algebra of finite type; if $\mathfrak{p}$ is the kernel of the homomorphism $A \to B$, one has also $B' = B \otimes_{A/\mathfrak{p}} (A'/\mathfrak{p}A')$; as the morphism $\operatorname{Spec}(A'/\mathfrak{p}A') \to \operatorname{Spec}(A/\mathfrak{p})$ is normal, one can replace A by $A/\mathfrak{p}$ and A′ by $A'/\mathfrak{p}A'$, and suppose hence that $A \subset B$.

II) *Reduction to the case where* B *is an integral* A*-algebra of finite type containing* A. — Let (B_α) be the filtered increasing family of sub-A-algebras of finite type of B, and let C_α be the integral closure of A in B_α. It follows immediately from the definition of the integral closure that C is union of the C_α; if one sets $B'_\alpha = B_\alpha \otimes_A A'$, $C'_\alpha = C_\alpha \otimes_A A'$, C'_α is contained in B'_α by flatness, and for the same reason B' is union of the filtered increasing family of the B'_α and C' union of the filtered increasing family of the C'_α. If one proves that C'_α is the integral closure of A' in B'_α, it will follow immediately that C' is the integral closure of A' in B'. One can therefore restrict to the case where B is an A-algebra of finite type; let $\mathfrak{q}_i$ $(1 \leqslant i \leqslant n)$ be its minimal prime ideals; as B is supposed *reduced*, it is identified with a *subring* of the product B_0 of the $B/\mathfrak{q}_i$; if C_0 is the integral closure of A in B_0, one has $C = B \cap C_0$; if one sets $B'_0 = B_0 \otimes_A A'$, $C'_0 = C_0 \otimes_A A'$, one has, by flatness, $C' = B' \cap C'_0$ $(\mathbf{0}_\mathrm{I},\ 6.1.3)$; it suffices therefore to prove that C'_0 is the integral closure of A' in B'_0. But C_0 is the direct product of the C_i, integral closures of A in the $B_i = B/\mathfrak{q}_i$; hence C'_0 is the direct product of the $C'_i = C_i \otimes_A A'$ and it suffices to show that C'_i is the integral closure of A' in $B'_i = B_i \otimes_A A'$. One is thus reduced to the case where B is integral and A-algebra of finite type; if $\mathfrak{p}$ is the kernel of the homomorphism $A \to B$, one has also $B' = B \otimes_{A/\mathfrak{p}} (A'/\mathfrak{p}A')$; as the morphism $\mathrm{Spec}(A'/\mathfrak{p}A') \to \mathrm{Spec}(A/\mathfrak{p})$ is normal, one can replace A by $A/\mathfrak{p}$ and A' by $A'/\mathfrak{p}A'$, and suppose hence that $A \subset B$. **IV-2** | 175

III) *Case where* A *is a field,* B *a field, finite extension of* A *and such that* A *is algebraically closed in* B. — One has then $C = A$, and A' is a Noetherian geometrically normal A-algebra, hence a direct product of integrally closed integral rings A'_i, the fields of fractions K'_i of the A'_i being *separable* extensions of A (4.6.1). The A'-algebra B' is therefore the direct product of the $B \otimes_A A'_i = B'_i$. One can therefore restrict to the case where A' is integral, its field of fractions K' being a separable extension of A. Now, as K' is a separable extension of A, $B \otimes_A K'$ is reduced (4.3.7), and as furthermore B is a primary extension of A, $B \otimes_A K'$ is integral (4.3.2); it is hence of the same type as B'. Let L' be the field of fractions of $B \otimes_A K'$ (which is also that of B'); it is obviously a composed field of $B(K')$ of its sub-fields B and K'; as A is algebraically closed in B, that K' is a separable extension of A, and that B and K' are linearly disjoint over A, K' is algebraically closed in $B(K') = L'$ (Bourbaki, *Alg.*, chap. V, § 9, exerc. 2); *a fortiori*, A', being integrally closed, is integrally closed in L', hence in B', which proves the proposition in this case.

IV) *Case where* A *is integral,* B *a field, finite extension of the field of fractions* K *of* A. — Then $B' = (A' \otimes_A K) \otimes_K B$ is a B-algebra Noetherian geometrically normal, and hence B' is a direct product of integral rings; the total ring of fractions L' of B' is then a direct product of finitely many fields. This being so, as B is the field of fractions of C, B' is a ring of fractions of C' and L' is therefore also the total ring of fractions of C'. Now $(\mathbf{0},\ 6.14.1)$ as C is a normal ring and $\mathrm{Spec}(A') \to \mathrm{Spec}(A)$ a normal morphism of Noetherian rings, C' is a normal ring; but it follows from (6.14.1.1) that C' is then integrally closed in L', and *a fortiori* in B', and hence is the integral closure of A' in B'.

V) *End of the proof.* — By part II), one can suppose that B is an A-algebra integral of finite type containing A. Let K be the field of fractions of A, L that of B, which is a finite type extension of K. Let M be the algebraic closure of K in L, which is a finite algebraic extension of K; let C_0 be the integral closure of A in M, which is also the integral closure of A in L; if one sets $C'_0 = C \otimes_A A'$, one has hence $C' = B' \cap C'_0$ by flatness $(\mathbf{0}_\mathrm{I},\ 6.1.3)$. Now, it follows from IV) that C'_0 is the integral closure of A' in $M' = M \otimes_A A'$; furthermore, M' is a Noetherian ring and the morphism $\mathrm{Spec}(M') \to \mathrm{Spec}(M)$ is normal (as we have seen in the course of IV)); applying III) to M and M' in place of A and A' and to L in place of B, one deduces that C'_0 is the integral closure of A' in L', and $C' = C'_0 \cap B'$ is the integral closure of A' in L', and hence C' is the integral closure of A' in B'. □ **IV-2** | 176

Corollary (6.14.5). — *Let* A *be a Noetherian ring,* A' *a Noetherian* A*-algebra such that the morphism* $\mathrm{Spec}(A') \to \mathrm{Spec}(A)$ *is normal. Let* B, C *be two* A*-algebras,* $\varphi : B \to C$ *an* A*-homomorphism,* D *the integral closure of* B *in* C. *If one sets* $B' = B \otimes_A A'$, $C' = C \otimes_A A'$, $D' = D \otimes_A A'$, D' *is the integral closure of* B' *in* C'.

Proof. Let (B_λ) be the filtered increasing family of sub-A-algebras of finite type of B, and set $B'_\lambda = B_\lambda \otimes_A A'$, so that B' is union of the filtered increasing family of the sub-A'-algebras of finite type B'_λ. Let D_λ be the integral closure of B_λ in C, and set $D'_\lambda = D_\lambda \otimes_A A'$, so that D is union of the D_λ and D' union of the D'_λ; if we prove that D'_λ is the integral closure of B'_λ in C', it will follow that D' is the integral closure of B' in C'. Now B_λ and B'_λ are Noetherian and the morphism

$\mathrm{Spec}(B'_\lambda) \to \mathrm{Spec}(B_\lambda)$ is normal (6.8.2); one can therefore apply (6.14.4) by replacing A, A′ and B by B_λ, B'_λ and C respectively, whence the corollary. □

One can for example apply (6.14.5) when A is its local ring *excellent* and A′ its completion $\widehat{A}$, since in this case $\mathrm{Spec}(A') \to \mathrm{Spec}(A)$ is a regular morphism (7.8.2).

6.15. Geometrically unibranch preschemes

(6.15.1). We shall say that a prescheme X is *unibranch* (resp. *geometrically unibranch*) at a point x, or that the point x is unibranch (resp. geometrically unibranch) in X if the local ring $\mathscr{O}_{X,x}$ is unibranch (resp. geometrically unibranch) (**0**, 23.2.1); we say that X is *unibranch* (resp. *geometrically unibranch*) if it is so at every point. It follows from this definition that, for X to be unibranch (resp. geometrically unibranch) at a point, it is necessary and it suffices that X_{red} be so at this point.

(6.15.2). One must take care that with the definitions of (6.15.1), a *local ring* A can be unibranch (resp. geometrically unibranch) *without* Spec(A) being so; in other terms, it can happen that there are prime ideals $\mathfrak{p}$ of A such that $A_\mathfrak{p}$ is not unibranch; it amounts to the same to say that on a prescheme, the notion of geometrically unibranch point *is not stable by generization*. We shall see this on the following example.

Let K be an algebraically closed field of characteristic 0, B the integral ring $K[U,V,W]/(U^2(U-W)-V^2(U+W))$ (U, V, W indeterminates) so that $Y=\mathrm{Spec}(B)$ is a "cone with vertex the origin, having a double generatrix". We shall designate by u, v, w the images of U, V, W in B. Let R be the field of fractions of B, and consider in R the element $t=v(u+w)/u$, which does not belong to B; let us show that $C=B[t]$ is the *integral closure* of B. One has indeed $t^2=u^2-w^2$, hence t is integral over B, and $v=tu/(u+w)$; the ring $C_1=K[t,u,w]$ is integrally closed, for it is isomorphic to $K[T,U,W]/(T^2-U^2+W^2)$ and is therefore the integral closure of the integrally closed ring $K[U,W]$ in the quadratic extension $K(U,W)(\sqrt{U^2+W^2})$ of its field of fractions (Bourbaki, *Alg. comm.*, chap. V, § 1, no 6, prop. 18). The ring of fractions $K[t,u,w,1/(u+w)]$ of C_1 is hence integrally closed. In the same way, one sees that the ring $C_2=K[t,v,w]$ is integrally closed, for t is a root of the equation $t(t-v)-w^2(2v-t)=0$, and hence $K[t,v,w,1/(t-v)]=K[t,v,w,\frac{tu}{u+w},w,\frac{u+w}{tw}]$ is integrally closed. Finally, taking into account the fact that u and w are algebraically independent over K, one proves easily that $C=K[t,u,v,w]=K[t,u,w,1/(u+w)]\cap K[t,v,w,1/(t-v)]$, which finishes showing that C is the integral closure of B. It is immediate that if $\mathfrak{m}_0$ is the maximal ideal of C lying over $\mathfrak{n}_0$, the ideal generated by u, v, w ("vertex of the cone"), there is only one maximal ideal of C lying over $\mathfrak{m}_0$, namely the ideal generated by t, u, v, w. If one sets $A=B_{\mathfrak{m}_0}$, one deduces easily that $A'=C_{\mathfrak{m}_0}$ is the integral closure of A, which is hence unibranch, and hence also geometrically unibranch since its residue field K is algebraically closed. But in A the prime ideal $\mathfrak{p}$ generated by u and v is such that the integral closure $A_\mathfrak{p}[t]$ of $A_\mathfrak{p}$ is not a local ring. **IV-2** | 177

We shall see further below (9.7.10) that when X is a locally Noetherian prescheme such that, if X′ is the normalization of X_{red}, the canonical morphism $X'\to X$ is *finite* (which will be the case if X is such that the rings of its affine open subsets are *universally Japanese* (**0**, 23.1.1))), then the set of points $x\in X$ where X is geometrically unibranch is *locally constructible*.

(6.15.3). We shall say for short that a morphism $f:X\to Y$ is *radicial at a point* $y\in Y$, if $f^{-1}(y)$ is empty or reduced to a single point x and if $\boldsymbol{k}(x)$ is a radicial extension of $\boldsymbol{k}(y)$. It amounts to the same to say that f is radicial at every point of Y or that f is radicial (**I**, 3.5.8). If $g:f^{-1}(y)\to\mathrm{Spec}(\boldsymbol{k}(y))$ is the base change inverse image of f by the base change $\mathrm{Spec}(\boldsymbol{k}(y))\to Y$, it amounts to the same to say that f is radicial at the point $y\in Y$, or that g is *radicial*.

Lemma (6.15.3.1). — *(i) Let $f:X\to Y$, $g:Y\to Z$ be two morphisms. If f is radicial at a point y and g radicial at the point $z=g(y)$, then $g\circ f$ is radicial at the point $g(y)$. The converse is true if f is surjective.*

(ii) Let $f:X\to Y$, $h:Y'\to Y$ be two morphisms, and let $f'=f_{|Y'}:X\times_Y Y'\to Y'$. Let $y'\in Y'$ and $y=h(y')$; then for f to be radicial at the point y, it is necessary and it suffices that f' be radicial at the point y'.

Proof. (i) If f is radicial at the point y and g radicial at the point z, $g^{-1}(z)$ is reduced to y and $f^{-1}(g^{-1}(z))=f^{-1}(y)$ is empty or reduced to a single point x; furthermore $\boldsymbol{k}(x)$ is a radicial **IV-2** | 178 extension of $\boldsymbol{k}(y)$ and $\boldsymbol{k}(y)$ a radicial extension of $\boldsymbol{k}(z)$, hence $\boldsymbol{k}(x)$ is a radicial extension of $\boldsymbol{k}(z)$. Conversely, suppose f surjective; if $g \circ f$ is radicial at the point $z = g(y)$, $g^{-1}(z)$ is reduced to the point y, for otherwise $f^{-1}(g^{-1}(z))$ would have at least two distinct points; furthermore, $f^{-1}(y) = f^{-1}(g^{-1}(z))$ is reduced to a single point x, and by hypothesis one has $\boldsymbol{k}(z) \subset \boldsymbol{k}(y) \subset \boldsymbol{k}(x)$, and $\boldsymbol{k}(x)$ is a radicial extension of $\boldsymbol{k}(z)$, hence $\boldsymbol{k}(y)$ is a radicial extension of $\boldsymbol{k}(z)$ and $\boldsymbol{k}(x)$ radicial over $\boldsymbol{k}(y)$.

(ii) Let $g : f^{-1}(y) \to \mathrm{Spec}(\boldsymbol{k}(y))$, $g' : f'^{-1}(y') \to \mathrm{Spec}(\boldsymbol{k}(y'))$ be the morphisms inverse images of f and f' respectively; as $f'^{-1}(y') = f^{-1}(y) \otimes_{\boldsymbol{k}(y)} \boldsymbol{k}(y')$ (**I**, 3.6.4), g' is the inverse image of g and the assertion reduces to (2.6.1, (v)). ☐

Suppose then X a prescheme *reduced* not having more than a *finite* number of irreducible components, and let X′ be its *normalization* (**II**, 6.3.8); we say (*loc. cit.*) that the canonical morphism $f : \mathrm{X}' \to \mathrm{X}$ is surjective. The definition (6.15.1) shows then that for X to be geometrically unibranch at a point, it is necessary and it suffices that f be *radicial at this point*; for X to be geometrically unibranch, it is necessary and it suffices that f be *radicial*.

(6.15.4). Generalizing the definition given in (**I**, 2.2.9), we shall say, for two reduced preschemes X, Y, a morphism $f : \mathrm{X} \to \mathrm{Y}$ is *birational* if the restriction of f to the set of maximal points of X is a *bijection* of this set onto the set of maximal points of Y, and if, for every maximal point y of Y, the morphism $\mathrm{X} \times_{\mathrm{Y}} \mathrm{Spec}(\mathscr{O}_y) \to \mathrm{Spec}(\mathscr{O}_y)$ induced by f is an isomorphism (in other words, if for the fibre $f^{-1}(y)$ reduced to a single point x (maximal in X) and if the homomorphism $\boldsymbol{k}(y) \to \boldsymbol{k}(x)$ induced by f is bijective); this notion reduces to that of (**I**, 2.2.9) when X and Y have only a *finite* number of irreducible components.

Lemma (6.15.4.1). — *Let $f : \mathrm{X} \to \mathrm{Y}$ be a morphism, $g : \mathrm{Y}' \to \mathrm{Y}$ a flat morphism, $\mathrm{X}' = \mathrm{X} \times_{\mathrm{Y}} \mathrm{Y}'$, $f' = f_{|\mathrm{Y}'} : \mathrm{X}' \to \mathrm{Y}'$. If f_{red} is birational, so is f'_{red}.*

Proof. Indeed, if y' is a maximal point of Y′, one knows (2.3.4, (ii)) that $y = g(y')$ is a maximal point of Y; there is a unique point x of X in $f^{-1}(y)$ by hypothesis; since moreover $\boldsymbol{k}(x) = \boldsymbol{k}(y)$. It follows therefore from (**I**, 3.4.9) that $f'^{-1}(y')$ is reduced to a single point x' and that $\boldsymbol{k}(x') = \boldsymbol{k}(y')$. We conclude from the reasoning that, noting (2.3.7, (ii)), every irreducible component of X′ dominates one irreducible component of Y′. ☐

Proposition (6.15.5). — *Let $f : \mathrm{X} \to \mathrm{Y}$ be a morphism such that f_{red} is entire and birational* (6.15.4), *hence surjective.*

- *(i) For Y to be geometrically unibranch at a point y, it is necessary and it suffices that f be radicial at the point y and that X be geometrically unibranch at the unique point x of $f^{-1}(y)$.*
- *(ii) For Y to be geometrically unibranch, it is necessary and it suffices that X be geometrically unibranch and that f be radicial.*

Proof. One can obviously restrict to the case where X and Y are *reduced*; the fact that f is *surjective* follows from the fact that f is closed (**II**, 6.1.10) and that $f(\mathrm{X})$ contains all the maximal points of Y. This also shows immediately that (i) implies (ii). Using (**I**, 3.6.5) and (**II**, 6.1.5), one can suppose, to prove (i), that $\mathrm{Y} = \mathrm{Spec}(\mathscr{O}_{\mathrm{Y},y})$, in other words $\mathrm{Y} = \mathrm{Spec}(\mathrm{A})$ (with $\mathrm{A} = \mathscr{O}_{\mathrm{X},x}$) is a local scheme. **IV-2** | 179
Note that $\mathrm{A}' = \mathscr{O}_{\mathrm{X}',x'}$ is by hypothesis a faithfully flat A-module, hence containing A, and hence the hypothesis that X is geometrically unibranch at the point x, or the hypothesis that X′ is geometrically unibranch at the point x', both imply that A is a local ring *integral* (since A, being reduced, is also isomorphic to a subring of $\mathrm{A}'_{\mathrm{red}}$). Let K be the field of fractions of A, B the integral closure of A, and set $\mathrm{Y} = \mathrm{Spec}(\mathrm{B})$; it amounts to the same to say that X is geometrically unibranch at the point x or that the morphism $g : \mathrm{Y} \to \mathrm{X}$ is radicial at the point x (6.15.3). Let $\mathrm{Y}' = \mathrm{Y} \otimes_k k' = \mathrm{Y} \times_{\mathrm{X}} \mathrm{X}'$ so that one has the commutative diagram

$$\begin{tikzcd} \mathrm{Y} \arrow[r, "h"] & \mathrm{Y}' \\ \mathrm{X} \arrow[u, "g"] \arrow[r, "f"'] & \mathrm{X}' \arrow[u, "g'"'] \end{tikzcd}$$

Note that f is a flat morphism; hence (6.15.4.1) the entire morphism g'_{red} is birational. As Y is normal, Y′ is geometrically unibranch (6.15.6). For X to be geometrically unibranch at the point x, it is necessary and it suffices therefore that g' be radicial at the point x' (6.15.5). Now, x is the projection of x' in X and it is equivalent to say that g is radicial at the point x or that g' is radicial at the point x' (6.15.3.1); finally, for X to be geometrically unibranch at this point, it is necessary and it suffices that g be radicial at this point, whence the proposition. □

Proposition (6.15.6). — *Let k be a field,* X *a k-prescheme. If* X *is normal, then, for every extension k' of k,* $\mathrm{X}' = \mathrm{X} \otimes_k k'$ *is* geometrically unibranch.

Proof. One knows that k' is an algebraic extension of a pure extension k_0 of k, and if k'' is the largest separable extension of k_0 contained in k', k' is a radicial extension of k'' and k'' a separable extension of k. One knows (6.14.2) that $\mathrm{X}'' = \mathrm{X} \otimes_k k''$ is normal; as $\mathrm{X} \otimes_k k' = \mathrm{X}'' \otimes_{k''} k'$, one sees that one can restrict to the case where the extension k' of k is *radicial*. Furthermore (**I**, 3.6.5), one can suppose that $\mathrm{X} = \mathrm{Spec}(\mathrm{A})$, where A is a *local integral and integrally closed* ring (since X is normal). The projection morphism $f : \mathrm{X}' \to \mathrm{X}$ is a universal homeomorphism, since $\mathrm{Spec}(k') \to \mathrm{Spec}(k)$ is a universal homeomorphism (2.4.5); as $\mathrm{X}' = \mathrm{Spec}(\mathrm{A}')$ where $\mathrm{A}' = \mathrm{A} \otimes_k k'$, one sees therefore that A′ is a local ring whose nilradical $\mathfrak{N}'$ is the unique minimal prime ideal, whence $\mathrm{X}'_{\mathrm{red}} = \mathrm{Spec}(\mathrm{A}'_0)$, where $\mathrm{A}'_0 = \mathrm{A}'/\mathfrak{N}'$ is a local integral ring; furthermore, if K is the field of fractions of A, the field of fractions K'_0 of A'_0 is radicial over K, since the morphism f is radicial. But A'_0 is integer over A, its integral closure B is also the integral closure of A, and one knows (Bourbaki, *Alg. comm.*, chap. V, § 2, no 3, lemma 3) that B is the set of $x \in \mathrm{K}'_0$ of which a power p^m-th (for m large enough) belongs to A (p being the characteristic exponent of K); furthermore there exists only a single prime ideal of B lying over every prime ideal of A; in particular B is a local ring and its residue field is a radicial extension of that of A, and *a fortiori* of the same type for A'_0, which proves that A'_0 is geometrically unibranch, and hence so is X′ as well. □

Proposition (6.15.7). — *Let k be a field,* X *a k-prescheme, k' an extension of k,* $\mathrm{X}' = \mathrm{X} \otimes_k k'$. *Let x' be a point of* X′*, x its projection in* X*. For* X *to be geometrically unibranch at the point x, it is necessary and it suffices that* X′ *be geometrically unibranch at the point x'. For* X *to be geometrically unibranch, it is necessary and it suffices that* X′ *be so.*

Proof. The second assertion follows from the first and from the fact that the projection $f : \mathrm{X}' \to \mathrm{X}$ is **IV-2** | 180
a surjective morphism. To prove the first assertion, one can, by virtue of (**I**, 5.1.8), restrict to the case where X is reduced, and by virtue of (**I**, 3.6.5), to the case $\mathrm{X} = \mathrm{Spec}(\mathrm{A})$ (with $\mathrm{A} = \mathscr{O}_{\mathrm{X},x}$) is a local scheme. Note that $\mathrm{A}' = \mathscr{O}_{\mathrm{X}',x'}$ is by hypothesis a faithfully flat A-module, hence containing A, and hence the hypothesis that X is geometrically unibranch at the point x, or the hypothesis that X′ is geometrically unibranch at the point x', both imply that A is a local ring *integral* (since A, being reduced, is also isomorphic to a subring of $\mathrm{A}'_{\mathrm{red}}$). Let K be the field of fractions of A, B the integral closure of A, and set $\mathrm{Y} = \mathrm{Spec}(\mathrm{B})$; it amounts to the same to say that X is geometrically unibranch at the point x or that the morphism $g : \mathrm{Y} \to \mathrm{X}$ is radicial at the point x (6.15.3). Let $\mathrm{Y}' = \mathrm{Y} \otimes_k k' = \mathrm{Y} \times_{\mathrm{X}} \mathrm{X}'$ so that one has the commutative diagram

$$\begin{tikzcd} \mathrm{Y} \arrow[r, "h"] & \mathrm{Y}' \\ \mathrm{X} \arrow[u, "g"] \arrow[r, "f"'] & \mathrm{X}' \arrow[u, "g'"'] \end{tikzcd}$$

Note that f is a flat morphism; hence (6.15.4.1) the entire morphism g'_{red} is birational. As Y is normal, Y′ is normal (and *a fortiori* geometrically unibranch) (6.14.1). For X′ to be geometrically unibranch at x', it is necessary and it suffices therefore that g' be radicial at this point (6.15.5); we conclude hence from (6.15.3.1) that f' is radicial at every point $x' \in p^{-1}(x)$, and it follows then from (6.15.5) that X′ is geometrically unibranch (hence integral since it is reduced) at each of these points. □

Lemma (6.15.8). — *Let k be a separably closed field (in other words, such that the algebraic closure of k is* radicial *over k), X a k-prescheme locally of finite type over k, x a closed point of X. If X is unibranch at the point x, it is* geometrically unibranch *at this point.*

Proof. Indeed, one knows (**I**, 6.4.2) that $\boldsymbol{k}(x)$ is an *algebraic* extension of k; as the residue field of the integral closure $(\mathscr{O}_x)_{\text{red}}$ (integral closure which is by hypothesis a local ring) is an algebraic extension of $\boldsymbol{k}(x)$, it is a radicial extension of k by hypothesis, hence also of $\boldsymbol{k}(x)$. □

Corollary (6.15.9). — *Let k be a field, X a k-prescheme locally of finite type over k, k' a separable extension close of k (in other words, such that the algebraic closure of k is radicial over k'); then, for X to be geometrically unibranch, it is necessary and it suffices that $X' = X \otimes_k k'$ be unibranch.*

Proof. In view of (6.15.7), one is reduced to proving that if X is unibranch and k separably closed, then X is geometrically unibranch. Now, X is geometrically unibranch at its closed points (6.15.8); we conclude from (10.4.9) that X is geometrically unibranch at all its points, relying on the fact (pointed out at the end of (6.15.2)) that the set of points where X is geometrically unibranch is constructible (of course, the corollary (6.15.9) will not be used before that point). □

This result justifies, to a certain extent, the terminology of "geometrically unibranch".

Proposition (6.15.10). — *Let Y, Y' be two locally Noetherian preschemes, $g : Y' \to Y$ a normal morphism (6.8.1), $f : X \to Y$ a morphism; set $X' = X \times_Y Y'$ and let $p : X' \to X$ be the canonical projection, x' a point of X'. Then, if X is reduced (resp. geometrically unibranch, resp. integral and geometrically unibranch) at the point $x = p(x')$, X' is reduced (resp. geometrically unibranch, resp. integral and geometrically unibranch) at the point x'.*

Proof. By virtue of (**I**, 3.6.5), one can restrict to the case where $Y = \operatorname{Spec}(A)$, $Y' = \operatorname{Spec}(A')$, **IV-2** | 181
$X = \operatorname{Spec}(B)$, where A, A', B are local rings, the homomorphisms $A \to A'$ and $A \to B$ being local, A, A' Noetherian rings, and x being the closed point of X; it suffices to prove that if B is reduced (resp. geometrically unibranch, resp. integral and geometrically unibranch) then $B' = B \otimes_A A'$ is also geometrically unibranch at the points of $p^{-1}(x)$, resp. $\operatorname{Spec}(B')$ is integral and geometrically unibranch at these points). Suppose first B reduced; B is union of the filtered increasing family of its sub-A-algebras of finite type B_λ, and by flatness, B' is union of the filtered increasing family of the sub-A'-algebras $B'_\lambda = B_\lambda \otimes_A A'$. Now, the morphism $\operatorname{Spec}(B'_\lambda) \to \operatorname{Spec}(B_\lambda)$ is normal (6.8.2), and *a fortiori* reduced; the fact that B'_λ is reduced is consequence of (3.3.5); one concludes that B' itself is reduced by (5.13.2).

Suppose now B geometrically unibranch; in view of (**I**, 5.1.8), one can furthermore suppose B reduced, hence *integral*. Let C be its integral closure, which is by hypothesis a local ring; set $Z = \operatorname{Spec}(C)$, $C' = C \otimes_A A'$, $Z' = \operatorname{Spec}(C') = Z \times_X X'$, so that one has the commutative diagram

$$\begin{tikzcd} Z \arrow[r] & Z' \\ X \arrow[u, "l"] \arrow[r, "p"'] & X' \arrow[u, "l'"'] \end{tikzcd}$$

By virtue of the first part of the reasoning, X' is *reduced*; on the other hand, as $Z' = Z \times_Y Y'$, it follows from (6.14.1) that Z' is normal (and *a fortiori* geometrically unibranch). As f is entire and birational, so is f' by (6.15.4.1), since p is flat. Finally, the hypothesis that X is geometrically unibranch at the point x implies that f is radicial at this point (6.15.5); we conclude hence from (6.15.3.1) that f' is radicial at every point $x' \in p^{-1}(x)$, and it follows then from (6.15.5) that X' is geometrically unibranch (hence integral since it is reduced) at each of these points. □

Remarks (6.15.11). — (i) In the proof of (6.15.10), one cannot dispense with appealing to (6.14.1), even when $X = Y$, for the argument then uses the integral closure of the ring B, which need not be Noetherian even when B is.

(ii) The example (6.5.5, (ii)) shows that in (6.15.10), one cannot replace "geometrically unibranch" by "integral" in the statement, even if the residue field $\boldsymbol{k}(x)$ is algebraically closed and the morphism g is étale.

Nor can "geometrically unibranch" be replaced there by "unibranch". Indeed, let

$$A = \mathbb{R}[[U, V]]/(U^2 + V^2)$$

and let u, v be the images of U, V in A; the maximal ideal of A is $Au + Av$. The integral closure of A is the ring $A[t]$, where $t = u/v$ satisfies $t^2 = -1$, so that $A[t]$ is isomorphic to the local ring $\mathbb{C}[[U]]$. Since the residue field of $\mathbb{C}[[U]]$ is $\mathbb{C}$, A is unibranch but not geometrically unibranch. Yet $A \otimes_{\mathbb{R}} \mathbb{C}$ is not integral: it is isomorphic to

$$\mathbb{C}[[U, V]]/((U - iV)(U + iV)).$$

§7. Relations between a Noetherian local ring and its completion. Excellent rings

This section is mainly devoted to the exposition of certain properties of Noetherian rings, generally stable under passage to an algebra of finite type or under localization, which hold for the rings most often encountered (algebras of finite type over $\mathbb{Z}$, or over a field, or over a complete Noetherian local ring), without holding for all Noetherian rings. A first series of properties, connected with dimension theory and notably with the chain condition, is the subject of nos. 1 and 2; all the properties considered hold for quotients of regular Noetherian rings, and their proofs in this case are for the most part easy and well known [30]; consequently, for these rings the developments of §§ 1 and 2 are of no interest.

This is no longer the case for the properties studied in nos. 3, 4 and 5 (which do not depend on nos. 1 and 2); their proofs, even in the case of localizations of algebras of finite type over a field or over $\mathbb{Z}$ (where they are due for the most part to Zariski and Nagata), are most often delicate. Classical examples are the equivalences A normal $\Longleftrightarrow$ $\widehat{A}$ normal, and A reduced $\Longleftrightarrow$ $\widehat{A}$ reduced. We develop a systematic method for formulating and proving such properties, with the aid of the properties of the *fibres* of the canonical morphism $\mathrm{Spec}(\widehat{A}) \to \mathrm{Spec}(A)$, and using the notions and results set out in § 6; the success of this method ultimately rests on the excellent properties of *complete local rings* and of the rings deduced from them by localization or passage to an algebra of finite type. In this regard, Nagata's theorem (6.12.7), saying that for such a ring the singular locus in $\mathrm{Spec}(A)$ is closed, plays a crucial role; the same is true (as concerns permanence properties) of the regularity criterion (**0**, 22.3.4), which is more technical in nature.

Finally, in nos. 6 and 7, we apply the results obtained to the study of the finiteness of the integral closure of Noetherian integral rings.

The reader will note that the most delicate results of § 7 will be used only sparingly in the remainder of Chapter IV, and even in the later chapters.

7.1. Formal equidimensionality and formally catenary rings **IV-2 | 183**

Definition (7.1.1). — We say that a local Noetherian ring A is *formally equidimensional* if its completion $\widehat{A}$ is equidimensional (**0**, 16.1.4).

Proposition (7.1.2). — *Let* A *be a local Noetherian ring,* $\mathfrak{p}_i$ *(*$1 \leqslant i \leqslant n$*) its minimal prime ideals. For* A *to be formally equidimensional, it is necessary and sufficient that the* $A/\mathfrak{p}_i$ *be formally equidimensional and that* A *be equidimensional (in other words, that the* $A/\mathfrak{p}_i$ *have the same dimension).*

Proof. Indeed, this follows from the fact that for every prime ideal $\mathfrak{p}'$ of $\widehat{A}$, $\mathfrak{p}' \cap A$ contains one of the $\mathfrak{p}_i$, hence $\mathfrak{p}'$ contains one of the $\mathfrak{p}_i\widehat{A}$, and $\widehat{A}/\mathfrak{p}_i\widehat{A} = (A/\mathfrak{p}_i) \otimes_A \widehat{A}$ is the completion of the local ring $A/\mathfrak{p}_i$ (**0**, 7.3.3), hence has the same dimension. Every maximal chain of prime ideals of $\widehat{A}$ therefore identifies canonically with a maximal chain of prime ideals of one of the $\widehat{A}/\mathfrak{p}_i\widehat{A}$, and conversely, whence the conclusion. □

Proposition (7.1.3). — *Let* A, A′ *be two local Noetherian rings,* $\mathfrak{m}$ *the maximal ideal of* A, $\varphi : A \to A'$ *a local homomorphism; suppose that* A′ *is a flat* A*-module, and that* A′ *is equidimensional and catenary. Then:*

i) A *is equidimensional and catenary.*
ii) *Suppose in addition that* $\mathfrak{m}A'$ *is an ideal of definition of* A′*. Then, if* $\mathfrak{a}$ *is an ideal of* A*, for* $A'/\mathfrak{a}A'$ *to be equidimensional, it is necessary and sufficient that* $A/\mathfrak{a}A$ *be so. In particular, for every prime ideal* $\mathfrak{p}$ *of* A, $A'/\mathfrak{p}A'$ *is equidimensional.*

Proof. Let us first prove the second assertion of (ii). Set $\mathrm{X} = \mathrm{Spec}(\mathrm{A})$, $\mathrm{X}' = \mathrm{Spec}(\mathrm{A}')$, $\mathrm{Y} = \mathrm{V}(\mathfrak{p}) = \mathrm{Spec}(\mathrm{A}/\mathfrak{p})$, $\mathrm{Y}' = \mathrm{V}(\mathfrak{p}\mathrm{A}') = \mathrm{Spec}(\mathrm{A}'/\mathfrak{p}\mathrm{A}')$; if $f : \mathrm{X}' \to \mathrm{X}$ is the morphism corresponding to φ, Y' is also the closed sub-prescheme $f^{-1}(\mathrm{Y})$ of X'. As $\mathfrak{m}\mathrm{A}'$ is an ideal of definition of A', we have

(7.1.3.1) $$\dim(\mathrm{X}) = \dim(\mathrm{X}')$$

by virtue of (6.1.3); similarly $\mathfrak{m}\mathrm{A}'/\mathfrak{p}\mathrm{A}'$ is an ideal of definition of $\mathrm{A}'/\mathfrak{p}\mathrm{A}'$ and Y' is flat over Y (2.1.4), hence (6.1.3)

(7.1.3.2) $$\dim(\mathrm{Y}) = \dim(\mathrm{Y}').$$

Let y be the generic point of Y, Y'_i $(1 \leqslant i \leqslant r)$ the irreducible components of Y', y'_i the generic point of Y'_i $(1 \leqslant i \leqslant r)$; we have $f(y'_i) = y$ for all i (2.3.4). On the other hand, y'_i is the maximal point of the fibre $f^{-1}(y)$ (**0**, 2.1.8), hence $\mathscr{O}_{\mathrm{X}',y'_i} \otimes_{\mathscr{O}_{\mathrm{X},y}} \boldsymbol{k}(y) = \mathscr{O}_{\mathrm{X}',y'_i}/\mathfrak{m}_y\mathscr{O}_{\mathrm{X}',y'_i}$ is of dimension 0, in other words $\mathfrak{m}_y\mathscr{O}_{\mathrm{X}',y'_i}$ is an ideal of definition of $\mathscr{O}_{\mathrm{X}',y'_i}$; we can again apply (6.1.3), which gives

(7.1.3.3) $$\dim(\mathscr{O}_{\mathrm{X}',y'_i}) = \dim(\mathscr{O}_{\mathrm{X},y})$$

that is to say (5.1.2)

(7.1.3.4) $$\mathrm{codim}(\mathrm{Y}'_i, \mathrm{X}') = \mathrm{codim}(\mathrm{Y}, \mathrm{X})$$

for all i. As A' is equidimensional and catenary, we have, by virtue of (**0**, 14.3.5) **IV-2** | 184

(7.1.3.5) $$\dim(\mathrm{X}') = \dim(\mathrm{Y}'_i) + \mathrm{codim}(\mathrm{Y}'_i, \mathrm{X}')$$

for all i; by virtue of (7.1.3.1), (7.1.3.2) and (7.1.3.4) and the inequality $\dim(\mathrm{Y}'_i) \leqslant \dim(\mathrm{Y}')$, we deduce

(7.1.3.6) $$\dim(\mathrm{X}) \leqslant \dim(\mathrm{Y}) + \mathrm{codim}(\mathrm{Y}, \mathrm{X})$$

hence the two sides of this inequality are equal by (**0**, 14.2.2.2); moreover this equality implies

(7.1.3.7) $$\dim(\mathrm{Y}'_i) = \dim(\mathrm{Y}') = \dim(\mathrm{Y})$$

for all i, which proves the second assertion of (ii).

Let us now prove the first assertion of (ii). Let $\mathfrak{p}_j$ $(1 \leqslant j \leqslant n)$ be the minimal prime ideals of A among those containing $\mathfrak{a}$, and let $\mathfrak{p}'_{jh}$ be the prime ideals of A' minimal among those containing $\mathfrak{p}_j\mathrm{A}'$ $(1 \leqslant h \leqslant m_j)$; we know then (2.3.4) that the $\mathfrak{p}'_{jh}$ $(1 \leqslant j \leqslant n, 1 \leqslant h \leqslant m_j$ for all $j)$ are also the minimal prime ideals among those containing $\mathfrak{a}\mathrm{A}'$. From what we have just seen, for all j, the dimensions of the rings $\mathrm{A}'/\mathfrak{p}'_{jh}$ $(1 \leqslant h \leqslant m_j)$ are all equal and are equal to $\dim(\mathrm{A}'/\mathfrak{p}_j\mathrm{A}')$, itself equal to $\dim(\mathrm{A}/\mathfrak{p}_j)$ by (7.1.3.2). To say that $\mathrm{A}'/\mathfrak{a}\mathrm{A}'$ is equidimensional therefore means that the dimensions of the $\mathrm{A}/\mathfrak{p}_j$ are all equal, that is to say that $\mathrm{A}/\mathfrak{a}$ is equidimensional.

Let us finally prove (i). Let $\mathfrak{r}'$ be a prime ideal of A' minimal among those containing $\mathfrak{m}\mathrm{A}'$, and set $\mathrm{A}'' = \mathrm{A}'_{\mathfrak{r}'}$; as A'' is a flat A'-module, it is also a flat A-module; moreover A'' is equidimensional and catenary (**0**, 16.1.4), and $\mathfrak{m}\mathrm{A}''$ is an ideal of definition of A''. We can therefore restrict ourselves to the case where $\mathfrak{m}\mathrm{A}'$ is an ideal of definition of A'. If then $\mathfrak{p}$ and $\mathfrak{q} \subset \mathfrak{p}$ are two prime ideals of A, we can apply (ii) to $\mathrm{A}/\mathfrak{q}$ and $\mathrm{A}'/\mathfrak{q}\mathrm{A}'$, which is equidimensional and flat over $\mathrm{A}/\mathfrak{q}$; if $\mathrm{Z} = \mathrm{Spec}(\mathrm{A}/\mathfrak{q})$ and $\mathrm{Y} = \mathrm{Spec}(\mathrm{A}/\mathfrak{p})$, we have $\dim(\mathrm{Z}) = \dim(\mathrm{Y}) + \mathrm{codim}(\mathrm{Y}, \mathrm{Z})$; moreover one can apply (7.1.3.6), which shows that $\mathrm{codim}(\mathrm{Y}, \mathrm{X}) = \dim \mathrm{X} - \dim \mathrm{Y}$; as X is equicodimensional, these relations show that it is biequidimensional by virtue of (**0**, 14.3.3). □

Corollary (7.1.4). — *Let* A *be a local Noetherian ring that is formally equidimensional. Then:*

i) A *is equidimensional and catenary (in other words, biequidimensional).*
ii) *Let* $\mathfrak{a}$ *be an ideal of* A*; for* $\mathrm{A}/\mathfrak{a}$ *to be equidimensional, it is necessary and sufficient that* $\mathrm{A}/\mathfrak{a}$ *be formally equidimensional. In particular, for every prime ideal* $\mathfrak{p}$ *of* A, $\mathrm{A}/\mathfrak{p}$ *is formally equidimensional.*

Proof. If $\mathfrak{m}$ is the maximal ideal of A, $\mathfrak{m}\widehat{\mathrm{A}}$ is an ideal of definition of $\widehat{\mathrm{A}}$. By hypothesis $\widehat{\mathrm{A}}$ is equidimensional, and on the other hand it is known to be catenary (5.6.4); it suffices then to apply (7.1.3) with $\mathrm{A}' = \widehat{\mathrm{A}}$. □

Corollary (7.1.5). — *Let* A *be a local Noetherian ring such that there exists a finite type* A*-module* M *that is a Cohen-Macaulay* A*-module and for which* $\mathrm{Supp}(\mathrm{M}) = \mathrm{Spec}(\mathrm{A})$ *(this holds for example if* A *is a Cohen-Macaulay ring). Then* A *is formally equidimensional, hence* (7.1.4) *for a quotient ring* B *of* A *to be formally equidimensional, it is necessary and sufficient that it be equidimensional.*

Proof. Indeed, $\widehat{M} = M \otimes_A \widehat{A}$ is a Cohen-Macaulay $\widehat{A}$-module (**0**, 16.5.2), with support equal to Spec($\widehat{A}$); hence (**0**, 16.5.4), $\widehat{A}$ is equidimensional. □ **IV-2** | 185

Remark (7.1.6). — We have seen (6.3.8) that under the hypotheses of (7.1.5), for every quotient ring B of A, the fibres of the canonical morphism $\operatorname{Spec}(\widehat{B}) \to \operatorname{Spec}(B)$ are preschemes of Cohen-Macaulay; hence (6.4.3) and (5.7.5), *for* B *to have no embedded associated prime ideals, it is necessary and sufficient that the same hold for* $\widehat{B}$.

Lemma (7.1.7). — *Let* A *be a local Noetherian ring,* $\mathfrak{p}_i$ $(1 \leqslant i \leqslant r)$ *its minimal prime ideals. Suppose that each of the rings* $A/\mathfrak{p}_i$ *is formally equidimensional. Then, for every prime ideal* $\mathfrak{q}$ *of* A *and every* i *such that* $\mathfrak{p}_i \subset \mathfrak{q}$, *the ring* $A_\mathfrak{q}/\mathfrak{p}_i A_\mathfrak{q}$ *is formally equidimensional.*

Proof. As $A_\mathfrak{q}/\mathfrak{p}_i A_\mathfrak{q}$ is the local ring of $A/\mathfrak{p}_i$ at the prime ideal $\mathfrak{q}/\mathfrak{p}_i$, we can restrict ourselves to the case where A is integral and formally equidimensional. Set $A' = \widehat{A}$, and let $\mathfrak{q}'$ be one of the prime ideals of A' minimal among those containing $\mathfrak{q}A'$; if we set $B = A_\mathfrak{q}$, $B' = A'_{\mathfrak{q}'}$, then B' is a flat B-module (**0**, 6.3.2). Set $C = \widehat{B}$, $C' = \widehat{B'}$; as B' is a flat B-module, we know that C' is a flat C-module (Bourbaki, *Alg. comm.*, chap. III, § 5, n° 4, prop. 4). As A' is catenary (5.6.4) and equidimensional by hypothesis, the same holds for $B' = A'_{\mathfrak{q}'}$ (**0**, 16.1.4); moreover, as A' is isomorphic to a quotient of a regular ring by the theorem of Cohen (**0**, 19.8.8), the same holds for B' (**0**, 17.3.9); we conclude therefore from (7.1.5) that C' is equidimensional. On the other hand, C' is catenary (5.6.4), hence C is equidimensional by virtue of (7.1.3), (ii). □

Theorem (7.1.8). — *Let* A *be a local Noetherian ring. The following conditions are equivalent:*

a) *Every integral quotient ring of* A *is formally equidimensional.*
b) *The quotient rings of* A *by its minimal prime ideals are formally equidimensional.*
c) *Every local ring* B *that is an A-algebra essentially of finite type* (1.3.8) *and that is equidimensional, is formally equidimensional.*

Proof. It is trivial that *c*) implies *a*) and that *a*) implies *b*). On the other hand, as every prime ideal of A contains a minimal prime ideal of A, *b*) implies *a*) by virtue of (7.1.4), (ii). It remains to see that *a*) implies *c*).

It suffices to prove that the quotients of B by its minimal prime ideals are formally equidimensional (7.1.2); as every quotient ring of B is also an A-algebra essentially of finite type (1.3.9), we can first suppose B *integral*. If $\mathfrak{q}$ is the inverse image in A of the maximal ideal of B, we know that B is also an $A_\mathfrak{q}$-algebra essentially of finite type (1.3.10), and it follows from *a*) and from (7.1.7) that every integral quotient of $A_\mathfrak{q}$ is formally equidimensional; we can therefore suppose that the homomorphism $A \to B$ is a *local* homomorphism. The kernel $\mathfrak{r}$ of this homomorphism is then a prime ideal of A, and by virtue of *a*), every integral quotient ring of $A/\mathfrak{r}$ is formally equidimensional; as B is an $(A/\mathfrak{r})$-algebra essentially of finite type, we see that we can also suppose that A is *integral* and is a subring of B. We know (1.3.11) that B is a quotient of a local ring of the form $C_\mathfrak{p}$, where $C = A[T_1, \ldots, T_n]$ is a polynomial algebra and $\mathfrak{p}$ is a prime ideal of C above the maximal ideal $\mathfrak{m}$ of A. By virtue of (7.1.7), it suffices to prove that $C_\mathfrak{p}$ is formally equidimensional, in other words one can restrict to the case where $B = C_\mathfrak{p}$. **IV-2** | 186

Set $A' = \widehat{A}$, and $C' = A'[T_1, \ldots, T_n] = C \otimes_A A'$; there is a unique prime ideal $\mathfrak{p}'$ of C' above the maximal ideal $\mathfrak{m}A'$ of A', hence above $\mathfrak{p}$; set $B' = C'_{\mathfrak{p}'}$; the homomorphism $B \to B'$ is local and makes B' a flat B-module. We know that $\widehat{B'}$ is a flat $\widehat{B}$-module (Bourbaki, *Alg. comm.*, chap. III, § 5, n° 4, prop. 4); as $\widehat{B'}$ is catenary (5.6.4), it will suffice to prove that $\widehat{B'}$ is *equidimensional*, in order to deduce by (7.1.3), (i) that $\widehat{B}$ is so as well, which will complete the proof.

Now, A' is a quotient of a regular ring by the theorem of Cohen (**0**, 19.8.8), hence by virtue of (7.1.5), to show that B' is formally equidimensional, it suffices to prove that B' is equidimensional, since C' is a quotient of a regular ring, hence catenary (5.6.4). But the minimal prime ideals of C' are the ideals $\mathfrak{q}'C'$, where $\mathfrak{q}'$ ranges over the minimal prime ideals of A' (5.5.3), and we have $C'/\mathfrak{q}'C' = (A'/\mathfrak{q}')[T_1, \ldots, T_n]$. As A' is equidimensional by hypothesis (since A is integral), the same holds for C' by (5.5.4). □

Definition (7.1.9). — When the equivalent conditions of (7.1.8) are satisfied, we say that A is a *formally catenary* ring.

For a local Noetherian ring, it is therefore equivalent to say that it is formally equidimensional or formally catenary and equidimensional, by virtue of (7.1.2).

Proposition (7.1.10). — *Every local quotient ring of a local Cohen-Macaulay ring is formally catenary.*

Proof. This follows immediately from (7.1.8) and (7.1.5) applied to the integral quotient rings of A. □

Proposition (7.1.11). — i) *A local Noetherian ring that is formally catenary is universally catenary.*

ii) *If* A *is a local Noetherian ring that is formally catenary, every local ring* B *that is an A-algebra essentially of finite type is formally catenary.*

Proof. Assertion (ii) follows immediately from condition c) of (7.1.8) and from the fact that if C is a B-algebra essentially of finite type, C is also an A-algebra essentially of finite type (1.3.9). For the proof of (i), let us first note that by virtue of condition b) of (7.1.8), a local Noetherian ring that is formally catenary A is catenary, since the quotients of A by its minimal prime ideals are so (7.1.4). If now E is an A-algebra of finite type, it follows from what precedes and from (ii) that every local ring of E at a prime ideal is catenary, hence E is catenary. Therefore A is universally catenary. □

Remarks (7.1.12). — *i)* We do not know if, conversely, a local Noetherian ring that is universally catenary is always formally catenary.

ii) A local Noetherian ring A of dimension 1 is necessarily equidimensional, since its maximal ideal cannot be minimal (for in that case A would have dimension 0). As $\dim(\widehat{A}) = 1$, this shows that A is even *formally equidimensional*, and *a fortiori* formally catenary (hence *universally catenary*). By contrast, the local ring of dimension 2 defined in (5.6.11), which is catenary but not universally catenary, is *a fortiori* not formally catenary.

IV-2 | 187

Corollary (7.1.13). — *Let* Y *be an irreducible prescheme locally Noetherian of dimension* 1*,* X *an irreducible prescheme,* $f : X \to Y$ *a dominant morphism of finite type,* ξ*,* η *the generic points of* X *and* Y *respectively. Then, for all* $y \in f(X)$*, the dimensions of the irreducible components of* $f^{-1}(y)$ *are all equal to* $\operatorname{deg.tr}_{\boldsymbol{k}(\eta)} \boldsymbol{k}(\xi)$.

Proof. By hypothesis, $f^{-1}(\eta)$ is irreducible of generic point ξ and of dimension $\operatorname{deg.tr}_{\boldsymbol{k}(\eta)} \boldsymbol{k}(\xi)$ (5.2.1). As Y is irreducible and of dimension 1, we have $\dim(\mathscr{O}_y) = 1$ for all $y \neq \eta$, and $\mathscr{O}_y$ is universally catenary by virtue of (7.1.12), (ii). If $y \in f(X)$ and if z is a generic point of an irreducible component Z of $f^{-1}(y)$, we have therefore, by (5.6.5)

$$\dim(Z) = 1 + \dim(f^{-1}(\eta)) - \dim(\mathscr{O}_{X,z}).$$

But we have $\dim(\mathscr{O}_{X,z}) \leqslant \dim(\mathscr{O}_y)$ (**0**, 16.3.9), and on the other hand, as z is not the generic point of X, $\dim(\mathscr{O}_{X,z}) > 0$; hence $\dim(\mathscr{O}_{X,z}) = 1$ and $\dim(Z) = \dim(f^{-1}(\eta))$. □

7.2. Strictly formally catenary rings

(7.2.1). *Notations.* — For an integral Noetherian ring A, we denote by $A^{(1)}$ the intersection of the local rings $A_{\mathfrak{p}}$, where $\mathfrak{p}$ ranges over the set of prime ideals of A of height 1 (5.10.17). If A is a *local* Noetherian integral ring, we denote by $A^{(\omega)}$ the intersection of the $A_{\mathfrak{p}}$ where this time $\mathfrak{p}$ ranges over the set of all the prime ideals of A *distinct from the maximal ideal*.

We will say that a local Noetherian ring A is *strictly equidimensional* if, for every prime ideal $\mathfrak{p} \in \operatorname{Ass}(A)$, we have $\dim(A/\mathfrak{p}) = \dim(A)$; this amounts to saying that A is equidimensional and *without embedded associated prime ideals*.

(7.2.1.1). *Example.* — Let A be a local Noetherian ring *of dimension* 1. Then the following conditions are equivalent:

a) A has no embedded associated prime ideals.

a′) $\widehat{A}$ has no embedded associated prime ideals.

b) A is strictly equidimensional.

b′) $\widehat{A}$ is strictly equidimensional.

c) A is a Cohen-Macaulay ring.

Indeed, $a)$ means that the maximal ideal $\mathfrak{m}$ of A is not associated to A, hence the associated prime ideals to A are the minimal ideals of A, all distinct from $\mathfrak{m}$, and for such an ideal $\mathfrak{p}$, we necessarily have $\dim(A/\mathfrak{p}) = 1$; hence $a)$ implies $b)$. Conversely, $b)$ implies that every associated prime ideal $\mathfrak{p} \in \mathrm{Ass}(A)$ is distinct from $\mathfrak{m}$, hence minimal, and therefore $b)$ implies $a)$. We already know that $a)$ and $c)$ are equivalent for a local ring of dimension 1 (5.7.8). As it comes to the same thing to say that A is a Cohen-Macaulay ring or that $\widehat{A}$ is a Cohen-Macaulay ring (**0**, 16.5.2), and since $\dim(\widehat{A}) = 1$, we see finally that $a')$ and $b')$ are equivalent to $c)$. **IV-2** | 188

Proposition (7.2.2). — *Let* A *be a local Noetherian integral ring; set* $A' = \widehat{A}$, $X = \mathrm{Spec}(A)$, $X' = \mathrm{Spec}(A')$ *and denote by* $f : X' \to X$ *the canonical morphism. Let* a *be the closed point of* X, $j : X - \{a\} \to X$ *the canonical injection. Let* $\mathscr{F}$ *be a coherent* $\mathscr{O}_X$*-Module,* $\mathscr{F}' = f^*(\mathscr{F}) = \mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{O}_{X'}$*; then the following conditions are equivalent:*

a) *The* $\mathscr{O}_X$*-Module* $j_*(\mathscr{F}|X - \{a\})$ *is coherent.*
b) *For all* $x' \in \mathrm{Ass}(\mathscr{F}')$, *we have* $\dim(\overline{\{x'\}}) \geqslant 2$.

Proof. Let a' be the closed point of X', which is the unique point of the fibre $f^{-1}(a)$, and let $j' : X' - \{a'\} \to X'$ be the canonical injection. As the morphism f is faithfully flat and quasi-compact, it is equivalent to say that $j_*(\mathscr{F}|X - \{a\})$ is coherent or that $j'_*(\mathscr{F}'|X' - \{a'\})$ is coherent. On the other hand, as A' is isomorphic to a quotient of a regular local ring by the theorem of Cohen (**0**, 19.8.8), it follows from (5.11.4) that condition $b)$ of the statement is equivalent to the fact that $j'_*(\mathscr{F}'|X' - \{a'\})$ is coherent. Whence the proposition.

Instead of applying (5.11.4) and using the theorem of Cohen, which (by (5.11.2)) implicitly appeals to the cohomological results of chap. III, one can also use the fact that A' is universally catenary (5.6.4) and universally Japanese by virtue of (7.6.5) (the proof of this last result not using (7.2.2)). □

Proposition (7.2.3). — *Let* A *be a local Noetherian integral ring. The notations being as in* (7.2.2), *the following conditions are equivalent:*

a) $A^{(1)}$ *is a finite A-algebra.*
b) *For every closed subset* T *of* X *of codimension* $\geqslant 2$, *if we denote by* $i : X - T \to X$ *the canonical injection,* $i_*(\mathscr{O}_{X-T})$ *is a coherent* $\mathscr{O}_X$*-Module.*
c) *For all* $x' \in \mathrm{Ass}(\mathscr{O}_{X'})$ *and every closed subset* T *of* X *of codimension* $\geqslant 2$, *we have* $\mathrm{codim}(f^{-1}(T) \cap \overline{\{x'\}}, \overline{\{x'\}}) \geqslant 2$.

Proof. Set $Z = Z^{(2)}(X)$ (5.10.13) and $Z' = f^{-1}(Z)$, which are stable parts under specialisation; the conditions $a)$ and $b)$ are equivalent respectively to the following properties: $a_1)$ $\mathscr{H}^0_{X/Z}(\mathscr{O}_X)$ is coherent; $b_1)$ $\mathscr{H}^0_{X/T}(\mathscr{O}_X)$ is coherent for every closed subset T of X of codimension $\geqslant 2$. Taking into account (5.9.5), these two properties are equivalent respectively to: $a'_1)$ $\mathscr{H}^0_{X'/Z'}(\mathscr{O}_{X'})$ is coherent; $b'_1)$ setting $T' = f^{-1}(T)$, $\mathscr{H}^0_{X'/T'}(\mathscr{O}_{X'})$ is coherent for every closed subset T of X of codimension $\geqslant 2$. Now, every point of $\mathrm{Ass}(\mathscr{O}_{X'})$ projects to the generic point of X since f is a flat morphism (3.3.2); as by definition this point does not belong to Z, we see that $\mathrm{Ass}(\mathscr{O}_{X'})$ does not meet Z'; the equivalence of a'_1 and b'_1 therefore follows from (5.11.5), since A' is isomorphic to a quotient of a regular local ring by the theorem of Cohen (**0**, 19.8.8) (or alternatively because A' is universally Japanese (7.6.5)). **IV-2** | 189
For this reason, conditions b'_1 and $c)$ are also equivalent by virtue of (5.11.4). □

Proposition (7.2.4). — *Let* A *be a local Noetherian ring and set* $X = \mathrm{Spec}(A)$. *The following conditions are equivalent:*

a) *For every integral quotient ring* B *of* A, *the ring* $B^{(1)}$ *is a finite B-algebra.*
b) *For every coherent* $\mathscr{O}_X$*-Module* $\mathscr{F}$ *and every subset* Z *stable under specialisation, and such that for all* $x \in \mathrm{Ass}(\mathscr{F}) \cap (X - Z)$, *we have* $\mathrm{codim}(\overline{\{x\}} \cap Z, \overline{\{x\}}) \geqslant 2$, *the* $\mathscr{O}_X$*-Module* $\mathscr{H}^0_{X/Z}(\mathscr{F})$ *is coherent.*
c) *For every closed subset* T *of* X *and every coherent* $\mathscr{O}_U$*-Module* $\mathscr{G}$ *(where* $U = X - T$*) such that, for all* $x \in \mathrm{Ass}(\mathscr{G})$, *we have* $\mathrm{codim}(\overline{\{x\}} \cap T, \overline{\{x\}}) \geqslant 2$, $i_*(\mathscr{G})$ *(where* $i : U \to X$ *is the canonical injection) is a coherent* $\mathscr{O}_X$*-Module.*
d) *For every integral quotient ring* B *of* A, *and every ideal* $\mathfrak{J}$ *of height* $\geqslant 2$ *in* B, *the ring* $\bigcap_{\mathfrak{p} \not\supset \mathfrak{J}} B_{\mathfrak{p}}$ *is a finite B-algebra.*

e) *For every integral quotient ring* B *of* A *and every local ring* $\mathrm{C} = \mathrm{B}_{\mathfrak{q}}$ *at a prime ideal* $\mathfrak{q}$ *of* B*, with* $\dim(\mathrm{C}) \geqslant 2$*, the ring* $\mathrm{C}^{(\omega)}$ *is a finite C-algebra (or, what amounts to the same, if* $\mathrm{Y} = \mathrm{Spec}(\mathrm{C})$ *and* U *is the complement in* Y *of the closed point of* C *and* $j : \mathrm{U} \to \mathrm{Y}$ *the canonical injection,* $j_*(\mathscr{O}_{\mathrm{U}})$ *is a coherent* $\mathscr{O}_{\mathrm{Y}}$*-Module).*

f) *For every integral quotient ring* B *of* A*, every local ring* $\mathrm{C} = \mathrm{B}_{\mathfrak{q}}$ *at a prime ideal* $\mathfrak{q}$ *of* B*, with* $\dim(\mathrm{C}) \geqslant 2$*, and every ideal* $\mathfrak{t} \in \mathrm{Ass}(\widehat{\mathrm{C}})$*, we have* $\dim(\widehat{\mathrm{C}}/\mathfrak{t}) \geqslant 2$*.*

Proof. We already know (5.11.6) that $a)$ and $b)$ are equivalent, as are $c)$ and $d)$, and that $a)$ implies $d)$. The equivalence of $a)$ and $d)$ in the present case follows from (7.2.3) applied to an integral quotient ring B of A, condition $d)$ being an equivalent formulation of condition (7.2.3), $b)$ by virtue of (5.9.3.1). The equivalence of $e)$ and $f)$ is a consequence of (7.2.2) applied to the coherent $\mathscr{O}_{\mathrm{Y}}$-Module $\mathscr{O}_{\mathrm{Y}}$ itself. We have already remarked (5.11.7), (ii) that if A satisfies $a)$, the same holds for every finite A-algebra and every ring of fractions of A. Condition $d)$ for A therefore implies (with the notations of $e)$) that the ring C satisfies $a)$, hence also $c)$; but as C is integral and $\dim(\mathrm{C}) \geqslant 2$, one can apply condition $c)$ to C by taking T to be the closed point of $\mathrm{Y} = \mathrm{Spec}(\mathrm{C})$, which proves that $d)$ implies $e)$. It remains to prove that $e)$ implies $a)$; we can obviously restrict ourselves to the case where A is integral and **IV-2** | 190
$\mathrm{B} = \mathrm{A}$, and it amounts to showing that condition $e)$ implies the condition (7.2.3), $c)$). Let us consider the notations of (7.2.3), $c)$), and let $y' \in f^{-1}(\mathrm{T}) \cap \overline{\{x'\}}$, and set $y = f(y')$ and $\mathrm{C} = \mathscr{O}_{\mathrm{X},y}$; as $y \in \mathrm{T}$, $\dim(\mathrm{C}) \geqslant 2$, and hence (with the notations of $e)$), $j_*(\mathscr{O}_{\mathrm{U}})$ is a coherent $\mathscr{O}_{\mathrm{Y}}$-Module. Set $\mathrm{Y}' = \mathrm{X}' \times_{\mathrm{X}} \mathrm{Y}$; since the morphism $f : \mathrm{X}' \to \mathrm{X}$ is flat, so is $g = f_{(\mathrm{Y})} : \mathrm{Y}' \to \mathrm{Y}$. The underlying space is identified with $f^{-1}(\mathrm{Y})$ (**I**, 3.6.5), and as A is integral and f flat, $\mathrm{Ass}(\mathscr{O}_{\mathrm{X}'})$ is contained in the fibre of the generic point of X (3.3.2); this last being contained in Y, we have $x' \in \mathrm{Y}'$. Let $\mathrm{U}' = g^{-1}(\mathrm{U})$, and let j' be the canonical injection $\mathrm{U}' \to \mathrm{Y}'$; as $j_*(\mathscr{O}_{\mathrm{U}})$ is a coherent $\mathscr{O}_{\mathrm{Y}}$-Module and g is flat, it follows from (5.9.4) that $j'_*(\mathscr{O}_{\mathrm{U}'})$ is a coherent $\mathscr{O}_{\mathrm{Y}'}$-Module. But we have $x' \in \mathrm{Ass}(\mathscr{O}_{\mathrm{U}'})$, hence we conclude from (5.10.10) that, in Y', $\mathrm{codim}(\{y'\} \cap \overline{\{x'\}}, \overline{\{x'\}}) \geqslant 2$. As y' is arbitrary in $f^{-1}(\mathrm{T}) \cap \overline{\{x'\}}$, we indeed have $\mathrm{codim}(f^{-1}(\mathrm{T}) \cap \overline{\{x'\}}, \overline{\{x'\}}) \geqslant 2$ in X'. □

Theorem (7.2.5). — *Let* A *be a local Noetherian ring. The following conditions are equivalent:*

a) *For every integral quotient ring* B *of* A*, the completion* $\widehat{\mathrm{B}}$ *is strictly equidimensional* (7.2.1)*.*

b) A *is formally catenary* (7.1.9) *and the fibres of the canonical morphism* $\mathrm{Spec}(\widehat{\mathrm{A}}) \to \mathrm{Spec}(\mathrm{A})$ *satisfy* (S_1) *(in other words, have no embedded associated prime cycle).*

c) A *is universally catenary* (5.6.2) *and for every integral quotient ring* B *of* A*, the ring* $\mathrm{B}^{(1)}$ *is a finite B-algebra (cf.* (7.2.4)*).*

d) A *is universally catenary and for every integral quotient ring* B *of* A *and every local ring* $\mathrm{C} = \mathrm{B}_{\mathfrak{q}}$ *at a prime ideal* $\mathfrak{q}$ *of* B*, with* $\dim(\mathrm{C}) \geqslant 2$*, the ring* $\mathrm{C}^{(\omega)}$ *is a finite C-algebra.*

e) A *is universally catenary and for every integral quotient ring* B *of* A *and every local ring* $\mathrm{C} = \mathrm{B}_{\mathfrak{q}}$ *at a prime ideal* $\mathfrak{q}$ *of* B*, with* $\dim(\mathrm{C}) \geqslant 2$*, the completed ring* $\widehat{\mathrm{C}}$ *is such that* $\mathrm{Spec}(\widehat{\mathrm{C}})$ *has no associated prime cycle of dimension* 1*.*

Moreover, when these conditions are satisfied, for every integral quotient ring B *of* A *that is strictly equidimensional, the completion* $\widehat{\mathrm{B}}$ *is strictly equidimensional.*

Proof. The equivalence of $c)$, $d)$ and $e)$ was proved in (7.2.4). To show that $a)$ and $b)$ are equivalent, recall (7.1.9) that to say that A is formally catenary means that for every integral quotient ring B of A, $\widehat{\mathrm{B}}$ is equidimensional. On the other hand, every fibre of the morphism $\mathrm{Spec}(\widehat{\mathrm{A}}) \to \mathrm{Spec}(\mathrm{A})$ at a point $x \in \mathrm{Spec}(\mathrm{A})$ is the fibre of the morphism $\mathrm{Spec}(\widehat{\mathrm{B}}) \to \mathrm{Spec}(\mathrm{B})$ at the generic point x of $\mathrm{Spec}(\mathrm{B})$, where $\mathrm{B} = \mathrm{A}/\mathfrak{I}_x$; to say that this fibre has no embedded associated prime cycle is equivalent to saying that $\widehat{\mathrm{B}}$ has no embedded associated prime ideals, by virtue of (3.3.3); this proves the equivalence of $a)$ and $b)$. The same reasoning shows that if $a)$ is satisfied, then, for every integral quotient ring B of A that has no embedded associated prime ideals, the completion $\widehat{\mathrm{B}}$ is also without embedded associated prime ideals; on the other hand, the hypothesis that A is formally catenary implies that if B is equidimensional, it is also the case for $\widehat{\mathrm{B}}$ (7.1.8); this establishes the last assertion of the theorem.

Let us show now that $a)$ implies $c)$. Condition $a)$ implies that A is universally catenary (7.1.11); let us show on the other hand that for every integral quotient ring B of A, $\mathrm{B}^{(1)}$ is then a finite B-algebra.

Taking into account (7.2.3) applied to B, it amounts to showing that if $X = \mathrm{Spec}(B)$, T is a closed subset of codimension $\geqslant 2$ in X, $X' = \mathrm{Spec}(\widehat{B})$, and $g : X' \to X$ is the canonical morphism, then for all $x' \in \mathrm{Ass}(\mathscr{O}_{X'})$, $\mathrm{codim}(g^{-1}(T) \cap \overline{\{x'\}}, \overline{\{x'\}}) \geqslant 2$. But by hypothesis X′ has no associated prime cycle of dimension 1, hence $\inf(\mathrm{codim}(g^{-1}(T) \cap \overline{\{x'\}}, \overline{\{x'\}}))$ when x' ranges over $\mathrm{Ass}(\mathscr{O}_{X'})$, is nothing other than $\mathrm{codim}(g^{-1}(T), X')$. Now, as g is a faithfully flat morphism, we have (6.1.4)

$$\mathrm{codim}(g^{-1}(T), X') = \mathrm{codim}(T, X) \geqslant 2.$$

It remains to prove that c) implies a). Let us reason by induction on $n = \dim(A)$, the theorem being trivial for $n = 0$; we can moreover restrict to the case where $A = B$ is integral. We proceed in two steps, n being $\geqslant 1$. **IV-2** | 191

I) *Suppose first that* A *satisfies* (S_2). — Set $X = \mathrm{Spec}(A)$, $A' = \widehat{A}$, $X' = \mathrm{Spec}(A')$ and let $u : X' \to X$ be the canonical morphism; it amounts to showing that for all $x' \in \mathrm{Ass}(\mathscr{O}_{X'})$, we have $\dim(\overline{\{x'\}}) = n$. Let $f \neq 0$ be an element of the maximal ideal of A, and set $C = A/fA$; we know (5.7.6) that A/fA satisfies (S_1); moreover, as the prime ideals of A minimal among those containing f have height 1 by virtue of the Hauptidealsatz, and as C is catenary, $C = A/fA$ is *strictly equidimensional* and $\dim(C) = n - 1$. We have $\widehat{C} = C \otimes_A A' = A'/fA'$, and f is A′-regular by flatness (**0**, 6.3.4); if we set $Y' = V(fA') = \mathrm{Spec}(\widehat{C})$, then, for every maximal point y' of $Y' \cap \overline{\{x'\}}$, we have $y' \in \mathrm{Ass}(\mathscr{O}_{Y'})$ by virtue of (3.4.3); on the other hand, we have $y' \neq x'$ since $u(x')$ is the generic point of X (3.3.2) and $u(y') \in V(fA)$; we conclude from (5.1.8) that

$$\dim(\overline{\{y'\}}) = \dim(\overline{\{x'\}}) - 1. \tag{7.2.5.1}$$

But the quotient ring $C = A/fA$ also satisfies hypothesis c) of the statement (5.6.1) and (5.11.7), (ii)), hence by the induction hypothesis, we have $\dim(\overline{\{y'\}}) = \dim(C) = n - 1$; the conclusion therefore follows in this case from (7.2.5.1).

II) *General case.* — As by hypothesis $A^{(1)}$ is a finite A-algebra, it is a semi-local ring and satisfies (S_2) by virtue of (5.10.17), (i); the same is true of each of its local rings $(A^{(1)})_{\mathfrak{n}}$ at a maximal ideal $\mathfrak{n}$. Moreover, as A is universally catenary, the rings $(A^{(1)})_{\mathfrak{n}}$ (in finite number) are all of *dimension* n (5.6.10); these rings also satisfy hypothesis c) of the statement (5.6.1) and (5.11.7), (ii). We know that the completion of $A^{(1)}$, equal to $\widehat{A} \otimes_A A^{(1)}$, is the direct product of the completions of the local rings $(A^{(1)})_{\mathfrak{n}}$. Set $X_1 = \mathrm{Spec}(A^{(1)})$, $X'_1 = \mathrm{Spec}((A^{(1)})^\wedge) = X' \times_X X_1$; for all $x'_1 \in \mathrm{Ass}(\mathscr{O}_{X'_1})$, it follows from what precedes and from case I) that $\dim(\overline{\{x'_1\}}) = n$. Let $u_1 = u_{(X_1)} : X'_1 \to X_1$ be the canonical morphism; as A and $A^{(1)}$ have the same field of fractions, the inverse image of the generic point x of X by the projection $X_1 \to X$ reduces to the generic point x_1 of X_1; the inverse image by the projection $X'_1 \to X'$ of the fibre $u^{-1}(x)$ is the fibre $u_1^{-1}(x_1)$, and this projection induces an isomorphism of the prescheme $u_1^{-1}(x_1)$ onto the prescheme $u^{-1}(x)$. This being the case, the points of $\mathrm{Ass}(\mathscr{O}_{X'})$ (resp. $\mathrm{Ass}(\mathscr{O}_{X'_1})$) are the generic points of the associated prime cycles to $u^{-1}(x)$ (resp. $u_1^{-1}(x_1)$) (3.3.1). For every $x' \in \mathrm{Ass}(\mathscr{O}_{X'})$, there is therefore an $x'_1 \in \mathrm{Ass}(\mathscr{O}_{X'_1})$ lying over x'; and if Z′ (resp. Z'_1) is the reduced closed sub-prescheme of X′ (resp. X'_1) having $\overline{\{x'\}}$ (resp. $\overline{\{x'_1\}}$) as underlying space, the projection $Z'_1 \to Z'$ is a finite and surjective morphism; we conclude from (5.4.2) that $\dim(\overline{\{x'\}}) = \dim(\overline{\{x'_1\}}) = n$. □

Definition (7.2.6). — When a local Noetherian ring A satisfies the equivalent conditions of (7.2.5), we say that it is *strictly formally catenary*.

Corollary (7.2.7). — *Let* A *be a local Noetherian ring such that there exists an* A*-module* M *of finite type that is a Cohen-Macaulay* A*-module and for which* $\mathrm{Supp}(M) = \mathrm{Spec}(A)$*; then* A *is strictly formally catenary.*

Proof. Indeed, A is formally catenary (7.1.5) and (7.1.9), and on the other hand the fibres of the canonical morphism $\mathrm{Spec}(\widehat{A}) \to \mathrm{Spec}(A)$ are preschemes of Cohen-Macaulay (6.3.8), hence *a fortiori* satisfy (S_1). □ **IV-2** | 192

Corollary (7.2.8). — *If* A *is a local Noetherian ring that is strictly formally catenary, every local ring* B *that is an A-algebra essentially of finite type is strictly formally catenary.*

Proof. Indeed, B is formally catenary (7.1.11) and it follows from (7.4.4)[15] that the fibres of $\operatorname{Spec}(\widehat{B}) \to \operatorname{Spec}(B)$ satisfy (S_1), whence the conclusion. □

Corollary (7.2.9). — *Every local Noetherian ring of dimension* 1 *is strictly formally catenary.*

Proof. Indeed, every *integral* quotient ring B of such a ring A is of dimension 0 or 1, hence its completion is strictly equidimensional (7.2.1.1). □

Remarks (7.2.10). — *i)* It follows from (7.2.7) and (7.2.8) that every quotient ring of a Cohen-Macaulay local ring is strictly formally catenary. A local Noetherian ring of dimension 2 satisfying (S_2) is strictly formally catenary, since it is a Cohen-Macaulay ring. Recall however that there exist integral local Noetherian rings of dimension 2 that are not universally catenary, nor *a fortiori* strictly formally catenary (5.6.11).

ii) We do not know if a ring that is formally catenary (7.1.9) is strictly formally catenary; this is because we do not know if for a local Noetherian integral ring B, $\widehat{B}$ has no embedded associated prime ideals (6.4.3). We also do not know if, in the equivalent conditions *c*), *d*), *e*) of (7.2.5), one can replace the hypothesis that A is universally catenary by the hypothesis that A is catenary; one can show that this is the case when A is Henselian (18.9.6).

7.3. Formal fibres of Noetherian local rings

(7.3.1). We will consider in this number and the two following properties $\boldsymbol{P}(Z, k)$ of the following form:

"Z is a locally Noetherian prescheme over a field k,
and for all $z \in Z$, we have $\boldsymbol{Q}(\mathscr{O}_z, k)$"

where $\boldsymbol{Q}(A, k)$ is a property of a local Noetherian ring A that is a k-algebra; one assumes that if k' is a field isomorphic to k, and if A′ is a local Noetherian ring that is a k'-algebra di-isomorphic to A, the properties $\boldsymbol{Q}(A, k)$ and $\boldsymbol{Q}(A', k')$ are equivalent.

If X, Y are two locally Noetherian preschemes, we will say that a morphism $f : X \to Y$ is a $\boldsymbol{P}$*-morphism* if: **IV-2** | 193

1° f is *flat*;
2° for all $y \in Y$, the property $\boldsymbol{P}(f^{-1}(y), \boldsymbol{k}(y))$ is true.

Lemma (7.3.2). — *Let* X, Y *be two locally Noetherian preschemes,* $f : X \to Y$ *a morphism. The following properties are equivalent:*

a) *f is a $\boldsymbol{P}$-morphism.*
b) *For all $x \in X$, if we set $y = f(x)$, then $\mathscr{O}_x$ is a flat $\mathscr{O}_y$-module and the property $\boldsymbol{Q}(\mathscr{O}_x \otimes_{\mathscr{O}_y} \boldsymbol{k}(y), \boldsymbol{k}(y))$ is true.*
c) *For all $x \in X$, if we set $y = f(x)$, the morphism $\operatorname{Spec}(\mathscr{O}_x) \to \operatorname{Spec}(\mathscr{O}_y)$ corresponding to the homomorphism $\mathscr{O}_y \to \mathscr{O}_x$ is a $\boldsymbol{P}$-morphism.*
c′) *For every closed point $x \in X$, the morphism $\operatorname{Spec}(\mathscr{O}_x) \to \operatorname{Spec}(\mathscr{O}_y)$ is a $\boldsymbol{P}$-morphism.*

Proof. The equivalence of *a*) and *b*) follows from the definitions; the same holds for *b*) and *c*), taking into account (**I**, 2.4.2); finally the equivalence of *b*) and *c*′) follows from the fact that, by (5.1.11), $\overline{\{x\}}$ contains a closed point. □

Corollary (7.3.3). — *Let* A, B *be two Noetherian rings, $\varphi : A \to B$ a homomorphism such that the corresponding morphism* $\operatorname{Spec}(B) \to \operatorname{Spec}(A)$ *is a $\boldsymbol{P}$-morphism. Then, for every multiplicative subset* S *of* A, *the morphism* $\operatorname{Spec}(S^{-1}B) \to \operatorname{Spec}(S^{-1}A)$ *is a $\boldsymbol{P}$-morphism.*

Proof. This follows immediately from (7.3.2) and (**I**, 1.6.2). □

(7.3.4). We will suppose throughout what follows that the property $\boldsymbol{Q}$ is such that the following three conditions are satisfied:

(P_I) *(transitivity).* — If $f : X \to Y$ is a regular morphism (6.8.1) and $g : Y \to Z$ is a $\boldsymbol{P}$-morphism, then $g \circ f$ is a $\boldsymbol{P}$-morphism.

---

[15] The corollary (7.2.8) is not used to prove (7.4.4).

($\mathrm{P_{II}}$) *(descent).* — If $f : \mathrm{X} \to \mathrm{Y}$ and $g : \mathrm{Y} \to \mathrm{Z}$ are morphisms of locally Noetherian preschemes such that f is faithfully flat and that $g \circ f$ is a $\boldsymbol{P}$-morphism, then g is a $\boldsymbol{P}$-morphism.

($\mathrm{P_{III}}$) — For every field k, the property $\boldsymbol{P}(\mathrm{Spec}(k), k)$ is true.

Remarks (7.3.5). — *i)* Let us note that the conditions ($\mathrm{P_I}$) and ($\mathrm{P_{III}}$) imply that *every regular morphism is a* $\boldsymbol{P}$*-morphism*.

ii) Let us note that the hypotheses of ($\mathrm{P_I}$) (resp. ($\mathrm{P_{II}}$)) imply that $h = g \circ f$ (resp. g) is flat (2.2.13); the hypotheses of ($\mathrm{P_I}$) or of ($\mathrm{P_{II}}$) imply on the other hand that for all $z \in \mathrm{Z}$, $f_z : h^{-1}(z) \to g^{-1}(z)$ is flat (2.1.4); as, for all $y \in g^{-1}(z)$, $f_z^{-1}(y)$ is isomorphic to $f^{-1}(y)$ (**I**, 3.6.4), this shows that it suffices, to verify conditions ($\mathrm{P_I}$) and ($\mathrm{P_{II}}$), to do it only when Z is the *spectrum of a field*.

iii) In certain cases, the property $\boldsymbol{Q}$ will be such that the following condition is also satisfied:

($\mathrm{P'_I}$) — If $f : \mathrm{X} \to \mathrm{Y}$ and $g : \mathrm{Y} \to \mathrm{Z}$ are two $\boldsymbol{P}$-morphisms, then $g \circ f$ is a $\boldsymbol{P}$-morphism.

IV-2 | 194

(7.3.6). We will say that the property $\boldsymbol{P}$ is *geometric* if it satisfies (in addition to ($\mathrm{P_I}$), ($\mathrm{P_{II}}$) and ($\mathrm{P_{III}}$)) the condition:

($\mathrm{P_{IV}}$) *(extension of finite type of the base field).* — If $\boldsymbol{P}(\mathrm{Z}, k)$ is true, then, for every extension k' of finite type over k, $\boldsymbol{P}(\mathrm{Z} \otimes_k k', k')$ is true.

Lemma (7.3.7). — *Let $f : \mathrm{X} \to \mathrm{Y}$ be a $\boldsymbol{P}$-morphism of locally Noetherian preschemes, $g : \mathrm{Y}' \to \mathrm{Y}$ a morphism locally of finite type. Then, if $\boldsymbol{P}$ satisfies the condition* ($\mathrm{P_{IV}}$)*, the morphism $f' = f_{(\mathrm{Y}')} : \mathrm{X} \times_{\mathrm{Y}} \mathrm{Y}' \to \mathrm{Y}'$ is a $\boldsymbol{P}$-morphism.*

Proof. Indeed, for all $y' \in \mathrm{Y}'$, if we set $y = g(y')$, $\boldsymbol{k}(y')$ is an extension of finite type of $\boldsymbol{k}(y)$ (**I**, 6.4.11) and $f'^{-1}(y') = f^{-1}(y) \otimes_{\boldsymbol{k}(y)} \boldsymbol{k}(y')$ (**I**, 3.6.4); it suffices therefore to apply ($\mathrm{P_{IV}}$). ☐

(7.3.8). *Examples.* — The following properties $\boldsymbol{P}(\mathrm{Z}, k)$ satisfy the conditions ($\mathrm{P_I}$), ($\mathrm{P_{II}}$) and ($\mathrm{P_{III}}$):

(i) (also denoted (i_n)) Z is of coprofundity $\leqslant n$.
(ii) Z is a prescheme of Cohen-Macaulay.
(iii) (also denoted (iii_n)) Z satisfies (S_n).
(iv) Z is regular.
(v) (also denoted (v_n)) Z satisfies (R_n).
(vi) Z is reduced.
(vii) Z is normal.

For properties (ii) to (vii), this follows from (6.6.1), which in fact proves the stronger condition ($\mathrm{P'_I}$). For (i), the property ($\mathrm{P_{II}}$) follows from (6.6.2); the property ($\mathrm{P_I}$) follows, by the same reasoning as in (6.6.1), (i), from (6.3.2) and from the fact that a regular prescheme has codepth 0.

Moreover, it follows from (6.7.1) that properties (i), (ii), and (iii) are geometric; by virtue of (6.7.8), the same is true of the following:

(iv') Z is geometrically regular.
(v') (also denoted (v'_n)) Z possesses the property (R_n) geometric.
(vi') Z is geometrically reduced.
(vii') Z is geometrically normal.

Remarks (7.3.9). — *i)* Each of the properties (iv'), (v'_n), (vi'), (vii') implies respectively the corresponding property (iv), (v_n), (vi), (vii). The property (iv) implies all the properties (i) to (vii), and the property (iv') implies all the properties enumerated in (7.3.8). Recall also that (i_0) is equivalent to (ii); the conjunction of (iii_1) and of (v_0) (resp. of (iii_1) and of (v'_0)) is equivalent to (vi) (resp. (vi')) (5.8.5); the conjunction of (iii_2) and of (v_1) (resp. of (iii_2) and of (v'_1)) is equivalent to (vii) (resp. (vii')) (5.8.6).

ii) In all the examples of (7.3.8), the property $\boldsymbol{Q}(\mathscr{O}_z, k)$ which serves to define $\boldsymbol{P}$ is such that, for every *generization* z' of z in Z, $\boldsymbol{Q}(\mathscr{O}_z, k)$ *implies* $\boldsymbol{Q}(\mathscr{O}_{z'}, k)$. By virtue of (2.3.4), it suffices to verify this for properties (i) to (vii) (and even (i) to (v), by (7.3.9), (i)): it is part of the definition for (iii) and (v) (5.7.2) and (5.8.2), it follows from (6.3.5), (i), for (i),[16] and finally from (**0**, 16.5.10) and (17.3.2) for (ii) and (iv).

IV-2 | 195

(7.3.10). We will say that a property $\boldsymbol{P}(\mathrm{Z}, k)$ is of the *first type* if the property $\boldsymbol{Q}(\mathrm{A}, k)$ which serves to define it defines a property $\boldsymbol{R}(\mathrm{A})$ *not involving* k and is true when A is a *field*; we will say that $\boldsymbol{P}(\mathrm{Z}, k)$ is of the *second type* if the property $\boldsymbol{Q}(\mathrm{A}, k)$ is of the form

> "For every extension k' of finite type over k and every point z' of $\mathrm{Spec}(\mathrm{A} \otimes_k k')$ above the closed point of $\mathrm{Spec}(\mathrm{A})$, we have $\boldsymbol{R}(\mathscr{O}_{z'})$"

$\boldsymbol{R}(\mathrm{A})$ being assumed true when A is a field. It is clear that in the examples of (7.3.8), the properties (i) to (vii) are of the first type, the properties (iv') to (vii') of the second type.

This being the case, if we take up the reasoning of (6.6.1) and (6.8.3), we observe that when $\boldsymbol{P}$ is of the first or second type for a property $\boldsymbol{R}(\mathrm{A})$, *the conditions* $(\mathrm{P_I})$ *and* $(\mathrm{P_{II}})$ *have the following consequences on* $\boldsymbol{R}$:

$(\mathrm{R_I})$ Let X, Y be two locally Noetherian preschemes, $f : \mathrm{X} \to \mathrm{Y}$ a *regular* morphism; then, for all $x \in \mathrm{X}$, the property $\boldsymbol{R}(\mathscr{O}_{f(x)})$ implies the property $\boldsymbol{R}(\mathscr{O}_x)$.

$(\mathrm{R_{II}})$ Let $\varphi : \mathrm{A} \to \mathrm{B}$ be a homomorphism of local Noetherian rings making B a flat A-module; then $\boldsymbol{R}(\mathrm{B})$ implies $\boldsymbol{R}(\mathrm{A})$.

Moreover, the property $(\mathrm{P_{III}})$ results from the fact that $\boldsymbol{R}(k)$ is true for every field k; finally, when $\boldsymbol{P}$ is of the second type, the condition $(\mathrm{P_{IV}})$ is a consequence of the definition of $\boldsymbol{P}$ and of the transitivity of extensions of finite type.

Remark (7.3.11). — We leave to the reader the task of formulating the property $\boldsymbol{R}$ corresponding to each of the examples of (7.3.8), and of verifying the conditions $(\mathrm{R_I})$ and $(\mathrm{R_{II}})$ in each case, with the help of the results of § 6. In fact, except for example (i) of (7.3.8), the property $\boldsymbol{R}$ satisfies in the other cases the following condition:

$(\mathrm{R'_I})$ Let X, Y be two locally Noetherian preschemes, $f : \mathrm{X} \to \mathrm{Y}$ a $\boldsymbol{P}$-morphism (for the property $\boldsymbol{P}$ of the first or second type defined by $\boldsymbol{R}$); then, for all $x \in \mathrm{X}$, the property $\boldsymbol{R}(\mathscr{O}_{f(x)})$ implies the property $\boldsymbol{R}(\mathscr{O}_x)$.

The reasoning of (6.6.1) and (6.8.3) proves that if $\boldsymbol{R}$ satisfies the conditions $(\mathrm{R'_I})$ and $(\mathrm{R_{II}})$, then $\boldsymbol{P}$ satisfies the conditions $(\mathrm{P'_I})$ (7.3.5), (iii), and $(\mathrm{P_{II}})$.

Proposition (7.3.12). — *Let* $\boldsymbol{P}$ *be a property of the first or the second type defined from a property* $\boldsymbol{R}$ *verifying the conditions* $(\mathrm{R_I})$ *and* $(\mathrm{R_{II}})$ *(resp.* $(\mathrm{R'_I})$ *and* $(\mathrm{R_{II}})$*). If for every locally Noetherian prescheme* X, $\mathrm{U}_{\boldsymbol{R}}(\mathrm{X})$ *denotes the set of* $x \in \mathrm{X}$ *such that* $\boldsymbol{R}(\mathscr{O}_x)$ *is true, then, for every regular morphism (resp. every* $\boldsymbol{P}$*-morphism)* $f : \mathrm{X} \to \mathrm{Y}$ *of locally Noetherian preschemes, we have*

$$\mathrm{U}_{\boldsymbol{R}}(\mathrm{X}) = f^{-1}(\mathrm{U}_{\boldsymbol{R}}(\mathrm{Y})). \tag{7.3.12.1}$$

Proof. This is an immediate consequence of the definitions. □

(7.3.13). Given a semi-local Noetherian ring A, we will call *formal fibres* of A the fibres of the canonical morphism $f : \mathrm{Spec}(\widehat{\mathrm{A}}) \to \mathrm{Spec}(\mathrm{A})$; for every prime ideal $\mathfrak{p}$ of A, the formal fibre at $\mathfrak{p}$ is therefore the scheme $\mathrm{Spec}(\widehat{\mathrm{A}} \otimes_{\mathrm{A}} \boldsymbol{k}(\mathfrak{p}))$; as the completion of the local ring $\mathrm{A}/\mathfrak{p}$ is $\widehat{\mathrm{A}}/\mathfrak{p}\widehat{\mathrm{A}} = (\mathrm{A}/\mathfrak{p}) \otimes_{\mathrm{A}} \widehat{\mathrm{A}}$, we see that the formal fibre of A at $\mathfrak{p}$ is also the *formal fibre of* $\mathrm{A}/\mathfrak{p}$ *at the generic point* (o) of $\mathrm{Spec}(\mathrm{A}/\mathfrak{p})$.

The property $\boldsymbol{P}$ being defined as in (7.3.1), we will say that *the formal fibres of* A *have the property* $\boldsymbol{P}$, or that A is a $\boldsymbol{P}$*-ring*, if, for all $x \in \mathrm{Spec}(\mathrm{A})$, $\boldsymbol{P}(f^{-1}(x), \boldsymbol{k}(x))$ is true. As the morphism f is *flat*, this amounts to saying that f is a $\boldsymbol{P}$-morphism. **IV-2 | 196**

Proposition (7.3.14). — *Let* A *be a semi-local Noetherian ring,* $\mathfrak{m}_i$ *(*$1 \leqslant i \leqslant r$*) its maximal ideals, and set* $\mathrm{A}_i = \mathrm{A}_{\mathfrak{m}_i}$*; for* A *to be a* $\boldsymbol{P}$*-ring, it is necessary and sufficient that each of the* A_i *be so.*

Proof. Indeed, $\widehat{\mathrm{A}}$ is the direct product of the $\widehat{\mathrm{A}}_i$, hence the formal fibre of A at a point $x \in \mathrm{Spec}(\mathrm{A})$ is the *sum* of the formal fibres at x of those A_i such that $x \in \mathrm{Spec}(\mathrm{A}_i)$. □

[16] The printed text cites (6.3.9), but §6.3 ends at Proposition (6.3.8); the codepth-under-generization statement used here is Corollary (6.3.5)(i).

Proposition (7.3.15). — *Let* A *be a semi-local Noetherian ring.*

i) *If* A *is a* $\boldsymbol{P}$*-ring, every quotient ring of* A *is a* $\boldsymbol{P}$*-ring.*
ii) *If in addition* $\boldsymbol{P}$ *satisfies the condition* $(\mathrm{P}_{\mathrm{IV}})$ (7.3.6)*, then every finite A-algebra is a* $\boldsymbol{P}$*-ring.*

Proof. For every ideal $\mathfrak{a}$ of A, $\widehat{\mathrm{A}} \otimes_{\mathrm{A}} (\mathrm{A}/\mathfrak{a})$ is the completion of $\mathrm{A}/\mathfrak{a}$, and the formal fibres of $\mathrm{A}/\mathfrak{a}$ are therefore the formal fibres of A at the points of $\mathrm{V}(\mathfrak{a})$, whence (i). On the other hand, if B is a finite A-algebra, B is a semi-local ring, we have $\widehat{\mathrm{B}} = \mathrm{B} \otimes_{\mathrm{A}} \widehat{\mathrm{A}}$, and (ii) follows from (7.3.7). ☐

Proposition (7.3.16). — *Suppose that the property* $\boldsymbol{P}$ *is of the first (resp. second) type, defined from a property* $\boldsymbol{R}$ (7.3.10)*. When* $\boldsymbol{P}$ *is of the second type, suppose moreover that the relation*

"for every finite extension k' *of* k*, and every* $z' \in \mathrm{Z} \otimes_k k'$*,* $\boldsymbol{R}(\mathscr{O}_{z'})$ *is true"*

implies $\boldsymbol{P}(\mathrm{Z}, k)$ *(this is verified for the examples (iv') to (vii') of* (7.3.8)*, by virtue of* (6.7.7) *and* (4.6.1)*).*

Let A *be a semi-local Noetherian ring. If the property* $\boldsymbol{R}$ *satisfies the conditions* $(\mathrm{R}_{\mathrm{I}})$ *and* $(\mathrm{R}_{\mathrm{II}})$*, the following properties are equivalent:*

a) A *is a* $\boldsymbol{P}$*-ring.*
b) *For every integral quotient ring* B *of* A *(resp. every finite integral A-algebra* B*) and every prime ideal* $\mathfrak{q}$ *of* $\widehat{\mathrm{B}}$ *whose inverse image in* B *is* 0*,* $\boldsymbol{R}(\widehat{\mathrm{B}}_{\mathfrak{q}})$ *is true.*

If in addition $\boldsymbol{R}$ *satisfies the condition* $(\mathrm{R}'_{\mathrm{I}})$*, the properties a) and b) are also equivalent to:*

c) *For every quotient ring* B *of* A *(resp. every finite A-algebra* B*), if we set* $\mathrm{Y} = \mathrm{Spec}(\mathrm{B})$*,* $\mathrm{Y}' = \mathrm{Spec}(\widehat{\mathrm{B}})$*, and if* $g : \mathrm{Y}' \to \mathrm{Y}$ *is the canonical morphism, we have (with the notations of* (7.3.12)*)*

$$\mathrm{U}_{\boldsymbol{R}}(\mathrm{Y}') = g^{-1}(\mathrm{U}_{\boldsymbol{R}}(\mathrm{Y})). \tag{7.3.16.1}$$

Proof. The equivalence of *a*) and *b*) is immediate when $\boldsymbol{P}$ is of the first type: indeed, for every prime ideal $\mathfrak{p}$ of A, the formal fibre of $\mathrm{B} = \mathrm{A}/\mathfrak{p}$ at the generic point $\mathfrak{p} \in \mathrm{Spec}(\mathrm{A})$ is nothing other than the formal fibre of A at the point $\mathfrak{p}$ (7.3.13). When $\boldsymbol{P}$ is of the second type, the equivalence of *a*) and *b*) follows from the more general lemma below. ☐

Lemma (7.3.16.2). — *Let* A, A′ *be two rings,* $\varphi : \mathrm{A} \to \mathrm{A}'$ *a homomorphism,* $f : \mathrm{Spec}(\mathrm{A}') \to \mathrm{Spec}(\mathrm{A})$ *the corresponding morphism. In order that for all* $x \in \mathrm{Spec}(\mathrm{A})$*, every finite extension* k *of* $\boldsymbol{k}(x)$ *and every point* z *of* $f^{-1}(x) \otimes_{\boldsymbol{k}(x)} k = \mathrm{Z}$*, the property* $\boldsymbol{R}(\mathscr{O}_{\mathrm{Z},z})$ *be true, it is* **IV-2 | 197** *necessary and sufficient that: for every integral finite A-algebra* B*, if* $g : \mathrm{Spec}(\mathrm{A}' \otimes_{\mathrm{A}} \mathrm{B}) \to \mathrm{Spec}(\mathrm{B})$ *is the morphism deduced from* f *by base extension to* B*, and if* $\mathrm{T} = g^{-1}(\xi)$ *is the fibre of the generic point* ξ *of* $\mathrm{Spec}(\mathrm{B})$*, then, for all* $t \in \mathrm{T}$*,* $\boldsymbol{R}(\mathscr{O}_{\mathrm{T},t})$ *is true.*

Proof. The condition is trivially necessary since x is the point of Spec(A) above which ξ lies, $\boldsymbol{k}(\xi)$ is a finite extension of $\boldsymbol{k}(x)$. Conversely, let us consider a point $x \in \mathrm{Spec}(\mathrm{A})$ and let k be a finite extension of $\boldsymbol{k}(x)$. If we set $\mathfrak{p} = \mathfrak{j}_x$, then $\boldsymbol{k}(x)$ is the field of fractions of $\mathrm{A}/\mathfrak{p}$, and there is a basis of k over $\boldsymbol{k}(x)$ consisting of elements integral over $\mathrm{A}/\mathfrak{p}$. If B is the subring of k generated by these elements, then B is a finite integral A-algebra and k is the field $\boldsymbol{k}(\xi)$ at the generic point ξ of Spec(B). Since x is the image of ξ in Spec(A), the fibre $g^{-1}(\xi)$ is none other than $f^{-1}(x) \otimes_{\boldsymbol{k}(x)} k$, which completes the proof of the lemma. ☐

End of the proof of (7.3.16). That *a*) implies *c*) is an immediate consequence of (7.3.15) and (7.3.12). On the other hand, specialise *c*) to the case where B is integral, and let y denote the generic point of $\mathrm{Y} = \mathrm{Spec}(\mathrm{B})$. Then $\mathscr{O}_{\mathrm{Y},y} = \boldsymbol{k}(y)$, so $y \in \mathrm{U}_{\boldsymbol{R}}(\mathrm{Y})$, since $\boldsymbol{R}(k)$ is true for every field k. Expressing that every point $y' \in g^{-1}(y)$ belongs to $\mathrm{U}_{\boldsymbol{R}}(\mathrm{Y}')$ gives statement *b*); thus *c*) implies *b*). ☐

Proposition (7.3.17). — *Suppose that the property* $\boldsymbol{R}$ *satisfies the conditions* $(\mathrm{R}'_{\mathrm{I}})$ *and* $(\mathrm{R}_{\mathrm{II}})$*, and that* $\boldsymbol{P}$ *is the property of the first (resp. second) type defined from* $\boldsymbol{R}$ (7.3.10)*. Then, if* A *is a* $\boldsymbol{P}$*-ring, the properties* $\boldsymbol{R}(\mathrm{A})$ *and* $\boldsymbol{R}(\widehat{\mathrm{A}})$ *are equivalent.*

Proof. This follows from (7.3.12.1) applied to $\mathrm{Y} = \mathrm{Spec}(\mathrm{A})$ and $\mathrm{X} = \mathrm{Spec}(\widehat{\mathrm{A}})$. ☐

Proposition (7.3.18). — *Suppose that* $\boldsymbol{P}$ *is a property of the first (resp. second) type defined from a property* $\boldsymbol{R}$ *satisfying the conditions* $(\mathrm{R}'_{\mathrm{I}})$ *and* $(\mathrm{R}_{\mathrm{II}})$*, and also the condition following:*

$(\mathrm{R}_{\mathrm{III}})$ *For every local Noetherian complete ring* C*, if we set* $\mathrm{Z} = \mathrm{Spec}(\mathrm{C})$*, the set* $\mathrm{U}_{\boldsymbol{R}}(\mathrm{Z})$ (7.3.12) *is open in* Z*.*

Then, if A *is a* $\boldsymbol{P}$*-ring and if we set* $\mathrm{X} = \mathrm{Spec}(\mathrm{A})$*, the set* $\mathrm{U}_{\boldsymbol{R}}(\mathrm{X})$ *is open in* X*.*

Proof. Indeed, if $X' = \operatorname{Spec}(\widehat{A})$ and if $f : X' \to X$ is the canonical morphism, $U_{\boldsymbol{R}}(X') = f^{-1}(U_{\boldsymbol{R}}(X))$ (7.3.12). As f is faithfully flat and quasi-compact (2.3.12), and as by hypothesis $U_{\boldsymbol{R}}(X')$ is open in X', the conclusion follows from (2.3.12). □

Remarks (7.3.19). — *i)* The property $\boldsymbol{R}$ which serves to define $\boldsymbol{P}$ satisfies the condition (R_{III}) in all the examples enumerated in (7.3.8). For (i), (ii) and (iii), this follows from (6.11.2) and the theorem of Cohen (**0**, 19.8.8); when $\boldsymbol{P}$ is one of the properties (iv), (iv′), (v), (v′), this follows from (6.12.7) and (6.12.9); when $\boldsymbol{P}$ is one of the properties (vii), (vii′), it follows from (6.12.7) and (6.13.4); finally, for (vi) and (vi′), the assertion of (7.3.18) is trivial, being true for every locally Noetherian prescheme.

IV-2 | 198

ii) We have already noted (6.4.3) that when $\boldsymbol{P}$ is one of the properties (ii) or (iii_1) of (7.3.8), we do not know whether every local Noetherian ring is a $\boldsymbol{P}$-ring. Recall, however, that when A is a quotient of a Cohen–Macaulay ring, the formal fibres of A are Cohen–Macaulay schemes (6.3.8).

iii) The most interesting instance of the notion of $\boldsymbol{P}$-ring is that corresponding to the strongest property (iv′) of (7.3.8): the rings whose formal fibres are geometrically regular. Fields, and more generally complete Noetherian local rings, trivially have this property.

iv) Let A be a local Noetherian ring of dimension 1. Then Spec(A) consists of the closed point a, corresponding to the maximal ideal $\mathfrak{m}$, and the maximal points b_i $(1 \leqslant i \leqslant r)$, corresponding to the minimal prime ideals of A. One has $\dim(\widehat{A}) = 1$, and the maximal ideal of $\widehat{A}$ is $\mathfrak{m}\widehat{A}$. The formal fibre of A at a is therefore $\operatorname{Spec}(k)$, where $k = A/\mathfrak{m}$ is the residue field of A; the formal fibre at each b_i is the spectrum of an Artinian ring whose residue fields are the residue fields L_{ij} of $\operatorname{Spec}(\widehat{A})$ at the maximal points b_{ij} lying over b_i. Since an Artinian ring is Cohen–Macaulay, A is a $\boldsymbol{P}$-ring when $\boldsymbol{P}$ is property (ii) of (7.3.8). Moreover, since a reduced Artinian ring is a direct sum of fields, the following properties are equivalent (6.7.7):

a) the formal fibres of A are geometrically reduced;
b) the formal fibres of A are geometrically normal;
c) the formal fibres of A are geometrically regular.

When A is reduced, they are also equivalent to:

d) $\widehat{A}$ is reduced and L_{ij} is a separable extension of K_i for every pair (i, j) (4.6.1).

In particular, if A is a discrete valuation ring, K its field of fractions, and $\widehat{K}$ the completion of K for the valuation corresponding to A (the field of fractions of $\widehat{A}$), then the formal fibres of A are geometrically regular if and only if $\widehat{K}$ is a separable extension of K. This is always so when K has characteristic 0.

7.4. Permanence of properties of formal fibres

(7.4.1). Throughout the rest of this number, we suppose that the property $\boldsymbol{P}$ is of the form defined in (7.3.1), and *satisfies the conditions* (P_I), (P_{II}) *and* (P_{III}) of (7.3.4). Moreover, we suppose that the property $\boldsymbol{Q}$ which serves to define $\boldsymbol{P}$ is such that, for every generization z' of z in Z, $\boldsymbol{Q}(\mathscr{O}_z, k)$ implies $\boldsymbol{Q}(\mathscr{O}_{z'}, k)$.

Lemma (7.4.2). — *Let* A, A′ *be two local Noetherian rings,* $\varphi : A \to A'$ *a local homomorphism such that* $f = {}^a\varphi : \operatorname{Spec}(A') \to \operatorname{Spec}(A)$ *is a* $\boldsymbol{P}$*-morphism. Then, if the formal fibres of* A′ *are geometrically regular,* A *is a* $\boldsymbol{P}$*-ring.*

IV-2 | 199

Proof. Consider the completed homomorphism $\widehat{\varphi} : \widehat{A} \to \widehat{A'}$ and the corresponding morphism $\widehat{f} = {}^a\widehat{\varphi}$; we have the commutative diagram

$$\begin{tikzcd} \operatorname{Spec}(\widehat{A}) \arrow[d, "g"'] & \operatorname{Spec}(\widehat{A'}) \arrow[l, "\widehat{f}"'] \arrow[d, "g'"] \\ \operatorname{Spec}(A) & \operatorname{Spec}(A') \arrow[l, "f"] \end{tikzcd}$$

where g and g' are the canonical morphisms. As by hypothesis f is a $\boldsymbol{P}$-morphism and g' a regular morphism, it follows from $(\mathrm{P_I})$ that $f \circ g' = g \circ \widehat{f}$ is a $\boldsymbol{P}$-morphism. On the other hand, the hypothesis that f is a $\boldsymbol{P}$-morphism implies that f is flat, hence it is the same for $\widehat{f}$ (Bourbaki, *Alg. comm.*, chap. III, § 5, n° 4, cor. of prop. 3), which is moreover a local homomorphism, hence faithfully flat (**0**, 6.6.2); it follows then from $(\mathrm{P_{II}})$ that g is a $\boldsymbol{P}$-morphism. □

Corollary (7.4.3). — i) *Let* A *be a* $\boldsymbol{P}$*-ring local Noetherian,* $\mathrm{A'} = \widehat{\mathrm{A}}$ *its completion. Suppose that for every prime ideal* $\mathfrak{p}'$ *of* A′*, the formal fibres of* $\mathrm{A'_{\mathfrak{p}'}}$ *are geometrically regular; then, for every prime ideal* $\mathfrak{p}$ *of* A*,* $\mathrm{A_{\mathfrak{p}}}$ *is a* $\boldsymbol{P}$*-ring.*

ii) *Suppose that* $\boldsymbol{P}$ *satisfies the condition* $(\mathrm{P_{IV}})$ (7.3.6)*. Let* A *be a* $\boldsymbol{P}$*-ring local Noetherian,* B *a local A-algebra essentially of finite type, and such that the homomorphism* $\mathrm{A} \to \mathrm{B}$ *is local. Set* $\mathrm{A'} = \widehat{\mathrm{A}}$*, and let* $\mathfrak{n}'$ *be the unique prime ideal of* $\mathrm{B'} = \mathrm{B} \otimes_{\mathrm{A}} \mathrm{A'}$ *above the maximal ideal of* B *and the maximal ideal of* A′*. If the formal fibres of* $\mathrm{B'_{\mathfrak{n}'}}$ *are geometrically regular, then* B *is a* $\boldsymbol{P}$*-ring.*

Proof. (i) As by hypothesis $\mathrm{Spec(A')} \to \mathrm{Spec(A)}$ is a $\boldsymbol{P}$-morphism, the same holds for $\mathrm{Spec(A'_{\mathfrak{p}'})} \to \mathrm{Spec(A_{\mathfrak{p}})}$ by virtue of (7.3.2), *b*)), for every prime ideal $\mathfrak{p}'$ of A′ above $\mathfrak{p}$ and every prime ideal $\mathfrak{p}$ of A. It suffices then to apply the lemma (7.4.2) to this morphism, noting that the morphism $\mathrm{Spec(A')} \to \mathrm{Spec(A)}$ is surjective.

(ii) By virtue of (7.4.2), it suffices to prove that the morphism $\mathrm{Spec(B'_{\mathfrak{n}'})} \to \mathrm{Spec(B)}$ is a $\boldsymbol{P}$-morphism. Now we have $\mathrm{B} = \mathrm{C_{\mathfrak{n}}}$, where C is a finite type A-algebra and $\mathfrak{n}$ is a prime ideal of C above the maximal ideal of A. If we set $\mathrm{C'} = \mathrm{C} \otimes_{\mathrm{A}} \mathrm{A'}$, it follows from the hypotheses and from (7.3.7) that $\mathrm{Spec(C')} \to \mathrm{Spec(C)}$ is a $\boldsymbol{P}$-morphism; as $\mathrm{B'_{\mathfrak{n}'}}$ is a local ring of C′ at a prime ideal of C′ above $\mathfrak{n}$, the conclusion follows from (7.3.2), *b*)). □

Theorem (7.4.4). — *The hypotheses on* $\boldsymbol{P}$ *being those of* (7.4.1)*, let* A *be a* $\boldsymbol{P}$*-ring local Noetherian.*

i) *For every prime ideal* $\mathfrak{p}$ *of* A*,* $\mathrm{A_{\mathfrak{p}}}$ *is a* $\boldsymbol{P}$*-ring.*

ii) *Suppose in addition that* $\boldsymbol{P}$ *satisfies the condition* $(\mathrm{P_{IV}})$*. Then every local ring that is an A-algebra essentially of finite type is a* $\boldsymbol{P}$*-ring.*

Proof. (i) Applying (7.4.3), (i), everything reduces to seeing that for every prime ideal $\mathfrak{p}'$ of $\mathrm{A'} = \widehat{\mathrm{A}}$, $\mathrm{A'_{\mathfrak{p}'}}$ has its formal fibres geometrically regular. Now, this has been proved in (**0**, 22.3.3) and (**0**, 22.5.8).

IV-2 | 200

(ii) Let B be an A-algebra essentially of finite type that is a local ring; if $\mathfrak{p}$ is the prime ideal of A above which the maximal ideal of B lies, B is also an $\mathrm{A_{\mathfrak{p}}}$-algebra essentially of finite type (1.3.8); by virtue of (i), we may therefore suppose that $\mathfrak{p}$ is the maximal ideal $\mathfrak{m}$ of A. We have then $\mathrm{B} = \mathrm{C_{\mathfrak{q}}}$, where C is a finite type A-algebra and $\mathfrak{q}$ is a prime ideal of C above $\mathfrak{m}$. Choose a maximal ideal $\mathfrak{n} \supset \mathfrak{q}$ of C, necessarily above $\mathfrak{m}$. If $k = \mathrm{A}/\mathfrak{m}$, then $\mathrm{C}/\mathfrak{m}\mathrm{C}$ is a finite type k-algebra, so the residue field k' of C at $\mathfrak{n}$ is finite over k (**I**, 6.4.2). By (i), it is enough to prove that $\mathrm{C_{\mathfrak{n}}}$ is a $\boldsymbol{P}$-ring, since $\mathrm{C_{\mathfrak{q}}}$ is a local ring at a prime ideal of $\mathrm{C_{\mathfrak{n}}}$. We are thus reduced to the following lemma. □

Lemma (7.4.4.1). — *Let* A *be a* $\boldsymbol{P}$*-ring local Noetherian,* k *its residue field,* C *a finite type A-algebra,* B *a local ring in a prime ideal* $\mathfrak{n}$ *of* C*, such that:* 1° *the homomorphism* $\mathrm{A} \to \mathrm{B}$ *is local;* 2° *the residue field* k' *of* B *is a finite extension of* k*. If* $\boldsymbol{P}$ *satisfies* $(\mathrm{P_{IV}})$*, then* B *is a* $\boldsymbol{P}$*-ring.*

Proof. Let $(x_i)_{1 \leqslant i \leqslant m}$ be a system of generators of the A-algebra C; let us show first that we can argue by induction on m. Let C′ be the sub-A-algebra of C generated by $x_1, \ldots, x_{m-1}$, and let $\mathfrak{n}' = \mathfrak{n} \cap \mathrm{C'}$. The homomorphism $\mathrm{A} \to \mathrm{C_{\mathfrak{n}}}$ factors through the local homomorphisms $\mathrm{A} \to \mathrm{C'_{\mathfrak{n}'}} \to \mathrm{C_{\mathfrak{n}}}$; if k'' is the residue field of $\mathrm{C'_{\mathfrak{n}'}}$, the extension $k \to k'$ factors through k'', hence k'' is a finite extension of k and k' a finite extension of k''. The induction hypothesis implies that $\mathrm{C'_{\mathfrak{n}'}}$ is a $\boldsymbol{P}$-ring. If $\mathrm{S'} = \mathrm{C'} - \mathfrak{n}'$, then $\mathrm{C_{\mathfrak{n}}}$ is a local ring of $\mathrm{S'^{-1}C} = \mathrm{C'_{\mathfrak{n}'}}[x_m/1]$; the induction hypothesis applied once more shows that $\mathrm{C_{\mathfrak{n}}}$ is a $\boldsymbol{P}$-ring. Thus the problem reduces to the case where C is an A-algebra generated by a *single* element t.

Applying (7.4.3), (ii), with $A' = \widehat{A}$, the ring $B' = B \otimes_A A'$ is a local ring of $C \otimes_A A'$ at a prime ideal above $\mathfrak{n}$; as A and A′ have the same residue field k, the residue field of $C \otimes_A A'$ at this prime ideal is equal to k'. Moreover $C \otimes_A A'$ is generated by a single element over A′. It follows therefore from (7.4.3), (ii) that one can restrict to proving (7.4.4.1) when $\boldsymbol{P}$ is the property (iv′) of (7.3.8), that A is *complete* and C generated by a single element t.

To show that the formal fibres of $B = C_{\mathfrak{n}}$ are then geometrically regular, let us apply the criterion (7.3.16), b)). Let B_1 be a finite integral B-algebra, hence generated by a finite number of elements integral over B. By multiplying these elements by an element of $S = C - \mathfrak{n}$, one can suppose that they are integral over C, and we can therefore write $B_1 = S^{-1}C_1$, where C_1 is a sub-C-algebra of B_1 generated by a finite number of integral elements over C, hence a finite integral C-algebra. On the other hand, B_1 is a semi-local ring, and every local ring B_2 of B_1 at a maximal ideal is a local ring of C_1, such that $A \to B_2$ is a local homomorphism; moreover, the residue field of B_2 is a finite extension of k', hence of k. We see therefore (taking into account (7.3.14) and (i)) that we are reduced to the following question: let C be a Noetherian integral ring containing a subring C_0 which is an A-algebra generated by a single element t and such that C is a finite C_0-algebra; if $\mathfrak{n}$ is a maximal ideal of C above the maximal ideal of A, and $B = C_{\mathfrak{n}}$, the question is to show that for every prime ideal $\mathfrak{q}$ of $\widehat{B}$ whose inverse image in B is 0, the ring $\widehat{B}_{\mathfrak{q}}$ is regular. One may moreover replace A by its image in C, which is a complete local ring (as a quotient of A) and integral. The desired conclusion follows from the more general lemma below. □ **IV-2** | 201

Lemma (7.4.4.2). — *Let* A *be a complete Noetherian local integral ring, k its residue field,* C *an integral ring containing* A*, such that there exists $t \in C$ for which* C *is a finite* $A[t]$*-algebra. Let $\mathfrak{n}$ be a maximal ideal of* C *above the maximal ideal $\mathfrak{m}$ of* A*; set $B = C_{\mathfrak{n}}$, $X = \operatorname{Spec}(B)$, $B' = \widehat{B}$, $X' = \operatorname{Spec}(\widehat{B})$; if $U = \operatorname{Reg}(X)$, $U' = \operatorname{Reg}(X')$, and if $f : X' \to X$ is the canonical morphism, then $f^{-1}(U) \subset U'$.*

Proof. The assertion needed for (7.4.4.1) follows from this lemma because, since B is integral, the generic point of X belongs to U. Since C is an A-algebra of finite type and $\mathfrak{n}$ is a maximal ideal of C, the residue field k' of $C_{\mathfrak{n}} = B$ (hence also of B′) is a finite extension of k (**I**, 6.4.11) and (6.4.2).

Set $Y = \operatorname{Spec}(C)$. It follows from (6.12.8) that $\operatorname{Reg}(Y)$ is open in Y; since the local rings of X are local rings of Y (**I**, 2.4.2), we have $U = X \cap \operatorname{Reg}(Y)$, hence U is open in X. On the other hand, (6.12.7) shows that U′ is open in X′, hence $S' = X' - U'$ is closed. Consequently $S' \cap f^{-1}(U)$ is locally closed in X′, and the whole question is to prove that this set is empty. If it were non-empty, (5.1.10) would give a prime ideal $\mathfrak{p}'$ in $S' \cap f^{-1}(U)$ such that $\dim(B'/\mathfrak{p}') \leqslant 1$. The prime ideal $\mathfrak{p}'$ cannot be the maximal ideal $\mathfrak{m}B'$ of B′, where $\mathfrak{m}$ is the maximal ideal of B. Indeed, this would mean that $B = B_{\mathfrak{m}}$ is regular, hence so is $B' = \widehat{B}$ (**0**, 17.1.5), and we would have $\mathfrak{m}B' \in U'$, contrary to the hypothesis. We must therefore have $\dim(B'/\mathfrak{p}') = 1$.

Set $\mathfrak{p} = B \cap \mathfrak{p}'$. By hypothesis $B_{\mathfrak{p}}$ is regular, whereas $B'_{\mathfrak{p}'}$ is not. Since $B'_{\mathfrak{p}'}$ is a flat $B_{\mathfrak{p}}$-module, (6.5.2) shows that the fibre Z of f at $\mathfrak{p}$ is not regular at $\mathfrak{p}'$. We may reduce to the case $\mathfrak{p} = 0$. Indeed, in general, set $\mathfrak{q} = \mathfrak{p} \cap C$ and $\mathfrak{r} = \mathfrak{p} \cap A$. Then $C/\mathfrak{q}$ is a finite $(A/\mathfrak{r})[\bar{t}]$-algebra, where $\bar{t}$ is the class of t modulo $\mathfrak{q}$; since $\mathfrak{p} = \mathfrak{q}B$, the ring $B/\mathfrak{p}$ is equal to $(C/\mathfrak{q})_{\mathfrak{n}/\mathfrak{q}}$, and $\mathfrak{n}/\mathfrak{q}$ is a maximal ideal of $C/\mathfrak{q}$ lying over the maximal ideal $\mathfrak{m}/\mathfrak{r}$ of $A/\mathfrak{r}$. Thus the hypotheses of (7.4.4.2) are still satisfied by $A/\mathfrak{r}$, $C/\mathfrak{q}$, and $B/\mathfrak{p}$; since the completion of $B/\mathfrak{p}$ is $B'/\mathfrak{p}B'$, this proves the reduction.

Suppose therefore that $\mathfrak{p} = 0$, so that Z is the generic fibre of f and the homomorphism $B \to B'/\mathfrak{p}'$ is injective. Set $V = B'/\mathfrak{p}'$, and distinguish two cases.

I) V *is a finite* A*-algebra.* Since $B \subset V$, B is *a fortiori* a finite A-algebra; as A is complete, so is B (Bourbaki, *Alg. comm.*, chap. IV, § 2, nº 5, cor. 3 of prop. 9). Hence $B' = B$ and $\mathfrak{p}' = 0$, so $B'_{\mathfrak{p}'}$ is a field, contrary to the hypothesis.

II) V *is not a finite* A*-algebra.* Since the local ring A is complete, V is not a quasi-finite A-algebra (**0**, 7.4.1) and (**0**, 7.4.2); but the residue field k' of V is a finite extension of the residue field k of A, hence (**0**, 7.4.4) the ideal $\mathfrak{m}V$ is not an ideal of definition of V. Since V is a one-dimensional Noetherian local integral ring, 0 is the only ideal of V that is not an ideal of definition, hence $\mathfrak{m}V = 0$. But $A \subset V$ and V is integral, so $\mathfrak{m} = 0$ and $A = k$ is a field. It follows first that $\dim(C) \leqslant 1$ (**0**, 16.1.5); but since $\dim(V) = 1$, the inequalities **IV-2** | 202

$$\dim(V) \leqslant \dim(B') = \dim(B) \leqslant \dim(C)$$

show that $\dim(C) = \dim(B) = \dim(B') = \dim(B'/\mathfrak{p}') = 1$, and consequently $\mathfrak{p}'$ is a minimal prime ideal of B'. We therefore obtain a contradiction once we prove that $B'_{\mathfrak{p}'}$ is a field, or equivalently that B' is reduced. Since C is a finite-type k-algebra, its integral closure C_1 is a finite C-algebra (Bourbaki, *Alg. comm.*, chap. V, § 3, n° 2, th. 2). If $S = C - \mathfrak{n}$, then $B_1 = S^{-1}C_1$ is the integral closure of B, hence a finite B-algebra and therefore a one-dimensional semi-local Noetherian integral and integrally closed ring (**0**, 16.1.5). If $\mathfrak{m}_j$ ($1 \leqslant j \leqslant h$) are its maximal ideals, the rings $(B_1)_{\mathfrak{m}_j}$ are discrete valuation rings (**II**, 7.1.6), and the completion B'_1 of B_1 is the direct product of the completed discrete valuation rings $(B_1)_{\mathfrak{m}_j}$ (Bourbaki, *Alg. comm.*, chap. III, § 2, n° 13, prop. 18). Thus B'_1 is reduced; since the completion B' of B is a subring of B'_1 (Bourbaki, *Alg. comm.*, chap. IV, § 2, n° 5, cor. 3 of prop. 9), B' is reduced as well. □

Corollary (7.4.5). — *Suppose that the property* $\boldsymbol{P}$ *satisfies the conditions* (P_I), (P_{II}), (P_{III}). *Let* A *be a Noetherian ring. The following conditions are equivalent:*

a) *For every prime ideal* $\mathfrak{p}$ *of* A, $A_{\mathfrak{p}}$ *is a* $\boldsymbol{P}$*-ring.*
b) *For every maximal ideal* $\mathfrak{m}$ *of* A, $A_{\mathfrak{m}}$ *is a* $\boldsymbol{P}$*-ring.*

If in addition $\boldsymbol{P}$ *satisfies* (P_{IV}), *the properties a) and b) are also equivalent to:*

c) *For every finite type A-algebra* B *and every prime ideal* $\mathfrak{q}$ *of* B, $B_{\mathfrak{q}}$ *is a* $\boldsymbol{P}$*-ring.*

Proof. The equivalence of *a*) and *b*) follows from (7.4.4), (i), and that of *a*) and *c*) from (7.4.4), (ii). When condition *a*) of (7.4.5) is satisfied, we say that A is a $\boldsymbol{P}$-ring; for semi-local Noetherian rings, this definition coincides with that of (7.3.13), when the conditions (P_I), (P_{II}) and (P_{III}) are satisfied. The ring $\mathbf{Z}$ is a $\boldsymbol{P}$-ring (7.3.19), (iv); every local Noetherian complete ring is a $\boldsymbol{P}$-ring. □

Proposition (7.4.6). — *Suppose that the property* $\boldsymbol{P}$ *satisfies the conditions* (P_I), (P_{II}) *and* (P_{III}). *Let* A *be a Noetherian ring,* $\mathfrak{J}$ *an ideal of* A, $\widehat{A}$ *the separated completion of* A *for the* $\mathfrak{J}$*-adic topology. Then, if* A *is a* $\boldsymbol{P}$*-ring* (7.4.5), *the canonical morphism* $\operatorname{Spec}(\widehat{A}) \to \operatorname{Spec}(A)$ *is a* $\boldsymbol{P}$*-morphism.*

Proof. Using (7.3.2), *c'*)), it suffices to prove that for every maximal ideal $\mathfrak{n}$ of $\widehat{A}$ with inverse image $\mathfrak{m}$ in A, the morphism $\operatorname{Spec}((\widehat{A})_{\mathfrak{n}}) \to \operatorname{Spec}(A_{\mathfrak{m}})$ is a $\boldsymbol{P}$-morphism. We know (Bourbaki, *Alg. comm.*, chap. III, § 3, n° 4, prop. 8) that the canonical homomorphism $A_{\mathfrak{m}} \to (\widehat{A})_{\mathfrak{n}}$ is injective, that the $\mathfrak{m}A_{\mathfrak{m}}$-adic topology on $A_{\mathfrak{m}}$ is induced by the $\mathfrak{n}(\widehat{A})_{\mathfrak{n}}$-adic topology, and that $A_{\mathfrak{m}}$ is dense in $(\widehat{A})_{\mathfrak{n}}$ for this topology, so that the completion of $A_{\mathfrak{m}}$ for the $\mathfrak{m}A_{\mathfrak{m}}$-adic topology identifies with that of $(\widehat{A})_{\mathfrak{n}}$ for the $\mathfrak{n}(\widehat{A})_{\mathfrak{n}}$-adic topology. We have therefore two morphisms

$$\operatorname{Spec}((A_{\mathfrak{m}})\widehat{\ }) \xrightarrow{f} \operatorname{Spec}((\widehat{A})_{\mathfrak{n}}) \xrightarrow{g} \operatorname{Spec}(A_{\mathfrak{m}})$$

such that f is faithfully flat. Since, by hypothesis, $g \circ f$ is a $\boldsymbol{P}$-morphism, it follows from (P_{II}) that g is a $\boldsymbol{P}$-morphism as well. □ **IV-2** | 203

Corollary (7.4.7). — *Suppose that* $\boldsymbol{P}$ *satisfies the conditions* (P_I), (P'_I), (P_{II}), (P_{III}) *and* (P_{IV}). *Then, if* A *is a* $\boldsymbol{P}$*-ring* (7.4.5), *the canonical morphism* $\operatorname{Spec}(A[[T_1, \ldots, T_r]]) \to \operatorname{Spec}(A)$ *is a* $\boldsymbol{P}$*-morphism. In particular, if in addition* A *is integral,* K *its field of fractions, and if* $\mathfrak{p}$ *is a prime ideal of* $B = A[[T_1, \ldots, T_r]]$ *such that* $\mathfrak{p} \cap A = 0$, *then the property* $\boldsymbol{P}(B_{\mathfrak{p}}, K)$ *is true.*

Proof. Indeed, $\operatorname{Spec}(B) \to \operatorname{Spec}(A)$ factorises as

$$\operatorname{Spec}(A[[T_1, \ldots, T_r]]) \xrightarrow{f} \operatorname{Spec}(A[T_1, \ldots, T_r]) \xrightarrow{g} \operatorname{Spec}(A).$$

It is clear that the morphism g is regular (**0**, 17.3.7); by virtue of (7.4.5), $A[T_1, \ldots, T_r]$ is a $\boldsymbol{P}$-ring, hence it follows from (7.4.6) that f is a $\boldsymbol{P}$-morphism; as g is regular, hence also a $\boldsymbol{P}$-morphism (7.3.5), (i), it follows from (P'_I) that $g \circ f$ is a $\boldsymbol{P}$-morphism.

One will note that the conclusion is still valid if, instead of supposing that $\boldsymbol{P}$ satisfies (P'_I) and that every regular morphism is a $\boldsymbol{P}$-morphism, one supposes only that a composite $g \circ f$ is a $\boldsymbol{P}$-morphism whenever g is regular and f is a $\boldsymbol{P}$-morphism (a condition in some sense symmetric to (P'_I)). □

Remark (7.4.8). — The preceding results pose the following problems:

A) Let A be a Zariski *complete* ring, and let $\mathfrak{J}$ be an ideal of definition of A; if the ring $A/\mathfrak{J}$ is a $\boldsymbol{P}$-ring, is A also a $\boldsymbol{P}$-ring? It would follow that for every Noetherian $\boldsymbol{P}$-ring A and every ideal $\mathfrak{J}$ of A, the separated completion $\widehat{A}$ for the $\mathfrak{J}$-adic topology would also be a $\boldsymbol{P}$-ring.

B) Let k be a valued field, complete and non-discrete; one calls *ring of restricted formal power series* $k\{T_1, \dots, T_n\}$ the subring of the formal power series ring $k[[T_1, \dots, T_n]]$ formed of the series whose coefficients *tend to* 0. Is such a ring a $\boldsymbol{P}$-ring?

C) If A is a linearly topologised $\boldsymbol{P}$-ring, S a multiplicative subset of A, are the rings $A\{S^{-1}\}$ (**0**, 7.6.1) and $A_{\{S\}}$ (**0**, 7.6.15) $\boldsymbol{P}$-rings?

7.5. A criterion for $\boldsymbol{P}$-morphisms

(7.5.0). This number will not be used in the sequel of Chapter IV and may therefore be omitted on a first reading. We shall moreover see later (7.9.8) that the results of the present number can be considerably improved when one has "resolution of singularities" at one's disposal.

In the sequel of this number, we shall consider a property $\boldsymbol{R}(A)$, and we shall denote by $\boldsymbol{P}(Z, k)$ the following property:

"Z is a locally Noetherian prescheme over a field k, and, for every finite extension k' of k, if $Z' = Z \otimes_k k'$, the property $\boldsymbol{R}(\mathscr{O}_{Z',z'})$ is true for every $z' \in Z'$."

Theorem (7.5.1). — *Let* A *and* B *be two complete Noetherian local rings, let* $\mathfrak{m}$ *be the maximal ideal of* A*, let* $k = A/\mathfrak{m}$ *be its residue field, and let* $\varphi : A \to B$ *be a local homomorphism such that:*

(i) the residue field of B *is a finite extension of* k*;*

(ii) B *is a flat* A*-module.*

Let $\boldsymbol{R}(C)$ *moreover be a property satisfying condition* (R_{III}) (7.3.18) *and the following condition:*

(R_{IV}) *For every local ring* C *at a prime ideal of a complete Noetherian local ring, and every* C*-regular element* t *in the maximal ideal of* C*, the property* $\boldsymbol{R}(C/tC)$ *implies* $\boldsymbol{R}(C)$*.*

Let $f = {}^a\varphi : \mathrm{Spec}(B) \to \mathrm{Spec}(A)$*, and suppose that* $\boldsymbol{P}(\mathrm{Spec}(B \otimes_A k), k)$ *is true. Then, for every* **IV-2 | 204**
$x \in \mathrm{Spec}(A)$*, the property* $\boldsymbol{P}(f^{-1}(x), \boldsymbol{k}(x))$ *is true.*

Proof. In other words, property $\boldsymbol{P}$ for the fibre over the closed point of Spec(A) entails the same property for all fibres of f; that is, f is a $\boldsymbol{P}$-morphism (7.3.1). We proceed in several steps.

I) Reduction to the study of the local rings of the generic fibre. Apply (7.3.16.2). It suffices to show that, for every finite integral A-algebra A′ with field of fractions K′, if $B' = B \otimes_A A'$, then every local ring of $\mathrm{Spec}(B' \otimes_{A'} K')$ satisfies $\boldsymbol{R}$. The ring A′ (resp. B′) is complete and semi-local, the latter because it is a finite B-algebra, and is therefore a direct product of complete local rings. Since A′ is integral it is local. Every maximal ideal $\mathfrak{n}'$ of B′ lies over the maximal ideal $\mathfrak{n}$ of B, hence over $\mathfrak{m}$, and its inverse image in A′ is consequently the maximal ideal $\mathfrak{m}'$ of A′. Every local ring of $\mathrm{Spec}(B' \otimes_{A'} K')$ is a local ring of Spec(B′), and hence of one of the $\mathrm{Spec}(B'_{\mathfrak{n}'})$ over the generic point of A′. Thus it is enough to prove that the local rings of

$$\mathrm{Spec}(B'_{\mathfrak{n}'} \otimes_{A'} K')$$

satisfy $\boldsymbol{R}$. Now A′ and $B'_{\mathfrak{n}'}$ are complete Noetherian local rings. The residue field of $B'_{\mathfrak{n}'}$ is a finite extension of that of B, hence also of k, and *a fortiori* of the residue field k' of A′. This observation and (2.1.4) show that A′ and $B'_{\mathfrak{n}'}$ satisfy conditions (i) and (ii) of the statement. On the other hand, if k'' is a finite extension of k', it is also a finite extension of k, and the local rings of

$$\mathrm{Spec}(B'_{\mathfrak{n}'} \otimes_{A'} k'')$$

are also local rings of $\mathrm{Spec}(B \otimes_A k'')$. The hypothesis $\boldsymbol{P}(\mathrm{Spec}(B \otimes_A k), k)$ therefore implies

$$\boldsymbol{P}(\mathrm{Spec}(B'_{\mathfrak{n}'} \otimes_{A'} k'), k').$$

We are thus reduced to the case where A is integral with field of fractions K, and to proving that the local rings of $\mathrm{Spec}(B \otimes_A K)$ satisfy $\boldsymbol{R}$.

II) The case $\dim(A) = 1$. Let A′ be the integral closure of A. By (**0**, 23.1.6), A′ is a finite A-algebra and a complete local ring. If $B' = B \otimes_A A'$, then

$$B \otimes_A K = B' \otimes_{A'} K.$$

The same argument as in I) shows that it suffices, for every maximal ideal $\mathfrak{n}'$ of B′, to prove that the local rings of $B'_{\mathfrak{n}'} \otimes_{A'} K$ satisfy $\boldsymbol{R}$; it also shows that A′ and $B'_{\mathfrak{n}'}$ satisfy hypotheses (i) and (ii), and that

$$\boldsymbol{P}(\mathrm{Spec}(B'_{\mathfrak{n}'} \otimes_{A'} k'), k')$$

is true, where k' is the residue field of A′. Since $\dim(\mathrm{A}') = 1$ (**0**, 16.1.5) and A′ is integral and integrally closed, it is a complete discrete valuation ring. We may therefore suppose that A itself is a complete discrete valuation ring. If u is a uniformizer of A, then u is A-regular, and the flatness of B over A implies that $t = \varphi(u)$ is B-regular and belongs to the maximal ideal of B. The hypothesis on $\mathrm{Spec}(\mathrm{B} \otimes_{\mathrm{A}} k)$ implies in particular that $\boldsymbol{R}(\mathrm{B}/t\mathrm{B})$ is true; hence $\boldsymbol{R}(\mathrm{B})$ is true by $(\mathrm{R}_{\mathrm{IV}})$. Thus $\mathrm{U}_{\boldsymbol{R}}(\mathrm{Spec}(\mathrm{B}))$ contains the closed point. It is open by $(\mathrm{R}_{\mathrm{III}})$, and Spec(B) is the only open subset of itself containing its closed point. Consequently all local rings of Spec(B), and in particular those of $\mathrm{Spec}(\mathrm{B} \otimes_{\mathrm{A}} \mathrm{K})$, satisfy $\boldsymbol{R}$.

III) The general case. The case $\dim(\mathrm{A}) = 0$ is trivial, since then $\mathrm{A} = k$; we may therefore suppose that $\dim(\mathrm{A}) \geqslant 1$. By (6.12.7), Spec(A) contains a non-empty open subset V all of whose points are regular. The intersection V′ of V with the complement of the closed point of Spec(A) is non-empty and therefore contains the generic point. It suffices to prove that

$$f^{-1}(\mathrm{V}') \subset \mathrm{U}_{\boldsymbol{R}}(\mathrm{Spec}(\mathrm{B})).$$

Equivalently, the intersection Z of $f^{-1}(\mathrm{V}')$ with the complement of $\mathrm{U}_{\boldsymbol{R}}(\mathrm{Spec}(\mathrm{B}))$ must be empty. Suppose otherwise. Since $\mathrm{U}_{\boldsymbol{R}}(\mathrm{Spec}(\mathrm{B}))$ is open by $(\mathrm{R}_{\mathrm{III}})$, Z is locally closed in Spec(B); if non-empty, it contains a point x such that $\dim(\overline{\{x\}}) \leqslant 1$ (5.1.10). Since $f(x) \in \mathrm{V}'$ is distinct from the closed point of Spec(A), x is distinct from the closed point of Spec(B), and therefore $\dim(\overline{\{x\}}) = 1$.

We show this is impossible. Let $\mathfrak{q}$ be the corresponding prime ideal of B, so that $\dim(\mathrm{B}/\mathfrak{q}) = 1$, and put $\mathfrak{p} = \varphi^{-1}(\mathfrak{q})$. Then $\mathfrak{p} \neq \mathfrak{m}$ and $\mathrm{A}_{\mathfrak{p}}$ is regular. Since $\mathfrak{p} \neq \mathfrak{m}$, the ideal $\mathfrak{m}(\mathrm{B}/\mathfrak{q})$ is non-zero, hence is an ideal of definition of the one-dimensional Noetherian local integral ring $\mathrm{B}/\mathfrak{q}$. By (i), the residue field of $\mathrm{B}/\mathfrak{q}$ is a finite extension of the residue field of $\mathrm{A}/\mathfrak{p}$, so $\mathrm{B}/\mathfrak{q}$ is a quasi-finite $(\mathrm{A}/\mathfrak{p})$-algebra (**0**, 7.4.4). But $\mathrm{A}/\mathfrak{p}$ is complete and $\mathrm{B}/\mathfrak{q}$ is separated for the $\mathfrak{m}$-preadic topology, which is its local-ring topology; hence $\mathrm{B}/\mathfrak{q}$ is finite over $\mathrm{A}/\mathfrak{p}$ by (**0**, 7.4.1). The injection $\mathrm{A}/\mathfrak{p} \to \mathrm{B}/\mathfrak{q}$ consequently gives

$$\dim(\mathrm{A}/\mathfrak{p}) = \dim(\mathrm{B}/\mathfrak{q}) = 1$$

by (**0**, 16.1.5). Apply II) to $\mathrm{A}/\mathfrak{p}$ and $\mathrm{B}/\mathfrak{p}\mathrm{B}$. Their residue fields are respectively those of A and B, $\mathrm{B}/\mathfrak{p}\mathrm{B}$ is flat over $\mathrm{A}/\mathfrak{p}$, and

$$(\mathrm{B}/\mathfrak{p}\mathrm{B}) \otimes_{\mathrm{A}/\mathfrak{p}} k = \mathrm{B} \otimes_{\mathrm{A}} k = \mathrm{B}/\mathfrak{m}\mathrm{B}.$$

It follows that the local rings of

$$\mathrm{Spec}\big((\mathrm{B}/\mathfrak{p}\mathrm{B}) \otimes_{\mathrm{A}/\mathfrak{p}} \boldsymbol{k}(\mathfrak{p})\big)$$

satisfy $\boldsymbol{R}$. In particular, $\mathrm{B}_{\mathfrak{q}}/\mathfrak{p}\mathrm{B}_{\mathfrak{q}}$ is one of these local rings. Moreover, $\mathrm{B}_{\mathfrak{q}}$ is flat over the regular local ring $\mathrm{A}_{\mathfrak{p}}$. We now use the following lemma.

Lemma (7.5.1.1). — *Let $\mathscr{C}$ be a full subcategory of the category of Noetherian local rings such that every quotient ring of a ring in $\mathscr{C}$ still belongs to $\mathscr{C}$. Suppose $\boldsymbol{R}(\mathrm{C})$ has the property that, if $\mathrm{C} \in \mathscr{C}$ and t is a regular element of the maximal ideal of C such that $\boldsymbol{R}(\mathrm{C}/t\mathrm{C})$ is true, then $\boldsymbol{R}(\mathrm{C})$ is true.* **IV-2 | 205**

Let C be a regular local ring with residue field k, let $\mathrm{D} \in \mathscr{C}$ be a local ring, and let $\psi : \mathrm{C} \to \mathrm{D}$ be a local homomorphism making D a flat C-module. If $\boldsymbol{R}(\mathrm{D} \otimes_{\mathrm{C}} k)$ is true, then $\boldsymbol{R}(\mathrm{D})$ is true.

Proof. Proceed by induction on $n = \dim(\mathrm{C})$. The assertion is true by hypothesis when $n = 0$, for then $\mathrm{C} = k$. Let $t \in \mathfrak{m} - \mathfrak{m}^2$. Then $\mathrm{C}/t\mathrm{C}$ is regular and $\dim(\mathrm{C}/t\mathrm{C}) = n - 1$ (**0**, 17.1.8) and (**0**, 16.3.4). Since

$$(\mathrm{D}/t\mathrm{D}) \otimes_{\mathrm{C}/t\mathrm{C}} k = \mathrm{D} \otimes_{\mathrm{C}} k$$

and $\mathrm{D}/t\mathrm{D} \in \mathscr{C}$, the induction hypothesis gives $\boldsymbol{R}(\mathrm{D}/t\mathrm{D})$. Moreover, t is C-regular, hence D-regular by flatness (**0**, 6.3.4); the assumed property of $\boldsymbol{R}$ therefore gives $\boldsymbol{R}(\mathrm{D})$. □

To finish the proof of (7.5.1), apply (7.5.1.1) with $\mathscr{C}$ the category of local rings of spectra of complete local rings, using $(\mathrm{R}_{\mathrm{IV}})$, and take $\mathrm{C} = \mathrm{A}_{\mathfrak{p}}$ and $\mathrm{D} = \mathrm{B}_{\mathfrak{q}}$. □

Corollary (7.5.2). — *Let A be a Noetherian local ring, let $\mathfrak{m}$ be its maximal ideal and $k = \mathrm{A}/\mathfrak{m}$ its residue field, let B be a Noetherian local ring, and let $\varphi : \mathrm{A} \to \mathrm{B}$ be a local homomorphism such that:*

- *(i) the residue field of B is a finite extension of k;*
- *(ii) B is a flat A-module.*

Let $\boldsymbol{R}(\mathrm{C})$ be a property satisfying $(\mathrm{R}_{\mathrm{II}})$ (7.3.10), $(\mathrm{R}_{\mathrm{III}})$ (7.3.18), and $(\mathrm{R}_{\mathrm{IV}})$ (7.5.1). Let $\boldsymbol{R}'(\mathrm{C})$ be a property satisfying:

$(\mathrm{R_V})$ *If* C *and* D *are Noetherian local rings and* $\psi : \mathrm{C} \to \mathrm{D}$ *is a local homomorphism such that* $g = {}^a\psi : \mathrm{Spec}(\mathrm{D}) \to \mathrm{Spec}(\mathrm{C})$ *is a* $\boldsymbol{P}$*-morphism, then* $\boldsymbol{R}'(\mathrm{C})$ *implies* $\boldsymbol{R}(\mathrm{D})$.

Suppose that the canonical morphism $\mathrm{Spec}(\widehat{\mathrm{A}}) \to \mathrm{Spec}(\mathrm{A})$ *is a* $\boldsymbol{P}'$*-morphism, where* $\boldsymbol{P}'$ *is defined from* $\boldsymbol{R}'$ *as* $\boldsymbol{P}$ *is defined from* $\boldsymbol{R}$ *in* (7.5.0)*. Let* $f = {}^a\varphi : \mathrm{Spec}(\mathrm{B}) \to \mathrm{Spec}(\mathrm{A})$*, and suppose that*

$$\boldsymbol{P}\big(\mathrm{Spec}(\widehat{\mathrm{B}} \otimes_{\widehat{\mathrm{A}}} k), k\big)$$

is true. Then $\boldsymbol{P}(f^{-1}(x), \boldsymbol{k}(x))$ *is true for every* $x \in \mathrm{Spec}(\mathrm{A})$*; in other words,* f *is a* $\boldsymbol{P}$*-morphism.*

Proof. We proceed in two steps.

I) Reduction to the study of the local rings of the generic fibre. Apply (7.3.16.2) once more. The only difference from part I) of the proof of (7.5.1) is that A' is now only a semi-local integral ring, not necessarily local. Every maximal ideal $\mathfrak{n}'$ of B' lies above a maximal ideal $\mathfrak{m}'$ of A'. Every local ring of $\mathrm{Spec}(\mathrm{B}' \otimes_{\mathrm{A}'} \mathrm{K}')$ is a local ring of $\mathrm{Spec}(\mathrm{B}')$, hence of one of the $\mathrm{Spec}(\mathrm{B}'_{\mathfrak{n}'})$ over the generic point of $\mathrm{Spec}(\mathrm{A}'_{\mathfrak{m}'})$. Thus it is enough to prove that the local rings of

$$\mathrm{Spec}(\mathrm{B}'_{\mathfrak{n}'} \otimes_{\mathrm{A}'_{\mathfrak{m}'}} \mathrm{K}')$$

satisfy $\boldsymbol{R}$. By definition of $\boldsymbol{P}'$, if $\boldsymbol{P}'(\mathrm{Z}, k)$ is true then so is $\boldsymbol{P}'(\mathrm{Z} \otimes_k k', k')$ for every finite extension k' of k; the same argument as in (7.3.7) shows that the formal fibres of $\mathrm{A}'_{\mathfrak{m}'}$ satisfy $\boldsymbol{P}'$. As in part I) of the proof of (7.5.1), the rings $\mathrm{A}'_{\mathfrak{m}'}$ and $\mathrm{B}'_{\mathfrak{n}'}$ satisfy conditions (i) and (ii) above. If k' is the residue field of $\mathrm{A}'_{\mathfrak{m}'}$, then

$$\boldsymbol{P}\big(\mathrm{Spec}(\widehat{\mathrm{B}'_{\mathfrak{n}'}} \otimes_{\widehat{\mathrm{A}'_{\mathfrak{m}'}}} k'), k'\big)$$

is true: indeed, the completion of $\mathrm{A}'_{\mathfrak{m}'}$ is one of the local components of $\widehat{\mathrm{A}}' = \widehat{\mathrm{A}} \otimes_{\mathrm{A}} \mathrm{A}'$, and the completion of $\mathrm{B}'_{\mathfrak{n}'}$ is one of the local components of

$$\widehat{\mathrm{B}}' = \widehat{\mathrm{B}} \otimes_{\mathrm{B}} \mathrm{B}' = \widehat{\mathrm{B}} \otimes_{\mathrm{A}} \mathrm{A}' = \widehat{\mathrm{B}} \otimes_{\widehat{\mathrm{A}}} \widehat{\mathrm{A}}'.$$

Part I) of the proof of (7.5.1) therefore proves the assertion. We may consequently suppose that A is integral and need only prove, for its field of fractions K, that the local rings of $\mathrm{Spec}(\mathrm{B} \otimes_{\mathrm{A}} \mathrm{K})$ satisfy $\boldsymbol{R}$.

II) Reduction to the case where A *and* B *are complete.* Let ξ be the generic point of $\mathrm{Spec}(\mathrm{A})$ and let $y \in f^{-1}(\xi)$. We must prove $\boldsymbol{R}(\mathscr{O}_y)$. By $(\mathrm{R_{II}})$, it is enough to find a point $z \in \mathrm{Spec}(\widehat{\mathrm{B}})$ over y such that $\boldsymbol{R}(\mathscr{O}_z)$ is true. The hypothesis on $\mathrm{Spec}(\widehat{\mathrm{B}} \otimes_{\widehat{\mathrm{A}}} k)$ and (7.5.1) imply that the morphism

$$\widehat{f} : \mathrm{Spec}(\widehat{\mathrm{B}}) \longrightarrow \mathrm{Spec}(\widehat{\mathrm{A}})$$

is a $\boldsymbol{P}$-morphism. For any point $z \in \mathrm{Spec}(\widehat{\mathrm{B}})$ above y—such a point exists because $\widehat{\mathrm{B}}$ is faithfully flat over B—its image x in $\mathrm{Spec}(\widehat{\mathrm{A}})$ lies in the fibre $h^{-1}(\xi)$ of the canonical morphism $h : \mathrm{Spec}(\widehat{\mathrm{A}}) \to \mathrm{Spec}(\mathrm{A})$. By the hypothesis on A, $\boldsymbol{R}'(\mathscr{O}_x)$ is true; hence $(\mathrm{R_V})$ gives $\boldsymbol{R}(\mathscr{O}_z)$. □

Examples (7.5.3). — Consider the following properties $\boldsymbol{R}(\mathrm{C})$, where C is a Noetherian local ring: **IV-2 | 206**

(i) also denoted (i_n), $\mathrm{coprof}(\mathrm{C}) \leqslant n$;
(ii) also denoted (ii_n), C satisfies (S_n);
(iii) C is a Cohen–Macaulay ring;
(iv) C is a regular ring;
(v) also denoted (v_n), C is integral, integrally closed, and satisfies (R_n);
(vi) C is integral and integrally closed;
(vii) C is integral;
(viii) C is reduced.

All these properties satisfy $(\mathrm{R_{III}})$, as was seen in (7.3.19), (i). They also satisfy $(\mathrm{R_{IV}})$. For (i), this follows from (**0**, 16.4.10), (ii); for (ii) and (iii), from (5.12.4) and the fact that a complete Noetherian local ring is catenary (5.6.4); for (iv), it is the special case (**0**, 17.1.8); for (vii), it follows from (3.4.5), and for (viii), from (3.4.6); for (vi), from (5.12.7) and the catenarity just recalled; and finally, for (v), from the preceding facts and (5.12.5).

Theorem (7.5.1) is therefore applicable when $\boldsymbol{R}$ is any one of the above properties. We have also observed in (7.3.11) that properties (i) to (viii) satisfy $(\mathrm{R_{II}})$, except that for (vii) this follows from (2.1.14). As for $(\mathrm{R_V})$, if one takes $\boldsymbol{R}' = \boldsymbol{R}$, it reduces to condition $(\mathrm{R'_I})$ of (7.3.11); properties (ii) to (vi), and (viii), satisfy this condition. For (i), one may take for $\boldsymbol{R}'$ the property of being Cohen–Macaulay, by (6.3.2). For (vii), condition $(\mathrm{R}'_{\mathrm{I}})$ is not satisfied, as shown by (6.15.11), (ii) or (6.5.5), (ii). However, $(\mathrm{R}_{\mathrm{V}})$ is true if $\boldsymbol{R}'$ is the property of being regular: apply (7.5.1.1) with $\mathscr{C}$ the category of all Noetherian local rings and with $\boldsymbol{R}(\mathrm{C})$ the property of being integral; this is possible by (3.4.5).

In particular, when $\boldsymbol{R}$ is any of properties (i) to (viii), the conclusion of (7.5.2) applies if the formal fibres of A are geometrically regular; see (7.8.2).

Remarks (7.5.4). — (i) It would be interesting to know whether (7.5.1) remains true without the finiteness hypothesis (i) on the residue field of B. The answer is affirmative when the residue field k of A has characteristic 0, by Hironaka's results on resolution of singularities; see (7.9.8). A particular case of the question is the following. Let A and B be complete Noetherian rings, let k be the residue field of A, and let $\varphi : \mathrm{A} \to \mathrm{B}$ be a local homomorphism making B a formally smooth A-algebra (**0**, 19.3.1); equivalently, B is flat over A and $\mathrm{B} \otimes_{\mathrm{A}} k$ is geometrically regular over k (**0**, 19.7.1). Are the fibres of ${}^a\varphi : \mathrm{Spec}(\mathrm{B}) \to \mathrm{Spec}(\mathrm{A})$ geometrically regular? This is so when the residue field k' of B is a finite extension of k, by (7.5.1); the answer is also affirmative when k' is an extension of finite type of k. We do not know the answer when $\mathrm{B} \otimes_{\mathrm{A}} k$ is a field equal to a separable closure of k.

(ii) One could state a result analogous to (7.5.1) for a finite-type A-module M and a finite-type B-module N, concerning the properties of

$$(\mathrm{M} \otimes_{\mathrm{A}} \mathrm{N})_y \otimes_{\mathscr{O}_{\mathrm{X},x}} \boldsymbol{k}(y),$$

where y runs through Spec(B) and $x = f(y)$, deduced from properties of the same type of M_x and N_y.

(iii) Suppose $\boldsymbol{R}$ satisfies $(\mathrm{R}'_{\mathrm{I}})$, $(\mathrm{R}_{\mathrm{II}})$, $(\mathrm{R}_{\mathrm{III}})$, and $(\mathrm{R}_{\mathrm{IV}})$, and hypotheses (i) and (ii) of (7.5.2) hold. Then $\boldsymbol{R}(\mathrm{A})$ and

$$\boldsymbol{P}\big(\mathrm{Spec}(\widehat{\mathrm{B}} \otimes_{\widehat{\mathrm{A}}} k), k\big)$$

imply $\boldsymbol{R}(\mathrm{B})$. By (7.5.3), this holds for the properties listed there except (i) and (vii). For (vii), it is nevertheless plausible that the following question has an affirmative answer. Let $\varphi : \mathrm{A} \to \mathrm{B}$ be a local homomorphism of Noetherian local rings making B a flat A-module. Suppose A is complete, integral, and geometrically unibranch, and that $\mathrm{Spec}(\mathrm{B} \otimes_{\mathrm{A}} k)$, where k is the residue field of A, is geometrically locally integral. Is B then integral? This is known when k has characteristic 0, by Hironaka's resolution of singularities (7.9.8); it is also true when B is an A-algebra essentially of finite type (1.3.8) (see (11.3.10) and (11.3.11)), or when $\mathrm{Spec}(\mathrm{B} \otimes_{\mathrm{A}} k)$ is geometrically normal, for then (7.5.3) shows that $\mathrm{Spec}(\mathrm{B}) \to \mathrm{Spec}(\mathrm{A})$ is normal and one concludes by (6.15.10). Even if the residue field of B equals that of A and B is complete, the general answer is unknown.

(iv) Consider the property $\boldsymbol{R}(\mathrm{C})$: "C is reduced, equidimensional, and satisfies (R_n)". It satisfies $(\mathrm{R}_{\mathrm{IV}})$ by (5.12.5), but it is not known whether it satisfies $(\mathrm{R}'_{\mathrm{I}})$, $(\mathrm{R}_{\mathrm{II}})$, or $(\mathrm{R}_{\mathrm{III}})$; the difficulty lies in verifying equidimensionality.

In what follows of this section, we will apply (7.5.1) to the study of *completed tensor products* $\mathrm{A}\widehat{\otimes}_k\mathrm{B}$ **IV-2** | 207
of local Noetherian rings which are algebras over a field k.

Lemma (7.5.5). — *Let k be a field,* A, B *two local Noetherian complete rings containing k, the residue field of* A *being a finite extension of k. Let* C *be the completed tensor product* $\mathrm{A}\widehat{\otimes}_k\mathrm{B}$ (**0**, 7.7.5). *Then:*

(i) C *is a semi-local Noetherian complete ring.*
(ii) C *is a flat* A*-module and a flat* B*-module.*
(iii) If $\mathfrak{m}$ *is the maximal ideal of* A, $\mathfrak{m}\mathrm{C}$ *is contained in the radical of* C, *and* $\mathrm{C}/\mathfrak{m}\mathrm{C}$ *is isomorphic to* $(\mathrm{A}/\mathfrak{m}) \otimes_k \mathrm{B}$.
(iv) The residue fields of the components of C *are finite extensions of the residue field of* B.

The properties (i), (iii) and the first assertion of (ii) are particular cases of (**0**, 19.7.1.2). *To prove that* C *is a flat* B*-module, note that for every $h > 0$,*

$$\mathrm{C}/\mathfrak{m}^h\mathrm{C} = (\mathrm{A}/\mathfrak{m}^h) \otimes_k \mathrm{B}$$

is a flat B*-module, since* k *is a field; it therefore suffices to apply* (**0**, 10.2.6) *to each local component of* C*. Finally, if* $\mathfrak{n}$ *is the maximal ideal of* B*, the residue fields of the local components of* C *are also those of the local components of the Artinian ring* $(\mathrm{A}/\mathfrak{m}) \otimes_k (\mathrm{B}/\mathfrak{n})$*, and hence are finite extensions of* $\mathrm{B}/\mathfrak{n}$*.*

Proposition (7.5.6). — *Let* k *be a field, and let* A *and* B *be complete Noetherian local rings containing* k*, whose residue fields are finite extensions of* k*. Let* $\boldsymbol{R}$ *be a property satisfying* $(\mathrm{R}'_{\mathrm{I}})$*,* $(\mathrm{R}_{\mathrm{III}})$ *and* $(\mathrm{R}_{\mathrm{IV}})$*, with* $\boldsymbol{P}$ *defined from* $\boldsymbol{R}$ *as in* (7.5.0)*. Suppose that* $\boldsymbol{R}(\mathrm{A})$ *and* $\boldsymbol{P}(\mathrm{Spec}(\mathrm{B}), k)$ *hold; the latter means that, for every finite extension* k' *of* k *and each complete local ring* B_h *occurring as a component of* $\mathrm{B} \otimes_k k'$*, one has* $\boldsymbol{R}(\mathrm{B}_h)$*. Then* $\boldsymbol{R}(\mathrm{C}_j)$ *holds for every complete local component* C_j *of* $\mathrm{A}\widehat{\otimes}_k\mathrm{B}$*.*

Proof. By (7.5.5), (iii), each homomorphism $\mathrm{A} \to \mathrm{C}_j$ is local; by (7.5.5), (ii), each C_j is flat over A; and by (7.5.5), (iv), its residue field is a finite extension of $\mathrm{A}/\mathfrak{m}$. Moreover,

$$\mathrm{C}/\mathfrak{m}\mathrm{C} = (\mathrm{A}/\mathfrak{m}) \otimes_k \mathrm{B},$$

so the definition of $\boldsymbol{P}$ and the fact that $\mathrm{A}/\mathfrak{m}$ is finite over k imply

$$\boldsymbol{P}\big(\mathrm{Spec}(\mathrm{C}_j \otimes_{\mathrm{A}} \mathrm{A}/\mathfrak{m}), \mathrm{A}/\mathfrak{m}\big).$$

Thus all the hypotheses of (7.5.1) hold for the local homomorphism $\mathrm{A} \to \mathrm{C}_j$, so $\mathrm{Spec}(\mathrm{C}_j) \to \mathrm{Spec}(\mathrm{A})$ is a $\boldsymbol{P}$-morphism. The conclusion follows from $(\mathrm{R}'_{\mathrm{I}})$ and $\boldsymbol{R}(\mathrm{A})$. □

Corollary (7.5.7). — *(Chevalley). — Let* k *be a perfect field (resp. algebraically closed),* A*,* B *two local Noetherian complete rings containing* k *and whose residue fields are finite extensions of* k*. Then, if* A *and* B *are reduced (resp. integral), the completed tensor product* $\mathrm{A}\widehat{\otimes}_k\mathrm{B}$ *is reduced (resp. integral).*

Proof. I) Suppose k is perfect and A and B are reduced. Let A_i (resp. B_j) be the quotients of A (resp. B) by its minimal prime ideals. Then A and B identify with subrings of $\prod_i \mathrm{A}_i$ and $\prod_j \mathrm{B}_j$. Since the tensor products are taken over a field, $\mathrm{A} \otimes_k \mathrm{B}$ identifies with a subring of $\prod_{i,j}(\mathrm{A}_i \otimes_k \mathrm{B}_j)$; the tensor-product topology is induced by the product of the corresponding topologies. Hence $\mathrm{A}\widehat{\otimes}_k\mathrm{B}$ embeds in $\prod_{i,j}(\mathrm{A}_i\widehat{\otimes}_k\mathrm{B}_j)$, and we are reduced to the case where A and B are integral.

Let A' and B' be their integral closures. By Nagata's finiteness theorem (**0**, 23.1.6), A' (resp. B') is a finite A-module (resp. B-module) and a complete local ring. It suffices to show that $\mathrm{A}\widehat{\otimes}_k\mathrm{B}$ embeds in $\mathrm{A}'\widehat{\otimes}_k\mathrm{B}$ and that the latter embeds in $\mathrm{A}'\widehat{\otimes}_k\mathrm{B}'$. This follows from the lemma below.

Lemma (7.5.7.1). — *Let* A*,* B *be two local Noetherian complete rings containing a field* k *and whose residue fields are finite extensions of* k*. Let* $\mathfrak{m}$ *be the maximal ideal of* A*. For every* A*-module* M *of finite type (equipped with the* $\mathfrak{m}$*-adic topology), the completed tensor product* $\mathrm{M}\widehat{\otimes}_k\mathrm{B}$ (**0**, 7.7.1) *identifies canonically with* $\mathrm{M} \otimes_{\mathrm{A}} (\mathrm{A}\widehat{\otimes}_k\mathrm{B})$*.*

Proof. Indeed, one has a canonical isomorphism $\mathrm{M} \otimes_k \mathrm{B} \xrightarrow{\sim} \mathrm{M} \otimes_{\mathrm{A}} (\mathrm{A} \otimes_k \mathrm{B})$, hence a canonical composite homomorphism

$$\varphi : \mathrm{M} \otimes_k \mathrm{B} \longrightarrow \mathrm{M} \otimes_{\mathrm{A}} (\mathrm{A} \otimes_k \mathrm{B}) \longrightarrow \mathrm{M} \otimes_{\mathrm{A}} (\mathrm{A}\widehat{\otimes}_k\mathrm{B})$$

and it is immediate that this homomorphism is continuous for the tensor product topologies; furthermore, $\mathrm{M} \otimes_{\mathrm{A}} (\mathrm{A}\widehat{\otimes}_k\mathrm{B})$ is separated and complete ((7.5.5) and (**0**, 7.7.8)), hence one also has by completion a continuous homomorphism

$$\widehat{\varphi} : \mathrm{M}\widehat{\otimes}_k\mathrm{B} \longrightarrow \mathrm{M} \otimes_{\mathrm{A}} (\mathrm{A}\widehat{\otimes}_k\mathrm{B})$$

It is immediate that this homomorphism is bijective when M is free of finite type; as one has an **IV-2** | 208
exact sequence $\mathrm{L}' \to \mathrm{L} \to \mathrm{M} \to 0$, where L and L' are free A-modules of finite type, one deduces a commutative diagram

$$\begin{tikzcd}
\mathrm{L}'\widehat{\otimes}_k\mathrm{B} \arrow[r] \arrow[d] & \mathrm{L}\widehat{\otimes}_k\mathrm{B} \arrow[r] \arrow[d] & \mathrm{M}\widehat{\otimes}_k\mathrm{B} \arrow[r] \arrow[d] & 0 \\
\mathrm{L}' \otimes_{\mathrm{A}} (\mathrm{A}\widehat{\otimes}_k\mathrm{B}) \arrow[r] & \mathrm{L} \otimes_{\mathrm{A}} (\mathrm{A}\widehat{\otimes}_k\mathrm{B}) \arrow[r] & \mathrm{M} \otimes_{\mathrm{A}} (\mathrm{A}\widehat{\otimes}_k\mathrm{B}) \arrow[r] & 0
\end{tikzcd}$$

where the rows are exact (the first by virtue of the definition of the completed tensor product and of (**0**, 13.2.2)); the first two vertical arrows being bijections, it follows that so is the third. □

The fact that $A\widehat{\otimes}_k B$ identifies with a subring of $A' \otimes_A (A\widehat{\otimes}_k B)$ follows from the inclusion $A \subset A'$ and from the fact that $A\widehat{\otimes}_k B$ is a flat A-module (7.5.5). One can thus further suppose that A and B are *integrally closed*; as moreover k is supposed *perfect*, $\mathrm{Spec}(A)$ and $\mathrm{Spec}(B)$ are *geometrically normal* over k, by virtue of (6.7.7), *b*)); one can then apply (7.5.6) taking for $\boldsymbol{R}$ the property (vi) of (7.5.3).

II) Suppose k is algebraically closed and A and B are integral. The argument in I) again reduces us to the case where A and B are integrally closed. By (7.5.6), $\mathrm{Spec}(A\widehat{\otimes}_k B)$ is normal, so $A\widehat{\otimes}_k B$ is a finite product of integrally closed complete local rings. It remains only to show that it is local. If $\mathfrak{m}$ and $\mathfrak{n}$ are the maximal ideals of A and B, it suffices to show that $(A/\mathfrak{m}) \otimes_k (B/\mathfrak{n})$ is local. Since both residue fields are finite extensions of the algebraically closed field k, they are equal to k, and the conclusion follows. □

Remark (7.5.8). — It would be interesting to determine whether, in (7.5.7), one can replace the hypothesis that k is perfect or algebraically closed by the hypothesis that $\mathrm{Spec}(A)$ or $\mathrm{Spec}(B)$ is *geometrically integral* over k, or at least by the hypothesis that A (for example) is integral and contains a subring A_0 isomorphic to a formal power series ring $k[\![T_1, \ldots, T_n]\!]$, such that the field of fractions K of A is *separable* over the field of fractions K_0 of A_0 (one can show that this condition entails that A is geometrically integral over k, and that the two properties are equivalent when $[k : k^p]$ is finite (p being the characteristic exponent of k)). Likewise, it would be desirable to develop variants of (7.5.6) and (7.5.7) where one would weaken the hypothesis of finiteness of the residue fields of A and B, by supposing for example that only one of them is a finite extension of k, the other being arbitrary.

7.6. Applications: I. Japanese local rings

Proposition (7.6.1). — *Let* A *be a reduced local Noetherian ring whose formal fibres are geometrically normal. Then the completion* $\widehat{A}$ *is reduced, the integral closure* A' *of* A *in its total ring of fractions is a finite* A*-algebra (hence a semi-local Noetherian ring), and its completion* $\widehat{A'}$ *is isomorphic to the integral closure of* $\widehat{A}$ *in its total ring of fractions.*

Proof. The formal fibres of A are *a fortiori* geometrically reduced, so the reducedness of A implies that of $\widehat{A}$ by (7.3.17). Let $\mathfrak{p}_i$ be the minimal prime ideals of A and put $B_i = A/\mathfrak{p}_i$. The formal fibres of the local rings B_i are geometrically normal (7.3.15); hence $\widehat{B}_i$ is reduced, and (**0**, 23.1.7), (i), shows that the integral closure B'_i of B_i in its field of fractions is finite over B_i, and therefore over A. Since $A' = \prod_i B'_i$ (**II**, 6.3.8), A' is a finite A-module.

Let $\mathfrak{m}_j$ be the maximal ideals of the semi-local ring A'. Its completion $\widehat{A'}$ identifies with the product of the completions $\widehat{A'_{\mathfrak{m}_j}}$ (Bourbaki, *Alg. comm.*, chap. III, § 2, n° 13, cor. of prop. 19).

By the hypothesis and (7.3.15), the formal fibres of each $A'_{\mathfrak{m}_j}$ are geometrically normal. Since A' is normal, so is each $A'_{\mathfrak{m}_j}$, and (7.3.17) then shows that each $\widehat{A'_{\mathfrak{m}_j}}$, and hence $\widehat{A'}$, is normal. **IV-2** | 209

Since A' is finite over A, one has $\widehat{A'} = A' \otimes_A \widehat{A}$ (Bourbaki, *Alg. comm.*, chap. IV, § 2, n° 5, cor. 3 of prop. 9, and chap. III, § 3, n° 4, th. 3). If R denotes the total ring of fractions of A, then

$$\widehat{A} \subset \widehat{A'} \subset R' = R \otimes_A \widehat{A}.$$

Flatness of $\widehat{A}$ over A implies that every regular element of A remains regular in $\widehat{A}$; hence R' embeds canonically in the total ring of fractions R'' of $\widehat{A}$ (Bourbaki, *Alg. comm.*, chap. II, § 2, n° 1, Remark 7). Since $\widehat{A'}$ is normal and finite over $\widehat{A}$, it is precisely the integral closure of $\widehat{A}$ in R''. □

Corollary (7.6.2). — *Under the hypotheses of* (7.6.1), *there is a bijective correspondence between the maximal ideals* $\mathfrak{m}_j$ *of* A' *(in other words, the set of closed points of* $\mathrm{Spec}(A')$ *above the closed point of* A*) and the set of minimal prime ideals* $\mathfrak{q}_j$ *of* $\widehat{A}$ *(in other words, the set of maximal points of* $\mathrm{Spec}(\widehat{A})$*); in this correspondence, the completion* $\widehat{A'_{\mathfrak{m}_j}}$ *of* $A'_{\mathfrak{m}_j}$ *is isomorphic to the integral closure of* $\widehat{A}/\mathfrak{q}_j$.

Proof. Indeed, one knows that the integral closure of $\widehat{A}$ in its total ring of fractions is the direct product of the integral closures of the $\widehat{A}/\mathfrak{q}_j$, which are complete local rings (**0**, 23.1.6). □

Corollary (7.6.3). — *Under the hypotheses of* (7.6.1), *for* $\widehat{A}$ *to be integral, it is necessary and sufficient that* A *be unibranch; for* $\widehat{A}$ *to be geometrically unibranch, it is necessary and sufficient that* A *be geometrically unibranch.*

Proof. This is a particular case of (7.6.2). □

Theorem (7.6.4). — *(Zariski-Nagata). — Let* A *be a semi-local Noetherian ring. The following conditions are equivalent:*

a) *For every finite reduced* A*-algebra* C*, the completion* $\widehat{C}$ *is a reduced ring.*

a′) *For every integral quotient ring* B *of* A*, with field of fractions* K*, the completion* $\widehat{B}$ *is reduced, and the fields* L_i *of the total ring of fractions of* $\widehat{B}$ *are separable extensions of* K*.*

a″) *The formal fibres are geometrically reduced (in other words, for every integral quotient ring* B *of* A*, with field of fractions* K*, the* K*-algebra* $\widehat{B} \otimes_B K$ *is separable* (4.6.2)*).*

b) *Every integral quotient ring* B *of* A *is a Japanese ring.*

Proof. To show that *a*) implies *a′*), it suffices to verify that the L_i are separable extensions of K, or equivalently (4.6.1) that for every finite extension K′ of K, the ring $\widehat{B} \otimes_B K'$ is reduced. The field K′ is generated by finitely many elements integral over B; these generate a finite B-subalgebra B′ of K′ whose field of fractions is K′. One has

$$\widehat{B'} = \widehat{B} \otimes_B B'$$

(**0**, 7.3.3) and Bourbaki, *Alg. comm.*, chap. IV, § 2, n° 5, cor. 3 of prop. 9.

Therefore, by associativity of the tensor product, **IV-2** | 210

$$\widehat{B} \otimes_B K' = \widehat{B'} \otimes_{B'} K'.$$

Now B′ is a finite integral A-algebra, so $\widehat{B'}$ is reduced by *a*). Since $\widehat{B'}$ is flat over B′, the nonzero elements of B′ are $\widehat{B'}$-regular; hence $\widehat{B'} \otimes_{B'} K'$ identifies with a subring of the total ring of fractions of $\widehat{B'}$, and is therefore reduced.

To see that *a′*) implies *a″*), consider any point *x* of $X = \operatorname{Spec}(A)$, and let Y be the integral closed subprescheme of X having $\overline{\{x\}}$ as its underlying space. Then $Y = \operatorname{Spec}(B)$, where B is an integral quotient ring of A, and $\operatorname{Spec}(\widehat{B}) = Y \times_X \operatorname{Spec}(\widehat{A})$. Thus the formal fibre of A at *x* is the same as that of B at its generic point, namely $\operatorname{Spec}(\widehat{B} \otimes_B K)$. Its local rings are those of $\operatorname{Spec}(\widehat{B})$ at the points of this fibre, so the hypothesis implies that $\widehat{B} \otimes_B K$ is reduced; the remaining condition in *a′*) then says that it is a separable K-algebra (4.6.1).

The condition *a″*) implies *a*), for it follows from (7.3.15) that the formal fibres of C are geometrically reduced, and if C is reduced, it follows hence that so is $\widehat{C}$ (particular case of (7.3.17)).

The fact that *a′*) implies *b*) is a particular case of (**0**, 23.1.7). It remains to prove that *b*) implies *a*). If C is a finite A-algebra and $\mathfrak{q}$ is a prime ideal of C, then the inverse image $\mathfrak{p}$ of $\mathfrak{q}$ in A is prime and $C/\mathfrak{q}$ is a finite $(A/\mathfrak{p})$-algebra. Thus *b*) implies that every integral quotient ring of C is Japanese. We are therefore reduced to proving that, under *b*), *the completion of every integral quotient ring of* A *is reduced*.

We argue by induction on $n = \dim(A)$, the assertion being trivial for $n = 0$. Replacing A by the quotients by its minimal prime ideals $\mathfrak{p}_i$, we may restrict to the case where A is integral. For every nonzero prime ideal $\mathfrak{p}$, the induction hypothesis already shows that the completion of $A/\mathfrak{p}$ is reduced; it therefore suffices to prove that $\widehat{A}$ is reduced.

Moreover, the integral closure A′ of A is, by hypothesis, a finite A-module, hence a semi-local Noetherian ring, and $\widehat{A}$ identifies with a subring of $\widehat{A'}$ (**0**, 7.3.3). It is therefore enough to prove that $\widehat{A'}$ is reduced. As observed above, *b*) also holds for A′, and $\dim(A') = n$ (**0**, 16.1.5); hence we may suppose that A is *integrally closed*. Let $t \neq 0$ belong to the Jacobson radical of A, and let $\mathfrak{q}_j$ $(1 \leqslant j \leqslant r)$ be the prime ideals minimal among those containing *t*A; then:

(i) *t* is regular.

(ii) A/tA has no immersed associated prime ideals.

(iii) The $A_{\mathfrak{q}_j}$ are discrete valuation rings.

(iv) The completions of the $A/\mathfrak{q}_j$ are reduced.

Indeed, (i) is trivial since A is integral and $t \neq 0$. As A is integrally closed, A/tA satisfies (S_1), that is to say (5.7.7) is without immersed associated prime ideals (Bourbaki, *Alg. comm.*, chap. VII, § 1, no 4, prop. 8). Since A is integrally

IV-2 | 211

closed, the $A_{\mathfrak{q}_j}$ are, and one knows (*loc. cit.*) that these rings are of dimension 1, hence they are discrete valuation rings, whence (iii). Finally, (iv) follows from the hypothesis of induction. The proof will be completed if we prove the

Lemma (7.6.4.1). — *(Zariski). — Let* A *be a semi-local Noetherian ring, t an element of its radical satisfying the conditions (i) to (iv) above; then* $\widehat{A}$ *is reduced.*

Proof. Set for simplicity $A' = \widehat{A}$, and consider t as an element of A'; one has $A'/tA' = (A/tA) \otimes_A A'$, and as A' is a flat A-module, it follows from (3.3.1) that the prime ideals of A' associated to the A'-module A'/tA' are the prime ideals $\mathfrak{q}'_{jh}$ such that $\mathfrak{q}'_{jh}$ lies above $\mathfrak{q}_j$ and is associated to the k_j-module $(A'/tA') \otimes_A k_j$, where k_j is the field of fractions of $A/\mathfrak{q}_j$. Now, $\operatorname{Spec}((A'/tA') \otimes_A k_j)$ is the formal fibre of A at the point $\mathfrak{q}_j$, or equivalently that of $A/\mathfrak{q}_j$ at its generic point. By (iv), the completion $A'/\mathfrak{q}_j A'$ of $A/\mathfrak{q}_j$ is reduced; hence so is its formal fibre at the generic point. This formal fibre therefore has no embedded associated prime, and its local rings at the generic points $\mathfrak{q}'_{jh}$ of its irreducible components are fields (3.2.1). It follows from (3.3.3) and (ii) that $\mathfrak{q}_j A'_{\mathfrak{q}'_{jh}}$ is the maximal ideal of $A'_{\mathfrak{q}'_{jh}}$ for every h. Since $A_{\mathfrak{q}_j}$ is a discrete valuation ring, its maximal ideal is principal; therefore the maximal ideal of the Noetherian local ring $A'_{\mathfrak{q}'_{jh}}$ is principal, and this ring is a discrete valuation ring (Bourbaki, *Alg. comm.*, chap. VI, § 3, n° 6, prop. 9). We have thus verified the relevant hypotheses for the *complete semi-local ring* A'. It therefore suffices to show that if A is complete and satisfies (i) to (iii), then A is reduced.

The hypotheses (i) and (ii) imply that, if $\varphi : A \to \prod_{j=1}^{r} A_{\mathfrak{q}_j}$ is the canonical homomorphism, then for every $m \geqslant 0$ one has $t^m A = \varphi^{-1}(\varphi(t^m A))$ (3.4.9). Since the image of tA in each discrete valuation ring $A_{\mathfrak{q}_j}$ is a power of its maximal ideal, the tA-adic topology on A is the inverse image under φ of the product topology on $\prod_{j=1}^{r} A_{\mathfrak{q}_j}$. As t belongs to the Jacobson radical of A, the tA-adic topology is separated, hence φ is injective. By (iii), the rings $A_{\mathfrak{q}_j}$ are integral; their product is reduced, and therefore so is A. □

Corollary (7.6.5). — *Let* A *be a semi-local Noetherian ring satisfying the equivalent conditions of (7.6.4); every semi-local* A*-algebra essentially of finite type also satisfies the conditions of (7.6.4).*

Proof. The condition a'') of (7.6.4) means indeed that A is a $\boldsymbol{P}$-ring, where $\boldsymbol{P}(Z, k)$ is the property "Z is geometrically reduced over k"; the corollary is then a consequence of the general theorem (7.4.4). □

Corollary (7.6.6). — *Let* A *be a semi-local Noetherian integral ring of dimension* 1*,* K *its field of fractions. For* A *to be a Japanese ring, it is necessary and sufficient that the completion* $\widehat{A}$ *be reduced and that, if* $\mathfrak{q}_j$ $(1 \leqslant j \leqslant n)$ *are the minimal prime ideals of* $\widehat{A}$*, the fields of fractions of the integral rings* $\widehat{A}/\mathfrak{q}_j$ *be separable extensions of* K*.* **IV-2** | 212

Proof. The integral quotients of A are A itself and fields, hence the condition b) of (7.6.4) is equivalent to the hypothesis that A is a Japanese ring, and the hypothesis a') to the conditions on $\widehat{A}$, whence the conclusion. □

Remarks (7.6.7). — *i)* The equivalent conditions of (7.6.6) mean again that the formal fibres of A are geometrically regular (7.3.19), (iv)). One has already observed (*loc. cit.*) that this condition is satisfied when A is a *discrete valuation ring whose field of fractions is of characteristic* 0.

ii) The same reasoning as in the first part of the proof of (7.6.4) shows that for a semi-local Noetherian ring A, the two following conditions are equivalent:

a) For every integral quotient ring B of A, the completion $\widehat{B}$ is reduced.

a′) The formal fibres of A are reduced.

Taking into account (**0**, 23.1.7), (i), these two conditions imply the following:

b) For every integral quotient ring B of A, the integral closure of B is a finite B-algebra.

When A is a universally catenary ring, one can prove that the condition b) conversely implies a); we will not need to use this result.

7.7. Applications: II. Universally Japanese rings

(7.7.1). Recall (**0**, 23.1.1) that one calls a ring *universally Japanese* a ring A such that every integral A-algebra *of finite type* is a Japanese ring. This amounts to saying that for every integral A-algebra B of finite type, the integral closure of B is a finite B-algebra.

Theorem (7.7.2). — *(Nagata). — Let* A *be a Noetherian ring. The following conditions are equivalent:*

a) A *is a universally Japanese ring.*
b) *Every integral quotient ring of* A *is a Japanese ring.*
c) *For every maximal ideal* $\mathfrak{m}$ *of* A*, every integral quotient ring of* $A_{\mathfrak{m}}$ *is a Japanese ring, and for every integral quotient ring* B *of* A*, with field of fractions* K*, every finite radicial extension* K′ *of* K *and every sub-*B*-algebra finite* B′ *of* K′*, with field of fractions* K′*, there exists* $f' \neq 0$ *in* B′ *such that* $B'_{f'}$ *is integrally closed (cf.* (6.13.7)*).*

Moreover, if A *satisfies these conditions, so does every ring of fractions* $S^{-1}A$ *of* A *and every* A*-algebra of finite type.*

Proof. Let us first show that *b*) implies *c*); every integral quotient ring of $A_{\mathfrak{m}}$ is a ring of fractions of an integral quotient ring of A, hence a Japanese ring (**0**, 23.1.1). On the other hand, every quotient B of A by one of its prime ideals is a Japanese ring (**0**, 23.1.1). One deduces that the set $\mathrm{Nor}(\mathrm{Spec}(B'))$ is open (6.13.3), hence contains a non-empty open set $D(f') = \mathrm{Spec}(B'_{f'})$.

Let us show secondly that, if A satisfies *c*), so does every A-algebra of finite type B. In the first instance, for every prime ideal $\mathfrak{q}$ of B, $B_{\mathfrak{q}}$ is a local ring in $S^{-1}B$, where $S = A - \mathfrak{p}$, $\mathfrak{p}$ being the inverse image of $\mathfrak{q}$ in A; as by hypothesis every integral quotient ring of $A_{\mathfrak{p}}$ is a Japanese ring, so is every integral quotient ring of $B_{\mathfrak{q}}$, since $S^{-1}B$ is an $A_{\mathfrak{p}}$-algebra of finite type (7.6.5). On the other hand, if C is an integral quotient ring of B, with field of fractions K, K′ a finite radicial extension of K and C′ a sub-C-algebra finite of K′, with field of fractions K′, C′ is an A-algebra integral of finite type, and in virtue of (6.13.7), the hypothesis *c*) on A entails that the spectrum of C′ contains a non-empty open part whose points are all normal; in other words, there is a $g' \neq 0$ in C′ such that $C'_{g'}$ is integrally closed, which proves our assertion. **IV-2 | 213**

This result shows that, to prove the equivalence of *a*), *b*) and *c*), it suffices to show that *c*) implies *b*), and even that for every integral quotient ring B of A, with field of fractions K, the integral closure B′ of B is a B-module of finite type. Now, condition *c*) implies that there exists $f \neq 0$ in B such that B_f is integrally closed, and thus condition (i) of (6.13.6) has been verified for B. Condition (ii) of (6.13.6) is also verified for B: for every maximal ideal $\mathfrak{q}$ of B, $B_{\mathfrak{q}}$ is a quotient of a local ring $A_{\mathfrak{p}}$, where $\mathfrak{p}$ is maximal in A; since $A_{\mathfrak{p}}$ is a Japanese ring by hypothesis, so is $B_{\mathfrak{q}}$. Moreover, for every prime ideal $\mathfrak{r}$ of B, $B_{\mathfrak{r}}$ is a ring of fractions of some $B_{\mathfrak{q}}$, where $\mathfrak{q}$ is a maximal ideal of B, and is therefore again a Japanese ring. This proves the assertion.

We have also seen above that if A satisfies the equivalent conditions *a*), *b*) and *c*), the same holds for every A-algebra of finite type. Moreover, if A satisfies *b*), so does every ring of fractions $S^{-1}A$: every integral quotient ring of $S^{-1}A$ is of the form $S^{-1}A/S^{-1}\mathfrak{p}$, where $\mathfrak{p}$ is a prime ideal of A; since $A/\mathfrak{p}$ is by hypothesis a Japanese ring, so is $S^{-1}(A/\mathfrak{p})$ (**0**, 23.1.1). This completes the proof of the last assertion of the statement. □

Corollary (7.7.3). — *Let* A *be a Noetherian ring satisfying the following conditions:*

(i) For every maximal ideal $\mathfrak{m}$ *of* A*, the formal fibres of* $A_{\mathfrak{m}}$ *are geometrically reduced.*
(ii) The equivalent conditions of (6.12.4) *are satisfied.*

Then A *is universally Japanese.*

Proof. Indeed, it follows then from (7.6.4) that every integral quotient ring of $A_{\mathfrak{m}}$ is a Japanese ring; whence the conclusion, by virtue of (7.7.2). □

Corollary (7.7.4). — *A Dedekind ring whose field of fractions is of characteristic* 0 *(in particular* **Z***) is a universally Japanese ring. A local Noetherian ring whose formal fibres are geometrically reduced (in particular a local Noetherian complete ring) is universally Japanese.*

Proof. The first assertion follows from (7.7.3), (7.6.7), (i) and (6.12.6). The second follows from (7.6.4) and (7.7.2). □

7.8. Excellent rings

(7.8.1). The previous paragraphs of this section (as well as (6.11), (6.12) and (6.13)) have been devoted to the study of problems frequently encountered in the use of rings and *Noetherian* preschemes, and which can be grouped into the following types:

A) For a *local* Noetherian ring A, do the properties of A "transfer" to its *completion* $\widehat{A}$? For example, if A is reduced (resp. integral, resp. integral and integrally closed), is the same true of $\widehat{A}$? Most of these questions are related to the properties of the local *formal fibres* of A (recall that these are the fibres of the canonical morphism $\operatorname{Spec}(\widehat{A}) \to \operatorname{Spec}(A)$). An exception is formed by the properties related to the notion of dimension, in particular the notion of being equidimensional; it is then the condition of *chains* and its various refinements that play the essential role. **IV-2 | 214**

B) For a locally Noetherian prescheme X (in particular for an affine scheme Spec(A)), does the set of $x \in X$ at which the local ring $\mathscr{O}_x$ possesses a certain property (for example being integrally closed, or being a Cohen-Macaulay ring, or being regular) form an *open* set?

C) For an *integral* ring A, is the integral closure of A in a finite extension of its field of fractions a finite A-module? Of course, this question can be reformulated for Noetherian preschemes (**II**, 6.3).

The problems of type B) or C) may also be posed for *local* rings, but it does not suffice in general that they be solved affirmatively for every local ring $A_\mathfrak{p}$ of a ring A for them to be solved for A (cf. (6.13.6)).

Let us also emphasise that in the study of these problems, we have been systematically concerned with whether an affirmative answer to one of them is *stable* under the two most important operations in Commutative Algebra: localisation and passage to an algebra of finite type.

The results obtained in the study of these problems lead to identifying a class of Noetherian rings whose behaviour in this regard is the best possible:

Definition (7.8.2). — A ring A is called *excellent* if it is Noetherian and satisfies the following conditions:

(i) A is universally catenary (or, equivalently by (5.6.3), (i), for every prime ideal $\mathfrak{p}$ of A, $A_\mathfrak{p}$ is universally catenary).
(ii) For every prime ideal $\mathfrak{p}$ of A, the formal fibres of $A_\mathfrak{p}$ are geometrically regular.
(iii) For every integral quotient ring B of A and every finite radicial extension K' of the field of fractions K of B, there exists a finite sub-B-algebra B' of K', containing B, having K' as field of fractions, and such that the set of regular points of $\operatorname{Spec}(B')$ contains a non-empty open set.

With this terminology, the essential content of the results of § 7 and of part of § 6 is summarised as follows:

Scholium (7.8.3). — (i) In the conditions (i) and (ii) of the definition (7.8.2) one may restrict to the maximal ideals $\mathfrak{p}$ in A. For a local Noetherian ring to be excellent, it is necessary and sufficient that it be universally catenary and that its formal fibres be geometrically regular. **IV-2 | 215**

(ii) If A is an excellent ring, so is every ring of fractions $S^{-1}A$ and every A-algebra of finite type.

(iii) A local complete ring (in particular a field) is excellent. A Dedekind ring whose field of fractions is of characteristic 0 (in particular **Z**) is excellent.

(iv) Let A be an excellent ring, $X = \operatorname{Spec}(A)$; the set $\operatorname{Reg}(X)$ (resp. $\operatorname{Nor}(X)$, $U_{R_n}(X)$) of points where X is regular (resp. normal, resp. satisfies (R_n)) is open in X. For every coherent $\mathscr{O}_X$-Module $\mathscr{F}$, the set $U_{C_n}(\mathscr{F})$ (resp. $U_{S_n}(\mathscr{F})$, $\operatorname{CM}(\mathscr{F})$) of $x \in X$ where $\operatorname{coprof}(\mathscr{F}_x) \leqslant n$ (resp. the points where $\mathscr{F}$ satisfies (S_n), resp. the points where $\mathscr{F}_x$ is a Cohen-Macaulay $\mathscr{O}_x$-Module) is open in X.

(v) Let A be an excellent ring, $\mathfrak{J}$ an ideal of A, and $\widehat{A}$ the separated completion of A for the $\mathfrak{J}$-adic topology. Then the canonical morphism $f : \operatorname{Spec}(\widehat{A}) \to \operatorname{Spec}(A)$ is regular (in other words, flat and with geometrically regular fibres). If we set $X = \operatorname{Spec}(A)$, $X' = \operatorname{Spec}(\widehat{A})$, use the notation of (iv), and put $\mathscr{F}' = \mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{O}_{X'}$, then

(7.8.3.1).

$$\operatorname{Reg}(X') = f^{-1}(\operatorname{Reg}(X)), \quad \operatorname{Nor}(X') = f^{-1}(\operatorname{Nor}(X)), \quad U_{R_n}(X') = f^{-1}(U_{R_n}(X))$$
$$U_{C_n}(\mathscr{F}') = f^{-1}(U_{C_n}(\mathscr{F})), \quad U_{S_n}(\mathscr{F}') = f^{-1}(U_{S_n}(\mathscr{F})), \quad \operatorname{CM}(\mathscr{F}') = f^{-1}(\operatorname{CM}(\mathscr{F}))$$

In particular, if $\mathfrak{J}$ is contained in the radical of A (for example if A is local and $\mathfrak{J}$ its maximal ideal), for A to be regular (resp. normal, resp. reduced, resp. to satisfy (R_n), resp. its codepth to be $\leqslant n$, resp. to satisfy (S_n), resp. to be a Cohen-Macaulay ring), it is necessary and sufficient that the same hold for $\widehat{\mathrm{A}}$; in particular, for A to have no immersed associated primes, it is necessary and sufficient that the same hold for $\widehat{\mathrm{A}}$.

(vi) An excellent ring is universally Japanese; in particular, if A is integral, its integral closure in every finite extension of its field of fractions is a finite A-algebra.

(vii) Let A be a reduced excellent local ring. Then the completion $\widehat{\mathrm{A}}$ is reduced, the integral closure A' of A in its total ring of fractions is a finite A-algebra (hence a semi-local Noetherian ring), and the integral closure of $\widehat{\mathrm{A}}$ in its total ring of fractions is isomorphic to the completion $\widehat{\mathrm{A}}'$ of A'. Furthermore, there is a bijective canonical correspondence between the set of maximal points of $\mathrm{Spec}(\widehat{\mathrm{A}})$ (in other words, the set of minimal prime ideals of $\widehat{\mathrm{A}}$) and the set of closed points of $\mathrm{Spec}(\mathrm{A}')$ (in other words, the set of maximal ideals of A'). For the local ring A to be unibranch, it is necessary and sufficient that $\widehat{\mathrm{A}}$ be integral; for A to be geometrically unibranch, it is necessary and sufficient that $\widehat{\mathrm{A}}$ be.

(viii) If A is an excellent integral ring, the integral closure of A is the intersection of the integral closures of the $\mathrm{A}_{\mathfrak{p}}$, where $\mathfrak{p}$ ranges over the set of prime ideals of A of height 1.

(ix) Let A be an excellent ring, $\mathrm{X} = \mathrm{Spec}(\mathrm{A})$, Z a closed subset of X, $\mathrm{U} = \mathrm{X} - \mathrm{Z}$, $i : \mathrm{U} \to \mathrm{X}$ the canonical injection, $\mathscr{F}$ a coherent $\mathscr{O}_{\mathrm{U}}$-Module. For the $\mathscr{O}_{\mathrm{X}}$-Module $i_*(\mathscr{F})$ to be coherent, it is necessary and sufficient that, for every $x \in \mathrm{Ass}(\mathscr{F})$, one has $\mathrm{codim}(\overline{\{x\}} \cap \mathrm{Z}, \overline{\{x\}}) \geqslant 2$. In particular, if A is integral and $\mathscr{F}$ torsion-free, for $i_*(\mathscr{F})$ to be coherent, it is necessary and sufficient that $\mathrm{codim}(\mathrm{Z},\mathrm{X}) \geqslant 2$.

(x) Let A be an excellent local ring. For every integral quotient ring B of A, $\widehat{\mathrm{B}}$ is equidimensional. **IV-2** | 216
For A to be equidimensional, it is necessary and sufficient that $\widehat{\mathrm{A}}$ be.

Proof. Most of these results have already been proved.

(i) The first assertion follows from (5.6.3), (i) and (7.4.4), (ii); the second from (7.4.4), (7.3.18), (6.12.7) and (6.12.4).

Assertion (ii) follows from (5.6.1), (5.6.3), (i), (7.4.4) and (6.12.4).

(iii) The first assertion has been seen in (5.6.4) and (7.4.4), taking into account (i). The second has been seen in (5.6.4) and (7.3.19), (iv), taking into account (i).

Assertion (iv) follows from (6.12.4), (6.13.5), (6.12.9) and (6.11.8) (taking into account (ii)).

The first assertion of (v) is a consequence of (7.4.6); the relations (7.8.3.1) follow, taking into account respectively (6.5.1), (6.5.4), (6.5.3), (6.3.5) and (6.4.2). The last assertion of (v) is a particular case corresponding to the property (S_n) for $n = 1$ (5.7.5).

Assertion (vi) follows from (7.7.3), and assertion (vii) from (7.6.1), (7.6.2) and (7.6.3).

For assertion (viii), let us note that the ring $\mathrm{A}^{(1)}$, intersection of the $\mathrm{A}_{\mathfrak{p}}$ for all prime ideals $\mathfrak{p}$ of height 1 of A, is a finite A-algebra, as it follows from (vi), from (7.8.2), (i) and (5.11.2). As the integral closure A' of A is a finite A-algebra, the prime ideals of height 1 of A' are exactly those which lie above prime ideals of height 1 of A (5.10.17), (iv); the conclusion follows hence from (**0**, 23.2.9).

The first assertion of (ix) is a consequence of (vi) and (5.11.4); the second is a particular case, since, when $\mathscr{F}$ is torsion-free, $\mathrm{Ass}(\mathscr{F})$ is reduced to the generic point of Spec(A). Finally, to prove (x), it suffices to observe that B is an excellent local ring by (ii). Since B is universally catenary and universally Japanese, the ring $\mathrm{B}^{(1)}$ is a finite B-algebra by (vi) and (5.11.2); this shows that B is strictly formally catenary by (7.2.5), *c*)), and completes the proof of (x).[17] □

Remarks (7.8.4). — (i) If one considers only the Noetherian rings A that satisfy the conditions (ii) and (iii) of the definition (7.8.2), one verifies by inspection of the preceding proofs that the assertions (ii), (iii), (iv), (v), (vi) and (vii) of (7.8.3) are still valid, replacing "excellent" by "satisfying (7.8.2), (ii) and (iii)".

(ii) The catenary local ring A constructed in (5.6.11) satisfies the conditions (ii) and (iii) (but not condition (i)) of the definition (7.8.2). Indeed, the formal fibre at the maximal ideal $\mathfrak{n}\mathrm{C}_{\mathfrak{n}}$ of A is trivially geometrically regular, and the formal fibre at every other prime ideal $\mathfrak{p}$ of A coincides with

[17] The printed text has A in this last clause; the argument and the first assertion of (x) require B.

that of the ring E at $\mathfrak{p}$. Now E is a V-algebra of finite type, and V is a discrete valuation ring, hence is excellent when its residue field k_0 has characteristic 0 by (7.8.3), (iii). Consequently E is excellent by (7.8.3), (ii), which proves that A satisfies condition (7.8.2), (ii).

On the other hand, the complement of the closed point in $\mathrm{Spec}(A)$ is isomorphic to an open subset of $\mathrm{Spec}(E)$, one of whose affine open subsets is the spectrum of an excellent ring and therefore satisfies condition (6.12.4), *a*)) by (7.8.3), (v). It follows that A itself satisfies condition (6.12.4), *a*)), hence also (6.12.4), *c*)), which is precisely condition (7.8.2), (iii). Nevertheless A does not satisfy condition (7.8.2), (i), since we saw in (5.6.11) that it is not universally catenary. **IV-2** | 217

(iii) One can replace the condition (i) of the definition (7.8.2) by the following (weaker in appearance, taking into account (5.6.10)):

(i′) *For every minimal prime ideal* $\mathfrak{p}_i$ *of* A $(1 \leqslant i \leqslant r)$, *let* A'_i *be the integral closure of the integral ring* $A_i = A/\mathfrak{p}_i$; *then, for every maximal ideal* $\mathfrak{m}'$ *of* A'_i, *denoting by* $\mathfrak{m}$ *the inverse image of* $\mathfrak{m}'$ *in* A,

(7.8.4.1).
$$\dim(A_{\mathfrak{m}}) = \dim(A'_{i,\mathfrak{m}'}).$$

Indeed, Remark (i) shows that, under only the hypotheses (ii) and (iii) of (7.8.2), the analogues of the properties (ii), (v), (vi) and (vii) of (7.8.3) remain valid. It follows first from (vi) and (ii) that the A'_i satisfy (7.8.2), (ii) and (iii); then (v) shows that the completions $((A'_i)_{\mathfrak{m}'})^\wedge$ are integral (and integrally closed). Let now $\mathfrak{m}$ be an arbitrary maximal ideal of A. For every i such that $\mathfrak{p}_i \subset \mathfrak{m}$, the integral closure of $A_{\mathfrak{m}}/\mathfrak{p}_i A_{\mathfrak{m}}$ is a finite $(A_{\mathfrak{m}}/\mathfrak{p}_i A_{\mathfrak{m}})$-algebra by (vi), hence is semi-local, and its local components are of the form $(A'_i)_{\mathfrak{m}'}$, where $\mathfrak{m}'$ is a prime ideal (necessarily maximal) of A'_i above $\mathfrak{m}/\mathfrak{p}_i$. It then follows from (vii), from what precedes, and from (7.8.4.1) that the quotients of the completion $(A_{\mathfrak{m}}/\mathfrak{p}_i A_{\mathfrak{m}})^\wedge$ by its minimal prime ideals all have the same dimension, equal to $\dim(A_{\mathfrak{m}})$. Consequently, by (7.1.9) and (7.1.8), *b*)), $A_{\mathfrak{m}}$ is formally catenary, and *a fortiori* universally catenary by (7.1.11). The same is therefore true of $A_{\mathfrak{p}}$ for every prime ideal $\mathfrak{p}$ of A by (5.6.3), (i), hence also of A.

In particular, if A is normal, or more generally if $A_{\mathfrak{m}}$ is unibranch for every maximal ideal $\mathfrak{m}$ of A, the condition (i′) is always satisfied, since $\mathfrak{m}$ can contain only a single prime ideal $\mathfrak{p}_i$ (**0**, 16.1.5); one can then omit (i) from the definition (7.8.2). More particularly, if A is a Noetherian *local unibranch ring*, it is excellent if and only if its formal fibres are geometrically regular.

(iv) Recall that a quotient ring of a local Cohen–Macaulay ring (and *a fortiori* a quotient ring of a regular local ring) also satisfies the properties (7.8.3), (ix) and (x) by virtue of (7.2.7); but the interest of quotient rings of regular rings lies above all in their cohomological properties (chap. III, 3^e Partie).

(v) We will see further on (§ 18) that if k is a field with a complete non-discrete valuation, the ring $k\{\{T_1, \dots, T_n\}\}$ of *convergent power series* (in a neighbourhood of 0 in k^n) is an *excellent ring*.

(7.8.5). One says that a locally Noetherian prescheme X is *excellent* if for some covering (U_α) of X by affine opens, each of the rings A_α of the U_α is excellent; this property is then true for *every* covering (U_α) of X by affine opens.

Proposition (7.8.6). — *Let* X *be an excellent prescheme.*

(i) If $f : X' \to X$ *is a morphism locally of finite type,* X′ *is excellent.*

IV-2 | 218

(ii) If X *is reduced, its normalization* X′ *(**II**, 6.3.8) is finite over* X.

(iii) The sets $\mathrm{Reg}(X)$, $\mathrm{Nor}(X)$, $\mathrm{U}_{\mathrm{R}_n}(X)$, *as well as* $\mathrm{U}_{\mathrm{C}_n}(\mathscr{F})$, $\mathrm{U}_{\mathrm{S}_n}(\mathscr{F})$ *and* $\mathrm{CM}(\mathscr{F})$ *for every coherent* $\mathscr{O}_X$*-Module* $\mathscr{F}$, *are open in* X.

Proof. This follows immediately from (7.8.3), (ii), (vi) and (iv). Let us also note that (7.8.3), (ix) is also valid without modification of the statement when X is an excellent prescheme. □

7.9. Excellent rings and resolution of singularities

(7.9.1). Given a *locally Noetherian reduced* prescheme X, one calls a *resolving morphism* for X a morphism $f : \mathrm{X}' \to \mathrm{X}$ such that X' is *regular* and that f is *proper* and *birational*. When such a morphism exists, one says that one can *resolve the singularities* of X (or more simply that one can *resolve* X). For example, if A is a *Japanese* ring of dimension 1, one can resolve $\mathrm{X} = \mathrm{Spec}(\mathrm{A})$ since the morphism $\mathrm{X}' \to \mathrm{X}$ (where X' is the *normalization* of X) is finite (hence proper) and birational, and the local rings of X' are integrally closed rings of dimension 1, hence discrete valuation rings, hence regular.

(7.9.2). It is clear that if one can resolve X, one can also resolve every prescheme induced on an *open subset* of X and every local prescheme $\mathrm{Spec}(\mathscr{O}_x)$ of X (**II**, 5.4.2). On the other hand, if one can resolve X, it is clear that there exists in X an open subset *everywhere* dense contained in $\mathrm{Reg}(\mathrm{X})$. These remarks show immediately that if, for every closed *integral* sub-prescheme Y of X and every Y-prescheme Y' *integral, finite* and *radicial* over Y, one can resolve Y', then the affine opens of X *satisfy condition* (iii) of (7.8.2).

On the other hand, for local schemes, one has the following proposition:

Proposition (7.9.3). — *Let* A *be a local Noetherian reduced ring, and suppose that one can resolve* $\mathrm{Spec}(\mathrm{A})$*. Then the fibres of the canonical morphism* $\mathrm{Spec}(\widehat{\mathrm{A}}) \to \mathrm{Spec}(\mathrm{A})$ *at the maximal points of* $\mathrm{Spec}(\mathrm{A})$ *are regular.*

Proof. Set $\mathrm{X} = \mathrm{Spec}(\mathrm{A})$, $\mathrm{X}' = \mathrm{Spec}(\widehat{\mathrm{A}})$, and let $g : \mathrm{X}' \to \mathrm{X}$ be the canonical morphism. Let $f : \mathrm{Y} \to \mathrm{X}$ be a resolving morphism; set $\mathrm{Y}' = \mathrm{X}' \times_{\mathrm{X}} \mathrm{Y}$, and let $f' : \mathrm{Y}' \to \mathrm{X}'$ and $g' : \mathrm{Y}' \to \mathrm{Y}$ be the canonical projections, so that one has a commutative diagram

$$\begin{tikzcd} \mathrm{X}' \arrow[d, "g"'] & \mathrm{Y}' \arrow[l, "f'"'] \arrow[d, "g'"] \\ \mathrm{X} & \mathrm{Y} \arrow[l, "f"] \end{tikzcd}$$

It will suffice to prove that the prescheme Y' is *regular*: indeed, as f is birational and of finite type, there is an open U dense in X such that the restriction $f^{-1}(\mathrm{U}) \to \mathrm{U}$ of f is an isomorphism and that $f^{-1}(\mathrm{U})$ is everywhere dense in Y (**I**, 6.5.5); the preschemes induced respectively on the open $g^{-1}(\mathrm{U})$ of X' and the open $g'^{-1}(f^{-1}(\mathrm{U}))$ of Y' are therefore isomorphic; this proves that $g^{-1}(\mathrm{U})$ is regular, and *a fortiori* so are the fibres of g at the maximal points of X, which are contained in U.

Let us note that the morphism f' is proper (**II**, 5.4.2), and in particular of finite type, hence Y' **IV-2** | 219
is Noetherian, since X' is Noetherian. Let a' be the closed point of X'; to see that Y' is regular, it will suffice to prove that *for every* $y' \in f'^{-1}(a')$*, the local ring* $\mathscr{O}_{\mathrm{Y}',y'}$ *is regular*. Indeed, one will then have $f'^{-1}(a') \subset \mathrm{Reg}(\mathrm{Y}')$. But as X' is the spectrum of a complete local ring and f' is of finite type, $\mathrm{Reg}(\mathrm{Y}')$ is *open* in Y' (6.12.8), and as the morphism f' is *closed* and $f'^{-1}(a') \subset \mathrm{Reg}(\mathrm{Y}')$, there exists a neighbourhood V' of a' in X' such that $f'^{-1}(\mathrm{V}') \subset \mathrm{Reg}(\mathrm{Y}')$. As $\widehat{\mathrm{A}}$ is a local ring, one necessarily has $\mathrm{V}' = \mathrm{X}'$, hence $\mathrm{Reg}(\mathrm{Y}') = \mathrm{Y}'$ and the proposition will be proved.

Now, if a is the closed point of X, one has $g^{-1}(a) = \{a'\}$ and the residue fields $\boldsymbol{k}(a)$ and $\boldsymbol{k}(a')$ are isomorphic; hence $g'^{-1}(f^{-1}(a)) = f'^{-1}(a')$ and the restriction $f'^{-1}(a') \to f^{-1}(a)$ of g' is an *isomorphism* of these two fibres. Let $y = g'(y')$ and set $\mathrm{B} = \mathscr{O}_{\mathrm{Y},y}$; if $\mathfrak{n} = \mathfrak{m}_y$ is the maximal ideal of B, what precedes shows that there exists in the (Noetherian) ring $\mathrm{B}' = \mathrm{B} \otimes_{\mathrm{A}} \widehat{\mathrm{A}}$ a single maximal ideal $\mathfrak{n}'$ above $\mathfrak{n}$ and that $\mathscr{O}_{\mathrm{Y}',y'} = \mathrm{B}'_{\mathfrak{n}'}$. To show that the local ring $\mathrm{B}'_{\mathfrak{n}'}$ is regular, it suffices to establish that its *completion* is regular (**0**, 17.1.5); but by hypothesis B is regular, hence so is its completion $\widehat{\mathrm{B}}$. The conclusion will follow from the following lemma:

Lemma (7.9.3.1). — *Let* A, B *be two local Noetherian rings,* $\rho : \mathrm{A} \to \mathrm{B}$ *a local homomorphism such that the ring* $\mathrm{B}' = \mathrm{B} \otimes_{\mathrm{A}} \widehat{\mathrm{A}}$ *is Noetherian. Then, for every maximal ideal* $\mathfrak{n}'$ *of* B' *above the maximal ideal* $\mathfrak{n}$ *of* B *and the maximal ideal of* $\widehat{\mathrm{A}}$*, the completions of* B *and of* $\mathrm{B}'_{\mathfrak{n}'}$ *are isomorphic.*

Proof. Let $\mathfrak{m}$ be the maximal ideal of A and set $\mathrm{B}'' = \mathrm{B}'_{\mathfrak{n}'}$. For every integer $h > 0$, one has $\mathrm{B}'/\mathfrak{m}^h\mathrm{B}' = \mathrm{B} \otimes_{\mathrm{A}} (\widehat{\mathrm{A}}/\mathfrak{m}^h\widehat{\mathrm{A}})$; but $\widehat{\mathrm{A}}/\mathfrak{m}^h\widehat{\mathrm{A}}$ is isomorphic to $\mathrm{A}/\mathfrak{m}^h$, hence $\mathrm{B}'/\mathfrak{m}^h\mathrm{B}'$ is isomorphic to $\mathrm{B}/\mathfrak{m}^h\mathrm{B}$, and in particular it is a local ring whose maximal ideal is $\mathfrak{n}'/\mathfrak{m}^h\mathrm{B}'$; consequently $\mathrm{B}''/\mathfrak{m}^h\mathrm{B}''$, isomorphic to $(\mathrm{B}'/\mathfrak{m}^h\mathrm{B}')_{\mathfrak{n}'}$, is B-isomorphic to $\mathrm{B}'/\mathfrak{m}^h\mathrm{B}'$, and finally isomorphic to $\mathrm{B}/\mathfrak{m}^h\mathrm{B}$; in particular, the maximal ideal of B'' is equal to $\mathfrak{n}\mathrm{B}''$, and $\mathrm{B}''/\mathfrak{n}^h\mathrm{B}''$ is isomorphic to $\mathrm{B}/\mathfrak{n}^h$ from what precedes. As $\widehat{\mathrm{B}}'' = \varprojlim_h(\mathrm{B}''/\mathfrak{n}^h\mathrm{B}'')$, the lemma is proved, as was (7.9.3). □

□

Corollary (7.9.4). — *Let* A *be a local Noetherian ring.*

(i) *If, for every integral quotient ring* B *of* A, *one can resolve* Spec(B), *then the formal fibres of* A *are regular.*

(ii) *Suppose that, for every integral quotient ring* B *of* A, *and every integral ring* B′ *containing* B, *which is a finite* B*-algebra and whose field of fractions is radicial over that of* B, *one can resolve* Spec(B′)*; then the formal fibres of* A *are geometrically regular.*

Proof. Every formal fibre of A being the formal fibre of an integral quotient ring of A at the generic point of its spectrum, it is clear that (i) is an immediate consequence of (7.9.3), and (ii) follows from (i) and (6.7.7). □

Proposition (7.9.5). — *Let* X *be a locally Noetherian prescheme, such that, for every integral prescheme* Y *finite over* X, *one can resolve* Y. *Then the rings of the affine opens of* X *satisfy the conditions (ii) and (iii) of* (7.8.2)*; if moreover* X *is universally catenary* (5.6.3) *(and in particular if* X *is* locally immersible in a regular prescheme (5.6.4)*),* X *is an* excellent prescheme. **IV-2** | 220

Proof. This follows immediately from (7.9.4) and (7.9.2). □

Remark (7.9.6). — It is possible that the converse of (7.9.5) is true, that is to say, that the hypothesis that X is reduced and that the rings of the affine opens of X satisfy the conditions (ii) and (iii) of (7.8.2) implies the possibility of resolving X (and consequently also the possibility of resolving every reduced prescheme locally of finite type over X, by virtue of (7.4.4) and (6.12.4)). This is in any case true when one limits oneself to reduced Noetherian preschemes whose residue fields are of *characteristic* 0, as shown by the recent results of Hironaka [35] (the latter states his results under hypotheses that are too restrictive, the reasoning being in fact valid under the only hypotheses (ii) and (iii) of (7.8.2) for the rings of the affine opens of X, combined with the fact that the residue fields are of characteristic 0). On the contrary, in the general case, it is known so far only how to resolve algebraic schemes of dimension 2 over a perfect field [36]. Given the importance that the resolution of singularities is acquiring in the topological study of schemes (particularly concerning their homological and homotopical properties), this gives a particular interest to the category of excellent rings and excellent preschemes.

One may also note in this regard that the less delicate part of the reasoning of Hironaka (*loc. cit.*) shows independently of any hypothesis on the characteristics of the residue fields, and using only the properties (ii) and (iii) of (7.8.2) for the local rings of X, the problem of resolution of singularities of a prescheme X reduces to the case where $\mathrm{X} = \mathrm{Spec}(\mathrm{A})$, A being a local Noetherian integral ring and *complete*. Consequently, if subsequent results were to disprove the more advanced conjecture above, and were to lead to formulating more restrictive conditions on the local rings of X, these could only be through the intermediary of restrictive conditions imposed on *complete local* rings (probably conditions on their residue fields, perhaps the condition $[k : k^p] < +\infty$ (p being the characteristic exponent of k)).

(7.9.7). Consider on the one hand a full subcategory $\mathscr{C}$ of the category of locally Noetherian preschemes, and on the other hand a property $\boldsymbol{R}(\mathrm{A})$, subject to the following conditions:

1° For every $\mathrm{X} \in \mathscr{C}$, every prescheme locally of finite type over X belongs to $\mathscr{C}$. For every Noetherian ring A such that $\mathrm{Spec}(\mathrm{A}) \in \mathscr{C}$ and every multiplicative subset S of A, one has $\mathrm{Spec}(\mathrm{S}^{-1}\mathrm{A}) \in \mathscr{C}$.

2° For every $\mathrm{X} \in \mathscr{C}$, the set $\mathrm{U}_{\boldsymbol{R}}(\mathrm{X})$ of $x \in \mathrm{X}$ such that $\boldsymbol{R}(\mathscr{O}_{\mathrm{X},x})$ is true is open in X.

3° For every local Noetherian ring A such that $\mathrm{Spec}(\mathrm{A}) \in \mathscr{C}$ and every regular element t of the maximal ideal of A, $\boldsymbol{R}(\mathrm{A}/t\mathrm{A})$ implies $\boldsymbol{R}(\mathrm{A})$.

Let us denote as in (7.5.0) by $\boldsymbol{P}(\mathrm{Z}, k)$, for a field k and a k-prescheme $\mathrm{Z} \in \mathscr{C}$, the following property:

"For every finite extension k' of k, all the local rings of $\mathrm{Z} \otimes_k k'$ satisfy the property $\boldsymbol{R}$."

We will further suppose that $\boldsymbol{R}$ satisfies the following condition: **IV-2** | 221

4° If $\boldsymbol{P}(\mathrm{Z}, k)$ is true, then, for every extension *of finite type* k'' of k, all the local rings of $\mathrm{Z} \otimes_k k''$ satisfy the property $\boldsymbol{R}$.

Let us note that these conditions are satisfied when one takes for $\mathscr{C}$ the category of *excellent* preschemes and for $\boldsymbol{R}$ one of the properties (i) to (viii) of (7.5.3); for condition 1°, this follows from (7.8.3), (iii), and for conditions 2° and 3°, from the arguments of (7.5.3), taking into account that every excellent ring is catenary. Finally, condition 4° follows, for (i), (ii), and (iii), from (6.7.1); for (iv), (v), and (vi), from (6.7.7); and for (viii), from (4.6.1). As concerns property (vii) of (7.5.3), the corresponding property $\boldsymbol{P}(\mathrm{Z}, k)$ implies that Z is locally integral (being locally Noetherian) and that each of the integral subpreschemes whose union is Z is geometrically integral, by (4.5.9) and (4.6.1); condition 4° follows in this case as well.

With these notations and hypotheses:

Proposition (7.9.8). — *Let* A *be a local Noetherian ring, k its residue field, and* B *a local Noetherian ring such that* $\mathrm{Spec}(\mathrm{B}) \in \mathscr{C}$. *Let $\varphi : \mathrm{A} \to \mathrm{B}$ be a local homomorphism making* B *a flat* A*-module; set* $\mathrm{Y} = \mathrm{Spec}(\mathrm{A})$, $\mathrm{X} = \mathrm{Spec}(\mathrm{B})$, *and let $f : \mathrm{X} \to \mathrm{Y}$ be the morphism corresponding to φ. Suppose that:*

1° the property $\boldsymbol{P}(\mathrm{B} \otimes_{\mathrm{A}} k, k)$ is true;

2° for every finite morphism $\mathrm{Y}_1 \to \mathrm{Y}$, one can resolve $(\mathrm{Y}_1)_{\mathrm{red}}$.

Then, for every $y \in \mathrm{Y}$, the property $\boldsymbol{P}(f^{-1}(y), \boldsymbol{k}(y))$ is true.

Proof. Let us note that condition 2° of (7.9.8) is still satisfied when one replaces Y by the spectrum of a local ring in a maximal ideal of a finite A-algebra (7.9.2); on the other hand, by virtue of condition 1° of (7.9.7), the spectrum of a ring of fractions of $\mathrm{B} \otimes_{\mathrm{A}} \mathrm{A}'$ also belongs to $\mathscr{C}$. The lemma (7.3.16.2) then shows (as in part I of the reasoning of (7.5.2)) that it suffices to prove that, if Y is integral and if y is the generic point of Y, the local rings of the fibre $f^{-1}(y)$ satisfy $\boldsymbol{R}$.

This being so, there exists by hypothesis a regular prescheme Y' and a proper birational morphism $g : \mathrm{Y}' \to \mathrm{Y}$. Since Y' is Noetherian and locally integral, the fact that g is birational implies that Y' is integral. Put $\mathrm{X}' = \mathrm{X} \times_{\mathrm{Y}} \mathrm{Y}'$, so that one has a commutative diagram

(7.9.8.1).

$$
\begin{tikzcd}
\mathrm{X} \arrow[d, "f"'] & \mathrm{X}' \arrow[l, "g'"'] \arrow[d, "f'"] \\
\mathrm{Y} & \mathrm{Y}' \arrow[l, "g"]
\end{tikzcd}
$$

where f' and g' are the canonical projections. Taking into account condition 2° of (7.9.7), the same reasoning as at the beginning of (7.9.3) shows that it suffices to prove

that $\mathrm{U}_{\boldsymbol{R}}(\mathrm{X}') = \mathrm{X}'$. If a denotes the closed point of X, it is enough to show that $g'^{-1}(a) \subset \mathrm{U}_{\boldsymbol{R}}(\mathrm{X}')$. **IV-2** | 222
Let $x' \in g'^{-1}(a)$, and set $z' = f'(x')$, so that $b = g(z')$ is the closed point of Y. We have

$$f'^{-1}(z') = f^{-1}(b) \otimes_k \boldsymbol{k}(z').$$

Since $\boldsymbol{k}(z')$ is an extension of finite type of k (because g is proper, hence of finite type), the hypothesis that $\boldsymbol{P}(f^{-1}(b), k)$ is true implies, by condition 4° of (7.9.7), that $\boldsymbol{P}(f'^{-1}(z'), \boldsymbol{k}(z'))$ is true. Moreover, $\mathscr{O}_{\mathrm{Y}',z'}$ is regular and $\mathrm{Spec}(\mathscr{O}_{\mathrm{X}',x'}) \in \mathscr{C}$ by condition 1° of (7.9.7); Lemma (7.5.1.1) therefore proves that $\boldsymbol{R}(\mathscr{O}_{\mathrm{X}',x'})$ is true, completing the proof. □

Corollary (7.9.9). — *Let* A, B *be two local Noetherian rings, $\varphi : \mathrm{A} \to \mathrm{B}$ a local homomorphism making* B *a flat* A*-module. Suppose that* A *is integral and geometrically unibranch, and that for every finite integral* A*-algebra* A' *one can resolve* $\mathrm{Spec}(\mathrm{A}')$ *(this will be the case if the formal fibres of* A *are geometrically regular and the residue field of* A *is of characteristic* 0, *by virtue of the results of Hironaka [35]). Let k be the residue field of* A *and suppose that* $\mathrm{Spec}(\mathrm{B} \otimes_{\mathrm{A}} k)$ *is geometrically punctually integral* (4.6.9). *Then* B *is integral.*

Proof. We apply (7.9.8), taking for $\mathscr{C}$ the category of all locally Noetherian preschemes and for $\boldsymbol{R}$ the property of being integral. The arguments of (7.5.3) and (7.9.7) show that conditions 1°, 2°, 3° and 4° of (7.9.7) are satisfied in this case. The hypothesis on $\mathrm{B} \otimes_{\mathrm{A}} k$ and Proposition (7.9.8) therefore show (with the notation of (7.9.8)) that the fibres $f^{-1}(y)$ are geometrically punctually integral for $y \in \mathrm{Y}$. In particular the $f^{-1}(y)$ are reduced; since A is integral, and hence reduced, it follows from (3.3.5) that B is reduced. It remains to prove that $\mathrm{X} = \mathrm{Spec}(\mathrm{B})$ is *irreducible*. Now, the proof of (7.9.8) shows that X′ is locally integral (being locally Noetherian). Since $g' : X' \to X$ is surjective, it is therefore enough to show that X′ is irreducible, or, since X′ is locally integral, that X′ is *connected*. For this it is enough to prove that the fibre $g'^{-1}(a)$ is connected. Indeed, if X′ were the sum of two non-empty open preschemes X'_1 and X'_2, then, for example, $g'^{-1}(a) \cap X'_2 = \varnothing$; but the restriction $X'_2 \to X$ of g' is proper (since X'_2 is also closed in X′), so $g'(X'_2)$ would be a non-empty closed subset of X not containing the closed point a, a contradiction. Finally,

$$g'^{-1}(a) = g^{-1}(b) \otimes_{\boldsymbol{k}(b)} \boldsymbol{k}(a).$$

The morphism $g : Y' \to Y$ is proper and birational; hence, in its Stein factorisation $Y' \xrightarrow{v} Y'' \xrightarrow{u} Y$ (**III**, 4.3.3), the finite morphism u is also birational, and consequently Y″ is integral. Since A is geometrically unibranch, it follows from (**III**, 4.3.4) that $g^{-1}(b)$ is geometrically connected, completing the proof. □

Remarks (7.9.10). — (i) We will show further on (18.8.11) that for a local Noetherian reduced ring B to be geometrically unibranch, it is necessary and sufficient that for every étale morphism $h : X' \to X = \operatorname{Spec}(B)$ and every point $x' \in X'$ above the closed point of X, $\mathscr{O}_{X',x'}$ is integral. One deduces that if, in (7.9.9) one supposes, not only that $\operatorname{Spec}(B \otimes_A k)$ is geometrically punctually integral, but also geometrically unibranch, then one can conclude that B is *geometrically unibranch*.

(ii) Let X, Y be two excellent preschemes, $f : X \to Y$ a flat morphism, and suppose that for every **IV-2** | 223
finite morphism $Y_1 \to Y$, one can resolve $(Y_1)_{\mathrm{red}}$. It follows from (7.9.8), taking for $\boldsymbol{R}$ the property of being *regular*, that the set U of $x \in X$ such that the fibre at the point $f(x)$ of the morphism

$$\operatorname{Spec}(\mathscr{O}_x \otimes_{\mathscr{O}_{f(x)}} \boldsymbol{k}(f(x))) \longrightarrow \operatorname{Spec}(\boldsymbol{k}(f(x)))$$

is *geometrically regular*, is *stable under generization*. We do not know if this set is *open* (or, which amounts to the same $(0_{\mathrm{III}}, 9.2.5)$, if it is *constructible*) even in the particular case where Y is the spectrum of **Z** or of a polynomial ring in one indeterminate $k[T]$ over a field k, and where consequently the condition of “resolvability” imposed on Y is trivially satisfied.

§8. Projective limits of preschemes

8.1. Introduction

IV-3 | 5

(8.1.1). In this paragraph, we will systematically study the following situation. Let I be a filtered preordered increasing set, $(\mathrm{A}_\lambda, \varphi_{\mu\lambda})$ an inductive system of rings having I for index set, $\mathrm{A} = \varinjlim \mathrm{A}_\lambda$ its inductive limit. For every $\alpha \in \mathrm{I}$ and every A_α-prescheme X_α, consider the A_λ-preschemes $\mathrm{X}_\lambda = \mathrm{X}_\alpha \otimes_{\mathrm{A}_\alpha} \mathrm{A}_\lambda$ for $\lambda \geqslant \alpha$, and the A-prescheme $\mathrm{X} = \mathrm{X}_\alpha \otimes_{\mathrm{A}_\alpha} \mathrm{A}$; it is clear that the preschemes X_λ (for $\lambda \geqslant \alpha$) form a *projective system*, and we will see (8.2.5) that X is a *projective limit* of this system in the category of preschemes. We propose to find conditions on X_α or on the A_λ allowing us to prove properties of the following type: for X to have a property **P** (for example, the property of being proper over $\mathrm{S} = \mathrm{Spec}(\mathrm{A})$, or irreducible, or connected, etc.), it is necessary and sufficient that there exist an index $\mu \geqslant \alpha$ such that, for every $\lambda \geqslant \mu$, X_λ has (with respect to $\mathrm{S}_\lambda = \mathrm{Spec}(\mathrm{A}_\lambda)$, as the case may be) the same property **P**. We will obtain analogous statements for properties of $\mathscr{O}_\mathrm{X}$-Modules, of A-morphisms of A-preschemes, etc. We will also show (8.9.1) that the datum of an A-prescheme of finite presentation (1.6.1) is essentially equivalent to the datum of an A_λ-prescheme of finite presentation X_λ for some sufficiently large λ, X being then *isomorphic to* $\mathrm{X}_\lambda \otimes_{\mathrm{A}_\lambda} \mathrm{A}$. There are also analogous statements for $\mathscr{O}_\mathrm{X}$-Modules of finite presentation, their homomorphisms, the A-morphisms of A-preschemes of finite presentation, etc.

(8.1.2). The utility of such results will appear, for example, in the following questions:

a) Let Y be a prescheme, y a point of Y, (U_λ) the projective system of filtered decreasing open affine neighbourhoods of y in Y; if A_λ is the ring of U_λ, the A_λ form a filtered increasing inductive system, whose inductive limit A is the local ring $\mathscr{O}_y$; moreover, if we denote by $\mathfrak{p}_\lambda$ the prime ideal $\mathfrak{j}_y$ in the ring A_λ, the inductive system (A_λ) is cofinal in every inductive system $(\mathrm{A}_\alpha)_f$, where f ranges over $\mathrm{A}_\alpha - \mathfrak{p}_\alpha$ (for a fixed α), since the $\mathrm{D}(f)$ form a fundamental system of neighbourhoods of y in U_α, hence in Y. The results of the present paragraph will therefore imply that the algebraic geometry of $\mathscr{O}_y$-preschemes of finite presentation (and the theory of Modules of finite presentation on these preschemes) is essentially equivalent to the algebraic geometry of preschemes of finite presentation on "sufficiently small" open neighbourhoods of y. Thus, the statement (8.10.5), (xii) implies that if a morphism of finite presentation $f : \mathrm{X} \to \mathrm{Y}$ is such that $\mathrm{X} \times_\mathrm{Y} \mathrm{Spec}(\mathscr{O}_y)$ is proper over $\mathrm{Spec}(\mathscr{O}_y)$, it is necessary and sufficient that there exist an open neighbourhood U of y in Y such that $f^{-1}(\mathrm{U})$ is proper over U. **IV-3 | 6**
